Cognitive and adaptive behavior evaluations. Cognitive evaluations should be performed in all children with autism by a psychologist or other trained professional. Cognitive instruments should be appropriate for the mental and chronologic age, provide a full range (in the lower direction) of standard scores and current norms independent of social ability, include independent measures of verbal and nonverbal abilities, and provide an overall index of ability. A measure of adaptive functioning should be collected for any child evaluated for an associated cognitive handicap. Consensus-based recommendations for using specific instruments include the Vineland Adaptive Behavior Scales and the Scales of Independent Behavior–Revised.[1]

Sensorimotor and occupational therapy evaluations. Evaluation of sensorimotor skills by a qualified experienced professional (occupational therapist or physical therapist) should be considered, including assessment of gross and fine motor skills, praxis, sensory processing abilities, unusual or stereotyped mannerisms, and the impact of these components on the autistic person's life. An occupational therapy

evaluation is indicated when deficits exist in functional skills or occupational performance in the areas of play or leisure, self-maintenance through activities of daily living, or productive school and work tasks. Although not routinely warranted as part of all evaluations of children with autism, the Sensory Integration and Praxis Tests may be used on an individual basis to detect specific patterns of sensory integrative dysfunction.

Neuropsychological, behavioral, and academic assessments. These assessments should be performed as needed, in addition to the cognitive assessment, to include social skills and relationships, educational functioning, problematic behaviors, learning style, motivation and reinforcement, sensory functioning, and self-regulation. Assessment of family resources should be performed by appropriate psychologists or other qualified health care professionals and should include assessment of parents' level of understanding of their child's condition, family (parent and sibling) strengths, talents, stressors and adaptation, resources and supports, as well as offer appropriate counseling and education.

Disclaimer. The Quality Standards Subcommittee (QSS) of the American Academy of Neurology (AAN) seeks to develop scientifically sound, clinically relevant practice parameters for the practice of neurology. Practice parameters are strategies for patient management that assist physicians in clinical decision making. A practice parameter is one or more specific recommendations based on analysis of evidence of a specific clinical problem. These might include diagnosis, symptoms, treatment, or procedure evaluation. This evidence-based review addresses the major management issues health care providers face in surveying, screening, and diagnosing children with autism. The clinical evidence is reviewed, management recommendations provided, and areas of continued research identified. This statement is provided as an educational service of the American Academy of Neurology. It is based on an assessment of current scientific and clinical information. It is not intended to include all possible proper methods of care for choosing to use a specific procedure. Neither is it intended to exclude any reasonable alternative methodologies. The AAN recognizes that specific patient care decisions are the prerogative of the patient and the physician caring for the patient, based on all of the circumstances involved.

Acknowledgment

The authors thank the following people who contributed to this endeavor by their participation in the NIH State of the Science in Autism: Screening and Diagnosis Working Conference, June 15 to 17, 1998: George Anderson, PhD, Anthony Bailey, MD, W. Ted Brown, MD, Susan E. Bryson, PhD, Rebecca Landa, PhD, Jeffrey Lewine, PhD, Catherine Lord, PhD, William McIlvane, PhD, Joseph Piven, MD, Ricki Robinson, MD, Bryna Siegel, PhD, Vijendra K. Singh, PhD, Frank Symons, PhD, and Max Wiznitzer, MD. The current authors, participants and NIH Liaisons also participated in this working conference. The Panel acknowledges with gratitude the valuable consultations of Frances P. Glascoe, PhD, and Donald J. Siegel, PhD, and the assistance of Cheryl Jess, Jody Sallah, and Starr Pearlman, PhD, in this endeavor. Special gratitude is extended for the additional assistance of Michael L. Goldstein, MD, and Roy Elterman, MD.

Appendix 1

Participating Organizations and Authors

Pauline A. Filipek, MD—Chair (Child Neurology Society, American Academy of Neurology and American Academy of Pediatrics); Judith S. Gravel, PhD (American Academy of Audiology); Edwin H. Cook, Jr., MD, and Fred R. Volkmar, MD (American Academy of Child and Adolescent Psychiatry); Isabelle Rapin, MD, and Barry Gordon, MD, PhD (American Academy of Neurology); Stuart W. Teplin, MD, Ronald J. Kallen, MD, and Chris Plauche Johnson, MEd, MD (American Academy of Pediatrics); Grace T. Baranek, PhD, OTR/L (American Occupational Therapy Association); Sally J. Rogers, PhD, Sally Ozonoff, PhD, and Wendy L. Stone, PhD (American Psychological Association); Geraldine Dawson, PhD (American Psychological Society); Barry M. Prizant, PhD, CCC-SLP (American Speech–Language–Hearing Association); Nancy J. Minshew, MD, and Roberto F. Tuchman, MD (Child Neurology Society); Susan E. Levy, MD (Society for Developmental and Behavioral Pediatrics); Pasquale J. Accardo, MD (Society for Developmental Pediatrics); and Stephen Ashwal, MD (Child Neurology Society, American Academy of Neurology Quality Standards Subcommittee).

Representatives were named from the following associations: Barbara Cutler, EdD, and Susan Goodman, JD (Autism National Committee); Cheryl Trepagnier, PhD (Autism Society of America); Daniel H. Geschwind, MD, PhD (Cure Autism Now); and Charles T. Gordon, MD (National Alliance for Autism Research). The National Institutes of Health also named liaisons to serve on this committee, including Marie Bristol–Power, PhD (National Institute of Child Health and Human Development); Judith Cooper, PhD (National Institute of Deafness and Communication Disorders); Judith Rumsey, PhD (National Institute of Mental Health); and Giovanna Spinella, MD (National Institute of Neurological Disorders and Stroke).

Appendix 2

Clinical questions addressed for surveillance, screening and diagnosing children with autism

Routine developmental surveillance and screening for autism

1. When and how often should developmental surveillance/screening be performed?
2. What are the appropriate developmental screening questionnaires that provide sensitive and specific information?
3. How are conventional developmental milestones defined?
4. Do parents provide reliable information regarding their child's development?
5. Can autism can be reliably diagnosed before 36 months of age?
6. Is there an increased risk of having another child with autism (recurrence)?
7. What screening laboratory investigations are available for developmental delay, with or without suspicion of autism?
8. What tools are available with appropriate psychometric properties to specifically screen for autism?

Diagnosis and evaluation of autism

1. Who should diagnose autism?
2. What are the medical and neurologic concerns in evaluating children with autism?
3. What are the specific deficits of the autistic child's developmental profile?
4. When and what laboratory investigations are indicated for the diagnosis of autism?

Appendix 3

Definitions for strength of the evidence

Class I. Must have all of a through d. a) Prospective study of a well-defined cohort which includes a description of the nature of the population, the inclusion/exclusion criteria, demographic characteristics such as age and sex, and seizure type. b) The sample size must be adequate with enough statistical power to justify a conclusion or for identification of subgroups for whom testing does

or does not yield significant information. c) The interpretation of evaluations performed must be done blinded to outcome. d) There must be a satisfactory description of the technology used for evaluations (e.g., EEG, MRI).

Class II. Must have a or b. a) Retrospective study of a well-defined cohort which otherwise meets criteria for class 1a, b and 1d. b) Prospective or retrospective study which lacks any of the following: adequate sample size, adequate methodology, a description of inclusion/exclusion criteria, and information such as age, sex and characteristics of the seizure.

Class III. Must have a or b. a) A small cohort or case report. b) Relevant expert opinion, consensus, or survey.

A cost-benefit analysis or a meta-analysis may be class I, II, or III, depending on the strength of the data upon which the analysis is based.

Definitions for strength of the recommendations

Standard. A principle for patient management that reflects a high degree of clinical certainty (usually requires one or more Class I studies that directly address the clinical question, or overwhelming Class II evidence when circumstances preclude randomized clinical trials).

Guideline. A recommendation for patient management that reflects moderate clinical certainty (usually requires one or more Class II studies or a strong consensus of Class III evidence).

Practice option. Strategy for patient management for which clinical utility is uncertain (inconclusive or conflicting evidence or opinion).

THE ORTHOPAEDIC FORUM

Screening for Idiopathic Scoliosis in Adolescents

An Information Statement*

By B. Stephens Richards, MD, and Michael G. Vitale, MD

Executive Summary

Many states mandate school screening to identify children at risk for scoliosis, though recent studies have cast some controversy on the effectiveness of routine scoliosis screening. Previous studies have both supported and discouraged routine screening.

Prevention of severe scoliosis is a major commitment of physicians caring for children with spinal deformities. For this reason, the American Academy of Orthopaedic Surgeons (AAOS), the Scoliosis Research Society (SRS), the Pediatric Orthopaedic Society of North America (POSNA), and the American Academy of Pediatrics (AAP) convened a task force to examine issues related to scoliosis screening and to put forth the present information statement. The societies acknowledge the important role of a systematic review of the literature as well as the role of consensus expert opinion in the common situation where the available evidence does not yet exist to speak definitely for, or against, an evaluation or intervention.

Costs involved with scoliosis screening are relatively low on a societal level and may justify the possibility of preventing surgery in adolescents with scoliosis. Adolescents without significant spinal deformity who are referred to a specialist for evaluation often do not require radiographs. For those who do need radiographic evaluation, it is important to know that the radiation exposure using current-day radiographic techniques, including digital radiography, is significantly smaller than in the past.

Opponents to scoliosis screening have focused on concerns about a low predictive value of screening and the cost-effectiveness of referral. There have also been concerns about the possibility of unnecessary treatment, including brace use, and the effect of exposure to radiation when radiographs are obtained.

With regard to early treatment in those adolescents detected with moderate scoliosis, the available data neither definitively support nor refute the efficacy of bracing. To most effectively answer this, a well-organized level I study is needed. Such a study, a five-year multicenter randomized controlled trial of bracing sponsored by the National In-

Disclosure: The authors did not receive any outside funding or grants in support of their research for or preparation of this work. Neither they nor a member of their immediate families received payments or other benefits or a commitment or agreement to provide such benefits from a commercial entity. Commercial entities (Biomet Spine, Medtronic, and Stryker Spine) paid or directed in any one year, or agreed to pay or direct, benefits in excess of $10,000 to a research fund, foundation, division, center, clinical practice, or other charitable or nonprofit organization with which one or more of the authors, or a member of his or her immediate family, is affiliated or associated.

**This statement has been reviewed by the Boards of Directors of the American Academy of Orthopaedic Surgeons (September 2007), Scoliosis Research Society (August 2007), Pediatric Orthopaedic Society of North America (August 2007), and the American Academy of Pediatrics (September 2007). All four boards have endorsed this statement. The American Academy of Orthopaedic Surgeons notes that the statement was developed as an educational tool based on the opinion of the authors. It is not a product of a systematic review. Readers are encouraged to consider the information presented in this Opinion Statement and reach their own conclusions.*

stitutes of Health/National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIH/NIAMS), is currently under way.

In 1996, the United States Preventive Services Task Force (USPSTF) concluded that there was insufficient evidence to make a recommendation for, or against, screening. However, in 2004, the USPSTF changed their position and recommended against the routine screening of asymptomatic adolescents for idiopathic scoliosis. The AAOS, SRS, POSNA, and AAP have concerns that this change in position by the USPSTF came in the absence of any significant change in the available literature, in the absence of any change in position statements by the AAOS, SRS, POSNA, and AAP, and in the absence of any significant input from specialists who commonly care for children with scoliosis.

As the primary care providers for adolescents with idiopathic scoliosis, the AAOS, SRS, POSNA, and AAP do not support any recommendation against scoliosis screening, given the available literature.

Information Statement:

Screening for Idiopathic Scoliosis in Adolescents

Purpose

The purpose of the current information statement is to provide material to patients, physicians, and decision makers regarding issues related to screening for scoliosis. Screening is defined as a clinical, rather than radiographic, examination.

Introduction

Adolescent idiopathic scoliosis is a spine deformity characterized by lateral and rotational curvature of the spine. It usually becomes evident in the early adolescent years and, although significant progress has been made in the genetic study of this disorder, its cause presently remains unknown, thus the label "idiopathic" scoliosis. Curve progression is unpredictable, though a subset of children with adolescent idiopathic scoliosis may exhibit rapid progression. Every year, thousands of operations are performed for the primary diagnosis of adolescent idiopathic scoliosis in patients between the ages of 10 and 18. This spinal disorder can have a significant impact on the physical and psychosocial health of affected individuals.

Prevention of severe scoliosis is a major commitment of orthopaedic surgeons caring for spinal deformities. Beginning in 1984, the AAOS and the SRS formally endorsed the concept of school screening for the early detection of scoliosis in children whose deformities may have gone unnoticed. This endorsement was based on the assumption that early detection in those children at risk for worsening would lead to the institution of nonoperative treatment that could have a positive impact on the long-term natural history of this disorder. Without treatment, many curves could be expected to worsen over the long-term, with some of them eventually needing surgical intervention. In addition, those children with more significant scoliosis, who may have no other symptoms, could be detected by clinical screening at a time when surgical treatment for their deformity could be performed most effectively.

Screening for Scoliosis—The Evidence For and Against

Routine clinical screening for scoliosis continues to be controversial with less than half of the states in the United States currently legislating school screening. Previous studies have both supported[1,2] and discouraged routine screening[3-5]. There have been no recent scientific publications on screening for scoliosis.

In 1993, Montgomery and Willner[2] supported the routine use of school screening. They reported that the introduction of school screening programs decreased the relative risk of progression into a surgical range by a factor of eight. They obtained an eight times greater risk of deterioration of the curve to 45°, which would be diagnosed as qualifying for surgery, without the screening program and without modifying the indications for treatment before and after the implementation of the screening program. Their conclusion was that screening decreased the demand for surgery because scoliosis would be detected at a younger age with smaller curves, thus having a better prognosis.

Conversely, other investigators provided different conclusions. Yawn et al.[3] reported on a population-based school screening program in Rochester, Minnesota. In this retrospective cohort study, 4.1% of the 2242 children screened positively and were referred for evaluation. The positive predictive value was low (0.05) and they concluded that roughly 450 children would need to be screened for every child who subsequently received treatment as a result of screening. A limitation of this study is that the community in Rochester is not representative of the general population, with more than 90% of the population being white, having higher-than-average income, and having excellent access to specialized care.

A year later, the same investigators[4] examined issues related to charges, including the primary care visit, orthopaedic surgeon visit, and radiographs. The total costs were estimated to be $34.40 per child screened, $4,198.67 per case identified, and $15,115.20 per child treated. These estimates were significantly higher than those previously reported.

Twenty years ago, Morais et al.[5] concluded that the prevalence of the disease was too low to benefit from a screening program. The authors commented on their concern of radiation exposure that the children may have undergone following clinical screening. Of note, radiation exposure is significantly reduced with current techniques of shielding, the use of special films, and the institution of digital radiography.

Each of the above studies has significant flaws with regard to methodological rigor. To date, no level I evidence studies have been performed

on screening for scoliosis, and such a study is unlikely to be performed at the current time. Therefore, definitive conclusions regarding the effectiveness of scoliosis screening cannot be made from the available evidence in the literature. This concern was echoed by the 1996 USPSTF report which concluded that there was insufficient evidence to make a recommendation for, or against, screening[6]. However, in 2004, the USPSTF changed their recommendation[7]. Citing a low predictive value of screening, a relatively small percentage of children whose curves progress, and the possibility of unnecessary treatment including brace use, they issued a recommendation against the routine screening of asymptomatic adolescents for idiopathic scoliosis. Of note, the Task Force's change in their recommendation was largely based on a change in methodological approach of the USPSTF, rather than any real change in available information.

A recent article (May 2007) examined professional opinion concerning the effectiveness of bracing relative to observation in adolescent idiopathic scoliosis[8]. The authors polled a group of clinicians with significant experience with scoliosis treatment. While there was significant variability in opinion among the expert panel, on average, the expert panel felt that bracing would decrease the risk of progression in premenarchal patients by 20% to 30%, depending on the exact clinical scenario. Thus, it appears that many of those who most commonly treat scoliosis perceive a potential positive effect of bracing.

Representing the primary care providers for adolescents with idiopathic scoliosis, the AAOS, SRS, POSNA, and AAP do not support any formal recommendations against scoliosis screening, given the available literature. All four societies recognize the benefits that can be provided by effective clinical screening programs, including (1) the potential prevention of deformity progression by brace treatment and (2) the earlier recognition of severe deformities requiring operative correction.

Treatment for Those Detected from Scoliosis Screening

In general, treatment must attempt to alleviate current problems and symptoms and to ultimately alter long-term natural history. Brace treatment for scoliosis is the most effective primary nonoperative method used over the past 40 years. In recent years, refinements have been made in identifying which patients with idiopathic scoliosis may benefit most with this treatment[9].

With the information available in the literature today, it is difficult to speak with absolute certainty about the effectiveness of bracing. There are no level I evidence bracing studies currently in the literature. Though nearly all brace studies are level III or level IV evidence studies, many of them represent important and well-organized research and most conclude that brace treatment is effective in diminishing curve progression[10-29]. The most common parameter used to assess the effectiveness of brace treatment is the amount of curve progression that occurs, usually with success defined by curve progression of ≤5 degrees at maturity. The other parameter used to assess the success of brace treatment is the prevention of surgery. A recent evidence-based review of the literature reported a 20% to 24% risk of needing surgery despite best efforts at bracing[30]. The risk of surgery without any brace treatment in the same patient population is currently unknown. This fact alone emphasizes the importance that a level I evidence study could have in clarifying the effectiveness of brace treatment in preventing the need for surgery. Such a study, a five-year multicenter randomized controlled trial of bracing sponsored by the NIH/NIAMS, is currently under way.

Scoliosis Screening in 2007

Although the AAOS, SRS, POSNA, and AAP recognize that support for scoliosis screening has limitations, the potential benefits that patients with idiopathic scoliosis receive from early treatment of their deformities can be substantial. Scoliosis screening, whether in the physician's office, nurses' clinics, or school environment, provides the opportunity to diagnose the condition and make referral for appropriate medical care. Brace treatment in children with significant scoliosis may avoid the need for surgical intervention. Those with deformities in need of surgery may be identified by screening at a time when operative intervention can be performed most effectively. Many of these patients may otherwise go undetected, particularly in patient populations underserved by medicine.

Females achieve adolescence about two years before males and are afflicted with a magnitude of scoliosis, requiring treatment three to four times more frequently than males. As a result, if scoliosis screening is undertaken, the AAOS, SRS, POSNA, and AAP agree that females should be screened twice, at age 10 and 12 (grades 5 and 7), and boys once, at age 13 or 14 (grades 8 or 9).

The AAOS, SRS, POSNA, and AAP believe that school screening personnel should be educated in the detection of spinal deformity. Screening should always include the forward bending test, the most specific test for true scoliosis, though no single test is completely reliable for screening. Therefore, considerable judgment on the part of the screener is necessary to achieve an appropriate referral rate and to avoid unnecessary referrals. To meet the objectives of scoliosis screening programs, the AAOS, SRS, POSNA, and AAP recognize the need to limit the number of referrals of those individuals suspected of having scoliosis.

The AAOS, SRS, POSNA, and AAP maintain their commitment to avoid the inappropriate use of spine radiographs. Not all children referred as a result of screening require radiographs. If radiographs are needed, physicians should take necessary precautions to limit the patient's exposure to radiation.

Educational materials that provide more specific guidelines for conducting school screening programs for scoliosis are available to physicians and school authorities.

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Screening for Retinopathy in the Pediatric Patient With Type 1 Diabetes Mellitus

ABSTRACT. Diabetic retinopathy (DR) is the leading cause of blindness in young adults in the United States. Early identification and treatment of DR can decrease the risk of vision loss in affected patients. This clinical report reviews the risk factors for the development of DR and screening guidance for pediatric patients with type 1 diabetes mellitus. ***Pediatrics*** **2005;116:270–273;** ***type 1 diabetes mellitus, diabetic retinopathy, ophthalmic screening.***

ABBREVIATIONS. DR, diabetic retinopathy; DCCT, Diabetes Control and Complications Trial.

BACKGROUND

Type 1 diabetes mellitus is one of the most common metabolic disorders in children, with a prevalence of approximately 2 per 1000 school-aged children in the United States. The prevalence of type 1 diabetes mellitus increases with age, and the overall incidence of the disease may be increasing. Although the incidence of type 2 diabetes in children is increasing, there are no data or guidelines regarding ophthalmic screening in children with this disorder. Diabetic retinopathy (DR) is one of the most important complications of type 1 diabetes mellitus, representing the leading cause of blindness in young adults. There are 3 main components of a strategy to minimize the risk of visual loss attributable to DR: (1) provide the most effective treatment of the underlying metabolic disorder and its comorbidities; (2) develop optimal treatment modalities for patients with ocular disease; and (3) identify risk factors for the development of ocular disease and implement effective screening programs to identify at-risk patients. The first 2 have been evaluated in well-conducted, large, prospective trials.

Optimizing Metabolic Control

The efficacy of providing intensive treatment of the underlying metabolic disorder was evaluated by the Diabetes Control and Complications Trial (DCCT),[1] which clearly demonstrated the benefits of improving glycemic control and decreasing hemoglobin A1c concentrations in decreasing the complication rate. In this study, patients who received intensive treatment with either an insulin pump or 3 or more daily insulin injections, frequent phone calls and clinic visits, and self-management education substantially decreased their risk of both onset and progression of retinopathy, compared with patients treated with conventional therapy. The risk of retinopathy was decreased by 53% in children 13 to 17 years of age and with no retinopathy at study entry, and the risk of retinopathy progression was decreased by 70% in those who had retinopathy at the beginning of the study.[2]

One of the concerns regarding the institution of intensive metabolic control had been the potential for the acceleration of DR on the basis of a report by Daneman et al[3] of 4 patients with poorly controlled diabetes mellitus and short stature who developed macular edema and severe proliferative DR shortly after initiation of appropriate insulin therapy. This complication was evaluated in patients enrolled in the DCCT, and early worsening over the first 6 to 12 months was found to be more prevalent in patients with intensive treatment (13.1%) compared with patients with conventional treatment (7.6%).[4] However, the long-term outcomes in the patients with early worsening were the same or better than those treated with conventional therapy. The Kroc Collaborative Study Group[5] also found that early worsening of DR was not sustained and was not associated with a worse long-term outcome. Additionally, the benefits of intensive therapy continued to be evident 7 years after the end of the DCCT, as demonstrated in the Epidemiology of Diabetes Interventions and Complications study.[6–8] Thus, in most cases the potential for early worsening should not restrict institution of intensive glycemic control.

Optimizing Treatment of Retinopathy

The development of optimal treatment modalities for ocular disease has also been evaluated in several

doi:10.1542/peds.2005-0875

studies, one of the most important of which is the Early Treatment of Diabetic Retinopathy Study.[9] This large study evaluated the benefit of early treatment for 2 ocular complications of type 1 diabetes mellitus, diabetic macular edema, and proliferative DR. Studies clearly demonstrated that patients with high-risk characteristics of these disorders experienced a marked improvement in outcome after laser therapy.[9,10] The risk of moderate vision loss (eg, a doubling of the visual angle or 20/20 vision reduced to 20/40) from diabetic macular edema was decreased by approximately 50% with appropriate focal laser photocoagulation for clinically significant macular edema (from approximately 25% without treatment to approximately 12% with treatment). The risk of severe vision loss (best corrected vision of 5/200 or worse) from proliferative DR was decreased to <2% with appropriate scatter (panretinal) laser photocoagulation.

Identification of Risk Factors for Ocular Disease

DR typically follows a predictable progression.[11] Early nonproliferative DR is characterized by changes in retinal blood flow and other microvascular changes, which may lead to ischemia, small retinal hemorrhages, and leakage of exudative fluid within the retina. More severe nonproliferative DR is characterized by intraretinal microvascular abnormalities, more extensive hemorrhages and microaneurysms, and changes in venous caliber and tortuosity, reflecting progressive capillary closure and retinal ischemia. Proliferative DR is marked by fibrovascular proliferations on either the optic disk (new vessels on the disk) or new vessels elsewhere on the retina. Proliferative DR may cause vision loss by vitreous hemorrhage or contraction of fibrovascular tissue with subsequent retinal detachment. Laser surgery is promptly indicated when an eye approaches or reaches high-risk proliferative DR. High-risk proliferative DR is clearly defined and characterized by one or more of the following lesions: (1) new vessels on the optic disk approximately one fourth to one third disk area or more in size; (2) new vessels on the optic disk less than one fourth the disk area in size when fresh vitreous hemorrhage or preretinal hemorrhage is present; or (3) new vessels elsewhere on the retina greater than or equal to one half the disk area in size when fresh vitreous hemorrhage or preretinal hemorrhage is present.

The goal of a regular eye examination is to identify and treat patients before the development of vision-threatening complications. Diabetic macular edema can be present with any level of nonproliferative or proliferative DR. The role of ophthalmologic screening programs for DR will be the focus of this report.

FACTORS THAT AFFECT ONSET OF DR

Several epidemiologic studies have evaluated risk factors for development of DR. Some of these factors are amenable to treatment, resulting in a decreased risk of DR, such as optimizing metabolic control as reported in the DCCT, discontinuing smoking, avoiding obesity, and monitoring blood pressure. Other factors such as patient age, duration of disease, and the effects of puberty and pregnancy are not modifiable. The impact of the individual risk factors may be difficult to isolate, because they are not independent of one another (ie, the longer the duration of the disease, the older the patient will be).

Duration of Disease

The duration of diabetes is unequivocally one of the most important risk factors for the development of DR. Essentially all studies demonstrate that the risk of DR increases with time in individuals with diabetes. In a study of 996 patients who had been diagnosed with type 1 diabetes mellitus when they were younger than 30 years, Klein et al[12] found that the prevalence of DR increased from 17% for patients with diabetes for less than 5 years to 98% for patients with diabetes for 15 or more years. The prevalence of proliferative DR increased from 1% in patients with diabetes for less than 10 years to 67% in patients with diabetes for 35 or more years. A few studies have reported mild DR in children with duration of disease as short as 1 to 2 years,[13,14] but in most studies the duration is 3 or more years, with typical durations of 8 to 10 years before development of DR.[15,16]

Age

The effect of age on the development of DR is linked to the duration of the disease (patients with longer durations are typically older). What is clear is that young children (younger than 10 years) with type 1 diabetes mellitus are at minimal risk of the development of significant ocular complications. The presence of any DR before 10 years of age has been reported rarely,[13,14] and these cases have been mild. In a series of 996 patients with type 1 diabetes mellitus who had been diagnosed before 30 years old, Klein et al[12] found that mild DR was identified in only 1 patient in the first decade of life, and moderate DR was identified in 1 patient between 10 and 14 years of age. Neither of these patients required treatment. In a follow-up study of 634 patients by Klein et al,[17] no patient who was younger than 10 years at the time of diagnosis of type 1 diabetes mellitus developed proliferative DR within 10 years of diagnosis. In a comprehensive review of the literature, no report of proliferative DR could be found in a patient in the first decade of life.

Puberty

The effect of puberty on the development of DR has been difficult to clearly elucidate. Although the duration of diabetes before puberty affects the onset of DR,[14,18] there is good evidence that the hormonal changes associated with puberty exert an effect that is independent of age and duration of disease. Rogers et al,[19] in a study of 76 patients, found a significantly higher prevalence of DR in late pubertal subjects compared with prepubertal subjects despite similar duration of disease and similar glycosylated hemoglobin concentrations. In a similar study, Murphy et al[20] found that the relative risk of having DR in a pubescent group of children compared with a prepubescent group was 4.8.

Pregnancy

Pregnancy represents another well-established risk factor for DR. Several studies have demonstrated progression of DR during pregnancy.[21–24] Factors that exacerbate the acceleration of DR during pregnancy include poor metabolic control, hypertension, and a baseline degree of retinopathy. The large studies of pregnancy and DR do not include pediatric patients, and we are unaware of any study that specifically addresses the effects of pregnancy in adolescent patients with type 1 diabetes mellitus.

GUIDELINES FOR OPHTHALMIC SCREENING FOR DR

Screening guidelines for DR have been published previously by the American Academy of Pediatrics,[25] the American Academy of Ophthalmology,[26] and the American Diabetes Association.[27] The recommendations regarding pediatric patients with type 1 diabetes mellitus are similar. The American Academy of Ophthalmology recommends annual screening beginning 5 years after the onset of diabetes.[26] The guidelines from the American Diabetes Association include annual screening beginning 3 to 5 years after diagnosis of diabetes once the patient is 10 years or older.[27] The American Academy of Pediatrics recommends an initial examination 3 to 5 years after diagnosis if older than 9 years, with annual follow-ups thereafter.[25]

The recommendations reflect the fact that the incidence of DR in young children is negligibly small, and therefore children younger than 9 years do not require screening for DR. The incidence of retinopathy in young adolescents is also very low, particularly for proliferative DR. Although the risk of DR typically does not increase significantly until 8 to 10 years after diagnosis, the recommendation for annual screening beginning 3 to 5 years after diagnosis (in children who are older than 9 years) is reasonable, given that DR has been reported occasionally within this time.

Because children with type 1 diabetes mellitus are at a greatly increased risk of visual loss over the course of their lives, special attention should be given to identifying other causes of visual loss in these patients. Screening for potentially treatable visual disorders such as amblyopia is recommended for all children[28] and should be performed with particular care in children with type 1 diabetes mellitus. Patient and parent education regarding the benefits of optimal metabolic control is also beneficial early in the course of the disease.

IMPLEMENTATION

The development of appropriate screening strategies for detecting DR in patients with type 1 diabetes mellitus is important, but guidelines are of little use if they are not implemented. Unfortunately, studies that evaluate this aspect of care have been discouraging. In a study by Witkin and Klein[29] that included 902 young patients with type 1 diabetes mellitus, 26% had never had an ophthalmologic examination, including 11% of patients at high risk of visual loss. In an Australian study that was performed before and one year after distribution of ophthalmic screening guidelines, McCarty et al[30] found that the guidelines had been distributed successfully, but there was no significant change in management practice. The usefulness of digital photography in detecting retinopathy has been demonstrated.[31] This technology holds great promise but is unlikely to become widely used until it can be performed rapidly, simply, and at a reasonable cost. Studies that evaluate methods to improve implementation of guidelines could potentially provide great benefit to patients with type 1 diabetes mellitus.

abstract

Secondhand tobacco smoke (SHS) exposure of children and their families causes significant morbidity and mortality. In their personal and professional roles, pediatricians have many opportunities to advocate for elimination of SHS exposure of children, to counsel tobacco users to quit, and to counsel children never to start. This report discusses the harms of tobacco use and SHS exposure, the extent and costs of tobacco use and SHS exposure, and the evidence that supports counseling and other clinical interventions in the cycle of tobacco use. Recommendations for future research, policy, and clinical practice change are discussed. To improve understanding and provide support for these activities, the harms of SHS exposure are discussed, effective ways to eliminate or reduce SHS exposure are presented, and policies that support a smoke-free environment are outlined. *Pediatrics* 2009; 124:e1017–e1044

INTRODUCTION

Secondhand tobacco smoke (SHS) is exhaled smoke, the smoke from burning tobacco, and smoke from the filter or mouthpiece end of a cigarette, pipe, or cigar. It contains many poisons, including nicotine (a pesticide), carbon monoxide, ammonia, formaldehyde, hydrogen cyanide, nitrogen oxides, phenol, sulfur dioxide, and others.[1] In 1992, the US Environmental Protection Agency classified SHS as a class A known human carcinogen.[2]

Tobacco use is a cycle of addiction and exposure that can begin at conception and persist throughout life.[3] Most (~80%) users of tobacco start before 18 years of age, prompted by exposure to parental and peer tobacco use, smoking in movies and media, advertising directed toward children and adolescents, and other factors.[4–11] More than 126 million nonsmokers are exposed to SHS in the United States, and the most common site of SHS exposure is the home.[1,12,13] Children, especially preschool-aged children, are more heavily exposed than adults, perhaps because they spend the most time near their parents[13,14] (Fig 1). The proportion of nonsmokers with detectable levels of cotinine (the primary metabolite of nicotine in humans) in serum fell from 88% in 1988–1991 to 43% in 2001–2002, corresponding to the decline in the rate of tobacco use.[14] The proportion of women who reported smoking during pregnancy has decreased by 50% over the past 15 years (from ~20% in 1989[15] to ~10% in 2004[16]), although many experts question the accuracy of self-reported tobacco use because of the social undesirability of smoking during pregnancy.[17] Tobacco use and smoking

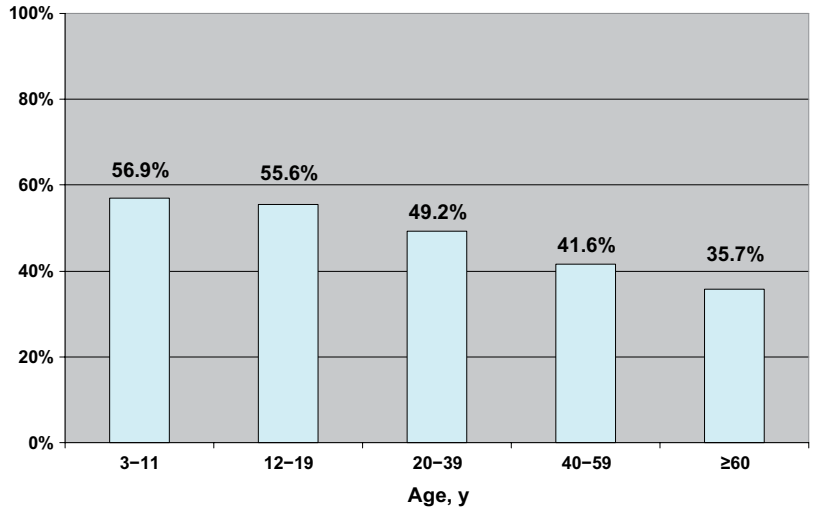

FIGURE 1
Prevalence of SHS exposure, indicated by a serum cotinine level of ≥0.05 ng/mL, United States, 2001–2002.[1]

rates are highest among American Indian and Alaska Native individuals.[18]

As with many risky health behaviors, the prevalence of tobacco use is greatest among adults who live below the poverty line and those with less than a high school education.[18] Correspondingly, children who live in poverty are more likely to be exposed to SHS than others.[19] In a study of serum cotinine levels in nonsmokers, black and white children had higher levels than did Hispanic children.[14] Differences in metabolism of nicotine may contribute to these higher concentrations.[20]

EFFECTS OF SHS EXPOSURE

The reports of direct health effects of SHS exposure are numerous and growing in number. The most recent comprehensive reports are the 2006 US Surgeon General's report, *The Health Consequences of Involuntary Exposure to Tobacco Smoke*,[1] and California's *Proposed Identification of Environmental Tobacco Smoke as a Toxic Air Contaminant*.[21] The major conclusions from the Surgeon General's report relevant to children are summarized in Table 1. In addition to confirming the conclusions of the US Surgeon General, the authors of the California report found sufficient evidence to impute a causal association

TABLE 1 Major Conclusions of the Health Consequences of Involuntary Exposure to Tobacco Smoke: A Report of the Surgeon General[1]

Exposure Type	Disease	Conclusion (Page No.)
Maternal exposure to SHS during pregnancy	Preterm delivery	The evidence is suggestive but not sufficient to infer a causal relationship (195).
	Low birth weight	The evidence is sufficient to infer a causal relationship (205).
Maternal exposure to SHS during pregnancy and postnatal SHS exposure	Childhood cancer, leukemia, lymphoma, and brain tumors	The evidence is suggestive but not sufficient to infer causal relationships (242).
Postnatal SHS exposure	Sudden infant death	The evidence is sufficient to infer a causal relationship (194).
	Lower respiratory illnesses	The evidence is sufficient to infer a causal relationship. The increased risk for lower respiratory illnesses is greatest from smoking by the mother (292).
	Middle-ear disease	The evidence is sufficient to infer a causal relationship between parental smoking and middle-ear disease in children, including acute and recurrent otitis media and chronic middle-ear effusion.
		The evidence is suggestive but not sufficient to infer a causal relationship between parental smoking and the natural history of middle-ear effusion (309).
	Cough, phlegm, wheeze, breathlessness, asthma	The evidence is sufficient to infer a causal relationship between SHS exposure from parental smoking and the onset of wheeze illnesses in early childhood (375).
		Among school-aged children, the evidence is sufficient to infer a causal relationship (355).
		The evidence is suggestive but not sufficient to infer a causal relationship between SHS exposure from parental smoking and the onset of childhood asthma (375).
		Among school-aged children, the evidence is sufficient to infer a causal relationship between parental smoking and ever having asthma (355).
Maternal smoking during pregnancy and postnatal SHS exposure	Lung function	The evidence is sufficient to infer a causal relationship between maternal smoking during pregnancy and persistent adverse effects on lung function across childhood (399).
		The evidence is sufficient to infer a causal relationship between exposure to SHS after birth and a lower level of lung function during childhood (399).

between SHS exposure of girls and an increased incidence of breast cancer, particularly in premenopausal women.[21] Many other effects for which the supporting evidence is incomplete or less compelling have been reported (Appendix 1).

One of the significant consequences of prenatal tobacco exposure is sensitization of the fetal brain to nicotine, which results in increased likelihood of addiction when the brain is exposed to nicotine at a later age. Studies of rodents[22–24] and primates[25] that were exposed prenatally to tobacco have demonstrated subtle brain changes that persist into adolescence and are associated with tobacco use and nicotine addiction.[26,27] Population-based human studies have demonstrated associations between prenatal tobacco exposure and early tobacco experimentation[28] as well as increased likelihood of tobacco use as an adolescent and adult.[29,30] Other studies showed associations between parental tobacco use and increased rates of child experimentation with tobacco and smoking uptake.[7,31–34] Most of these studies did not control for prenatal tobacco or postnatal SHS exposure, which makes it difficult to draw conclusions about the influence of SHS exposure, because the 3 factors are linked. By definition, in households with a smoker, someone presents a role model of smoking, which may further increase the likelihood of initiation of tobacco use by preadolescents and adolescents.[7,35]

The evidence supporting the association of SHS exposure of children with respiratory illnesses is strong. Increased rates of lower respiratory illness, middle-ear infections, tonsillectomy and adenoidectomy, cough, asthma and asthma exacerbations, hospitalizations, and sudden infant death syndrome have been reported.[1,21] The scope of these illnesses is huge: it has been estimated that SHS exposure causes asthma symptoms in 200 000 to 1 000 000 children and contributes to as many as 8000 to 26 000 new cases of asthma per year.[36] SHS exposure exacerbates many chronic diseases. Children with sickle cell disease who are exposed to SHS have a higher risk of crises that require hospitalization than do unexposed children.[37]

Another effect of SHS exposure is increased school absenteeism. Analysis of data from the Third National Health and Nutrition Examination Survey showed that SHS-exposed children were twice as likely to miss 6 or more school days per year than were unexposed children (odds ratio: 2.0 [95% confidence interval: 1.4–2.8]).[38] A study of California schoolchildren showed that SHS-exposed children had a similar increased risk of absence from school, with risk increasing as the number of household smokers increased (relative risk: 1.29 [95% confidence interval: 1.02–1.63]).[39]

Children and the elderly represent a disproportionate share of fire victims, and smoking materials are the most common ignition source of fatal residential fires.[40–43] It has been estimated that smoking causes approximately 30% of US fire deaths overall, with at least 100 000 fires each year caused by children playing with ignition materials. The rate of fire deaths has decreased as smoking has decreased.[44] The technology of "fire-safe" cigarettes has been available for many years, although implementation of the technology was blocked by the tobacco industry for years.[45] In 2004, New York implemented a law that requires all cigarettes sold in the state to have "reduced ignition propensity."[46] Since then, many states and Canada have adopted similar laws.

COSTS TO FAMILIES

The cost of buying tobacco products is considerable; a family in which 1 member smokes 1 pack per day would spend more than $1600 on cigarettes each year (average price per pack in 2007: $4.49).[47] These expenditures can reduce a family's ability to meet essential needs; among low-income families, food insecurity is more likely if a family member uses tobacco.[48]

There are other, hidden costs to a family that are attributable to tobacco use. A 1997 analysis of National Longitudinal Survey of Youth data showed that tobacco users' wages were reduced by 4% to 8%, even after controlling for differences in education and other characteristics. The authors hypothesized that these differences were attributable to a combination of discrimination against tobacco users, increased absenteeism, poor health, and self-selection of jobs that include employer-provided health insurance at the expense of lower wages.[49] An additional effect may be decreased ability of SHS-exposed adults to care for children, because SHS exposure causes premature death and disease in nonsmokers, including coronary heart disease and lung cancer.[1]

COSTS TO SOCIETY

Estimates of the high medical costs of children's exposure to SHS and tobacco use in general have been made, several of which are summarized in Table 2. The health care cost of tobacco use, in both dollars and disease, is tremendous and is estimated to be more than $260 million each day in the United States.[50] Smoking by parents alone contributed estimated direct medical expenditures of $4.6 billion and loss-of-life costs of $8.2 billion in 1993.[51,52] A study that used National Medical Expenditure Survey data showed that health care costs for respiratory illnesses alone were increased by $120 per year for children 5 years or younger and by $175 per year for children 2 years or younger who were exposed to SHS by maternal

TABLE 2 Some Costs of Tobacco Use and SHS Exposure

Item	Cost	Source	Years Data Collected	Citation
Smoking during pregnancy: neonatal health care	Smoking-attributable fraction for neonatal costs: 2.2% (all states); $700/infant born to a mother who smoked during pregnancy	Centers for Disease Control and Prevention Pregnancy Risk Assessment Monitoring System (PRAMS) database	1995	Adams et al (2002)[136]
SHS exposure of pregnant women: early intervention services delivered to children with developmental delay attributed to maternal SHS exposure during pregnancy	$99 million for early-intervention services delivered to 8300 New York City children ($11 900/child)	New York City data	2002	Miller et al (2006)[137]
SHS exposure of children: health care costs	9% of total direct medical costs in the first year of life	Birth cohort study in Hong Kong	1997–1998	Leung et al (2003)[51]
SHS exposure of children: respiratory disease, sudden infant death, burns, costs to the family	Direct medical expenditures of $4.6 billion; loss-of-life costs of $8.2 billion	Literature synthesis	1980–1996	Aligne and Stoddard (1997)[3]
SHS exposure of children: medical expenditures for childhood respiratory illness	Respiratory-related health care expenditures: 19% of expenditures for childhood respiratory conditions ($120/child aged ≤5 y; $175/child aged ≤2 y)	National Medical Expenditure Survey	1987	Stoddard and Gray (1997)[52]
Overall smoking in the United States	6%–8% of total annual expenditures for health care, with some estimates up to 14%	Literature synthesis	Through 1998	Warner et al (1999)[138]

smoking (1995 dollars).[52] Tobacco users are more likely to be absent from work, to be disabled, and to die prematurely. The corresponding loss of productivity was estimated to be $92 billion for the period 1997–2001.[53]

INTERVENTIONS

Although household smoking bans reduce children's SHS exposure, even a strict ban does not eliminate exposure.[52,54] SHS can enter the home in the air, on dust, in or on clothing, or via the smoker's exhaled breath.[55] Nearly 90% of households of nonsmokers have an indoor smoking ban; households that include smokers have a much lower rate of smoking bans.[56–58] Individuals who consider SHS exposure to be harmful are most likely to report having an indoor home smoking ban.[57,59–62] Fewer parents ban smoking in the car than in the home,[56,59,61,63] although recent state legislative efforts to outlaw smoking in a car carrying a child may increase the rate of car bans.†

There is strong evidence that adult tobacco users can successfully quit and that counseling and pharmacotherapies help them succeed. Each year, 4% to 9% of tobacco users quit without support[64]; tobacco users who receive counseling and use pharmacotherapies significantly increase their likelihood of quitting.[65]

The 2008 update of the US Public Health Service clinical practice guideline, *Treating Tobacco Use and Dependence*,[65] provides guidelines for clinical practice and presents meta-analyses of approximately 8700 scientific articles on cessation of tobacco use. The review covers assessment of tobacco use; brief, intensive clinical interventions; systems interventions; pharmacotherapies; special populations such as pregnant women, children, and teenagers; and other topics such as weight gain and cost-effectiveness.

Addressing Tobacco Dependence in the Pediatric Setting

The US Public Health Service guideline recommends that all clinicians strongly advise patients who use tobacco to quit and states: "Clinicians in a pediatric setting should offer smoking cessation advice and interventions to parents that limit children's exposure to second-hand smoke."[65] Few studies have evaluated ways to protect children from SHS exposures through promotion of smoking bans or tobacco-cessation interventions delivered to family members through pediatric practices. Interventions that have been successful in decreasing the SHS exposure of children generally provide intensive, home-based counseling[66,67]; these interventions have not been translated effectively from academic to community settings.[68,69] In a randomized trial of practice-based counseling and reminders to promote tobacco cessation by mothers, Groner et al[70] reported no significant effect of the intervention on cessation, although mothers in the intervention group re-

†For more information on states with bans on smoking in cars that carry children, contact the American Academy of Pediatrics (AAP) Division of State Government Affairs.

ported smoking outside more often than did mothers in the control group. A Cochrane collaboration review of programs to reduce exposure of children to SHS concluded that "brief counseling interventions, successful in the adult health setting when coming from physicians, cannot be extrapolated to adults in the setting of child health."[71]

Despite the paucity of evidence supporting the effectiveness of counseling delivered in the pediatric setting, the arguments for asking about tobacco use and SHS exposure, advising all families to make their home and cars smoke free, counseling users to quit, and referring users to cessation programs are compelling. The pediatric visit provides many opportunities to deliver tobacco use-cessation counseling to parents. Because parents of younger children are themselves typically young and healthy, many see their child's pediatrician more often than they see their own primary care clinician. Pediatric visits offer many "teachable moments"[72] to discuss tobacco use, from both the prevention and cessation perspectives, and parents may be motivated to change their behavior for the benefit of their child's health. Another important counseling opportunity is the new parent who quit using tobacco during pregnancy: 48% to 70% of mothers who quit smoking during pregnancy relapse after delivery.[73–76]

Barriers to Counseling Parents

Because it is an accepted role of the pediatrician to counsel parents in behavior changes that will improve the life and health of their child, including changes in sensitive areas such as diet and discipline, one might expect that counseling parents to make their homes and cars smoke free or to quit using tobacco would be included routinely in the pediatric visit. However, many opportunities to counsel parents are missed. Tanski et al[77] reported that during the period 1997–1999, only 1.5% of ambulatory care visits, 4.1% of well-child visits, 4.4% of acute illness visits for asthma, and 0.3% of acute illness visits for otitis media included delivery of tobacco counseling. One possible reason for these low rates of counseling may be concerns about alienation of the parent.[78,79] However, many parents who smoke welcome advice to quit; in a sample of Vermont parents who smoked, 52% said they would welcome a pediatrician's advice to quit using.[80] Other studies of parents have concurred.[80–83]

Other challenges to counseling parents in the pediatric setting are writing prescriptions for cessation medications and the lack of a charting system for parents. Prescription of medications used to support cessation attempts by their child's pediatrician is accepted by parents; in a 2003 telephone survey of parents who smoked, 85% of respondents reported that it was acceptable for their child's doctor to prescribe a smoking-cessation medication for them.[84] Only 8% had received such a prescription; in a different survey of pediatricians,[78] only 13% said they would prescribe or recommend nicotine-replacement therapy (NRT) to parents who smoke and have children 5 years or younger.

Although writing prescriptions for people who are not patients raises concerns about propriety, malpractice, and ethics, writing prescriptions for family members of a patient has precedent. For instance, prophylactic therapy or immunization for household members of a person exposed to invasive *Haemophilus influenzae* type b disease, hepatitis A, meningococcal disease, head lice, pertussis, plague, scabies, or varicella is recommended by the AAP Committee on Infectious Diseases.[85] Many of the antibiotic agents used for these treatments are associated with significant adverse effects and a prescription is required, whereas several NRT products are available without a prescription.‡ However, the need for good record-keeping persists, and some clinicians may decide to set up a separate chart for their patients' household members.

Practices may adopt strategies to encourage parents to seek care from their own clinicians or seek help from other cessation resources, including local or state health departments. A key aspect of this counseling is to convey the importance of seeking help and the benefits of cessation programs that fit the needs of the parent, including both appropriate counseling and pharmacotherapy.

Other concerns include lack of time and reimbursement for services. As of 2006, 76.5% of states (including the District of Columbia) provided Medicaid coverage for some component of tobacco use treatment,[86] and of those, only 1 (New Mexico) offered coverage for all of the treatments recommended in the US Public Health Service guideline.[65] Coverage provided by private insurance plans varies widely, and few plans cover over-the-counter NRTs or individual face-to-face counseling.[87] The lack of coverage for tobacco-dependence treatments that have been shown to be both efficacious and cost-effective is an important issue in healthy policy.

Coding for SHS Exposure and Treatment

To further develop the evidence supporting the benefits of tobacco-dependence treatment in the pediatric setting, coding for diagnosis and treatment is important. Two codes may be particularly useful[88]:

‡Except for people 18 years or younger or if required for reimbursement or insurance coverage.

- 989.84 (toxic effects of tobacco); and
- V15.89 (other specified personal history presenting hazards to health [list SHS exposure as the hazard]).

Similarly, naming SHS as a factor in insurance claims, death certificates, and other documents can aid in assessing the effects of SHS exposure on health and the need for reimbursement for treatment of SHS exposure.

Tobacco-Cessation Treatment of Adults

There is strong evidence that adult tobacco users can successfully quit and that counseling and pharmacotherapy help them succeed.[65] Each attempt to quit increases the likelihood of success. Without counseling, 4% to 9% of tobacco users quit each year[64]; with counseling and pharmacotherapies, 17% to 44% of attempts are successful.[89]

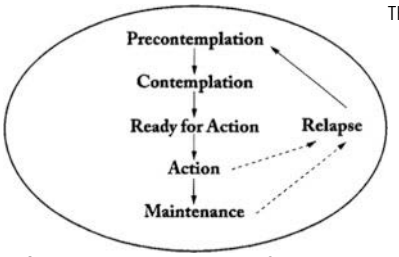
In adult medical care settings, simply asking about tobacco use and SHS exposure and recommending that users quit has been shown to increase the number of quit attempts and the success rates of those attempts.[65] Counseling does not need to be extensive and is additive, resulting in an increase in quit attempts, and the success rates of quit attempts as the amount of counseling delivered increases even if the counseling is delivered over the course of several visits.

Tailoring the message to the needs of the individual increases the likelihood of success. Although tobacco-cessation counseling is equally effective with women as with men, women may more often have concerns about weight gain or be using nicotine to alleviate depression. Studies of counseling tailored to women have suggested that addressing these gender-specific issues may increase success.[65] Counseling of pregnant women has been also shown to be effective; the US Public Health Service guideline[65] recommends more intensive counseling, particularly person-to-person psychosocial interventions that exceed the minimal advice to quit. Counseling techniques and resources tailored to pregnant women are available (www.ahrq.gov/path/tobacco.htm#Pregnant).

The most successful counseling and behavioral therapies to promote cessation include problem-solving/skills training and social supports. Most structured counseling is based on the "stages-of-change" theory, which explains how individuals change personal behaviors.[90] When used in the context of tobacco-use cessation, the goal is to help a user progress through 6 stages in a stepwise manner (Table 3). Specific counseling methods, such as motivational interviewing, may help identify and overcome barriers to cessation. Motivational interviewing is a client-centered, directive counseling method to enhance readiness for change by helping clients explore and resolve ambivalence toward change[91] (Table 4). Both stages-of-change theory and motivational interviewing techniques can be used to understand and address health behaviors other than tobacco use.

The process of effective tobacco-use cessation counseling can be broken into 5 steps, called the 5 A's: ask, advise, assess, assist, and arrange follow-up (Table 5).[65] Identifying the benefits to the child of parental smoking cessation may be an important motivation to parents. Not every parent will be ready to consider quitting. Using the 5 R's (Table 6) to help overcome

TABLE 3 Stages of Change[90]



The theory supporting stages of change is that people progress through several stages on their way to a behavior, and to change the behavior, they must pass through several stages as well. When used in the context of tobacco-use cessation, the goal is to help a user progress through 6 stages in a stepwise manner. Structured cessation counseling based on the stages of change focuses on helping the precontemplator become a contemplator, a contemplator become ready for action, etc, until the user enters termination and no longer perceives any cues to use tobacco.

Precontemplation is the period in which users are not thinking about quitting (at least not within the next 6 mo). Educating the user in the harms of tobacco use to themselves and their children may help the tobacco user move toward the contemplation stage.

Contemplation is the period of time in which users are seriously thinking about quitting within the next 6 mo but are not ready to start the process. Addressing barriers to quitting and helping parents overcome their fear of living without tobacco by discussing each barrier may move users toward preparing to quit.

Ready for action is the period during which users seriously think about quitting in the next month. The definition also applies to users who have tried to quit in the previous year. These users are ready to learn about quitting and are ready to set a quit date. The clinician should be prepared to help the user follow through with a quit date in the next 4 to 6 wk.

Action is the period ranging from 0 to 6 mo after users quit. This is the busiest period of change. The clinician can help the (now former) user avoid relapse by reminding him or her of successes and the reasons for quitting.

Maintenance is the period beginning 6 mo after action started and continuing until tobacco use is terminated as a problem. Maintenance involves development of new responses to situations that might trigger relapse. In this stage, clinicians continue to provide support for the quitter to remain tobacco free.

Relapse is technically any time the user, or ex-user, moves back in the cycle, but the person is usually thought of as a user who has quit for some period of time and uses tobacco again.

Termination is when the addictive behavior is entirely extinguished; this may take years.

TABLE 4 Principles of Motivational Interviewing[91]

Express Empathy	Acceptance Facilitates Change
	Skillful, reflective listening is fundamental.
	Ambivalence is normal.
Develop discrepancy	The client, rather than the counselor, should present the arguments for change.
	Change is motivated by a perceived discrepancy between present behavior and important personal goals or values.
Roll with resistance	Avoid arguing for change.
	Resistance is not directly opposed.
	New perspectives are invited but not imposed.
	The client is a primary resource in finding answers and solutions.
	Resistance is a signal to respond differently.
Support self-efficacy	A client's belief in the possibility of change is an important motivator.
	The client, not the counselor, is responsible for choosing and carrying out change.
	The counselor's own belief in the client's ability to change becomes a self-fulfilling prophecy.

barriers to cessation can provide a framework for counseling.[65]

Correctly used pharmacotherapy significantly increases the odds of success.[65] NRT products are available without prescription in patch, gum, and lozenge forms. NRT nasal spray and inhalers require prescriptions. Most NRT products are priced comparably to the cost of smoking a pack of cigarettes each day. Because these products are not available as single units, this cost can be prohibitive for many patients (ie, $50 or more for 1 package). NRTs are relatively easy to use, and some forms can provide rapid relief for difficult moments. However, NRT products have not been as successful in improving long-term cessation rates during pregnancy[92] or when used by adolescents[93] as they have been in the general population. Bupropion and varenicline are available only by prescription; both reduce the number and severity of urges to smoke, with results for varenicline somewhat better than for bupropion.[94] Clinicians should be familiar with NRTs and other pharmacotherapies used to treat tobacco dependence and promote their use for adolescent and young adult patients and parents. The American Academy of Family Physicians has an excellent guide (see "Prescribing Guidelines" at www.aafp.org/online/en/home/clinical/publichealth/tobacco/nrt.html for quick access to information on dosing, precautions, and adverse effects of tobacco-cessation medications that have been approved by the US Food and Drug Administration).

Many users make multiple attempts to quit before succeeding, and although most relapses occur early in the quitting process, some occur months or even years later.[65] Because of the chronic relapsing nature of tobac-

TABLE 5 A Systematic Method for Counseling About Tobacco: The 5 A's[65]

Ask
- Obtain a tobacco-use and SHS-exposure history for all patients and their parents/households, including current use or exposure as well as use or exposure before and during pregnancy.
- Ask about SHS exposures in child care settings and homes visited by the child.
- Use charting prompts or other cues to increase initiation of history-taking and documentation of family tobacco use and SHS exposures. When selecting or designing electronic health records and paper records, include tobacco-history-documentation prompts in the selection and design criteria.
- Questions asked should be phrased to limit misunderstanding about whether the query is about smoking "in (inside) the home" or smoking status of household members. When asking about smoking inside the home, say "does anyone smoke inside your home, even in the basement or garage?" rather than "does anyone smoke around the baby?"

Advise
- Provide information about elimination of children's SHS exposure to all parents and information about tobacco-use cessation, as indicated. Provide strong messages on harm from SHS exposure.
- Engage parents in discussions about their tobacco use. Provide a strong quit-using message that is clear. For example, you can say, "As your child's doctor, I think the very best thing you can do for your health and your child's health is to quit smoking." Personalize the child's health risk by saying, "It is very likely that Alicia's ear infections are worsened by your smoking," or, "Paul's asthma attacks may improve if he is not exposed to your smoking; it is important that you quit smoking."

Assess
- Determine the parent's readiness to quit. Is the parent a precontemplator or a contemplator? Is he or she ready to quit within the next month?

Assist
- Precontemplation stage: Provide a motivational message (the 5 R's [see Table 6]).
- Contemplation stage: If parents are not ready to set a quit date, ask them to make a list of everything they like and do not like about smoking to help get them thinking about tobacco use in a more specific way.
- Preparation stage: Help them set a quit date. Address their concerns about quitting, including withdrawal symptoms and perceived barriers to quitting. Perceived barriers to quitting can be addressed by educating the user about the quitting process, including what to expect and how long symptoms will last, weight gain, triggers to smoking, feelings of deprivation, and flagging motivation. Acute nicotine withdrawal can last from several days to weeks after cessation, typically peaking between 1 and 3 wk after the last cigarette is smoked.[65]
- Refer to supports such as quit-smoking groups, community quitlines, and other supports, as available.

Arrange follow-up
- Plan to follow-up on any behavioral commitments that parents make on follow-up visits for health care maintenance or for ongoing medical problems.

TABLE 6 Counseling to Overcome Resistance to Quitting Tobacco Use: The 5 R's[65]

Relevance
Ask parents to consider the personal importance of quitting.
Advise parents that (1) their personal health will improve (they will feel better physically and perform better in physical activities, they will have fewer wrinkles and their skin will not age as fast, food will taste better, their sense of smell will improve), (2) the children's health will improve (they will have healthier infants and children, they will set a good example for children), (3) their home, car, clothing, and breath will smell better, (4) they will save money, and (5) they will be able to say they are a "former smoker" and can stop worrying about quitting and about exposing others to smoke.
Try to personalize the benefits of quitting to the parents' situation.
Risks
Ask parents to identify the negative consequences of tobacco use.
Highlight the consequences that seem most relevant.
Rewards
Ask parents to identify the benefits of quitting.
Highlight the benefits that seem most relevant.
Roadblocks
Help parents to identify barriers to quitting.
Identify possible solutions such as pharmacotherapy or changes in daily patterns that may alleviate those barriers.
Repetition
Repeat the message every time parents who use tobacco visit the office.
Convey to tobacco users that most people make several quit attempts before they are successful.

co dependence, pediatricians should continue to deliver the "stay-quit" message whenever possible. Relapse-prevention counseling is especially important right after the quit date and can be delivered during scheduled office visits, during telephone calls, on postcards, or by using other methods.[65]

If a "lapse" occurs, discuss the cues that promoted the lapse and what the parent learned about cues and quitting. It is important to remind the parent that the urge to smoke lasts only a few minutes, so distraction techniques can be helpful during "craving attacks."[65] Other topics to address include the parent's success to date and anticipatory guidance regarding weight gain, cravings, environmental cues, and other tobacco users in the household or family.

Quitlines and Other Resources

A variety of resources are available to clinicians to guide care. The US Public Health Service clinical practice guideline[65] presents information on how to assess tobacco use; brief and intensive clinical interventions; systems interventions; pharmacotherapy; special populations such as pregnant women, children, and teenagers; and special topics such as weight gain and cost-effectiveness. The national Quit Line, 1-800-QUIT NOW, provides evidence-based, effective telephone counseling and is available throughout the United States. In many states, "fax-back" forms can be used to refer a tobacco user to the Quit Line directly, rather than instructing the patient or parent to call the Quit Line. The use of fax-back referrals has been shown to significantly increase the number of tobacco users who use the Quit Line.[95] The American Cancer Society, the American Lung Association, and many hospitals provide group counseling and other cessation resources. Appendix 2 describes many resources for clinicians and tobacco users.

COST AND EFFECTIVENESS OF TREATING TOBACCO USE AND NICOTINE ADDICTION

Tobacco-use counseling, NRT products, and other tobacco-addiction treatments have been shown to be both cost-effective and efficacious when used in the internal medicine or family practice setting to treat adult smokers.[65,76,96,97] The benefits of insurance coverage of cessation interventions, whether intensive or minimal, accrue to both insurers and employers.[98] Brief physician-delivered smoking-cessation counseling is more cost-effective than many other widely recommended screening tests and interventions.[99]

PERSONAL AND PROFESSIONAL POLICIES

Tobacco is a product that, when used as intended, causes significant morbidity and mortality. Accepting funds from the tobacco industry for support of activities, regardless of whether it is related to tobacco control, is contradictory to the mission of health promotion for children and their families.

The tobacco industry has demonstrated their intent to manipulate public opinion,[100] scientific research,[101–107] regulation,[108] and education[109–111] to promote tobacco products throughout the world. Furthermore, by funding prestigious researchers at respected institutions, the tobacco industry gains credibility. Many articles demonstrating the intent of the tobacco industry to promote smoking and tobacco use, as demonstrated by documents internal to the industry, have been published. The American Legacy Foundation maintains the Legacy Tobacco Documents Library at the University of California, San Francisco (http://legacy.library.ucsf.edu); much of the literature on the tobacco industry is based on the documents in the library. One additional example of the influence of the tobacco industry on the practice of medicine is a successful effort to invalidate and remove the ICD (International Classification of Diseases) e-code for SHS exposure on Medicare billing form 1500. The code became available in 1994 and remained invalid until at least 2004. This apparently mi-

nor step has had a significant effect on our understanding of SHS exposure.[112]

PUBLIC POLICIES

A growing number of communities and states have implemented statewide bans on smoking in public places.§ Bans on smoking at workplaces, restaurants, child care settings, public parks, and beaches and in other public venues have been extremely successful in decreasing and, in some cases, eliminating SHS exposure.[113] Other positive effects of bans are increases in quitting attempts and successes,[96,114–117] increased prevalence of smoke-free homes and cars in the surrounding community,[61,118,119] improved air quality and health outcomes for employees[120–122] and children,[123] and decreased social acceptability of tobacco use.[58,124,125] Studies of restaurants and bars that compared income before and after a ban have shown no adverse effect on the economics of the hospitality industry.[126] Enforcement of smoke-free policies in public space typically is not an issue after a break-in period.[1]

Mass-media campaigns and comprehensive community interventions contribute to the overall social unacceptability of SHS exposure of children.[113,127,128]

Other areas of public policy in which tobacco use should be addressed include housing, child care settings, and foster care. Several groups are leading efforts to make multiunit housing smoke free, and many cooperative apartment buildings and condominiums already have done so. Appendix 3 lists several resources on this issue. Most states regulate smoking in child care settings, although many allow smoking on the premises when children are not present, resulting in exposure of children to "thirdhand" smoke. The National Resource Center for Health and Safety in Child Care and Early Education provides a list of state regulations applicable to child care settings (http://nrc.uchsc.edu/STATES/states.htm). Exposure of foster children to SHS has been prohibited by several states and counties.[129] The National Voice of Foster Parents, an organization of and for foster parents, supports legislation and rules that prohibit the use of tobacco in foster homes and vehicles used to transport foster children.[130] It is important to provide treatment for tobacco dependence when implementing and enforcing these restrictions.

TOBACCO-CONTROL EDUCATION

Although there have been many successes in efforts to reduce the prevalence and harms of smoking, the pediatric community lags behind the internal medicine, family medicine, and obstetric/gynecology communities in tobacco-control and education efforts.[131–133] Using provider education and having providers implement self-reminder systems to ensure that tobacco cessation is raised during the clinical examination has been shown to be effective, especially when used as part of a multicomponent clinical program.[65] Training in best practices in smoking-cessation counseling is not required in medical schools, pediatric clerkships, or pediatric residency programs, with the sole exception of such training listed in the program requirements for residency and fellowship education in adolescent medicine.[134,135] This absence of educational requirements in these key training periods is critical, because clinical practices may become established during training and difficult to change after completion of training.[131–133] All clinicians should be skilled in counseling to prevent tobacco use and SHS exposure and for tobacco-use cessation.

RESEARCH

There are significant gaps in the body of evidence related to pediatric tobacco control. Study of prevention approaches and interventions to limit SHS exposures in primary care settings are particularly needed. Other areas that require further study include pharmacologic effects of nicotine; use and efficacy of NRT products and other pharmacotherapy used to treat nicotine addiction of children, pregnant women, and families; effects of SHS exposure of children; and the effect of indoor air-quality laws and price/tax controls.

SUMMARY

SHS exposure of children and their families causes significant morbidity and mortality. Pediatricians have many opportunities to advocate for elimination of SHS exposure of children in their personal and professional roles.

§For more information on states with public smoking bans, contact the AAP Division of State Government Affairs.

APPENDIX 1: DISEASES AND OTHER ADVERSE HEALTH EVENTS WITH WHICH SHS OR PRENATAL TOBACCO-SMOKE EXPOSURE HAS BEEN ASSOCIATED

Note that these studies have not been critically evaluated. The reader is advised to perform his or her own evaluation before drawing conclusions. See www.aap.org/richmondcenter/AAP_Tobacco_Policy.html for updates.

Effects on the Fetus of Prenatal Tobacco Exposure Attributable to Maternal Tobacco Use

Increased risk of:

- Growth abnormalities, including
  - low birth weight[1–15] and amplification of risk of low birth weight in fetus' with cystic fibrosis[16] and
  - intrauterine growth retardation/small for gestational age[1,5,12,17]
- Delivery complications, including
  - premature rupture of membranes,[17]
  - placenta previa and abruption,[17–20]
  - preterm delivery, stillbirth, spontaneous abortion,[1,3,5,11,15,17–22] and
  - admission to NICUs[3]
- Orofacial clefts[23–31] (recent studies have been less supportive, although Honein et al[32] found fairly strong evidence for specific types of clefts)
- Septal and right-sided obstructive cardiac defects[33]
- Increased systolic blood pressure at 2 months of age[34]

Effects on the Fetus of Prenatal Tobacco Exposure Attributable to Maternal SHS Exposure

Increased risk of:

- Decreased birth weight,[35–39]
- Fetal mortality,[36,40] and
- Preterm delivery[36] and spontaneous abortion[40]

Effects on the Child of Prenatal Tobacco Exposure Attributable to Maternal Tobacco Use

Increased risk of:

- Nicotine-withdrawal symptoms during the neonatal period[41]
- Infant death
  - from all causes[3,13,17,18,40] and
  - from sudden infant death syndrome[3,17,18,42–45]
- Persistent pulmonary hypertension of the newborn[46]
- Poor sleep[47]
- Infection, including neonatal infection[18,48]
- Hypoparathyroidism[49]
- Respiratory effects, including
  - reduced lung function in infants and children,[50–53]
  - lower respiratory tract illnesses (such as pneumonia and bronchiolitis),[54]
  - increased diagnosis of asthma[55] and use of bronchodilating drugs,[47] and
  - otitis media[56,57]
- Poor growth[58]
- Behavioral and neurocognitive effects, including
  - abnormal neonatal neurobehavior, developmental delay, attention-deficit/hyperactivity disorder, conduct disorder and other aggressive behaviors,[59–61] and psychiatric disorders,[62–87] and
  - speech-processing ability[88]
- Febrile seizures[89]
- Experimentation with tobacco and addiction to tobacco as an older child or adult[76,90–92]
- Gastrointestinal disease, including
  - colic,[93–96]
  - pyloric stenosis,[97] and
  - diabetes[98]
- Legg-Calvé-Perthes disease[99]
- Some cancers[100–103]
- Development of allergies[104,105]
- Hospitalization for any illness[106–113]
- Office visits for any illness[106–110]
- Hyperopia[114]
- Significant reductions in cortical gray matter and total parenchymal volumes and head circumference[115]
- Altered development of white matter microstructure[116]
- Craniosynostosis[117] (rather weak evidence)

Effects on the Child of Prenatal Tobacco Exposure Attributable to Maternal SHS Exposure

Increased risk of:

- Reduced cognitive development[118]
- Conduct disorder[59]

Effects on Breastfeeding Attributable to Maternal Tobacco Use or SHS Exposure

Increased risk of:

- Decreased initiation and duration of breastfeeding[119–125]
- Decreased iodine levels in human milk[126]

Effects on the Child of SHS Exposure

Increased risk of:

- Allergic sensitization[111,127–152]
- Poor sleep, in breastfed infants[153]
- Lower respiratory disease, including
  - persistent decreased lung function,[106–109,137,139,149,154] amplified in children with cystic fibrosis,[16]
  - infections,[137,139,151,154–157]
  - bronchiolitis,[158] wheezing,[47] and use of bronchodilating drugs,[47]
  - asthma prevalence,[159] and
  - frequency and severity of asthma exacerbations‖

‖Refs 106, 110, 111, 128, 134, 140, 149, 156, 157, and 160–185.

- Upper respiratory infections, including
  - otitis media,¶
  - cough[106,110,111,189,190] and use of cough medicines,[47]
  - rhinitis[47] and nasal obstruction,[192]
  - tonsillectomy, adenoidectomy, and placement of pressure-equalizing tubes,[168,179,180,193,194] and
  - respiratory complications associated with anesthesia[195–199]
- Infections, including
  - invasive meningitis,[200,201]
  - infection with *Mycobacterium tuberculosis* in children who live in a household with a patient with tuberculosis,[202] and
  - infection with *Helicobacter pylori*[203,204]
- Hospitalization for
  - any illness,[106,110,111,113,205–207]
  - respiratory disease,# and
  - serious infections[206]
- Gastrointestinal disease, including
  - colic[47,93–96,209] and
  - reflux[209–211]
- Increased complications of type 1 diabetes mellitus[212] (study was small, included active smokers)
- Behavioral and neurocognitive effects[69,70,85–87,213,214]
- Dental disease[215,216]
- School absences[106,110,112,139,217,218]
- Molecular, genetic, and cellular changes[219–222]
- Experimentation with tobacco and addiction to tobacco as an older child or adult[110,223–226]
- Injury and death attributable to fires[110,227–231]
- Hyperopia[114]

¶Refs 106, 110, 111, 160, 165, 177, 178, 182, 183, and 186–191.

#Refs 54, 106, 110, 111, 129, 134, 205, and 208.

Effects on the Adult of Prenatal Tobacco Exposure Attributable to Maternal Tobacco Use

Increased risk of:

- Asthma[232]
- Elevated cholesterol levels in young adults[233]
- Hypertension[234]
- Younger age at menopause[235] (suggestive)

Effects on the Adult of Childhood SHS Exposure

Increased risk of:

- Altered lipid profiles and endothelium effects in adolescents and young adults[236–238]
- Asthma[232,239]
- Chronic dry cough and phlegm[240]
- Lung cancer, leukemia, and lymphoma, as an adult[220,221,241,242]
- Increased risk of spontaneous abortion in women exposed as children to SHS by both parents[243,244]

APPENDIX 2: RESOURCES

See www.aap.org/richmondcenter/AAP_Tobacco_Policy.html for updates.

General

1-800-QUIT-NOW

- http://1800quitnow.cancer.gov: 1-800-QUIT-NOW is the toll-free national telephone counseling service to help people stop smoking or quit other forms of tobacco use.

Addressing Tobacco in Healthcare

- www.atmc.wisc.edu: The Addressing Tobacco in Healthcare Research Network, supported by the Robert Wood Johnson Foundation, connects researchers, health care providers, and other partners interested in developing and implementing changes to health care systems that will improve the delivery of evidence-based tobacco-dependence treatment.

Agency for Healthcare Research and Quality

- www.ahrq.gov
- www.ahrq.gov/clinic/tobacco/tobaqrg.pdf—clinical practice guideline *Treating Tobacco Use and Dependence*: This Public Health Service guideline contains strategies and recommendations designed to assist clinicians, tobacco-dependence treatment specialists, and health care administrators, insurers, and purchasers in delivering and supporting effective treatments for tobacco use and dependence.
- www.ahrq.gov/clinic/tobacco/tobaqrg.htm—*Treating Tobacco Use and Dependence*, quick reference guide for clinicians: This is a quick how-to guide to assist clinicians in implementing the clinical practice guidelines.
- www.ahrq.gov/clinic/tobacco/clinhlpsmksqt.htm—Helping Smokers Quit: A Guide for Clinicians: This guide gives clinicians easy access to information to help their patients quit smoking. The tool is based on the 5 A's approach to cessation intervention (ask, advise, assess, assist, and arrange) and offers other helpful resources.

Alliance for the Prevention and Treatment of Nicotine Addiction

- www.aptna.org: The mission of the Alliance for the Prevention and Treatment of Nicotine Addiction is to work toward reduction in tobacco-caused morbidity and mortality by providing services that promote effective treatment and prevention of nicotine addiction. Services are targeted to health care providers, clinicians, administrators, organizations, and educational institutions to promote policies that lead to an increase in implementing effective smoking-cessation strategies among high-risk tobacco users.

American Academy of Allergy Asthma & Immunology

- www.aaaai.org: The American Academy of Allergy Asthma & Immunology is the largest professional medical specialty organization in the United States, representing allergists, asthma specialists, clinical immunologists, allied health professionals, and others with a special interest in the research and treatment of allergic disease.

American Academy of Family Physicians

- www.aafp.org/online/en/home/clinical/publichealth/tobacco.html: This Web site provides up-to-date resources for clinicians. In particular, there is an excellent resource on pharmacotherapies used to treat tobacco dependence: www.aafp.org/online/en/home/clinical/publichealth/tobacco/nrt.html

American Academy of Pediatrics

- www.aap.org: The AAP is a 60 000-member organization dedicated to the health and well-being of infants, children, adolescents, and young adults.
- AAP Julius B. Richmond Center: www.aap.org/richmondcenter
- Committee on Environmental Health: www.aap.org/visit/cmte16.htm
- Department of Community Pediatrics: www.aap.org/commpeds

American Cancer Society

- www.cancer.org: The American Cancer Society is the nationwide community-based voluntary health organization dedicated to eliminating cancer as a major health problem.

American College of Obstetricians and Gynecologists

- www.acog.org/departments/dept_web.cfm?recno=13: The American College of Obstetricians and Gynecologists is the leading group of professionals providing health care for women. It has several resources for providers and patients.

American Legacy Foundation

- www.americanlegacy.org: The American Legacy Foundation concentrates on tobacco prevention and cessation, because smoking is the largest preventable cause of death in America. Its programs are working to engage all Americans in the dialogue about tobacco and to foster an understanding about its harmful effects.

American Lung Association

- www.lungusa.org: Founded in 1904 to fight tuberculosis, the American Lung Association fights lung disease in all its forms, with special emphasis on asthma, tobacco control, and environmental health.

Ask and Act

- www.aafp.org/online/en/home/clinical/publichealth/tobacco.html: The American Academy of Family Physicians' new tobacco use-cessation campaign encourages 100% of family physicians to ask about the tobacco-use habits of all their patients and act on that information.

Centers for Disease Control and Prevention

- www.cdc.gov
- www.cdc.gov/tobacco—Office on Smoking and Health: The Office on Smoking and Health offers information on all aspects of tobacco control and prevention.
- www.cdc.gov/tobacco/quit_smoking/cessation/practical_guide—A Practical Guide to Working with Health-Care Systems on Tobacco-Use Treatment: This guide was designed to increase public health professionals' comfort with and skill in establishing collaborative relationships with leaders of health care systems and to facilitate the creation of long-term partnerships that promote effective system-wide tobacco-use treatment.
- www.cdc.gov/tobacco/media_communications/countermarketing/mcrc/index.htm—Media Campaign Resource Center for Tobacco Prevention and Control: The Media Campaign Resource Center provides access to effective media campaign materials for tobacco-use prevention.

The Health Consequences of Involuntary Exposure to Tobacco Smoke: A Report of the Surgeon General

- www.surgeongeneral.gov/library/secondhandsmoke: US Surgeon General Richard H. Carmona issued this comprehensive scientific report (June 2006), which concludes that there is no risk-free level of exposure to SHS.

The Health Consequences of Smoking: A Report of the Surgeon General

- www.cdc.gov/tobacco/data_statistics/sgr/sgr_2004/index.htm: A comprehensive report on the hazards of smoking and the benefits of quitting published by the US Department of Health and Human Services in May 2004.

Motivational Interviewing

- www.motivationalinterview.org: Motivational interviewing is a client-centered, directive method for enhancing intrinsic motivation to change by exploring and resolving ambivalence. This Web site is intended to provide resources for those seeking information on motivational interviewing. It includes general information about the approach as well as links, training resources, and information on reprints and recent research.

National Tobacco Technical Assistance Consortium

- www.ttac.org: The National Tobacco Technical Assistance Consortium: is dedicated to assisting organizations in building and developing highly effective tobacco-control programs.

Professional Assisted Cessation Therapy

- www.endsmoking.org: Professional Assisted Cessation Therapy is an independent consortium of leaders in the treatment of tobacco dependence whose mission is to lower barriers to broader use of cessation therapy through education and advocacy.

Smoke Free Homes

- www.kidslivesmokefree.org: Smoke Free Homes' mission is to reduce secondhand smoke exposure of children by increasing the awareness and understanding of the health benefits of creating smoke-free environments for children among members of the pediatric community.

Smokefree.gov

- www.smokefree.gov: This National Institutes of Health Web site was developed by using evidenced-based research. The site features "LiveHelp," which connects smokers with a cessation counselor via instant messaging, and an interactive Web-based cessation guide based on the National Cancers Institute's "Clearing the Air" booklet.

US Environmental Protection Agency Smoke-Free Homes

- www.epa.gov/smokefree: This site offers a wealth of information on the health effects of SHS on children and helps families establish a smoke-free home.

Medical Students

Smoking Cessation: Effective Intervention Strategies

- http://nosmoking.msm.edu: This course is a collaborative effort of the Morehouse School of Medicine and the Mercer School of Medicine. It is intended primarily for medical students, who can register to receive academic curriculum credit.

Prevention and Cessation Education for Medical Students

- www.teachtobacco.org: Prevention and Cessation Education for Medical Students (PACE) is a consortium of 12 US medical schools funded by the National Cancer Institute to assess and improve tobacco teach-

ing. PACE aims to successfully incorporate tobacco education modules into a number of US medical schools to ensure that graduating students at these schools will be able to skillfully perform tobacco use-prevention and -cessation counseling for children, adolescents, and adults.

Nurses

Helping People Quit Smoking: Nursing Best Practice Guidelines

- www.rnao.org/smokingcessation: This training Web site developed by the Registered Nurses Association of Ontario comprises a minicourse and 4 modules focusing on how nurses can provide brief interventions for smoking cessation.

Tobacco-Free Nurses

- www.tobaccofreenurses.org: A smoking-cessation site tailored for nurses and nursing students who want to quit smoking.

Perinatal

Mom's Quit Connection

- www.snjpc.org/mqc: Mom's Quit Connection is a free program of the Southern New Jersey Perinatal Cooperative that provides cessation counseling to pregnant and parenting women and teenagers who want to stop smoking. Perinatal smoking-cessation community and professional education programs are offered to health care providers, schools, and service agencies, including a practice-based, on-site American College of Obstetricians and Gynecologists 5 A's brief intervention training for clinicians.

The National Partnership for Smoke-Free Families

- www.helppregnantsmokersquit.org: Smoke-Free Families is a national program supported by the Robert Wood Johnson Foundation working to discover the best ways to help pregnant smokers quit before, during, and after pregnancy. This Web site provides information about effective, evidence-based smoking-cessation treatments to care professionals and consumers.

Counseling and Treatment Trainings, Including Systems Change

CEASE: Clinical Effort Against SHS Exposure

- www.massgeneral.org/children/professionals/cease/default.aspx: The Clinical Effort Against SHS Exposure program was developed by child health care clinicians to help other child health care clinicians adjust their office setting to address parental tobacco use in a routine and effective manner.

Clean Air for Healthy Children & Families

- www.cleanairforhealthychildren.org: The Clean Air for Healthy Children & Families program is a smoking-cessation counseling training program primarily targeted to health care professionals who care for pregnant women, mothers, and caregivers of young children and teenagers.

Mayo Clinic Nicotine Dependence Center

- www.mayoclinic.org/ndc-rst: The Nicotine Dependence Center offers educational activities to health care professionals who are interested in incorporating nicotine-dependence treatment into their practice and/or developing a service to meet the needs of tobacco-dependent patients.

Quitters Win, No Ifs, Ands or Butts

- www.mdhelpquit.org: This Web-based continuing education activity examines smoking cessation in primary care, with the goal of affecting physicians' clinical practices regarding smoking-cessation counseling and use of valuable resources such as "quitlines."

Rx for Change

- http://rxforchange.ucsf.edu: Rx for Change: Clinician-Assisted Tobacco Cessation is a comprehensive, turnkey, tobacco use-cessation training program that equips health professional students and licensed clinicians with state-of-the-art knowledge and skills for assisting patients with quitting.

Smoking Cessation in the Pediatric Office

- www-cme.erep.uab.edu/scpo/index.html: Sponsored by the University of Alabama, among others, this program assists pediatric health care providers in determining the smoking status of the parents of pediatric patients and influencing those who smoke to quit.

TobaccoCME.com

- www.tobaccocme.com: TobaccoCME.com is a Web-based program that provides training in tobacco treatment that prepares physicians to provide clinical tobacco interventions for prevention and cessation.

Treating Tobacco Use and Dependence

- www.medscape.com/viewprogram/3607: A continuing medical education credit course for physicians, nurses, and pharmacists developed by the University of Wisconsin Center for Tobacco Research and Intervention and offered through Medscape.

University of Massachusetts Center for Tobacco Prevention and Control Tobacco Treatment Specialist: Training and Certification Program

- www.umassmed.edu/tobacco/index.aspx: The Tobacco Treatment Spe-

cialist: Training and Certification Program is a nationally recognized, professional certification program.

University of Medicine and Dentistry of New Jersey School of Public Health's Tobacco Dependence Program

- www.tobaccoprogram.org: The Tobacco Dependence Program has developed certified trainings to prepare professionals to provide intensive specialist treatment for tobacco dependence.

Youth

Helping Young Smokers Quit

- www.helpingyoungsmokersquit.org: The Helping Young Smokers Quit initiative works to fill a gap in knowledge about the numbers and distribution of youth cessation programs, as well as the types of treatment approaches and program components that are currently offered across the United States.

Youth Tobacco Cessation Collaborative

- www.youthtobaccocessation.org: The Youth Tobacco Cessation Collaborative was created to address the gaps in knowledge about what cessation strategies are most effective in assisting youth to quit smoking.

Patients and Consumers

1-800-QUIT-NOW

- http://1800quitnow.cancer.gov: 1-800-QUIT-NOW is the toll-free national telephone counseling service to help people stop smoking or quit other forms of tobacco use. Spanish-speaking counselors are available.

Become an EX

- www.becomeanex.org: This free quit plan sponsored by the American Legacy Foundation uses a systematic program to help prepare a customized quitting plan for each person.

Freedom From Smoking Online

- www.ffsonline.org: This online smoking-cessation program sponsored by the American Lung Association is an interactive course designed to educate and modify the behavior patterns of a smoker. Freedom From Smoking Online can be accessed day or night, 7 days per week, on any schedule the smoker chooses. It is ready whenever a smoker wants to start the process of quitting and is free of charge (registration is required).

Nicotine Anonymous

- www.nicotine-anonymous.org: Nicotine Anonymous welcomes all those seeking freedom from nicotine addiction, including those using cessation programs and nicotine-withdrawal aids. The organization offers group support and recovery using the "12 steps," as adapted from Alcoholics Anonymous, to achieve abstinence from nicotine.

QuitNet

- www.quitnet.com: This Web site includes a quitting guide, a national directory, pharmaceutical product overview, and Web resource directory with links to other online resources, programs, and self-help materials. Registered users can access customized advice, peer support, quitting tools and tips, and referrals to counselors.

Smokefree.gov

- www.smokefree.gov: This National Institutes of Health Web site was developed by using evidence-based research. The site features "LiveHelp," which connects smokers with a cessation counselor via instant messaging, and an interactive Web-based cessation guide based on the National Cancer Institute's "Clearing the Air" booklet.

SHS Exposure Reduction

California EPA Office of Environmental Health Hazard Assessment

- www.oehha.ca.gov: This office's overall mission is to protect and enhance public health and the environment by scientific evaluation of risks posed by hazardous substances.

US Environmental Protection Agency Smoke-Free Homes

- www.epa.gov/smokefree: This site offers a wealth of information on the health effects of SHS on children and helps families establish a smoke-free home. Materials are available in Spanish.

Policy and Advocacy

Addressing Tobacco in Health Care

- www.atmc.wisc.edu: The Addressing Tobacco in Healthcare Network, supported by the Robert Wood Johnson Foundation, connects researchers, health care providers, and other partners interested in developing and implementing changes to health care systems that will improve the delivery of evidence-based tobacco-dependence treatment.

Allergy & Asthma Network Mothers of Asthmatics

- www.aanma.org: AANMA is a national nonprofit network of families whose desire is to overcome, not cope with, allergies and asthma.

American Legacy Foundation

- www.americanlegacy.org: The American Legacy Foundation was established in March 1999 as a result of the Master Settlement Agreement between a coalition of attorneys general in 46 states and 5 US territories and the tobacco industry. The foundation is dedicated to promoting tobacco-free generations.

Americans for Nonsmokers' Rights

- www.no-smoke.org: Americans for Nonsmokers' Rights is the leading national lobbying organization dedicated to nonsmokers' rights, taking on the tobacco industry at all levels of government to protect nonsmokers from SHS and youth from tobacco addiction.

Campaign for Tobacco-Free Kids

- http://tobaccofreekids.org: The campaign is dedicated to protecting children from tobacco addiction by raising awareness of its use.

Global Tobacco Research Network

- http://tobaccoresearch.net: The Global Tobacco Research Network's mission is to enhance research by promoting collaboration and partnerships, providing information, facilitating training, and sharing research tools with the goal of reducing the burden of disease and death caused by tobacco.

Institute for Global Tobacco Control

- www.jhsph.edu/global_tobacco: Established in 1998 in the Department of Epidemiology at the Johns Hopkins Bloomberg School of Public Health, the Institute for Global Tobacco Control works to prevent death and disease from tobacco use through research, education, and policy development.

National Action Plan for Tobacco Cessation

- www.ctri.wisc.edu/Researchers/NatActionPlan%2002–04.pdf: This report, prepared by the Interagency Committee on Smoking and Health's Subcommittee on Cessation, outlines a series of feasible, science-based action steps to promote smoking cessation, reduce smoking prevalence, and prevent millions from starting to smoke.

National African American Tobacco Education Network

- www.naaten.org: The National African American Tobacco Education Network is a collaborative of national African American stakeholders that have an interest in establishing or augmenting tobacco prevention and control activities within their organizations as well as the African American community.

National African American Tobacco Prevention Network

- www.naatpn.org: The National African American Tobacco Prevention Network is a national organization dedicated to facilitating the development and implementation of comprehensive and community-competent tobacco-control programs to benefit communities and people of African descent.

National Latino Council on Alcohol and Tobacco Prevention

- www.nlcatp.org: The National Latino Council on Alcohol and Tobacco Prevention is the only Latino national organization dedicated solely to reducing the harm caused by alcohol and tobacco in the Latino community through research, advocacy, policy analysis, community education, training, and information dissemination.

North American Quitline Consortium

- www.naquitline.org: The North American Quitline Consortium seeks to unite quitline professionals in the United States and Canada to enable them to work together to increase access to and the effectiveness of quitline services that help people in their quitting attempts.

Policy Advocacy on Tobacco and Health

- www.thepraxisproject.org: Policy Advocacy on Tobacco and Health is an initiative of the Praxis Project Inc, designed to simultaneously build bridges between tobacco-control policy initiatives and strengthen the voice and capacity of communities of color in the tobacco-control movement.

Smoke Free Movies

- www.smokefreemovies.ucsf.edu: This project aims to sharply reduce the US film industry's usefulness to the tobacco industry's domestic and global marketing.

Smoking Cessation Leadership Center

- http://smokingcessationleadership.ucsf.edu: The Smoking Cessation Leadership Center is a national program office of the Robert Wood Johnson Foundation that aims to increase smoking-cessation rates and increase the number of health professionals who help smokers quit.

Tar Wars

- www.tarwars.org: Tar Wars is a pro-health, tobacco-free education program and poster contest of the American Academy of Family Physicians designed to discourage tobacco use among fourth- and fifth-grade students.

Tobacco.org

- www.tobacco.org: Tobacco news and information.

Tobacco Policy Change

- www.tobaccopolicychange.org: This national initiative of the Robert Wood Johnson Foundation was created to provide resources and technical assistance for community, regional, and national organizations and tribal groups interested in advocating for effective tobacco use-prevention and -cessation policy initiatives.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Danette Glassy, MD; Judith Romano, MD; and the Committee on Early Childhood, Adoption, and Dependent Care

Selecting Appropriate Toys for Young Children: The Pediatrician's Role

ABSTRACT. Play is essential for learning in children. Toys are the tools of play. Which play materials are provided and how they are used are equally important. Adults caring for children can be reminded that toys facilitate but do not substitute for the most important aspect of nurture—warm, loving, dependable relationships. Toys should be safe, affordable, and developmentally appropriate. Children do not need expensive toys. Toys should be appealing to engage the child over a period of time. Information and resources are provided in this report so pediatricians can give parents advice about selecting toys.

Children learn from the time they are born, and parents/guardians are primarily responsible for providing quality experiences from which their children learn. Parents often ask their pediatrician for advice about appropriate toys, books, and computer or video games, because they know that these tools may be important in their child's development. Pediatricians can use questions about toys as opportunities to discuss the importance of a child's environment at home and in child care. A young child's growth and development can be supported and enhanced through play. Toys bring parents or caregivers and children together in play. Early brain development is enhanced through these relationships.[1] These discussions are also an opportunity for the pediatrician to help parents understand the role of play in all areas of development, including cognitive, language, social, physical, and emotional development.

Toys can provide a bridge for a child's interactions with parents or other caregivers.[1] Although toys should never be used as a substitute for loving, unconditional attention from parents and other caregivers, toys can enhance these interactions. When adults participate in the play of children, learning is enhanced.[1] Parents are able to observe the skills their child currently has and also help expand those skills. For example, if an 18-month-old who is starting to enter the world of pretend play is building a tower with blocks, a parent can introduce the idea that the blocks can also become a garage for the cars or a house for the stuffed animals. A child's self-esteem and level of mastery are also enhanced when adults participate in play.[1] Toys can facilitate the development of relationships as parent and child share in the mutual joy and delight of new discoveries.[1]

When pediatricians advise parents, it is important to stress that toys serve a supportive role in enhancing a child's development. Play materials should match the developmental and individual needs of each child. Some children may need toys that have been adapted to accommodate a motor, visual, or other disability.[2] All children benefit from toys that promote safe physical activity.

Some toys pose emotional or social risks. Graphic depictions of violence presented in an interactive way, such as in some computer or video games, can lead to acts of violence by the child.[3,4] Although video games are rated, even those deemed for "everyone" may contain significant violence.[5] Toy weapons or other toys that promote violence should be discouraged. Parents also should consider whether a toy promotes negative racial, ethnic, cultural, or gender stereotypes. The toys parents provide (or do not provide) send children a message about what is valued.

Some toy marketing includes claims that specific toys will facilitate specific developmental milestones. There is no scientific evidence to suggest that any toy is necessary or sufficient for optimal learning. These advertisements can promote misinformation, inappropriate expectations, and unnecessary expenditures. Even worse is the unfounded guilt parents experience when they cannot afford or choose not to make such purchases.

Government regulations, improved safety standards for the manufacture and use of toys, and product testing have made most toys safe when used appropriately for recommended ages and stages of development. Just because a product is on the market, though, does not mean it is safe. In determining toy safety, the characteristics of the toy should be considered as well as how the toy might be used or abused and the amount of supervision or help needed for safe play. It is important for pediatricians to be familiar with current recommendations about

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

toy safety and guidelines on the safe cleaning and maintenance of toys.[6–10]

Pediatricians can use the information provided in this report to guide them in selecting and maintaining the toys in their office and make this information available to parents (see resource list). Although there appears to be no increased rate of acute illness for children who have just visited a pediatrician's office,[11] toys in the office should be routinely cleaned. Toys that are available in a pediatric office and how they are maintained will serve as a model for parents.

ADVICE FOR PEDIATRIC OFFICES

1. Office toys should be safe for all ages.
   - Do not provide small toys or toys with easily dislodged parts that fit in an infant's or toddler's mouth.[2,5–8]
   - Do not provide toys with loose string, rope, ribbons, or cord.[2,6–9]
   - Do not provide toys with sharp edges.[2,6–9]
   - Do not provide toys that make loud or shrill noises.[2,6–9]
   - Provide only toys made of nontoxic materials.[2,6–9]
   - Always store toys safely, and avoid toy chests with lids.[2,6–9]
   - Choose toys that are easily and routinely cleaned. When possible, each time a toy has been in contact with saliva or other body fluids, it should be sanitized (2 minutes of contact with a 10% bleach solution [1 tablespoon of household bleach per quart of water], made fresh daily, or use of an Environmental Protection Agency-registered sanitizing solution according to manufacturer's instructions), then rinsed and air dried.[10]
2. Office toys should be engaging and encourage creativity.[2,6]
3. Offices should include at least as many developmentally appropriate books and magazines as toys.
4. Posters from the American Academy of Pediatrics and the Consumer Product Safety Commission concerning toys and safety recalls should be prominently displayed in the office.
5. For a list of appropriate and safe toys, see the Goodson and Bronson resource *Which Toy for Which Child*, available by order or online.[9]

ADVICE FOR PARENTS AND CAREGIVERS

1. Keep in mind that the most educational toy is one that fosters the interaction of an adult with a child in supportive, unconditional play. Toys are never substitutes for the attention of devoted caregivers.[1]
2. Provide children with safe, affordable toys that are developmentally appropriate. Include toys that help promote learning and growth in all areas of development. Avoid toys that discourage children from using their imaginations. Social/emotional and cognitive skills are developed and enhanced as children use play to work out real-life problems.[2,6–9]
3. Make a thoughtful selection of toys and remember that a good toy does not have to be trendy or expensive.[2,6]
4. Use books and magazines to play and read together.
5. Be skeptical of educational or developmental claims made by advertisers, especially product claims of intellectual enhancement.
6. Seek the pediatrician's advice in distinguishing between safe and unsafe toys (see resource list).[2,6–9]
7. Remember that some toys promote violence or negative social, racial, or gender stereotypes. These toys are not recommended for children.[3]
8. Limit video game and computer game use. Total screen time, including television and computer use, should be less than 1 to 2 hours per day.[4] Children younger than 5 years should play with computer or video games only if they are developmentally appropriate, and they should be accompanied by the parent or caregiver.[1]
9. For a list of appropriate and safe toys, see the Goodson and Bronson resource *Which Toy for Which Child*, available by order or online.[9]

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Sexuality, Contraception, and the Media

abstract

FREE

From a health viewpoint, early sexual activity among US adolescents is a potential problem because of the risk of pregnancy and sexually transmitted infections. New evidence points to the media adolescents use frequently (television, music, movies, magazines, and the Internet) as important factors in the initiation of sexual intercourse. There is a major disconnect between what mainstream media portray—casual sex and sexuality with no consequences—and what children and teenagers need—straightforward information about human sexuality and the need for contraception when having sex. Television, film, music, and the Internet are all becoming increasingly sexually explicit, yet information on abstinence, sexual responsibility, and birth control remains rare. It is unwise to promote "abstinence-only" sex education when it has been shown to be ineffective and when the media have become such an important source of information about "nonabstinence." Recommendations are presented to help pediatricians address this important issue. *Pediatrics* 2010;126:576–582

INTRODUCTION

Early sexual activity among teenagers can be problematic. According to the 2009 Youth Risk Behavior Survey, 46% of all high school seniors have had sexual intercourse, and 14% have had 4 partners or more.[1] Although pregnancy rates have generally been decreasing since 1991, the United States still has the highest teen pregnancy rate in the Western world,[2] and for the first time in 15 years, the birth rate increased 3% from 2005 to 2006.[3] Early intercourse also increases the risk of contracting a sexually transmitted infection (STI), including HIV, and adolescents have one of the highest STI rates of any age group.[4] Although 15- to 24-year-olds account for only one-quarter of the sexually active population in the United States, they contract nearly half of all new STIs every year.[4] A recent study by the Centers for Disease Control and Prevention revealed that 1 in 4 teenagers has had an STI.[5] Ten percent of young women who had first had sex in their teenage years reported that their first time was involuntary, and the younger they were, the more likely that was the case.[6]

WHAT CHILDREN AND TEENAGERS LEARN FROM THE MEDIA

American children and teenagers spend more than 7 hours/day with a variety of different media.[7] Those media are filled with sexual messages and images, many of which are unrealistic.[2] On television (TV), which remains the predominant medium in terms of time spent for all young people, more than 75% of prime-time programs contain sexual

content, yet only 14% of sexual incidents mention any risks or responsibilities of sexual activity.[8,9] Talk about sex on TV can occur as often as 8 to 10 times per hour.[10] Between 1997 and 2001 alone, the amount of sexual content on TV nearly doubled.[9]

So-called reality TV has also entered the picture. In 1997, there were only 3 reality dating shows; by 2004, there were more than 30.[11] Some shows, such as *Temptation Island*, bring participants together for the sole purpose of seeing who "hooks up." A study of college students revealed that viewing such shows correlated with beliefs in a double standard—that men are sex driven and that men and women are sexual adversaries.[11] It is interesting to note that the less sexually experienced students were more likely than sexually experienced students to be watching reality shows, which suggests the importance of such programs for sexual socialization.[12,13]

In addition to TV, other media provide frequent messages about sexual behavior.

- Music continues to be a major source of sexual suggestiveness. In 1 study, 40% of lyric lines contained sexual material, and only 6% contained healthy sexual messages.[14] An analysis of the 279 most popular songs in 2005 revealed that 37% contained sexual references and that degrading sexual references were common.[15]
- Virtually every R-rated teen movie since the 1980s has contained at least 1 nude scene and, often, several instances of sexual intercourse (eg, the *American Pie* movie series).[16] Teen movies also contain distorted views of romance and normal adolescent sexuality.[16–18]
- Teen magazines are popular with preadolescent and adolescent girls and devote an average of 2.5 pages per issue to sexual topics.[19] Coverage of sex as a health issue in magazines is more common than on TV, but the overarching focus seems to be on deciding when to lose one's virginity.[12,20]
- The Internet has become an abundant source of both sexual information and pornography that cannot be regulated.[21,22] Online pornography is now a $1 billion industry.[12] In a national sample of 1500 10- to 17-year-olds, nearly half of the Internet users had been exposed to online pornography in the previous year.[23] In addition, unwanted sexual solicitations and harassment are not uncommon,[24] although they may not be as frequent as parents fear.[25]
- Social networking Web sites and home pages enable teenagers to present themselves publicly, sometimes in sexually suggestive ways.[12,26] One study of 233 teen home pages revealed that nearly 10% mentioned sex, and girls were 3 times more likely to do so than boys.[27] A recent study of 500 publicly available MySpace profiles revealed that nearly one-quarter of them referenced sexual behaviors.[28] Also, a national survey of nearly 1300 teenagers and young adults revealed that 20% reported having sent or posted nude pictures or videos of themselves ("sexting").[29]
- Advertisements often use sex to sell. Women are as likely to be shown in suggestive clothing (30%), partially clad (13%), or nude (6%) as they are to be fully clothed.[30] As one expert noted, "When sexual jokes are used to sell everything from rice to roach-killer, from cars to carpets, it's hard to remember that sex can unite two souls, can inspire awe. Individually, these ads are harmless enough, sometimes even funny, but the cumulative effect is to degrade and devalue sex."[31] Advertisements for erectile dysfunction drugs are ubiquitous. In the first 10 months of 2004, the makers of these drugs spent nearly $350 million on advertising.[32] At the same time, advertisements for birth control products are rare.[2]

Because so many sex education programs have recently been focused on abstinence only, the media have arguably become one of the leading sex educators in the United States today.[2] Adolescents frequently cite the media as a source of sexual information.[2] For example, in a national survey the media rivaled parents and schools as a source of information about birth control.[33] The media are powerful sources for behavioral "scripts" concerning sexual situations, especially for inexperienced teenagers.[2,34] Yet, parents and legislators fail to understand that although they may favor abstinence-only sex education (despite the lack of any evidence of its effectiveness),[35] the media are decidedly not abstinence only. In fact, the United States has some of the most sexually suggestive media in the world.[2] American media make sex seem like a harmless sport in which everyone engages, and results of considerable research have indicated that the media can have a major effect on young people's attitudes and behaviors.[12–18] In fact, the media may function as a "superpeer" in convincing adolescents that sexual activity is a normative behavior for young teenagers.[2,36,37] In a survey of 2100 11- to 17-year-old girls, only the 11-year-olds reported that they did not feel pressure from the media to begin having sex.[38]

IMPACT OF SEXUAL CONTENT ON ADOLESCENT BEHAVIOR

Numerous studies have delineated the media's powerful influence on adolescents' sexual attitudes, values, and beliefs.[2,39–42] Unlike the media violence re-

search literature, in which some 2000 studies exist, there have been only a handful of studies on the effects of sexual content on actual behavior. At least a dozen correlational studies have examined the relationship between the amount of sexual content viewed on TV and early onset of sexual intercourse.[43–53] The most recent studies have revealed that (1) listening to sexually degrading lyrics is associated with earlier sexual intercourse,[40,53] (2) black female teenagers' exposure to rap music videos or X-rated movies is associated with the likelihood of multiple sexual partners or testing positive for an STI,[49] (3) teenagers whose parents control their TV-viewing habits are less sexually experienced,[51,52] and (4) exposure to sexual content in the media is a significant factor in the intention to have sex in the near future.[52–54]

Nine longitudinal studies have given potential answers to the question of whether sexy media contribute to early sexual activity, and the answer seems to be "yes."[41,55–62] Results of 7 of these studies have shown that exposure to sexual content in TV and other media in early adolescence—particularly for white teenagers—can as much as double the risk of early sexual intercourse. Adolescents whose parents limit their TV-viewing are less likely to engage in early sex.[58] Younger children who have viewed adult-oriented TV shows and movies are more likely to begin having sexual intercourse earlier.[61] The study samples together total nearly 10 000 teenagers nationwide, and the most ambitious studies included other media such as movies, music, and magazines.[57] In addition, a recent study revealed that early exposure to sexual content doubled the risk of teen pregnancy.[60] Clearly, the media play a major role in determining whether certain teenagers become sexually active earlier rather than later,[63] and sexually explicit media may be particularly important.[41,64]

CONTRACEPTIVE ADVERTISING

The United States is the only Western nation that still subscribes to the dangerous myth that giving teenagers access to birth control—and media represent a form of access—will make them sexually active at a younger age. Other countries advertise birth control products widely and have a much lower rate of teen pregnancy.[12,16] Although the teen birth rate had been declining in the United States up until 2005–2006, it has declined just as much or more in other countries. A recent study revealed that 86% of the recent decline in teen pregnancies could be attributed to increased contraceptive use, and only 14% was attributable to increased abstinence.[65] The recent 3% increase in teen births could be a "blip," or it could be attributable to an increase in abstinence-only sex education and the concomitant reduction in accurate information about contraception.[66–68]

Eight peer-reviewed, controlled clinical trials have revealed that giving teenagers freer access to condoms does not increase their sexual activity or encourage virginal teenagers to begin having sex, but it does increase the use of condoms among those who are already sexually active.[69–76] Advertising condoms, birth control pills, and emergency contraception on TV and radio could further decrease the teen pregnancy rate. Yet, several networks refuse such advertisements.[77,78]

Telling teenagers, "Wait until you're older to begin having sex, but if you can't wait, use birth control" is a double message. But, it is a double message that every teenager in America can understand and benefit from, and it is consistent with normal adolescent psychology, because it acknowledges that adolescents do not always listen to their elders.[2] In 2007, both CBS and FOX refused a condom advertisement as "inappropriate" because it mentioned preventing pregnancy rather than preventing HIV/AIDS.[78] Advertisements for emergency contraception are virtually nonexistent on American TV, despite the fact that every year, American women have 3 million unplanned pregnancies, which lead to 1.3 million abortions. Advertising for emergency contraceptives could be an important way to reduce the number of abortions in the United States.[79]

POSITIVE IMPACT

The media can be powerful vehicles for sexual health education. Socially responsible messages can be embedded into mainstream programming—a practice dubbed "entertainment-education" or "edutainment."[39] Collaborative efforts between the Kaiser Family Foundation and the producers of the hit TV show *ER* resulted in successful story lines about the risks of human papillomavirus and the usefulness of emergency contraception.[80] In 2002, *Friends* aired an episode about condoms, and 27% of a national sample of teenagers saw the program; many of them reported that they talked about condom effectiveness with an adult as a direct result of the episode.[81] In 2008, a study showed that viewers of a *Gray's Anatomy* episode learned that HIV-positive women could still have HIV-negative infants.[82] The Soap Opera Summit in Hollywood and international efforts to embed story lines into popular soap operas are other examples of prosocial efforts. The media giant Viacom and the Kaiser Family Foundation have launched an ambitious project to produce $120 million worth of public service announcements and print advertisements concerning HIV/AIDS and to encourage Viacom producers to include story lines in their TV shows that will raise AIDS awareness.[83] Such ef-

forts demonstrate that the entertainment industry can be receptive to outside input and that healthier content can be introduced into mainstream media without government pressure or the threat of censorship.

Mass media have also been used proactively to increase parent-child communication about sex. In North Carolina, a mass media campaign using billboards and radio and TV public service announcements delivered the message, "Talk to your kids about sex. Everyone else is." In follow-up research, exposure to the message correlated significantly with parents talking to their children about sex during the following month.[84]

RECOMMENDATIONS

1. Pediatricians can help parents and teenagers to recognize the importance of the media by asking at least 2 media-related questions at each well visit[77]: (1) How much time do you spend daily with entertainment media? and (2) Is there a TV set or Internet access in your bedroom? Research has shown that bedroom TVs are associated with greater substance use and sexual activity by teenagers.[85] A recent study revealed that office-based counseling is effective and could result in nearly 1 million more children and adolescents adhering to the American Academy of Pediatrics recommendation to limit media time to less than 2 hours/day.[86]
2. Pediatricians should counsel parents to recognize the importance of the media, exert control over their children's media choices, keep their children's bedrooms free of TVs and Internet connections, and avoid letting their children see PG-13– and R-rated movies that are inappropriate for them.[61,87,88] Pediatricians and parents also need to be aware of the importance of social networking sites and how they work so that they can effectively counsel children and adolescents about them.[89]
3. Pediatricians and child advocacy groups should encourage the entertainment industry to produce more programming that contains responsible sexual content and that focuses on the interpersonal relationship in which sexual activity takes place (Table 1). One way to do this would be to hold annual seminars for writers, producers, and directors in Hollywood, perhaps in cooperation with other groups. Similarly, Madison Avenue and advertisers need to be encouraged to stop using sex to sell products. Educational seminars might help to achieve this goal.
4. Pediatricians should urge schools to insist on comprehensive sex education programs (to counter the influence of sexually suggestive and explicit media) that incorporate basic principles of media literacy into their sex education programs. Studies have shown that effective media literacy programs can be protective against unhealthy media effects.[90,91] Federal money should be spent on comprehensive sex education programs but not on abstinence-only programs, which have been found to be ineffective.[35,65–68,92–94]
5. Pediatricians should urge the broadcast industry to air advertisements for birth control products. The federal government also needs to encourage the advertising of birth control, especially emergency contraceptives.
6. Pediatricians should urge the broadcast industry to limit advertisements for erectile dysfunction drugs until after 10 PM.
7. Pediatricians should urge the broadcast media to include healthy messages about sex and sexuality in their programming, especially in media that children and early teenagers use most frequently.[95]
8. Pediatricians, the broadcast industry, the federal government, and private foundations should support further research into the impact of sexual content in the media on children's and adolescents' knowledge and behavior.[96] A national task force on children, adolescents, and the media should be convened by child advocacy groups in conjunction with the Centers for Disease Control and Prevention and/or the National Institutes of Health to study the issue of children, adolescents, and media, devise new research, locate funding sources, and make recommendations to Congress, the broadcast industry, and the American people.

TABLE 1 Guide to Responsible Sexual Content in TV, Films, and Music: Some Suggestions for the Presentation of Responsible Sexual Content

Recognize sex as a healthy and natural part of life.
Parent and child conversations about sex are important and healthy and should be encouraged.
Demonstrate that not only the young, unmarried, and beautiful have sexual relationships.
Not all affection and touching must culminate in sexual intercourse.
Portray couples having sexual relationships with feelings of affection, love, and respect for one another.
Consequences of unprotected sex should be discussed or shown.
Miscarriage should not be used as a dramatic convenience for resolving an unwanted pregnancy.
Use of contraceptives should be indicated as a normal part of a sexual relationship.
Avoid associating violence with sex or love.
Rape should be depicted as a crime of violence, not one of passion.
The ability to say "no" should be recognized and respected.

CLINICAL REPORT

Self-injectable Epinephrine for First-Aid Management of Anaphylaxis

Guidance for the Clinician in Rendering Pediatric Care

Scott H. Sicherer, MD, F. Estelle R. Simons, MD, and the Section on Allergy and Immunology

ABSTRACT

Anaphylaxis is a severe, potentially fatal systemic allergic reaction that is rapid in onset and may cause death. Epinephrine is the primary medical therapy, and it must be administered promptly. This clinical report focuses on practical issues concerning the administration of self-injectable epinephrine for first-aid treatment of anaphylaxis in the community. The recommended epinephrine dose for anaphylaxis in children, based primarily on anecdotal evidence, is 0.01 mg/kg, up to 0.30 mg. Intramuscular injection of epinephrine into the lateral thigh (vastus lateralis) is the preferred route for therapy in first-aid treatment. Epinephrine autoinjectors are currently available in only 2 fixed doses: 0.15 and 0.30 mg. On the basis of current, albeit limited, data, it seems reasonable to recommend autoinjectors with 0.15 mg of epinephrine for otherwise healthy young children who weigh 10 to 25 kg (22–55 lb) and autoinjectors with 0.30 mg of epinephrine for those who weigh approximately 25 kg (55 lb) or more; however, specific clinical circumstances must be considered in these decisions. This report also describes several quandaries in regard to management, including the selection of dose, indications for prescribing an autoinjector, and decisions regarding when to inject epinephrine. Effective care for individuals at risk of anaphylaxis requires a comprehensive management approach involving families, allergic children, schools, camps, and other youth organizations. Risk reduction entails confirmation of the trigger, discussion of avoidance of the relevant allergen, a written individualized emergency anaphylaxis action plan, and education of supervising adults with regard to recognition and treatment of anaphylaxis.

INTRODUCTION

Anaphylaxis is an acute, life-threatening reaction, usually mediated by an immunologic mechanism involving immunoglobulin E, that results in sudden systemic release of mast-cell and basophil mediators such as histamine and tryptase.[1] Anaphylaxis has many clinical presentations, but respiratory compromise and cardiovascular collapse cause the greatest concern, because they can potentially lead to fatalities. Although a variety of different triggers for anaphylaxis episodes have been identified, food and insect stings are the most common identifiable triggers reported in the community setting.[2–4] Food allergies[5] and other allergies have increased in the past several years, and pediatricians increasingly need to prescribe emergency care plans for patients in the event of anaphylaxis outside the hospital/medical setting. Epinephrine is the primary medical therapy for a life-threatening allergic reaction.[1] This clinical report focuses on practical issues concerning the administration of self-injectable epinephrine for first-aid treatment of

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

anaphylaxis in the community. In addition, several quandaries in management will be identified and possible solutions described.

DEFINITION AND FEATURES OF ANAPHYLAXIS

There is no current, universally accepted definition of anaphylaxis; however, at a recent symposium cosponsored by the National Institutes of Health and the Food Allergy & Anaphylaxis Network, the following definition was proposed: "Anaphylaxis is a serious allergic reaction that is rapid in onset and may cause death."[6,7] Three clinical criteria for anaphylaxis based on symptoms and history were also proposed at the symposium. These criteria, as well as various signs and symptoms that may occur during anaphylaxis, are listed in Table 1. The clinician must also appreciate that certain disorders may appear to be anaphylaxis but are not (eg, vasovagal syncope or panic attack). Fatal anaphylaxis in the pediatric population has particularly been associated with known preexisting asthma, failure to administer epinephrine promptly, and the adolescent age group.[8,9]

TABLE 1 Clinical Criteria for Diagnosing Anaphylaxis (Fulfilling Any 1 Criterion Indicates That Anaphylaxis Is Highly Likely)[7]

Criterion 1	Acute onset of an illness (minutes to several hours) with involvement of the skin and/or mucosal tissue (eg, generalized hives, pruritus, or flushing, swollen lips/tongue/uvula) and at least 1 of the following: a. Respiratory compromise (eg, dyspnea, wheeze/bronchospasm, stridor, reduced peak expiratory flow, hypoxemia) b. Reduced blood pressure or associated symptoms of end-organ dysfunction (eg, hypotonia [collapse], syncope, incontinence)
Criterion 2	Two or more of the following that occur rapidly after exposure to a likely allergen for that patient (minutes to several hours): a. Involvement of the skin/mucosal tissue (eg, generalized hives, itch/flush, swollen lips/tongue/uvula) b. Respiratory compromise (eg, dyspnea, wheeze/bronchospasm, stridor, reduced peak expiratory flow, hypoxemia) c. Reduced blood pressure or associated symptoms (eg, hypotonia [collapse], syncope, incontinence) d. Persistent gastrointestinal symptoms (eg, crampy abdominal pain, vomiting)
Criterion 3	Reduced blood pressure after exposure to known allergen for that patient (minutes to several hours)

Less common presentations also occur (eg, sudden isolated hypotension without a known allergen exposure). Additional symptoms and signs that may occur during anaphylaxis include morbilliform rash, conjunctival erythema, pruritus and tightness in the throat, dysphagia, dysphonia, hoarseness, dry staccato cough, sensation of pruritus in the external auditory canals, nasal pruritus, nasal congestion, rhinorrhea, sneezing, chest pain, dysrhythmia, feeling of faintness/dizziness (near-syncope), paleness, cyanosis, confusion/altered mental status, an aura of doom, and uterine contractions. Skin signs aid in recognition but may be absent or not observed in 10% of children with anaphylaxis; moreover, they may not be observed in reactions that end in fatality.

The clinical criteria were adapted from Sampson HA, Muñoz-Furlong A, Campbell RL, et al. *J Allergy Clin Immunol*. 2006;117:391–397.

ROLE OF EPINEPHRINE

Epinephrine, the medication of choice for first-aid treatment of an episode of anaphylaxis, is a direct-acting sympathomimetic agent with effects on many target organs, including increased vasoconstriction, decreased mucosal edema, increased inotropy/chronotropy, and bronchodilation. In addition, epinephrine downregulates further mast-cell release of histamine, tryptase, and other mediators of inflammation. Delayed administration of epinephrine in anaphylaxis is associated with poor outcomes including fatality.[8–11] Oral H_1 antihistamines are not an optimal first-line therapy for anaphylaxis, because they have a slow onset of action (1 or more hours), primarily relieve cutaneous symptoms, and do not relieve respiratory symptoms or shock.[12] For children with known preexisting asthma who experience anaphylaxis, administration of an asthma-reliever medication (such as the inhaled selective β_2-adrenergic agonist albuterol) may provide adjunctive therapy for wheezing, coughing, and shortness of breath but does not relieve upper airway edema or shock, and therefore does not replace injected epinephrine in anaphylaxis management.

ROUTE OF ADMINISTRATION OF EPINEPHRINE

For first-aid treatment of anaphylaxis, administration of epinephrine by either the subcutaneous or intramuscular route has been recommended traditionally. However, studies on the rate of absorption of epinephrine injected by different routes and in different locations (eg, arm or thigh) have shown significant differences in time to peak concentrations, favoring intramuscular injection in the lateral thigh (vastus lateralis muscle), which leads promptly to peak plasma epinephrine concentrations. In a prospective, randomized, blinded study of children at risk of anaphylaxis,[13] the time to maximum epinephrine concentrations was 8 ± 2 minutes after injection of 0.30 mg of epinephrine from an EpiPen (Dey LP, Napa, CA) intramuscularly in the vastus lateralis. In contrast, the time to maximum plasma epinephrine concentration was 34 ± 14 minutes (range: 5–120 minutes) after injection of 0.01 mg/kg of epinephrine subcutaneously in the deltoid region.[13] These findings have been confirmed and extended in a randomized, double-blind, placebo-controlled crossover study in adults.[14] On the basis of studies in an animal model of anaphylaxis, achieving high plasma and tissue concentrations of epinephrine may be critical for reversal of hypotension.[15] The ½-inch (14.29-mm) needle on autoinjectors likely provides an intramuscular dose in most children, although it may not do so in obese adolescents, especially girls.[16]

It is not ethical to perform randomized, double-blind, placebo-controlled comparative studies on route of administration of epinephrine in children who are experiencing anaphylaxis, so definitive evidence-based recommendations on route of dosing cannot be made. On the

basis of the aforementioned available data at this time, intramuscular injection of epinephrine into the lateral thigh seems to be the preferred route for therapy in first-aid treatment. Intravenous administration carries risks of dilution errors and dosing errors, and many of the serious adverse effects attributed to epinephrine have followed large overdoses given intravenously. This route of administration should be reserved for those with severe anaphylaxis that does not respond to intramuscular epinephrine and/or individuals with anaphylaxis who are being treated in hospital settings.

EPINEPHRINE DOSING FOR FIRST-AID TREATMENT IN THE COMMUNITY

The recommendation for epinephrine dosing in children with anaphylaxis, based primarily on anecdotal evidence, is to inject 0.01 mg/kg, up to 0.30 mg.[17–19] Epinephrine autoinjectors are currently available in 2 fixed doses: 0.15 and 0.30 mg. Physicians, therefore, face a quandary with regard to dosing children who do not weigh approximately 15 kg (33 lbs [for whom the 0.15-mg dose is ideal]) or 30 kg (66 pounds or more [for whom the 0.30-mg dose is recommended]). The *Physician's Desk Reference*[20] and product inserts provide ambiguous advice and place the responsibility of dose selection entirely on the prescribing physician. Not surprisingly, therefore, both autoinjector doses are dispensed across almost the entire pediatric age range, indicating the potential for overdosing with the 0.15-mg dose in many infants, overdosing with the 0.30-mg dose in some young children, and underdosing with the 0.15-mg dose in many adolescents.[21] In a prospective, randomized, double-blind, parallel-group study of children at risk of anaphylaxis who self-injected either EpiPen 0.30 mg or EpiPen Jr 0.15 mg, pharmacologic effects such as pallor, tremor, and anxiety were observed transiently after injection of both doses, and additional effects including palpitations, headache, and nausea were observed in those who received the higher dose.[22] This study showed that the therapeutic effects of epinephrine could not be dissociated from the nontherapeutic effects. In the absence of availability of additional fixed doses (eg, 0.05, 0.10, 0.20, and 0.25 mg) in autoinjectors, the manufacturers' advice should be taken in the context of these benefits and risks.

The Risks of Prescribing an Epinephrine Ampule, Syringe, and Needle

Physicians face a particularly difficult dilemma in prescribing epinephrine doses for infants and children who weigh less than 15 kg (33 lb). One option may be to prescribe an epinephrine ampule/syringe/needle and instruct caregivers on how to draw up and inject epinephrine using these supplies. This approach was studied in 18 parents who were trained in the technique and whose speed and accuracy of drawing up an infant epinephrine dose (0.09 mL) was compared with that of 54 physicians and nurses (controls).[23] The parents took significantly ($P < .05$) longer than the controls to draw up the dose. The mean ± SEM times for drawing up doses were 142 ± 13 seconds (range: 83–248 seconds) for parents, 52 ± 3 seconds (range: 30–83 seconds) for physicians, 40 ± 2 seconds (range: 26–71 seconds) for general duty nurses, and 29 ± 0.09 seconds (range: 27–33 seconds) for emergency department nurses. The epinephrine content of the doses drawn up by parents, who were asked to draw up 0.09 mL, ranged from 0.004 to 0.151 mL (ie, nearly 40-fold). There was no correlation between speed of drawing up the epinephrine and accuracy of dosing. Parents had many concerns about successfully preparing and administering a dose by this method and about teaching other caregivers to use the method. The study was undertaken in a relaxed atmosphere, and one might expect more difficulties if the dosing were undertaken by laypersons while a child was experiencing anaphylaxis.[24]

Unfortunately, the current lack of autoinjectors with a low or adjustable dose and the problems involved with prescribing an epinephrine ampule along with a syringe/needle require that the physician and family arrive at a reasonable compromise for safe and effective administration of epinephrine in the event of anaphylaxis. In a survey of 29 pediatricians, 80% responded that they would prescribe the 0.15-mg autoinjector dose for a child who weighs 10 kg (22 lb); 100% responded that they would prescribe it for a child who weighs 15 kg (33 lb); and 70% responded that they would prescribe it for a child who weighs 20 kg (44 lb).[25] In a study of epinephrine-dispensing patterns,[21] 72% of prescriptions for infants younger than 6 months (weighing less than approximately 7 kg [15 lb]) were for a 0.15-mg autoinjector, and 20% were for ampule/syringe/needle; 95% of prescriptions for infants 6 to 12 months of age (likely weighing up to approximately 10 kg [22 lb]) were for a 0.15-mg autoinjector. Until a wider range of epinephrine autoinjector doses is available, pediatricians are forced to consider prescribing an autoinjector with a known, albeit not ideal, dose rather than risk likely overdosing or underdosing with ampule/syringe/needle.

Epinephrine Autoinjectors: 0.15 or 0.30 mg?

In the absence of a strong evidence base and a larger selection of premeasured autoinjector doses, and in light of studies showing elevated plasma concentrations and relatively modest adverse effects in children who weigh approximately 25 kg (55 lb) injected with approximately a 1.2-fold overdose of intramuscular epinephrine, it seems appropriate to switch most children from the 0.15-mg dose to the 0.30-mg dose at approximately 25 kg (55 lb)—that is, to provide a slightly higher dose (0.012 mg/kg) rather than an underdose (0.006 mg/kg) for a 25-kg (55-lb) child. For children who have asthma

or other additional risk factors for fatality from anaphylaxis, switching to the higher dose at a lower weight might be considered.[19] There are no data at this time to support specific recommendations for children who weigh less than 15 kg (33 lb). It is not known whether the adverse effects from a previously studied 1.2-fold overdose are similar in infants and very young, small children to those reported in children who weigh approximately 25 kg (55 lb). Considering the ease of use of self-injectable epinephrine compared with the ampule/syringe/needle technique and the preferences of pediatricians[21,25] and parents,[23] it seems reasonable to consider autoinjectors containing 0.15 mg of epinephrine for otherwise healthy infants/young children who weigh 10 to 25 kg (22–55 lb), although the physician is cautioned that manufacturers suggest alternative modalities for those who weigh less than 15 kg (33 lb). Clearly, specific clinical circumstances must be considered in this decision. For infants who weigh less than 10 kg (22 lb), dosing with 0.15-mg autoinjectors would exceed 1.5-fold overdosage, and although this situation is unacceptable from the standpoint of autoinjector availability, it is apparent that many pediatricians opt for the certainty of an autoinjector dose compared with the uncertainty of an ideal dose when the epinephrine ampule/syringe/needle technique is used.[21] Still, physicians and families should consider and discuss the benefits and risks of choosing between an autoinjector or epinephrine ampule/syringe/needle for this age group on a case-by-case basis. Current dilemmas in selecting a dose and factors that may sway a decision to switch to a particular dose unit are listed in Table 2. Lack of worldwide availability of autoinjectors[26] often requires prescription of the less costly epinephrine ampule/syringe/needle technique in developing countries despite the fact that it requires additional training, is error prone, and may lead to delay in injection.[23] Preloading the syringe with an appropriate dose of epinephrine is a possible partial solution, but contamination and degradation of the drug, particularly in hot climates, are serious concerns.[27]

Repeating the Epinephrine Dose

Anecdotal evidence generally suggests that in the absence of a response to epinephrine, the epinephrine injection may be repeated at 5- to 20-minute intervals.[1,28] Retrospective studies have suggested that a sec-

TABLE 2 **Epinephrine Autoinjectors for Infants and Children: Dilemmas in Dosing and Possible Solutions[19]**

Patient's Weight, kg (lb)	Optimal Dose (0.01 mg/kg), mg	Availability of Autoinjector[a]	Alternatives/Implications[b]	Comments/Recommendations[c]
≤10 (≤22)	≤0.10	No	Fixed-dose 0.15-mg autoinjector provides ≥1.5-fold overdose; ampule/syringe/needle technique may lead to delay in injection and inaccurate dosing	Evaluate degree of overdose vs ability to use ampule/syringe/needle; no specific evidence base for decision except that ampule/syringe/needle technique is delay and error prone, and autoinjector (0.15 mg) is more commonly prescribed for infants by physicians forced to choose
15 (33)	0.15	Yes	0.15-mg autoinjector provides optimum dose	Prescribe autoinjector (0.15 mg)
20 (44)	0.20	No	0.15-mg autoinjector provides 1.3-fold underdose; 0.30-mg autoinjector provides 1.5-fold overdose	Usually prescribe 0.15-mg autoinjector, but increasing weight of child over 20 kg and high risk on the basis of clinical history[d] may be considered an appropriate rationale for prescribing a 0.30-mg autoinjector
25 (55)	0.25	No	0.15-mg autoinjector provides 1.7-fold underdose; 0.30-mg autoinjector provides 1.2-fold overdose	Usually prescribe 0.30-mg autoinjector; a small overdose in a healthy child generally carries a low risk of adverse effects compared with the risk of an underdose during anaphylaxis
≥30 (≥66)	0.30	Yes	0.30-mg autoinjector provides optimum dose	Prescribe autoinjector (0.30 mg)

[a] For situations in which an autoinjector containing an appropriate dose is not available, the situation is never truly acceptable, because using an epinephrine ampule/syringe/needle (see text) is prone to delay in dosing or inaccurate dosing. However, until such autoinjectors are manufactured and fixed doses of 0.05, 0.10, 0.20, and 0.25 mg are available in addition to the 0.15- and 0.30-mg doses currently available, the physician has to determine the risk versus the benefit of selecting a fixed dose that is either too low or too high and the risk/benefit of an optimal technique of administration (autoinjector) versus a technique (ampule/syringe/needle) that may be prone to delay and error in the hands of non–health care professionals.

[b] There are no studies that have provided details about risks of overdose and underdose of epinephrine in the context of first-aid treatment of anaphylaxis at most dose ranges, particularly in children who weigh less than 15 kg (33 lb). It is presumed, on the basis of limited data, that otherwise healthy children (normal cardiac status, not taking other sympathomimetics, tricyclic antidepressants, or monoamine oxidase inhibitors, etc) would tolerate modest overdoses of epinephrine. In older children not experiencing anaphylaxis, a 1.2-fold overdose has been associated with adverse pharmacologic effects.

[c] Distributors' recommendations regarding autoinjector indications for weight/age differ from country to country, but an alternative form of epinephrine for self-injection, such as ampule/syringe/needle rather than an autoinjector, has been suggested for children who weigh less than 15 kg (33 lb). The perceived comfort and ability of families and caregivers to provide accurate doses of epinephrine for infants using an epinephrine ampule/syringe/needle should be considered in deciding the best modality and the potential degree of overdose or underdose if an autoinjector were prescribed. Although not per manufacturer's advice, it is suggested that the available evidence (error rates of ampule/syringe/needle of no dose to almost 40-fold overdose in the hands of non–health care professionals, adverse pharmacologic effects of a modest overdose in a healthy child, lack of additional fixed-dose autoinjectors) may warrant prescription of a 0.15-mg autoinjector for most healthy children who weigh 10 kg (22 lb) and more; however, individual circumstances may vary. Depending on the circumstances, provision of an autoinjector to those who weigh less than 10 kg (22 lb) may also be warranted.

[d] In addition to consideration of body weight, clinical issues that may add risk to underdosing and indicate a relative benefit for a higher dose may include 1 or more of the following: concurrent asthma; previous anaphylaxis to peanut, tree nut, milk, egg, seafood, and/or fin fish; poor access to emergency services; and/or lack of supervision.

ond dose may be required in 18% to 35% of cases, although data in this regard are limited.[29,30] As stated previously, some of the effects of epinephrine (pallor, tremor, anxiety, and palpitations) and even severe adverse effects (such as cough from pulmonary edema) can mimic some of the symptoms of anaphylaxis. Caregivers should be aware of these issues and avoid unnecessary repeat dosing.

In some adults experiencing anaphylaxis who were raised from the supine to the upright position during transport to a hospital, death occurred suddenly, presumably from an "empty-ventricle syndrome" caused by blood pooling in the legs during anaphylactic shock.[31] The implications of this observation for children, who more typically succumb to respiratory insufficiency during anaphylaxis and who often vomit during anaphylaxis, are not known. Nevertheless, caregivers should be advised that individuals with severe anaphylaxis who may benefit from being in a supine position with legs raised should remain in that position and be transported that way by emergency personnel until advanced care can be accessed (eg, additional medications and intravenous fluids).

PRESCRIPTION OF SELF-INJECTABLE EPINEPHRINE

The primary indication for prescription of self-injectable epinephrine is a history of anaphylaxis in an individual who may re-encounter the triggering agent outside of a medical setting or who has idiopathic anaphylaxis, which is uncommon in childhood. Identification of individuals who have experienced anaphylaxis is not necessarily easy. It is clear that persons with a previous episode of anaphylaxis that was characterized by respiratory or cardiovascular compromise to a trigger that may be encountered outside the hospital should carry self-injectable epinephrine, but only approximately 70% of individuals with anaphylaxis have respiratory symptoms, and even fewer (only approximately 10%) experience cardiovascular symptoms.[32] Skin manifestations such as urticaria, angioedema, flushing, or itching occur in more than 80% of children with anaphylaxis. When present, these symptoms are helpful in the recognition of anaphylaxis; when absent, they make the recognition of anaphylaxis more difficult.[32] Moreover, acute generalized urticaria and angioedema alone may not necessarily warrant a diagnosis of "anaphylaxis" (a point of controversy). However, on the basis of available evidence, self-injectable epinephrine should be prescribed for a child who has experienced generalized acute urticaria after an insect sting, because the risk of a more severe reaction from a future sting is approximately 10%.[33] Finally, physicians cannot assume that patients and caregivers necessarily recognize and report all symptoms, because even trained health care professionals underrecognize anaphylaxis.[2] For all of these reasons, a high index of suspicion is needed to identify those who have had anaphylaxis and require an epinephrine prescription.

An additional point of judgment regarding prescription of self-injectable epinephrine is that a physician may identify a child who has not yet experienced anaphylaxis but may nevertheless be at increased risk of anaphylaxis and may warrant prescription of self-injectable epinephrine. Vander Leek et al[34] showed that among 24 young children with peanut allergy whose first reaction was isolated to the skin after ingestion or skin contact, 18 (75%) experienced symptoms beyond the skin in a subsequent reaction. Indeed, severity of a previous reaction is a poor guide to symptoms during a future reaction.[9,11,35] In young children with peanut- or tree nut–related anaphylaxis, episodes may worsen progressively with time, perhaps related to the fact that increased numbers of such children develop asthma as they get older.[36] Asthma, which is associated with severe and fatal anaphylaxis,[8,9,28] is an important comorbidity that should influence the decision to prescribe self-injectable epinephrine. Some "high-risk" circumstances that may justify prescription of self-injectable epinephrine in the absence of previous anaphylaxis are summarized in Table 3.[18,37,38] Definitive evaluations of such children by an allergy/immunology specialist with American Board of Allergy and Immunology certification or international equivalent should be encouraged.[39]

In summary, epinephrine should be prescribed for children who have experienced anaphylaxis and may re-encounter the trigger outside of a hospital setting. In some circumstances, epinephrine for self-injection should be prescribed for persons who have not experienced anaphylaxis but are at increased risk of anaphylaxis on the basis of their specific comorbid medical conditions and medical-social evaluation.

INSTRUCTIONS FOR WHEN TO USE EPINEPHRINE

Physicians should carefully instruct patients and families on the indications for, and the technique for using,

TABLE 3 **Examples of Factors That May Indicate the Need to Prescribe Epinephrine for Persons "at Risk" of Anaphylaxis[18,37,38]**

Reaction history
Reaction to trace allergen exposure
Repeat exposures likely
Specific food triggers known to be associated with severe/fatal reactions (eg, peanut, tree nut, seafood, milk)
Generalized urticaria from insect venom
Certain comorbidities
Asthma
Use of nonselective β-blockers
Additional factors
Initial reaction details unclear, possible anaphylaxis
Those living in a remote area away from medical care/access

An at-risk person can be, for example, one with a confirmed allergy to food or insect venom who has not experienced anaphylaxis. Note: a first episode of anaphylaxis can be fatal.[10,11]

self-injectable epinephrine. Prompt administration of epinephrine is clearly indicated for treatment of significant respiratory or cardiovascular symptoms of anaphylaxis, but considerable judgment is required in many actual or possible allergic reactions in which life-threatening symptoms have not yet developed but may develop. Previous guidelines have suggested that epinephrine should be administered promptly at the onset of symptoms after exposure to an allergen that had previously caused anaphylaxis and possibly even in the absence of symptoms if there was a known exposure to an allergen that previously caused anaphylaxis with cardiovascular collapse.[28] Generalized acute urticaria itself is not a life-threatening symptom, yet in the context of a known exposure to an allergen that previously triggered anaphylaxis, the recommendation for an exposure outside of a medical setting is to inject epinephrine.[28] Whether an individual with generalized acute urticaria has "anaphylaxis" and should be given epinephrine is controversial. In many circumstances, astute clinical judgment is required to differentiate symptoms that may mimic aspects of an episode of anaphylaxis (eg, viral syndrome with acute urticaria, asthma, choking, a panic episode) or represent a mild allergic reaction that does not require epinephrine. In the community setting, individuals who experience anaphylaxis, whose judgment may be clouded by anxiety or central nervous system symptoms, or caregivers without medical training, whose judgment may be clouded by anxiety, are required to evaluate symptoms.[39] Consequently, physicians should always instruct these individuals to err on the side of injecting epinephrine rather than waiting too long.[28]

Individuals and caregivers are often reluctant to use self-injectable epinephrine in anaphylaxis despite instruction to do so. This probably occurs for a variety of reasons, including failure to recognize anaphylaxis; spontaneous recovery from a previous episode; incorrectly thinking the episode is mild; reliance on oral H_1 antihistamines or asthma-relief inhalers such as albuterol; fear of needles and injections; epinephrine autoinjector not being available; and concern about adverse effects of epinephrine.[19] In contrast to transient pallor, tremor, anxiety, and palpitations, which are common and anticipated pharmacologic effects of epinephrine, serious adverse effects are generally not a concern for otherwise healthy children, although they have been reported when epinephrine was given in overdose, especially when it was administered intravenously in an overdose, given at an inappropriately high concentration, or infused too rapidly.[11,22,40]

It seems that adolescents are at particular risk of fatal anaphylaxis, possibly because they are more likely to engage in risky behaviors, fail to recognize triggers, deny symptoms, and not carry or use emergency medications.[8,9] Additional efforts to provide anaphylaxis education for adolescents and their friends and peers are needed.

Prompt administration of epinephrine for anaphylaxis is key. Sampson et al[9] described 6 children with fatal reactions to food, all of whom had asthma, previous reactions to foods, and delay in treatment with epinephrine. None of the children received epinephrine before onset of severe respiratory symptoms (obvious respiratory distress, retractions, wheezing, and, in some cases, cyanosis), and 7 children in the same study with near-fatal food anaphylaxis received epinephrine before or within 5 minutes of severe respiratory symptoms. Only 1 of the children with fatal reactions had cutaneous symptoms; in contrast, all of those with near-fatal reactions had cutaneous symptoms. This raises the concern that absence of, or failure to recognize, skin symptoms and other symptoms could result in a delay in treatment and a poor outcome. Among 32 food-anaphylaxis fatalities recorded in a registry maintained through the Food Allergy & Anaphylaxis Network,[8] all but 1 individual had a known allergy to the food, only 10% had self-injectable epinephrine available, peanut or tree nut caused 94% of the reactions (milk and fish caused the others), most of those who died were adolescents or young adults, and 96% had asthma.

Gold and Sainsbury[41] surveyed families of children for whom self-injectable epinephrine was prescribed for a previous reaction with respiratory or cardiovascular involvement. Although recurrences were common, epinephrine was injected in only 12% of subsequent reactions. When it was given, although it was seldom injected before onset of respiratory or cardiovascular symptoms, it resulted in a significantly lower hospitalization rate and reduced morbidity.

When developing an anaphylaxis emergency action plan for an individual to use in the community in the absence of a health care professional, presumably for a circumstance in which definitive diagnosis is unlikely, it seems advisable to instruct patients/caregivers to inject epinephrine promptly when symptoms occur after known exposure to a trigger that previously caused a significant reaction. For the occasional child or adolescent who has idiopathic anaphylaxis, where "exposure" is an irrelevant issue, a symptom-based approach is required.

Patients and caregivers must also be instructed in the techniques of autoinjector use or epinephrine ampule/syringe/needle use. Although the autoinjector devices are not particularly difficult to use, errors are common.[25] The injection may be given through clothing, although care must be taken to avoid obstructions such as seams or items in pockets. Accidental injection of epinephrine into a digit can cause vasoconstriction and necrosis and should be promptly evaluated and treated, if necessary, with warming, topical nitroglycerin cream, or locally injected phentolamine or other vasodilator.[42] Review

and practice of injection technique using "trainers" and review of manufacturer's educational materials (eg, DVDs) are strongly recommended. Proper storage of the epinephrine, away from extremes of temperature and direct sunlight to protect the drug from degradation, is also important. Degradation may occur without discoloration or precipitation.[43] It is important to remind patients and families to check autoinjector expiration dates and renew prescriptions promptly.

Preparation for first-aid treatment of anaphylaxis additionally requires medical home development and review of a personalized anaphylaxis emergency action plan that lists potential anaphylaxis symptoms and gives instructions for the indications for self-injectable epinephrine, the technique for using epinephrine autoinjectors, and the necessity of taking the patient to an emergency department after an epinephrine injection. Downloadable examples of written plans that can be personalized are available through the Food Allergy & Anaphylaxis Network Web site (www.foodallergy.org/actionplan.pdf [in English] or www.foodallergy.org/spanishaction.pdf [in Spanish]) and from the American Academy of Allergy, Asthma and Immunology Web site (www.aaaai.org/members/resources/anaphylaxis_toolkit/action_plan.pdf).[39] The emergency action plan and coaching with regard to use of self-injectable epinephrine should be reviewed with the patient on a regular basis. Additional important considerations include diagnostic confirmation/reconfirmation of the triggering allergen, instructions with regard to trigger avoidance (for foods, insect stings, etc), and medical identification (eg, bracelet, wallet card[39]). When relevant, specific preventive measures should be recommended (eg, for venom anaphylaxis, allergen-specific immunotherapy should be instituted to provide long-lasting protection).[44] For exercise-induced anaphylaxis, physicians should recommend appropriate avoidance of food or medication co-triggers, and if no co-trigger has been identified, they should advise individuals to avoid ingestion of anything within 3 to 4 hours of strenuous exercise. Evaluation by an allergy/immunology specialist (with American Board of Allergy and Immunology or international equivalent certification) is typically required to address these issues. Lay organizations such as the Food Allergy & Anaphylaxis Network (www.foodallergy.org) are an important resource for educational materials and support. Omission of these preventive strategies may contribute to poor outcomes.[9,11]

In summary, epinephrine is the drug of choice for first-aid treatment of anaphylaxis and should be injected promptly in the event of an anaphylactic reaction or when progression to anaphylaxis is likely and advanced care is not promptly available. Asthma puffers and/or antihistamines cannot be depended on in anaphylaxis.[39]

SPECIAL ISSUES FOR SCHOOLS

Protection of children at risk of anaphylaxis while in school, child care, or camp requires a concerted effort.[28] Several organizations have developed thoughtful summaries of shared responsibilities concerning food allergies for use by schools, children, adolescents, and parents (a list is available online at www.foodallergy.org/school/SchoolGuidelines.pdf). The physician should work with school administrators, teachers, school nurses, and others to ensure that an appropriate diagnosis has been obtained and that an appropriate anaphylaxis emergency action plan is prescribed.

SUMMARY

1. Epinephrine is the medication of choice for first-aid treatment of an episode of anaphylaxis. Prompt injection of epinephrine is nearly always effective in the treatment of anaphylaxis, and delayed injection of epinephrine is associated with poor outcomes including fatality. Antihistamines and, for those with asthma, inhaled selective β_2-adrenergic agonists such as albuterol provide adjunctive therapy but cannot replace epinephrine. Advanced care for anaphylaxis should be sought promptly (call 911 or equivalent for additional care and emergency transport to a hospital/emergency department) after epinephrine injection for first-aid treatment of anaphylaxis.
2. The recommended epinephrine dose for anaphylaxis in children, based primarily on anecdotal evidence, is 0.01 mg/kg, up to 0.30 mg.
3. On the basis of the available data at this time, intramuscular injection of epinephrine into the lateral thigh (vastus lateralis) seems to be the preferred route for therapy in first-aid treatment, assuming that an early peak epinephrine concentration is important to effective management. Intravenous administration of epinephrine carries increased risks of dilution errors and dosing errors, with consequent increased risk of overdose and adverse effects such as cardiac dysrhythmias.
4. Epinephrine autoinjectors, preferred for ease of use compared with an ampule, syringe, and needle, are currently available in only 2 fixed doses: 0.15 and 0.30 mg. The lack of additional autoinjector doses is a serious concern. Nevertheless, pediatricians are advised to prescribe the optimal dose from an autoinjector for each child, even when that dose cannot possibly be precisely 0.01 mg/kg. On the basis of current, albeit limited, data, it seems reasonable to recommend autoinjectors with 0.15 mg of epinephrine for otherwise healthy young children who weigh 10 to 25 kg (22–55 lb) and autoinjectors with 0.30 mg of epinephrine for those who weigh approximately 25 kg (55 lb) and more. However, specific clinical

circumstances must be considered when making these decisions. For children who weigh less than 10 kg (22 lb), the physician and family should weigh the risks of delay in dosing and dosing errors when an ampule/syringe/needle is used against accepting non-ideal autoinjector doses, taking into consideration the specific health needs of the individual child and abilities of the caregivers.

5. Epinephrine should be prescribed for children who have experienced anaphylaxis who may re-encounter the trigger outside of a health care setting. In some circumstances, epinephrine for self-injection should be prescribed for persons who have not yet experienced anaphylaxis but are at increased risk of anaphylaxis on the basis of their specific trigger for anaphylaxis, comorbid medical conditions such as asthma, and/or limited ability to recognize anaphylaxis.
6. Epinephrine should always be prescribed in the context of an anaphylaxis emergency action plan developed by the medical home with the families. Effective care for individuals at risk of anaphylaxis requires a comprehensive management approach. Patients and caregivers must be carefully instructed on the technique for use of, and indications for, self-injectable epinephrine, how to recognize the symptoms of anaphylaxis, and the need to activate emergency services (call 911 or equivalent) in the event of anaphylaxis. Instructions on allergen avoidance are key. Optimally, evaluation by an allergy/immunology specialist with American Board of Allergy and Immunology or international equivalent certification should be obtained to confirm allergic triggers, to provide education on trigger avoidance, and to initiate specific preventivetreatment (eg, venom-injection immunotherapy for insect-sting anaphylaxis). Written emergency action plans and review of care plans in the child's medical home with specific responsibilities for school, child care, or camp personnel; families; and children are needed to ensure a safe environment for those at risk.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Barbara L. Frankowski, MD, MPH; and the Committee on Adolescence

Sexual Orientation and Adolescents

ABSTRACT. The American Academy of Pediatrics issued its first statement on homosexuality and adolescents in 1983, with a revision in 1993. This report reflects the growing understanding of youth of differing sexual orientations. Young people are recognizing their sexual orientation earlier than in the past, making this a topic of importance to pediatricians. Pediatricians should be aware that some youths in their care may have concerns about their sexual orientation or that of siblings, friends, parents, relatives, or others. Health care professionals should provide factual, current, nonjudgmental information in a confidential manner. All youths, including those who know or wonder whether they are not heterosexual, may seek information from physicians about sexual orientation, sexually transmitted diseases, substance abuse, or various psychosocial difficulties. The pediatrician should be attentive to various potential psychosocial difficulties, offer counseling or refer for counseling when necessary and ensure that every sexually active youth receives a thorough medical history, physical examination, immunizations, appropriate laboratory tests, and counseling about sexually transmitted diseases (including human immunodeficiency virus infection) and appropriate treatment if necessary.

Not all pediatricians may feel able to provide the type of care described in this report. Any pediatrician who is unable to care for and counsel nonheterosexual youth should refer these patients to an appropriate colleague. *Pediatrics* **2004;113:1827–1832;** ***sexual orientation, adolescents, homosexuality, gay, lesbian, bisexual.***

ABBREVIATIONS. STD, sexually transmitted disease; HIV, human immunodeficiency virus; AAP, American Academy of Pediatrics; AIDS, acquired immunodeficiency syndrome.

INTRODUCTION

Pediatricians are being asked with increasing frequency to address questions about sexual behavior and sexual orientation. It is important that pediatricians be able to discuss the range of sexual orientation with all adolescents and be competent in dealing with the needs of patients who are gay, lesbian, bisexual, or transgendered or who may not identify themselves as such but who are experiencing confusion with regard to their sexual orientation. Young people whose sexual orientation is not heterosexual can have risks to their physical, emotional, and social health, primarily because of societal stigma, which can result in isolation.[1,2] Because self-awareness of sexual orientation commonly occurs during adolescence, the pediatrician should be available to youth who are struggling with sexual orientation issues and support a healthy passage through the special challenges of the adolescent years. Pediatricians may be called on to help parents, siblings, and extended families of nonheterosexual youth. Also, nonheterosexual youth and adults are part of peer groups with whom all pediatric patients and their parents spend time in the neighborhood, at school, or at work. Thus, pediatricians may be called on to help promote better understanding of issues involving nonheterosexual youth.

Gay, lesbian, and bisexual people in the United States have unique health risks. The US Department of Health and Human Services has identified 29 *Healthy People 2010* objectives in which disparities exist between homosexual or bisexual persons and heterosexual persons. These focus areas include access to care, educational and community-based programs, family planning, immunization and infectious disease, sexually transmitted diseases (STDs) including human immunodeficiency virus (HIV) infection, injury and violence prevention, mental health and mental disorders, substance abuse, and tobacco use.[3]

DEFINITIONS

Sexual orientation[4,5] refers to an individual's pattern of physical and emotional arousal toward other persons. Heterosexual individuals are attracted to persons of the opposite sex, homosexual individuals are attracted to persons of the same sex, and bisexual individuals are attracted to persons of both sexes. Homosexual males are often referred to as "gay"; homosexual females are often referred to as "lesbian." In contrast, gender identity is the knowledge of oneself as being male or female, and gender role is the outward expression of maleness or femaleness. Gender identity and gender role usually conform to anatomic sex in both heterosexual and homosexual individuals. Exceptions to this are transgendered individuals and transvestites. Transgendered individuals feel themselves to be of a gender different from their biological sex; their gender identity does not match their anatomic or chromosomal sex. Transvestites are individuals who dress in the clothing of the opposite gender and derive pleasure from such ac-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

tions; their gender role does not match societal norms. Transgendered individuals and transvestites can be heterosexual, homosexual, or bisexual.

Sexual orientation is not synonymous with sexual activity or sexual behavior (the way one chooses to express one's sexual feelings). Certain sexual behaviors can put individuals of any sexual orientation at risk of pregnancy (penile-vaginal sexual intercourse) and/or certain diseases (penile-vaginal, oral, and anal sexual intercourse). Especially during adolescence, individuals may participate in a variety of sexual behaviors. Many homosexual adults report having relationships and sexual activity with persons of the opposite sex as adolescents,[6,7] and many adults who identify themselves as heterosexual report sexual activity with persons of the same sex during adolescence.[8–10] Also, many youth label themselves as gay, lesbian, or bisexual years after labeling their attractions as such.[11] In addition, adolescents may also self-identify as nonheterosexual without ever being sexually active. Pediatricians need to understand that they should inquire about sexual attraction or orientation even when youth do not report being gay or lesbian.

ETIOLOGY AND PREVALENCE

Homosexuality has existed in most societies for as long as recorded descriptions of sexual beliefs and practices have been available.[4] Societal attitudes toward homosexuality have had a decisive effect on the extent to which individuals have hidden or made known their sexual orientation.

Human sexual orientation most likely exists as a continuum from solely heterosexual to solely homosexual. In 1973, the American Psychiatric Association reclassified homosexuality as a sexual orientation or expression and not a mental disorder.[12] The mechanisms for the development of a particular sexual orientation remain unclear, but the current literature and most scholars in the field state that one's sexual orientation is not a choice; that is, individuals do not choose to be homosexual or heterosexual.[8,11]

A variety of theories about the influences on sexual orientation have been proposed.[5] Sexual orientation probably is not determined by any one factor but by a combination of genetic, hormonal, and environmental influences.[2] In recent decades, biologically based theories have been favored by experts. The high concordance of homosexuality among monozygotic twins and the clustering of homosexuality in family pedigrees support biological models. There is some evidence that prenatal androgen exposure influences development of sexual orientation, but postnatal sex steroid concentrations do not vary with sexual orientation. The reported association in males between homosexual orientation and loci on the X chromosome remains to be replicated. Some research has shown neuroanatomic differences between homosexual and heterosexual persons in sexually dimorphic regions of the brain.[5] Although there continues to be controversy and uncertainty as to the genesis of the variety of human sexual orientations, there is no scientific evidence that abnormal parenting, sexual abuse, or other adverse life events influence sexual orientation.[4,5] Current knowledge suggests that sexual orientation is usually established during early childhood.[1,2,4,5]

The estimated proportion of Americans who are homosexual is imprecise at best, because surveys are hampered by the stigmatization and the climate of fear that still surround homosexuality. Past studies asked more often about sexual behavior and not sexual orientation. Kinsey et al,[9,13] from their studies in the 1930s and 1940s, reported that 37% of adult men and 13% of adult women had at least 1 sexual experience resulting in orgasm with a person of the same sex and that 4% of adult men and 2% of adult women are exclusively homosexual in their behavior and fantasies. A more recent review of various US studies estimated that 2% of men are exclusively homosexual and 3% are bisexual.[14] Other current studies conclude that somewhere between 3% and 10% of the adult population is gay or lesbian, and perhaps a larger percentage is bisexual.[4,5] Sorenson[15] surveyed a group of 16- to 19-year-olds and reported that 6% of females and 17% of males had at least 1 sexual experience with a person of the same sex. Remafedi et al,[10] in a large, population-based study of junior and senior high school students performed in the late 1980s that measured sexual fantasy, emotional attraction, and sexual behavior, found that more than 25% of 12-year-old students felt uncertain about their sexual orientation. This uncertainty decreased with the passage of time and increasing sexual experience to only 5% of 18-year-old students. Only 1.1% of students reported themselves as predominantly homosexual or bisexual. However, 4.5% reported primary sexual attractions to persons of the same sex, which better reflects actual sexual orientation. The Garofalo et al study,[16] based on the 1995 Massachusetts Youth Risk Behavior Survey, found that 2.5% of youth self-identified as gay, lesbian, or bisexual.

These data illustrate the complexity of labeling sexual orientation in adolescents. Health care professionals should be aware that a large number of adolescents have questions about their sexual feelings; some are attracted to and may have sexual relations with people of the same sex, and a small number may know themselves to be gay or lesbian.

SPECIAL NEEDS OF NONHETEROSEXUAL AND QUESTIONING YOUTH

The overall goal in caring for youth who are or think they might be gay, lesbian, or bisexual is the same as for all youth: to promote normal adolescent development, social and emotional well-being, and physical health. If their environment is critical of their emerging sexual orientation, these adolescents may experience profound isolation and fear of discovery, which interferes with achieving developmental tasks of adolescence related to self-esteem, identity, and intimacy.[17,18] Nonheterosexual youth often are subjected to harassment and violence; 45% of gay men and 20% of lesbians surveyed were victims of verbal and physical assaults in secondary school specifically because of their sexual orientation.[1,19]

Nonheterosexual youth are at higher risk of dropping out of school, being kicked out of their homes, and turning to life on the streets for survival. Some of these youth engage in substance use, and they are more likely than heterosexual peers to start using tobacco, alcohol, and illegal drugs at an earlier age.[20] Nonheterosexual youth are more likely to have had sexual intercourse, to have had more partners, and to have experienced sexual intercourse against their will,[20] putting them at increased risk of STDs including HIV infection. In a recent study of HIV seroprevalence, 7% of 3492 15- to 22-year-old males who have sex with males living in 7 US cities were HIV-seropositive. Among adolescent males who have sex with males, HIV seroprevalence rates in descending order were highest among black adolescents, then "mixed race or other" adolescents, and then Hispanic adolescents and were lowest among Asian and white adolescents.[21] Women having sex with women have the lowest risk of any STD, but lesbian adolescents remain at significant risk because they are likely to have had sexual intercourse with males. Youth in high school who identify themselves as gay, lesbian, or bisexual; engage in sexual activity with persons of the same sex; or report same-sex romantic attractions or relationships are more likely to attempt suicide, be victimized, and abuse substances.[20,22] Although only representing a portion of youth who someday will self-identify as gay, lesbian, or bisexual, school-based studies have found that these adolescents, compared with heterosexual peers, are 2 to 7 times more likely to attempt suicide,[16,19,23,24] are 2 to 4 times more likely to be threatened with a weapon at school,[16,23] and are more likely to engage in frequent and heavy use of alcohol, marijuana, and cocaine. It is important to note that these psychosocial problems and suicide attempts in nonheterosexual youth are neither universal nor attributable to homosexuality per se, but they are significantly associated with stigmatization of gender nonconformity, stress, violence, lack of support, dropping out of school, family problems, acquaintances' suicide attempts, homelessness, and substance abuse.[2,25] In addition to suicidality, young gay and bisexual men might also suffer body image dissatisfaction and disordered eating behaviors for some of the same reasons.[26]

Nonheterosexual youth are represented within all populations of adolescents, all social classes, and all racial and ethnic groups. Ethnic minority youth who are nonheterosexual are required to manage more than one stigmatized identity, which increases their level of vulnerability and stress.[27] They retain their minority status when they seek help in the predominately white gay and lesbian support communities. In addition, sexual minority youth are represented among handicapped adolescents, homeless adolescents, and incarcerated youth.[1]

Most nonheterosexual youths are "invisible" and will pass through pediatricians' offices without raising the issue of sexual orientation on their own. Therefore, health care professionals should raise issues of sexual orientation and sexual behavior with all adolescent patients or refer them to a colleague who can. Such discussions normalize the notion that there is a range of sexual orientation. The portrayal of openly gay or lesbian characters in media is starting to change how adolescents view these differences. Even adolescents who are quite sure of their own heterosexuality are likely to have friends, relatives, teachers, etc whom they know or suspect to be gay or lesbian or who are struggling with questions about their sexual orientation. Rather than asking patients whether they have a "boyfriend" or "girlfriend," pediatricians could ask, "Have you ever had a romantic relationship with a boy or a girl?" or "When you think of people to whom you are sexually attracted, are they men, women, both, neither, or are you not sure yet?" By doing so, pediatricians open the door to additional communication and start to break down stereotypes and stigmatization. It implies that any of the options is possible and that an adolescent may not be sure of his or her sexual orientation. If these issues are addressed, specifically targeted medical screening, medical treatment, and anticipatory guidance can be provided to adolescents who need it. Pediatricians can have an important positive effect on young people and their families by addressing sexual orientation and sexual behavior on several levels: office and hospital policies, clinical care, and community advocacy.[2]

OFFICE PRACTICE: ENSURE A SAFE AND SUPPORTIVE ENVIRONMENT

A pediatric encounter may give adolescents a rare opportunity to discuss their concerns about their sexual orientation and/or activities. Adolescents' level of comfort in the pediatric office sets the tone for their other health care interactions. The way sexuality and other important personal issues are discussed also sets an example for all adolescents and their parents. In the office, pediatricians are encouraged to[28]:

1. Assure the patient that his or her confidentiality is protected.[29]
2. Implement policies against insensitive or inappropriate jokes and remarks by office staff.
3. Be sure that information forms use gender-neutral, nonjudgmental language.
4. Consider displaying posters, brochures, and information on bulletin boards that demonstrate support of issues important to nonheterosexual youth and their families (eg, the American Academy of Pediatrics [AAP] brochure "Gay, Lesbian, and Bisexual Teens: Facts for Teens and their Parents").
5. Provide information about support groups and other resources to nonheterosexual youth and their friends and families if requested.

COMPREHENSIVE HEALTH CARE FOR ALL ADOLESCENTS

Pediatricians are not responsible for labeling or even identifying nonheterosexual youth. Instead, the pediatrician should create a clinical environment in which clear messages are given that sensitive personal issues including sexual orientation can be discussed whenever the adolescent feels ready to do so. A major obstacle to effective medical care is adoles-

cents' misunderstanding of their right to confidential care.[30] The pediatrician should be ready to raise and discuss issues of sexual orientation with all adolescents, particularly those in distress or engaged in high-risk behaviors. The pediatrician should be able to explore the adolescent's understanding and concerns about sexual orientation, dispel any misconceptions, provide appropriate medical care and anticipatory guidance, and connect the adolescent to appropriate supportive community resources. Pediatricians are encouraged to[29,31]:

1. Be aware of the special issues surrounding the development of sexual orientation.[29]
2. Assure the patient that his or her confidentiality is protected.[29]
3. Discuss emerging sexuality with all adolescents.[32]
   - Be knowledgeable that many heterosexual youth also may have sexual experiences with people of their own sex. Labeling as homosexual an adolescent who has had sexual experiences with persons of the same sex or is questioning his or her sexual orientation could be premature, inappropriate, and counterproductive.
   - Use gender-neutral language in discussing sexuality; use the word "partner" rather than "boyfriend" or "girlfriend," and talk about "protection" rather than just "birth control."
   - Give evidence of support and acceptance to adolescents questioning their sexual orientation.
   - Provide information and resources regarding gay, lesbian, and bisexual issues to all interested adolescents.
   - Ask all adolescents about risky behaviors, depression, and suicidal thoughts.
   - Encourage abstinence, discourage multiple partners, and provide "safer sex" guidelines to all adolescents.[33] Discuss the risks associated with anal intercourse for those who choose to engage in this behavior, and teach them ways to decrease risk.
   - Counsel all adolescents about the link between substance use (alcohol, marijuana, and other drugs) and unsafe sexual intercourse.
   - Ask all adolescents about personal experience with violence including sexual or intimate-partner violence.

   Provide additional screening and education as indicated for each adolescent's sexual activity:
   - STD testing from appropriate sites[34]
   - HIV testing with appropriate support and counseling[35]
   - Pregnancy testing and counseling[36,37]
   - Papanicolaou testing
   - Hepatitis B and, when appropriate, hepatitis A immunization
4. Ensure that colleagues to whom adolescents are referred or with whom you consult are respectful of the range of adolescents' sexual orientation.

SPECIAL CONSIDERATIONS FOR NONHETEROSEXUAL YOUTH

For adolescents who self-identify as gay, lesbian, or bisexual, pediatricians should be particularly aware of several points:

1. Be prepared to refer adolescents' care if you have personal barriers to providing such care. Many individuals have strong negative attitudes about homosexuality or may simply feel uncomfortable with the subject. Even discomfort expressed through body language can send a very damaging message to nonheterosexual youth. It is an ethical and professional obligation to make an appropriate referral in these situations for the good of the child or adolescent.
2. Assure the patient that his or her confidentiality is protected.[29] Discuss with adolescents and, if appropriate, their parents whether they wish to have their sexual orientation recorded in office and hospital charts. Many nonheterosexual adults prefer to have this information recorded so that health care professionals will not assume heterosexuality.
3. Help the adolescent think through his or her feelings carefully; strong same-sex feelings and even sexual experiences can occur at this age and do not define sexual orientation.
4. Carefully identify all risky behaviors (sexual behaviors; use of tobacco, alcohol, and drugs; etc) and offer advice and treatment if indicated.
5. Ask about mental health concerns and evaluate or refer patients with identified problems.
6. Offer support and advice to adolescents faced with or anticipating conflicts with families and/or friends.
7. Encourage transition to adult health care when age-appropriate.

Pediatricians should be aware that the revelation of an adolescent's homosexuality (also called disclosure or "coming out") has the potential for intense family discord.[1,2,28] In many families, it precipitates physical and/or emotional abuse or even expulsion. The pediatrician can advise the adolescent to use certain language that may be helpful at the time of disclosure, such as "I am the same person, you just know one more thing about me now." However, there is no one disclosure technique that will preclude negative reactions. Parents, siblings, and other family members may require professional help to deal with their confusion, anger, guilt, and feelings of loss, and professionals who work with adolescents may be required to intervene on the adolescent's behalf. If the pediatrician has a relationship with the parents from ongoing primary care, he or she can be an important initial source of support and information. However, adolescents should be counseled to think carefully about the consequences of disclosure and to take their time in sharing information that could have many repercussions.[1]

With regard to parents of nonheterosexual adolescents, pediatricians are encouraged to:

1. Advise adolescents about whether, when, and how to disclose their nonheterosexuality to their parents. If unsure, assist the adolescent in finding a knowledgeable professional who can help.
2. Be knowledgeable about the process of disclosure.

3. Be supportive of parents of adolescents who have disclosed that they are not heterosexual. Most states have chapters of Parents and Friends of Lesbians and Gays (PFLAG) to which interested families may be referred.
4. Remind parents and adolescents that gay and lesbian individuals can be successful parents themselves.[38–41]
5. Be prepared to refer parents if you do not feel personally comfortable accepting this responsibility.

COMMUNITY ADVOCACY

Despite AAP statements issued in 1983[42] and 1993[43] urging excellent clinical care for nonheterosexual adolescents, these patients still experience many risks to their physical and mental health and safety that occur outside the scope of usual office practice. Some pediatricians may wish to take a broader role in their communities to help decrease these risks. Pediatricians could model and provide opportunities for increasing awareness and knowledge of homosexuality and bisexuality among school staff, mental health professionals, and other community leaders. They can make themselves available as resources for community HIV and acquired immunodeficiency syndrome (AIDS) education and prevention activities. It is critical that schools find a way to create safe and supportive environments for students who are or wonder about being nonheterosexual or who have a parent or other family member who is nonheterosexual. Support from respected pediatricians can facilitate these efforts greatly. Pediatricians who choose to be active on these issues may wish to[2,28]:

1. Help raise awareness among school and community leaders of issues relevant to nonheterosexual youth.
2. Help with the discussion of when and how factual materials about sexual orientation should be included in school curricula and in school and community libraries.
3. Support the development and maintenance of school- and community-based support groups for nonheterosexual students and their friends and parents.
4. Support HIV and AIDS prevention and education efforts.
5. Develop and/or request continuing education opportunities for health care professionals related to issues of sexual orientation, nonheterosexual youth, and their families.

SUMMARY OF PHYSICIAN GUIDELINES

The AAP reaffirms the physician's responsibility to provide comprehensive health care and guidance in a safe and supportive environment for all adolescents, including nonheterosexual adolescents and young people struggling with issues of sexual orientation. Some pediatricians might choose to assume the additional role of advocating for nonheterosexual youth and their families in their communities. The deadly consequences of HIV and AIDS, the damaging effects of violence and ostracism, and the increased prevalence of adolescent suicidal behavior underscore the critical need to address and seek to prevent the major physical and mental health problems that confront nonheterosexual youths in their transition to a healthy adulthood.

CLINICAL REPORT

Sexuality of Children and Adolescents With Developmental Disabilities

Guidance for the Clinician in Rendering Pediatric Care

Nancy A. Murphy, MD, Ellen Roy Elias, MD, for the Council on Children With Disabilities

ABSTRACT

Children and adolescents with developmental disabilities, like all children, are sexual persons. However, attention to their complex medical and functional issues often consumes time that might otherwise be invested in addressing the anatomic, physiologic, emotional, and social aspects of their developing sexuality. This report discusses issues of puberty, contraception, psychosexual development, sexual abuse, and sexuality education specific to children and adolescents with disabilities and their families. Pediatricians, in the context of the medical home, are encouraged to discuss issues of sexuality on a regular basis, ensure the privacy of each child and adolescent, promote self-care and social independence among persons with disabilities, advocate for appropriate sexuality education, and provide ongoing education for children and adolescents with developmental disabilities and their families.

INTRODUCTION

Sexual development is a multidimensional process, intimately linked to the basic human needs of being liked and accepted, displaying and receiving affection, feeling valued and attractive, and sharing thoughts and feelings. It not only involves anatomic and physiologic functioning, but it also relates to sexual knowledge, beliefs, attitudes, and values. Sexuality should be considered in a context that extends beyond genital sex to include gender-role socialization, physical maturation and body image, social relationships, and future social aspirations.[1] Like all adolescents, teens with disabilities may express desires and hopes for marriage, children, and normal adult sex lives. In fact, adolescents with physical disabilities are as sexually experienced as their peers without disabilities.[2] However, parents and health care professionals are often pessimistic regarding the potential of children with disabilities to enjoy intimacy and sexuality in their relationships.[3] People with disabilities are often erroneously regarded as childlike, asexual, and in need of protection. Conversely, they may be viewed as inappropriately sexual or as having uncontrollable urges.[4] People without disabilities are more willing to accept people with disabilities as fellow employees or casual friends and less willing to accept them as dating, sexual, or marriage partners.[5] Societal and psychosocial barriers may be more of a hindrance to an adolescent's sexual development than the limitations of the disability itself.[3]

PUBERTY AND SPECIAL CONSIDERATIONS

Puberty in US children typically has an onset between 8.5 and 13 years of age in females and between 9 and 14 years of age in males. Among children with cerebral palsy, puberty tends to begin earlier and end later than in typically developing children.[6] The median age of menarche for white females with cerebral palsy is 14.0 years, contrasting with 12.8 years in the general population. In general, children with neurodevelopmental disabilities are 20 times more likely to experience early pubertal changes.[7] Although idiopathic precocious puberty occurs in approximately 1 in 1000 girls, the incidence approaches 20% among females with spina bifida.[8] Although the reasons for this increased incidence are poorly understood, malformations of the central nervous system and nutritional influences on the hypothalamic-pituitary axis are known to affect the timing of puberty.[9] Precocious puberty can further challenge children with disabilities, who may be socially immature, by affecting an already altered body image and self-esteem, increasing the complexity of self-care and hygiene activities, and heightening the risk of sexual victimization. Gonadotropin-releasing hormone agonists can effectively manage true central precocious puberty in most females.[10]

All females deserve appropriate gynecologic care, including children and adolescents with developmental disabilities. During the first 2 years after menarche, anovulatory menstrual cycles are generally associated with abnormal uterine bleeding; however, thyroid disease, anticonvulsant therapy, and neuroleptic medications may also contribute to these symptoms.[11] If the adolescent is not sexually active, a pelvic examination is rarely indicated.[12] When pelvic examinations are indicated, females with disabilities should be informed about the procedures and instruments to be used and approached with respect for their personal privacy. Adolescents should be given the option of having a trusted caregiver present during the examination. Positioning during the pelvic examination should be modified as needed to accommodate the needs of women with orthopedic or neuromuscular disorders. Rather than stirrups, frog-leg position, V position, or elevation of the legs without hip abduction may increase comfort and decrease anxiety when examinations are indicated. Rectoabdominal examinations may offer an acceptable alternative to pelvic examinations and are best performed after the bowel has been evacuated by an enema.[12]

Adolescents and young adults with disabilities must be well informed when making decisions regarding abstinence, contraception, and pregnancy. For example, some antiepileptic medications induce hepatic enzyme activity and decrease the effectiveness of oral and implanted contraceptives.[9] The risk of thrombotic diseases in females with mobility impairments needs to be considered when prescribing estrogen-progestin–containing contraceptives such as pills, transdermal patches, and vaginal contraceptive rings.[13] Barrier devices, including condoms, cervical caps, and diaphragms, require motivation, cognitive understanding, and physical dexterity.[1] In addition, these devices often contain latex, which are contraindicated in the presence of latex sensitivities. Polyurethane male and female condoms are available but provide less protection against pregnancy and transmission of sexually transmitted diseases (STDs) and are more likely to break during sexual intercourse when compared with latex condoms.[14,15] However, nonlatex condoms still provide an acceptable alternative for those with latex sensitivity or allergy.[16] Although depot medroxyprogesterone acetate, an injectable contraceptive, can effectively minimize or eliminate menstrual flow, prolonged use has been linked recently to bone density loss in healthy adolescent females, which may not reverse completely after discontinuation of the medication.[17] Adolescents who are already at risk of osteopenia from chronic medical conditions may be at even greater risk of bone mineral density loss from depot medroxyprogesterone acetate use. Historically, sterilization of minors with developmental disabilities was performed without appropriate regard for their decision-making capacities, abilities to care for children, feelings, or interests. Such decisions should be made only in the context of the individual's capacity to make decisions, the consequences of reproduction for the person and any children that might be born, and applicable local, state, and federal laws.[18,19]

Most adolescents with myelomeningocele desire to marry and have children, but fewer than 20% have sought information regarding their sexual or reproductive function and only 16% of those who were sexually active have used contraception.[20] Adolescents with myelomeningocele and spinal cord injury have unique educational and medical needs that must be addressed to enjoy safe and satisfying sexual lives. When genital sensation is diminished or absent, alternative ways to appreciate sexual pleasure and satisfaction should be discussed. Fertility is generally preserved in females but reduced in males with spina bifida and spinal cord injury. Prepregnancy counseling should include informing women with spina bifida of the 5 in 100 risk of bearing children with neural tube defects, the protective effect of folate supplementation, and the potential complications associated with pregnancy. When 4 mg per day of folate is taken for at least 3 months before and during the first month of pregnancy, the recurrence risk is reduced by 50% to 75%.[21] Because unplanned pregnancies can occur, females of childbearing age with myelomeningocele may be offered the option of taking 4 mg per day of folate on an ongoing basis.[22]

PSYCHOSOCIAL CONSIDERATIONS

Early social experiences play a critical role in the psychosexual development of children and adolescents and may be limited or qualitatively different between a parent and child when a disability is present. Key milestones of adolescent development include attaining an adult body capable of reproducing, having and maintaining intimate relationships, managing a range of complex emotions, and independently thinking and problem solving.[23] The successful attainment of these developmental goals by individuals with disabilities may be hindered directly by functional limitations or indirectly by intentional or unintentional social isolation. Adolescents with physical and developmental disabilities generally participate in fewer social activities and intimate relationships when compared with typically developing peers, and most report that they lack information on parenthood, birth control, and STDs.[24]

Promoting independence and the acquisition of socially appropriate behaviors involves teaching and reinforcing skills for children with disabilities. Just as children learn academic concepts starting with the basics and moving to the more complex, they develop social independence in a developmentally appropriate, stepwise manner. A critical component of social and sexual maturity is attaining independence in basic self-care tasks. Whereas typically developing children complete self-care tasks independently by 8 years of age, children with disabilities may need frequent cues, supervision, formalized instruction, adaptive technology, and reinforcement in these activities well into adolescence and adulthood to achieve and maintain successes.

It is important to encourage the development of self-esteem in children with disabilities. Like all children, those with disabilities feel better about themselves and are more readily accepted by peers when provided with stylish and age-appropriate clothing that is easily donned and doffed. Social development is largely experiential, and children with disabilities generally have fewer opportunities for social interactions than their typically developing peers. Promoting typical teen activities, such as going to the mall or a movie with peers or participating in social activities at school, may require extra parental planning but afford invaluable opportunities to develop social skills. By mastering appropriate greetings, eye contact, body language, issues of personal space, self-advocacy skills, and telephone and computer skills, children build a strong foundation for the development of more complex social skills.

ISSUES OF SEXUAL ABUSE

The National Center on Child Abuse and Neglect has reported that children with disabilities are sexually abused at a rate that is 2.2 times higher than that for children without disabilities.[25] Other investigators have similarly reported significantly higher rates of sexual abuse among children with disabilities.[12,26] The US Department of Justice reports that 68% to 83% of women with developmental disabilities will be sexually assaulted in their lifetimes and less than half of them will seek assistance from legal or treatment services.[27] Children and adolescents with disabilities may be more vulnerable to sexual abuse because of dependence on others for intimate care, increased exposure to a large number of caregivers and settings, inappropriate social skills, poor judgment, inability to seek help or report abuse, and lack of strategies to defend themselves against abuse.[28] These fears may lead parents to protect their children from unsupervised social contacts and even from knowledge about sex. Some fear that talking about sexuality will promote sexual behavior. Yet, lack of education poses greater risks. When sexual questions and behaviors of individuals are freely discussed within a family, sexual development is promoted and the likelihood of abuse may be reduced or eliminated.[5,29] Children can learn to be assertive in protecting the privacy of their own bodies and in reporting violations to trusted adults.

The United Nations (UN) Convention on the Rights of the Child has established international recognition that all children have the right to respect for privacy and protection from exploitation and abuse.[30] Pediatricians can advocate for children with disabilities to ensure that their rights are upheld. Clinicians should recognize that when children with disabilities demonstrate alterations in bowel and bladder patterns, appetite, sleep, mood, behaviors, and community participation, they may be subjects of sexual abuse, and clinicians should thoroughly investigate these possibilities.

SEXUALITY EDUCATION

To overcome barriers to discussing the sexual development of children with disabilities, pediatricians can introduce issues of physical, cognitive, and psychosexual development to parents and their children at an early age and continue discussions at most visits throughout adolescence and young adulthood. When sexuality is discussed routinely and openly, conversations are easier to initiate, more comfortable to continue, and more effective and informative for all participants. Clinicians can explore the expectations of parents for their child's sexual development while providing general, factual information about sexuality in people with similar disabilities. With insights into the normal stages of child and adolescent sexual development, parents can better understand their own child's behaviors. For example, by recognizing that masturbation is normal toddler behavior, parents can better understand and shape the self-stimulatory behaviors of their teenager who functions developmentally at the level of a 3-year-old child. The problem is not the child's behaviors per se but the inability to distinguish between behaviors that are publicly and privately appropriate.

Children need to be provided developmentally appropriate sexuality education to help them attain a life with more personal fulfillment and protect them from exploitation, unplanned pregnancy, and STDs. An underlying premise of sexuality education is that sexuality is a source of pleasure and a basis for bonding and human relationships. One goal of sexuality education in its broadest sense is to give children a sense of being attractive members of their genders with expectations of having satisfying adult relationships. As an aspect of social functioning, sexuality education must incorporate the family's values on issues ranging from personal modesty to adult sexuality. This goal is best accomplished when parents are the principle teachers and offer sexuality education appropriate to the cognitive and functional abilities of their child.

Topics of substance abuse, sexual development, sexual orientation, STDs, contraception (including abstinence), and the health implications of pregnancy should be discussed with all adolescents, including those with disabilities. The pediatrician who understands typical sexual development and appreciates the unique cognitive and emotional abilities of each child is best equipped to discuss these topics in a way that each child can understand. In the context of the medical home, pediatricians can advocate for independence in children with disabilities by discussing many of these issues in private with the child while also informing the parents of the topics of discussion.

Children with disabilities have the right to the same education about sexuality as their peers, but often there must be modification to the program to allow the information to be presented in such a way that the child can understand and learn it. Modifications such as simplifying information, teaching in a special needs rather than a regular education setting, using special teaching materials such as anatomically correct dolls, role playing, and frequently reviewing and reinforcing the material may be required.[31,32] Individualized education plans (IEPs) should include the provision of sexuality education for children with disabilities. An appropriate program for children with disabilities includes the following topics: body parts, pubertal changes, personal care and hygiene, medical examinations, social skills, sexual expression, contraception strategies, and the rights and responsibilities of sexual behavior. Many adolescents with disabilities receive inadequate information regarding sexuality or do not understand the information presented. Among surveyed adults with cerebral palsy, 52% requested more education regarding sexuality.[33] Educational materials are available to promote successful sexuality education for all children, and pediatricians are encouraged to help identify materials to meet the individual needs of the children and families for whom they care.

THE PEDIATRICIAN'S ROLE

Pediatricians can facilitate the gradual transition of children with disabilities into adulthood by addressing sexual development and encouraging open discussion with children and their families, beginning in early childhood and continuing into early adulthood. However, there are several barriers. First, open and detailed discussion about sexuality may be hindered by discomfort among parents, children, and pediatricians on the basis of cultural, religious, and personal experiences. Second, acute medical and developmental issues may occupy most of the clinical visit, leaving only a few minutes for time-consuming discussions. Third, parents may infantilize their children with developmental disabilities, especially if there are long-term needs for assistance with self-care activities such as toileting, bathing, and dressing. Typically developing teenagers are unlikely to let their parents forget their quest for independence, but children with disabilities, particularly those with impairments of communication, may be less likely to do so. Finally, it is natural for caregivers to fall into comfortable patterns of behavior and interaction with their children, thus overlooking opportunities for their children to achieve greater maturity and independence. Pediatricians are in a unique position to advocate for successful transition of adolescents with disabilities and their families into adulthood.

Pediatricians, in the context of the medical home, play a critical role in the development of sexuality in children with disabilities. The pediatrician is encouraged to:

1. discuss issues of physical development, maturity, and sexuality on a regular basis, starting during early childhood and continuing through the adolescent years;
2. ensure the privacy of each child and adolescent;
3. assist parents in understanding how the cognitive abilities of their children affect behavior and socialization;
4. encourage children with disabilities and their parents to optimize independence, particularly as related to self-care and social skills;
5. be aware of special medical needs, such as modified gynecologic examinations, latex-free protection from STDs and unplanned pregnancies, and genetic counseling when appropriate;
6. recognize that children with disabilities are at an increased risk of sexual abuse and monitor for early indications of abuse;
7. advocate for developmentally appropriate sexuality education in home, community, and school settings;
8. encourage parents to be the principal teachers of developmentally appropriate sexuality education for

their children, incorporating family values, cultural traditions, and religious beliefs; and

9. provide families with information regarding appropriate community programs that address issues of sexuality for children and adolescents with disabilities.

CONCLUSIONS

The UN Convention on the Rights of the Child has established international recognition that all children have needs and are entitled to have their needs met. The needs of children include respect for privacy, opportunities for play, access to education, access to appropriate guidance and support, protection from exploitation and abuse, and opportunities to be listened to and respected. The UN Convention on the Rights of the Child challenges traditional views of children as passive recipients of care and protection and asserts that children with disabilities have the same rights as children without disabilities.[30] Pediatricians should incorporate guidance on sexuality education, socially appropriate behavior, and sexual abuse prevention into the clinical supervision of all children, including children with disabilities.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Psychosocial Aspects of Child and Family Health and Committee on Adolescence

Sexuality Education for Children and Adolescents

ABSTRACT. Children and adolescents need accurate and comprehensive education about sexuality to practice healthy sexual behavior as adults. Early, exploitative, or risky sexual activity may lead to health and social problems, such as unintended pregnancy and sexually transmitted diseases, including human immunodeficiency virus infection and acquired immunodeficiency syndrome. This statement reviews the role of the pediatrician in providing sexuality education to children, adolescents, and their families. Pediatricians should integrate sexuality education into the confidential and longitudinal relationship they develop with children, adolescents, and families to complement the education children obtain at school and at home. Pediatricians must be aware of their own attitudes, beliefs, and values so their effectiveness in discussing sexuality in the clinical setting is not limited.

ABBREVIATIONS. STD, sexually transmitted disease; HIV, human immunodeficiency virus; AIDS, acquired immunodeficiency syndrome; AAP, American Academy of Pediatrics.

BACKGROUND

Recent federal surveys for the Department of Health and Human Services have found a decline in sexual activity among adolescents 15 to 19 years of age in the United States during the last decade.[1] However, initiation of sexual intercourse during adolescence remains the norm for American youth.[1] Rates of hormonal contraception and condom use have risen throughout the last 5 years and adolescent birth rates have been decreasing,[2] yet the percentage of births to unmarried women of all ages, including adolescents, remains high.[2,3] Among women 15 to 19 years of age, most pregnancies are unintended,[3,4] and approximately 1 in 3 end in abortion.[3]

Overall rates of sexually transmitted diseases (STDs) in the United States are among the highest in the industrialized world. Every year, an estimated 1 in 4 (approximately 3 million) sexually active adolescents acquire an STD.[5] Additionally, only 57% of the 1 in 3 adolescents who reported having been sexually active in the past 3 months reported that they had used barrier contraception the last time they had intercourse.[6]

Children most likely to engage in earlier sexual activity include children with learning problems or low academic attainment; children with other social, behavioral, or emotional problems (including mental health disorders and substance abuse); those from low-income families; children of some ethnic minorities; victims of physical and sexual abuse; and children in families with marital discord and low levels of parental supervision.[7,8] Risky sexual behaviors, defined as having multiple partners, having sex with strangers, or having intercourse without a latex condom, are also associated with alcohol consumption.[7,8] Many gay, lesbian, and bisexual youth are also at high risk because of unsafe sexual practices with same or opposite sex partners and because of increased rates of depression, dropping out of school, homelessness (running away or being thrown out of the home), and substance abuse.[9]

In the Youth Risk Behavior Surveillance survey conducted by the Centers for Disease Control and Prevention, almost all (>90%) adolescents reported having received human immunodeficiency virus (HIV) prevention education in school in 1997, and many also reported discussing HIV and acquired immunodeficiency syndrome (AIDS) with a parent or guardian.[6] However, the content of such discussions may not provide complete information. Additionally, school-based interventions do not provide confidential opportunities for individual risk assessments or targeted preventive counseling. Although as many as two thirds of adolescent patients reported wanting information about STDs and pregnancy from their physicians, many fewer have ever discussed these issues with their physician.[10] In fact, fewer than half of primary care providers routinely ask adolescents about their sexual activity, and far fewer ask specifically about STDs, condom use, sexual orientation, number of partners, or sexual abuse,[11] despite the fact that care guidelines universally recommend obtaining comprehensive sexual histories from adolescents.[12–14] Slightly more than half of adolescents who reported having a health care visit reported that they had an opportunity to talk alone (without a parent or other adult present) with their physician,[15] and fear of disclosure was a major reason for adolescents having missed care they believed that they needed.[16]

SOURCES, CONTENT, AND EFFECTIVENESS OF SEXUALITY EDUCATION PROGRAMS

Sexuality education classes have become a routine part of junior high and high school curricula in many parts of the country.[1] Sexuality education is also often a component of community-based programs targeting pregnancy prevention, substance abuse prevention, violence reduction, youth development,

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

or reproductive health services. Several sexuality education programs that were evaluated using quasi-experimental or experimental designs had impact on the sexual behavior of adolescents.[17] To delay onset of sexual debut, it is necessary to present programs to fifth and sixth graders. Abstinence-only programs have not demonstrated successful outcomes with regard to delayed initiation of sexual activity or use of safer sex practices.[8,17] Effective programs tend to provide practical skills, such as exercising control and increasing communication and negotiation skills through role playing or interactive discussion. Programs that encourage abstinence as the best option for adolescents, but offer a discussion of HIV prevention and contraception as the best approach for adolescents who are sexually active, have been shown to delay the initiation of sexual activity and increase the proportion of sexually active adolescents who reported using birth control. Programs that have linked educational curricula with access to reproductive health services and comprehensive community-based interventions have also documented reductions in pregnancy rates.[18–20] Despite these findings, among the 69% of public schools that provide district-wide sexuality education, 14% treat abstinence as an option for adolescents, 51% teach abstinence as the preferred option for adolescents but permit discussion about contraception as an effective means of protection against unintended pregnancy and STDs (an abstinence-plus policy), and more than 1 in 3 (35%) teach abstinence only, with discussion of contraception prohibited or limited to discussion of its lack of effectiveness.[21]

ROLE OF THE PEDIATRICIAN

The American Academy of Pediatrics (AAP) has published policy statements about sexuality and adolescence.[22–24] Pediatricians are in an ideal position to provide longitudinal sexuality education to children and adolescents as part of preventive health care, and many tools are available to guide their efforts.[22–24] Additionally, pediatricians' efforts may be useful in complementing school or community-based programs.

Unlike school-based instruction, discussion of sexuality with pediatricians provides opportunities for personalized information, for confidential screening of risk status, and for health promotion and counseling. Children and adolescents may ask questions, discuss potentially embarrassing experiences, or reveal highly personal information to their pediatricians. Families and children may obtain education together or in a separate but coordinated manner. Prevention and counseling can be targeted to the needs of youth who are and those who are not yet sexually active and to groups at high risk for early or unsafe sexual activity.[7,8]

Recommendations for pediatricians are as follows:

1. Put sexuality education into a lifelong perspective. Actively encourage parents to discuss sexuality and contraception consistent with the family's attitudes, values, beliefs, and circumstances beginning early in the child's life. Do not impose values on the family. Be aware of the diversity of family circumstances, such as families with same-sex parents. Guide these families or refer them to agencies or clinicians that can help them if they report difficulties or if you are not comfortable assisting them.
2. Encourage parents to offer sexuality education and discuss sex-related issues that are appropriate for the child's or adolescent's developmental level.
   - Use proper terms for anatomic parts.
   - Discuss masturbation and other sexual behaviors of all children, even those as young as preschool age, openly with parents.
   - Initiate discussions about sexuality with children at relevant opportunities, such as the birth of a sibling or pet. Encourage parents to answer children's questions fully and accurately. Offer parents resources to assist their communication efforts at home.
3. Provide sexuality education that respects confidentiality and acknowledges the individual patient's and family's issues and values.
   - Promote communication and safety within social relationships between partners.[25] Ask about special friendships and relationships and explore their character. Complement school-based sexuality education, which typically emphasizes unintended pregnancy, STDs, and other potential risks of sex. When appropriate, acknowledge that sexual activity may be pleasurable but also must be engaged in responsibly.
   - Address knowledge, questions, worries, or misunderstandings of children and adolescents regarding anatomy, masturbation, menstruation, erections, nocturnal emissions ("wet dreams"), sexual fantasies, sexual orientation, and orgasms. Information regarding availability and access to confidential reproductive health services and emergency contraception should also be discussed with early adolescents and with parents. During these discussions, also be open and nonjudgemental toward those with homosexual or bisexual experiences or orientation (see the AAP statement "Homosexuality and Adolescence"[9]).
   - Acknowledge the influence of media imagery on sexuality as it is portrayed in music and music videos, movies, television, print, and Internet content.
   - Obtain a comprehensive sexual history from all adolescents, including knowledge about sexuality, sexual practices, partners and relationships, sexual feelings and identity, and contraceptive practices and plans.
   - In discussing reasons to delay sexual activity or use contraception, frame the suggestions in terms of the individual's development, language, motivation, and history. Be sensitive to cultural and family norms, values, beliefs, and attitudes, and integrate these factors into health promotion or behavior change counseling. Also be aware of the potential for, and ask about,

abuse or coercion in relationships or sexual activity.

- Counsel parents about sexuality. Suggest opportunities for them to provide guidance about abstinence and responsible sexual behavior to their children. Encourage reciprocal and honest dialogue between parents and children. Counsel parents and adolescents about circumstances that are associated with earlier sexual activity, including early dating, excessive unsupervised time, truancy, and alcohol use.[7,8] Ensure that adolescents have opportunities to practice social skills, assertiveness, control, and rejection of unwanted sexual advances.[17]

4. Provide specific, confidential, culturally sensitive, and nonjudgmental counseling about key issues of sexuality.
   - ***General counseling***. Counsel children and parents about normal sexual development before the onset of sexual activity, and encourage parent-child communication about sexuality. Parents should be encouraged to discuss explicit expectations for abstinence, for delaying sexual activity, and for responsible expression of one's sexuality. Advise children and adolescents to discontinue high-risk sexual behavior and avoid or discontinue coercive relationships.[26] Discourage alcohol and other drug use and abuse not only for the direct benefits to the adolescent's health but also to prevent unwanted sexual activity or adverse consequences of sexual activity. Some pediatricians may want to consider the use of established curricula to ensure that all major points are covered.[27] Additionally, handouts to reinforce safe sex practices and responsible decision-making should be available in the office or clinic. Pediatricians may directly provide this counseling, and other members of the office staff, such as nurses, social workers, or health educators, may also provide counseling and health education.
   - ***Preventing unintended pregnancy***. Discuss methods of birth control with male and female adolescents ideally before the onset of sexual intercourse (see the AAP statement "Contraception and Adolescents"[22]). Barrier methods should always be used during intercourse in combination with spermicide or with hormonal contraceptives. Providing access to contraception for adolescents who are sexually active is an important method of reducing pregnancy rates.[26]
   - ***Strategies to avoid STDs, including HIV infection and AIDS***. Abstinence should be promoted as the most effective strategy for preventing HIV infection and other STDs as well as for prevention of pregnancy. Adolescents who become sexually active need additional advice and health care services. Adolescents should be counseled regarding the importance of consistent use of safer sex precautions. Pediatricians should assist adolescents in practicing communication and negotiation skills regarding use of condoms in every sexual encounter[28] and should consider providing adolescents with information and demonstrations about how condoms should be used. Comprehensive recommendations for HIV counseling, testing, and partner notification are addressed in detail in the AAP statement "Adolescents and Human Immunodeficiency Virus Infection: The Role of the Pediatrician in Prevention and Intervention."[29]
5. Provide appropriate counseling or referrals for children and adolescents with special issues and concerns.
   - ***Gay, lesbian, and bisexual youth***. Maintain nonjudgmental attitudes and avoid a heterosexual bias in history taking to encourage adolescents to be open about their behaviors and feelings (see the AAP statement "Homosexuality and Adolescence"[9]).[30,31] If adolescents are certain of homosexual or bisexual orientation, discuss advantages and potential risks of disclosure to family and peers, and support families in accepting children who identify themselves as gay, lesbian, or bisexual. Adolescents who are homosexual should be screened carefully for depression, risk of suicide, and adjustment-related mental health problems. Similar issues are important to children unsure of their sexual orientation.
   - ***Children and adolescents with disabilities***. Rates of sexual activity for adolescents with disabilities are the same as those for adolescents without disabilities.[32] However, children in special education may not receive sexuality education in school. Children and youth with disabilities should be provided developmentally appropriate sexuality education. Parents may need reassurance and support in getting sexuality education for children and adolescents with disabilities. Discussions should be initiated with parents or guardians of children with disabilities at a young age to encourage self-protection and acceptable forms of sexual behavior. Community resources and support groups may also be of assistance.
   - ***Other children at risk***. Identify children at risk for early or coercive and unintended sexual behaviors at an early age. Children who have been victims of physical or sexual abuse or have witnessed sexual violence or physical abuse; children with precocious puberty; and children with social risk factors, such as learning problems, drug or alcohol use, and antisocial behavior, may be at increased risk. Provide or arrange for counseling about sexuality for these children or adolescents. Refer to mental health services if appropriate.
6. Routine gynecologic services should be provided to female adolescents who have become sexually active. Screening for cervical cancer and STDs should be performed for sexually active females, and screening for STDs should be performed for sexually active males, as recommended in *Guidelines for Health Supervision III*.[12]

7. Become knowledgeable about sexuality education offered in schools, religious institutions, and other community agencies. Encourage schools to begin sexuality education in the fifth or sixth grade as a component of comprehensive school health education and to use curricula that provide effective and balanced approaches to puberty, abstinence, decision-making, contraception, and STD and HIV prevention strategies and information about access to services. Because nearly one third of school districts do not provide any information about contraception regardless of whether students are sexually active or at risk,[21] pediatricians should consider presenting material at the school. The American College of Obstetricians and Gynecologists publishes the *Adolescent Sexuality Kit: Guides for Professional Involvement*.[33] This series addresses AIDS, date rape, contraceptive options, and other topics that may be useful to pediatricians who plan to provide sexuality education. Participate in community activities to monitor the effectiveness of prevention strategies and revise approaches to decrease the rate of untoward outcomes. Consider serving as a referral source for students who need comprehensive reproductive health services.
8. Work with local public planners to develop a comprehensive strategy to decrease the rates of unsafe adolescent sexual behavior and adverse outcomes.

RECOMMENDATIONS

1. Every pediatrician should integrate sexuality education into clinical practice with children from early childhood through adolescence. This education should respect the family's individual and cultural values.
2. Educational materials, such as handouts, pamphlets, or videos, should be available to reinforce office-based educational efforts.
3. Pediatricians should be knowledgeable about community services that provide appropriate high-quality sexuality education and additional services that children, adolescents, or families need.
4. Pediatricians should consider participating in the development and implementation of sexuality education curricula for schools or in public efforts to decrease the rates of unsafe adolescent sexual behavior and adverse outcomes.
5. Linguistically appropriate materials could be provided in the office or the pediatrician should have a way of helping children, adolescents, and their families get information in their language of choice.

POLICY STATEMENT

Shopping Cart–Related Injuries to Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Injury, Violence, and Poison Prevention

ABSTRACT

Shopping cart–related injuries to children are common and can result in severe injury or even death. Most injuries result from falls from carts or cart tip-overs, and injuries to the head and neck represent three fourths of cases. The current US standard for shopping carts should be revised to include clear and effective performance criteria to prevent falls from carts and cart tip-overs. Pediatricians have an important role as educators, researchers, and advocates to promote the prevention of these injuries.

BACKGROUND

Injuries associated with shopping carts are an important cause of pediatric morbidity, especially among children younger than 5 years.[1–6] An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries.[7] The most common anatomic site of injury is the head and neck region, accounting for 74% of shopping cart–related injuries among children younger than 15 years, 79% among children younger than 5 years, and 92% among children younger than 1 year. Approximately 4% of children younger than 15 years treated in an emergency department for a shopping cart–related injury require admission to the hospital. Children younger than 5 years account for 93% of these hospital admissions. Fractures are the most common injury resulting in admission, representing 45% of all hospitalizations.[1] Deaths have been reported from falls from shopping carts and cart tip-overs.[8,9]

Injuries to children associated with shopping carts occur via several mechanisms: falling from carts, carts tipping over, and other mechanisms such as becoming entrapped in a cart, falling off a cart while riding on the outside, striking against a cart, and being run over by a cart.[2] Falls from shopping carts and cart tip-overs accounted for 58% and 26% of injuries, respectively, in one study.[2] Among children younger than 2 years in this study, tip-over injuries accounted for 38% of shopping cart–related injuries.[2] Additional details regarding pediatric shopping cart–related injuries are available in the accompanying technical report[10] and a patient safety sheet for distribution to families,[11] both in this month's *Pediatrics Electronic Pages*.

PREVENTION

Increased prevention of shopping cart–related injuries can be achieved by public education, adult supervision, separation of the child from the hazard, legislation, safety design, and revision of the current shopping cart safety standard (American

Society for Testing and Materials [ASTM] F2372-04).[12] Details are included in the accompanying technical report.[10]

RECOMMENDATIONS

1. The current US standard (ASTM F2372-04) for shopping carts should be revised to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs. To the extent possible, the US Consumer Product Safety Commission should closely monitor compliance and enforce the performance standard for shopping carts.
2. The US Consumer Product Safety Commission should continue to monitor closely the trends of shopping cart–related injuries to children. This will be important for evaluating the effectiveness of ASTM F2372-04.
3. Existing and future state and federal laws regarding shopping cart safety should incorporate an effective performance standard to prevent falls from carts and cart tip-overs, and parents should only transport their child in carts that meet this minimum safety standard.
4. Child health and advocacy professionals and organizations should advocate for a revision of ASTM F2372-04 to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs.
5. Health care professionals, child advocates, and parents should encourage businesses that provide customers with shopping carts to adopt safety strategies to help prevent shopping cart–related injuries to children. These may include supervised in-store child-play areas; pick-up areas or assistance bringing purchases to the vehicle to help parents avoid placing their children in carts to take them through parking lots; cart modifications to improve child restraint and cart stability; strollers or wagons provided for in-store use; in-store and community-wide consumer education and warnings; and customer incentives (such as stickers for children, other giveaway items, or cash off at the register) to adopt shopping cart safety behaviors.
6. Health care professionals should educate patients' families about the risks of transporting children in shopping carts, especially about falls from carts and cart tip-overs.
7. Health care professionals should inform the public through the media about shopping cart hazards.
8. The effectiveness of education programs and public-awareness initiatives regarding shopping cart safety should be evaluated.
9. Because of the current variability of shopping cart design and stability and because most parents are not able to ascertain the relative safety of a cart by visual inspection, parents should carefully consider the potential for injury before transporting their child in a shopping cart. Parents are strongly encouraged to seek alternatives to transporting their child in a shopping cart until an effective revised performance standard for shopping cart safety is implemented in the United States.
10. If a parent chooses to transport his or her child in a shopping cart, then an effective, age- and size-appropriate restraining device should be worn by the child at all times. Children should not be left unattended in a shopping cart, be allowed to stand up in a cart, be transported in the basket, or ride on the outside of a cart.

TECHNICAL REPORT

Shopping Cart–Related Injuries to Children

Gary A. Smith, MD, DrPH, for the Committee on Injury, Violence, and Poison Prevention

ABSTRACT

An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries. Approximately 4% of shopping cart–related injuries to children younger than 15 years require admission to the hospital. Injuries to the head and neck represent three fourths of all injuries. Fractures account for 45% of all hospitalizations. Deaths have occurred from falls from shopping carts and cart tip-overs. Falls are the most common mechanism of injury and account for more than half of injuries associated with shopping carts. Cart tip-overs are the second most common mechanism, responsible for up to one fourth of injuries and almost 40% of shopping cart–related injuries among children younger than 2 years. Public-awareness initiatives, education programs, and parental supervision, although important, are not enough to prevent these injuries effectively. European Standard EN 1929-1:1998 and joint Australian/New Zealand Standard AS/NZS 3847.1:1999 specify requirements for the construction, performance, testing, and safety of shopping carts and have been implemented as national standards in 21 countries. A US performance standard for shopping carts (ASTM [American Society for Testing and Materials] F2372-04) was established in July 2004; however, it does not adequately address falls and cart tip-overs, which are the leading mechanisms of shopping cart–related injuries to children. The current US standard for shopping carts should be revised to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs. This is imperative to decrease the number and severity of shopping cart–related injuries to children. Recommendations from the American Academy of Pediatrics regarding prevention of shopping cart–related injuries are included in the accompanying policy statement.

BACKGROUND

Injuries associated with shopping carts are an important cause of pediatric morbidity, especially among children younger than 5 years.[1–6] An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries. Fifty-one percent of these injured children were female.[7] The most common anatomic site of injury is the head and neck region, accounting for 74% of shopping cart–related injuries among children younger than 15 years, 79% among children younger than 5 years, and 92% among children younger than 1 year. Injury to a finger represents 10% of injuries, and injury to another site on the upper or lower extremities accounts for 12% of the cases. Among children

younger than 15 years who are treated and released home from the emergency department, contusions and abrasions (43%) and lacerations (22%) are the most common injuries. Approximately 4% of children younger than 15 years treated in an emergency department for a shopping cart–related injury require admission to the hospital. Children younger than 5 years account for 93% of these hospital admissions. Fractures are the most common injury resulting in admission, representing 45% of all hospitalizations.[1] Deaths have been reported from falls from shopping carts and cart tip-overs.[8,9]

The height of a fall and the energy-absorbing capacity of the surface on which a child lands are major determinants of the likelihood and severity of injury. In one study of shopping cart–related injuries to children, more than two thirds of children landed on hard surfaces such as linoleum (53%) or asphalt or concrete (15%). Although most injuries occurred inside stores, 16% of cases occurred in store parking lots.[2]

Injuries to children associated with shopping carts occur via several mechanisms: falling from carts, carts tipping over, and other mechanisms such as becoming entrapped in a cart, falling off a cart while riding on the outside, striking against a cart, and being run over by a cart.[2] The most common mechanism is a fall from a shopping cart, representing 58% of the cases in one study.[2] Another 26% of children are injured when a cart tips over. This is the second most common mechanism of injury and occurs primarily among children younger than 2 years.[2] In one emergency department–based study, tip-over injuries accounted for 38% of all shopping cart–related injuries among children younger than 2 years.[2]

The mechanism of injury is associated with the child's position in the cart. Falls from the cart are associated with the child standing in the cart basket, and tip-over injuries are associated with the sitting position. Siblings often contribute to cart tip-overs when attempting to climb in or out of a cart or when standing up in a cart. In one study, 56% of cart tip-over injuries involved the action of a sibling.[2] Parents are present at the time of injury in more than 90% of episodes. Shopping cart–related injuries rarely are caused by a malfunction of the cart.[2]

PREVENTION

Shopping cart–related injuries to children are common and can result in severe injury and death. Prevention efforts should focus on falls from carts and cart tip-overs.

Public Education

When used alone, public education and warnings are not adequate to prevent shopping cart–related injuries to children. One study demonstrated that an intensive educational effort with flyers, signs, and audiotaped messages over the public address system in stores resulted in limited change (from 1% to 14%) in shopping cart seat belt use by shoppers, and when a study representative approached shoppers with young children to encourage use of seat belts, belt usage increased to 51%.[10] Another study found that shopping cart–restraint usage increased from 15% to 49% when study personnel greeted shoppers with young children at the entrance to stores and recommended the use of appropriate shopping cart restraints if they were going to transport a child in a cart. Although there was a significant improvement in restraint use, half of the children were still being transported in shopping carts without adequate restraint.[11]

Adult Supervision

It is difficult to browse shelves in a store and closely supervise a child in a shopping cart at the same time. More than 80% of adults leave their children unattended at least once during a shopping trip.[12] Shopping cart–related injuries can and do occur in the time it takes to reach for something on a shelf. The fact that more than 90% of parents are present at the time of injury indicates that adult supervision will not reliably prevent these injuries.

Separating the Child From the Hazard

Providing adult caregivers with alternatives to placing a child in a cart while they shop can effectively prevent shopping cart–related injuries. Some stores provide supervised play areas for children. Parents may be able to arrange for another adult to accompany them and watch the child during a shopping trip. Other parents may be able to transport a young child in a stroller, wagon, frontpack, or backpack. An older child can be asked to walk. Some parents may be able to leave their child at home with an adult while they shop, but this is not an option for many others. Some stores offer shopping via the Internet with or without home delivery.

Shopping Cart Safety Design and a National Performance Standard

The most effective injury prevention strategies are those that do not require frequent human action and vigilance.[13] Therefore, modifying the design of shopping carts to automatically prevent falls and tip-overs offers the best preventive solution for shopping cart–related injuries. Adequate safety design must provide for effective child restraint to prevent falls from the cart and must also ensure adequate shopping cart stability to prevent tip-overs.

Child-restraint systems for shopping carts can be active or passive. Active restraint systems require action by the parent to secure the child in the restraint and are, therefore, less effective. The most commonly used active restraint is a lap belt. In some shopping carts, 3-point or 5-point harnesses are used in the cart seat area, in infant carriers attached to the cart basket, or in combination with an attachment to shopping carts that places toddler-aged children on plastic seats between the shopper and the rear of the cart. All of these systems require the

shopper to initially secure the child correctly in the restraint and to remain vigilant to ensure that the child stays in the restraint. As previously noted, attempts to modify shoppers' safety behaviors to increase the number of children appropriately restrained while being transported in shopping carts have had limited success.[10,11]

A passive (or automatic) child-restraint system for shopping carts could also be used that would result in increased restraint use. Such a system could be designed to automatically secure the child in place when the child is seated in the cart. It could also be designed to prevent the cart from moving while carrying a child passenger unless the automatic restraint was engaged. In 1994, the inventor of an automatic child restraint for carts petitioned the US Consumer Product Safety Commission (CPSC) to require automatic restraints on shopping carts, but this petition was denied.[14]

Not all types of buckles on child-restraint systems are equally child resistant. Nineteen (27%) of 70 children 2 to 3 years of age in one study were able to open 1 of 3 types of buckles.[15] The CPSC was petitioned in 1999 to require that buckles that fasten child-restraint systems in various products, including shopping carts, meet a child-resistance standard. The petition requested that the buckles be required to use a double-action release mechanism in which 2 distinctly separate actions are necessary for buckle release. Currently, infant crib side rails, medicine bottles, and some stroller and high chair buckles use double-action safety mechanisms to prevent children from defeating them. Citing a lack of evidence to support the petition and recognizing that buckles are only one part of a restraint system, the CPSC denied this petition in August 2000.[16]

In February 2002, the CPSC issued a report with findings from its 2-year Child Restraint Project.[17] The report analyzed why restraint systems fail and made recommendations for voluntary standards that would address these failures. It focused on high chairs and strollers, because these products account for most incidents of reported restraint failure among juvenile products. The findings of the Child Restraint Project can help direct the development of a performance requirement for a child-restraint system in shopping carts.

Child-restraint systems in shopping carts have limitations. Their effectiveness in preventing falls is unknown, and they do not adequately protect against injuries in shopping cart tip-overs. An infant restrained in a carrier seat bolted across the top of the cart basket or a child restrained in the seating area high in the cart may actually increase the likelihood of a tip-over by contributing to a higher center of gravity. The use of shopping cart restraints may also create a false sense of security among some parents. Because up to 38% of shopping cart–related injuries to children younger than 2 years are associated with cart tip-overs, the use of restraining devices alone will not adequately protect children in this age group unless cart stability is also ensured.

Because the severity of a fall is related to the height of the fall, locating the seating position for a child closer to the ground is a desirable modification of cart design. Cart designs introduced during recent years incorporate this solution by locating the child in a stroller-like seat or a miniature model of a motor vehicle in front of a smaller-sized shopping cart basket.[18,19] Placing the child lower in the cart lowers the center of gravity and, thereby, decreases tip-over potential. These modifications also accommodate large toddlers and preschool-aged children who are too big to fit in the typical seating position in a cart and, therefore, are often placed unrestrained in the cart basket. Because toddlers and preschool-aged children are commonly injured by a fall from the cart basket, these cart modifications offer an important alternative location for these children to ride more safely.

Shopping carts vary significantly in design characteristics including height, weight, center of gravity, and wheelbase dimensions. Some carts have a relatively narrow wheelbase in relation to their height, which makes them more likely to tip over. An important variable affecting rearward tip-over potential is the location of the handle and child seating area in relation to the rear axle. If a vertical line is dropped from the handle, the horizontal distance between that line and the rear axle can vary significantly. The greater this horizontal distance, the more likely downward pressure on the handle will cause the cart to tip over backward. A vertical force as little as 16 lb applied downward on the handle is all that is required to tip some carts over.[20] An average adult can apply this amount of force without difficulty with forearms resting on the top of the cart handle. In addition, if the child seating area is located farther rearward in relation to the rear axle of the cart, or if the child in the seating area leans toward the rear of the cart, the cart will more easily tip over backward.

Parents and other child caregivers cannot be expected to ascertain the relative stability of a shopping cart by visual inspection. Most parents, therefore, are unable to make informed decisions regarding the safety of transporting their child in the cart. For this reason, an effective US performance standard for shopping carts is needed. European Standard EN 1929-1:1998[21] has been implemented in 19 countries: Austria, Belgium, Czech Republic, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Italy, Luxembourg, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the United Kingdom. Australia and New Zealand also have a joint national standard, AS/NZS 3847.1:1999.[22]

European Standard EN 1929-1:1998 was approved by the European Committee for Standardization on April 30, 1998. This is part of a series of standards for shopping carts currently under preparation. It contains requirements for the construction, performance, testing, and

safety specifications for general-purpose self-service shopping carts with or without a child-carrying seat. This standard includes a cart-stability test but does not contain specifications for shopping cart accessories, including child safety restraints.[21] The joint Australian/New Zealand Standard AS/NZS 3847.1:1999 was approved on behalf of the Council of Standards Australia on October 30, 1998, and on behalf of the Council of Standards New Zealand on October 19, 1998. It was published January 5, 1999. This standard specifies materials, construction, performance, and testing requirements for shopping carts with and without a child-carrying seat for children up to 18 kg in body weight (approximately 3 years of age). It includes a cart-stability test and a child-restraint requirement. However, there is no performance standard for the restraint system. The standard states that the child restraint "may take any form, examples being a strap or straps or a tray table. If straps are provided, the minimum shall be a waist strap or straps."[22] A shopping cart–performance standard for the United States should include a clear and comprehensive performance requirement for the child safety restraint system in the cart to adequately address cart-related pediatric injuries.

The CPSC denied petitions to promulgate mandatory standards for shopping carts in 1975,[23] automatic child restraints in carts in 1994,[14] and preventing cart tip-overs in 1998.[20] At the time the petition was denied in 1975, the industry indicated that it would pursue development of a voluntary standard for shopping carts, but no action was taken until 2002. Thomas H. Moore, 1 of 3 CPSC commissioners who reviewed the petition in 1998 requesting a performance standard to prevent shopping cart tip-overs, indicated in a written minority opinion that he favored deferring a decision on the petition and pursuing a voluntary standard with the industry.[24] The CPSC engineering staff stated at that time that it would be "a relatively straightforward matter" to develop a performance standard for shopping cart stability.[25] However, the other 2 commissioners did not agree with Moore, and the petition was denied. In 1995, an industry spokesman articulated the view that "injuries involving shopping carts are due to consumer misuse of the product and are not flaws in the current design or a lack of safety mechanism."[26] In September 2002, American Society for Testing and Materials (ASTM) International formed Subcommittee F15.56 on Shopping Carts to develop a voluntary standard for shopping carts. The Standard Consumer Safety Performance Specification for Shopping Carts F2372-04 was published in July 2004.[27]

However, unlike the standards in 21 other countries, the ASTM standard does not address shopping cart stability. Stating that there were "not sufficient frequencies and severity of 'tip-over' injuries, relating to the cart's stability, to warrant requirements and testing for 'tip-over,' "[28] the ASTM subcommittee voted to overrule the negative vote of the American Academy of Pediatrics (AAP) against the draft standard and the recommendation of the AAP that a stability performance standard and test procedure be included in the shopping cart standard.

In addition, ASTM F2372-04 states under section 7.4.1, "Buckles or closures shall be tested in parallel with 16 CFR 1700."[27] The regulation at 16 CFR 1700 describes the testing procedure for poison-prevention packaging. It is not entirely consistent with the testing needs of shopping cart buckles or closures and would need to be modified to be applicable. Because test procedures must be specified exactly if they are to be applied uniformly and be enforceable, the language in section 7.4.1 is inadequate. It should be revised to describe the test procedure in precise terms as it applies to shopping cart–restraint systems. More importantly, section 7.4.1 only provides for the testing of buckles or closures and does not test the entire restraint system. A child may not be able to defeat the buckle while easily wiggling out of the restraint. A comprehensive test procedure for the entire restraint system, testing its ability to keep children safely restrained, is needed for adequate protection of children. This is critical for preventing falls from carts, which is the leading injury mechanism. The AAP also raised these concerns in its negative vote against the draft standard, but the subcommittee again voted the objections of the AAP as nonpersuasive.

Thus, the ASTM F2372-04 standard does not adequately address falls and tip-overs, the leading mechanisms of shopping cart–related injury to children. Indeed, it does not address cart stability to prevent tip-overs at all. Until a revised standard is adopted that establishes clear and effective performance criteria to protect against both of these injury mechanisms, parents and other caregivers will not be able to make informed decisions regarding injury risk when placing a child in a shopping cart, because the cart may not provide minimum acceptable safety protections under the current standard.

Shopping Cart Safety Legislation

New York state statute currently requires every commercial business that provides its customers with shopping carts with seats for children to equip and maintain not less than 25% of its carts with child restraints.[29] Shopping cart child-restraint legislation was introduced in Massachusetts[30] and Minnesota[31] in 1999 but was not enacted. State laws such as these would be strengthened by incorporation of an effective performance standard for shopping cart child-restraint systems and stability. Although state laws have the potential to promote shopping cart safety for children, without an effective shopping cart–performance standard, the existing New York law and the other bills that have been introduced will not be sufficient to prevent shopping cart–related injuries to children. No federal legislation regarding shopping cart safety has been introduced to date.

RECOMMENDATIONS

Recommendations from the AAP regarding prevention of shopping cart–related injuries are included in the accompanying policy statement.[32]

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

POLICY STATEMENT

SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment

abstract

FREE

Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death that occur during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from focusing only on SIDS to focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths, including SIDS. The recommendations described in this policy statement include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunizations, consideration of using a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in the accompanying "Technical Report—SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment," which is included in this issue of *Pediatrics* (www.pediatrics.org/cgi/content/full/128/5/e1341). *Pediatrics* 2011;128:1030–1039

INTRODUCTION

Sudden infant death syndrome (SIDS) is a cause assigned to infant deaths that cannot be explained after a thorough case investigation, including a scene investigation, autopsy, and review of the clinical history.[1] Sudden unexpected infant death (SUID), also known as sudden unexpected death in infancy, is a term used to describe any sudden and unexpected death, whether explained or unexplained (including SIDS), that occurs during infancy. After case investigation, SUIDs can be attributed to suffocation, asphyxia, entrapment, infection, ingestions, metabolic diseases, arrhythmia-associated cardiac channelopathies, and trauma (accidental or nonaccidental). The distinction between SIDS and other SUIDs, particularly those that occur during an observed or unobserved sleep period (sleep-related infant deaths), such as ac-

TABLE 1 Summary and Strength of Recommendations

Level A recommendations
Back to sleep for every sleep
Use a firm sleep surface
Room-sharing without bed-sharing is recommended
Keep soft objects and loose bedding out of the crib
Pregnant women should receive regular prenatal care
Avoid smoke exposure during pregnancy and after birth
Avoid alcohol and illicit drug use during pregnancy and after birth
Breastfeeding is recommended
Consider offering a pacifier at nap time and bedtime
Avoid overheating
Do not use home cardiorespiratory monitors as a strategy for reducing the risk of SIDS
Expand the national campaign to reduce the risks of SIDS to include a major focus on the safe sleep environment and ways to reduce the risks of all sleep-related infant deaths, including SIDS, suffocation, and other accidental deaths; pediatricians, family physicians, and other primary care providers should actively participate in this campaign
Level B recommendations
Infants should be immunized in accordance with recommendations of the AAP and Centers for Disease Control and Prevention
Avoid commercial devices marketed to reduce the risk of SIDS
Supervised, awake tummy time is recommended to facilitate development and to minimize development of positional plagiocephaly
Level C recommendations
Health care professionals, staff in newborn nurseries and NICUs, and child care providers should endorse the SIDS risk-reduction recommendations from birth
Media and manufacturers should follow safe-sleep guidelines in their messaging and advertising
Continue research and surveillance on the risk factors, causes, and pathophysiological mechanisms of SIDS and other sleep-related infant deaths, with the ultimate goal of eliminating these deaths entirely

These recommendations are based on the US Preventive Services Task Force levels of recommendation (www.uspreventiveservicestaskforce.org/uspstf/grades.htm).
Level A: Recommendations are based on good and consistent scientific evidence (ie, there are consistent findings from at least 2 well-designed, well-conducted case-control studies, a systematic review, or a meta-analysis). There is high certainty that the net benefit is substantial, and the conclusion is unlikely to be strongly affected by the results of future studies.
Level B: Recommendations are based on limited or inconsistent scientific evidence. The available evidence is sufficient to determine the effects of the recommendations on health outcomes, but confidence in the estimate is constrained by such factors as the number, size, or quality of individual studies or inconsistent findings across individual studies. As more information becomes available, the magnitude or direction of the observed effect could change, and this change may be large enough to alter the conclusion.
Level C: Recommendations are based primarily on consensus and expert opinion.

cidental suffocation, is challenging and cannot be determined by autopsy alone. Scene investigation and review of the clinical history are also required. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. This document focuses on the subset of SUIDs that occurs during sleep.

The recommendations outlined herein were developed to reduce the risk of SIDS and sleep-related suffocation, asphyxia, and entrapment among infants in the general population. As defined by epidemiologists, risk refers to the probability that an outcome will occur given the presence of a particular factor or set of factors. Although all of the 18 recommendations cited below are intended for parents, health care providers, and others who care for infants, the last 4 recommendations are also directed toward health policy makers, researchers, and professionals who care for or work on behalf of infants. In addition, because certain behaviors, such as smoking, can increase risk for the infant, some recommendations are directed toward women who are pregnant or may become pregnant in the near future.

Table 1 summarizes the major recommendations, along with the strength of each recommendation. It should be noted that there have been no randomized controlled trials with regards to SIDS and other sleep-related deaths; instead, case-control studies are the standard.

Because most of the epidemiologic studies that established the risk factors and on which these recommendations are based include infants up to 1 year of age, these recommendations for sleep position and the sleep environment should be used consistently for infants up to 1 year of age. Individual medical conditions might warrant that a physician recommend otherwise after weighing the relative risks and benefits.

For the background literature review and data analyses on which this policy statement and recommendations are based, please refer to the accompanying "Technical Report—SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment," available in the online version of this issue of *Pediatrics*.[2]

RECOMMENDATIONS

1. Back to sleep for every sleep—To reduce the risk of SIDS, infants should be placed for sleep in a supine position (wholly on the back) for every

sleep by every caregiver until 1 year of life.[3–7] Side sleeping is not safe and is not advised.[4,6]

a. The supine sleep position does not increase the risk of choking and aspiration in infants, even those with gastroesophageal reflux, because they have protective airway mechanisms.[8,9] Infants with gastroesophageal reflux should be placed for sleep in the supine position for every sleep, with the rare exception of infants for whom the risk of death from complications of gastroesophageal reflux is greater than the risk of SIDS (ie, those with upper airway disorders, for whom airway protective mechanisms are impaired),[10] including infants with anatomic abnormalities such as type 3 or 4 laryngeal clefts who have not undergone antireflux surgery. Elevating the head of the infant's crib while the infant is supine is not recommended.[11] It is ineffective in reducing gastroesophageal reflux; in addition, it might result in the infant sliding to the foot of the crib into a position that might compromise respiration.

b. Preterm infants are at increased risk of SIDS,[12,13] and the association between prone sleep position and SIDS among low birth weight infants is equal to, or perhaps even stronger than, the association among those born at term.[14] Preterm infants and other infants in the NICU should be placed in the supine position for sleep as soon as the infant is medically stable and significantly before the infant's anticipated discharge, by 32 weeks' postmenstrual age.[15] NICU personnel should endorse safe-sleeping guidelines with parents of infants from the time of admission to the NICU.

c. There is no evidence that placing infants on the side during the first few hours of life promotes clearance of amniotic fluid and decreases the risk of aspiration. Infants in the newborn nursery and infants who are rooming in with their parents should be placed in the supine position as soon as they are ready to be placed in the bassinet.

d. Although data to make specific recommendations as to when it is safe for infants to sleep in the prone or side position are lacking, studies that have established prone and side sleeping as risk factors for SIDS include infants up to 1 year of age. Therefore, infants should continue to be placed supine until 1 year of age. Once an infant can roll from supine to prone and from prone to supine, the infant can be allowed to remain in the sleep position that he or she assumes.

2. Use a firm sleep surface—A firm crib mattress, covered by a fitted sheet, is the recommended sleeping surface to reduce the risk of SIDS and suffocation.

a. A crib, bassinet, or portable crib/play yard that conforms to the safety standards of the Consumer Product Safety Commission and ASTM International (formerly the American Society for Testing and Materials) is recommended.[16] In addition, parents and providers should check to make sure that the product has not been recalled. Cribs with missing hardware should not be used, and the parent or provider should not attempt to fix broken components of a crib, because many deaths are associated with cribs that are broken or have missing parts (including those that have presumably been fixed). Local organizations throughout the United States can help to provide low-cost or free cribs or play yards for families with financial constraints.

b. Only mattresses designed for the specific product should be used. Mattresses should be firm and maintain their shape even when the fitted sheet designated for that model is used, such that there are no gaps between the mattress and the side of the crib, bassinet, portable crib, or play yard. Pillows or cushions should not be used as substitutes for mattresses or in addition to a mattress. Soft materials or objects such as pillows, quilts, comforters, or sheepskins, even if covered by a sheet, should not be placed under a sleeping infant. If a mattress cover to protect against wetness is used, it should be tightly fitting and thin.

c. Infants should not be placed for sleep on beds because of the risk of entrapment and suffocation.[17,18] In addition, portable bed rails should not be used with infants because of the risk of entrapment and strangulation.

d. The infant should sleep in an area free of hazards, such

as dangling cords, electric wires, and window-covering cords, because they might present a strangulation risk.

e. Sitting devices, such as car safety seats, strollers, swings, infant carriers, and infant slings, are not recommended for routine sleep in the hospital or at home.[19–23] Infants who are younger than 4 months are particularly at risk, because they might assume positions that can create risk of suffocation or airway obstruction. When infant slings and cloth carriers are used for carrying, it is important to ensure that the infant's head is up and above the fabric, the face is visible, and that the nose and mouth are clear of obstructions.[24] After nursing, the infant should be repositioned in the sling so that the head is up, is clear of fabric, and is not against the adult's body or the sling. If an infant falls asleep in a sitting device, he or she should be removed from the product and moved to a crib or other appropriate flat surface as soon as is practical. Car safety seats and similar products are not stable on a crib mattress or other elevated surfaces.[25–29]

3. Room-sharing without bed-sharing is recommended—There is evidence that this arrangement decreases the risk of SIDS by as much as 50%.[5,7,30,31] In addition, this arrangement is most likely to prevent suffocation, strangulation, and entrapment that might occur when the infant is sleeping in an adult bed.

   a. The infant's crib, portable crib, play yard, or bassinet should be placed in the parents' bedroom close to the parents' bed. This arrangement reduces SIDS risk and removes the possibility of suffocation, strangulation, and entrapment that might occur when the infant is sleeping in the adults' bed. It also allows close parental proximity to the infant and facilitates feeding, comforting, and monitoring of the infant.

   b. Devices promoted to make bed-sharing "safe" (eg, in-bed co-sleepers) are not recommended.

   c. Infants may be brought into the bed for feeding or comforting but should be returned to their own crib or bassinet when the parent is ready to return to sleep.[6,32] Because of the extremely high risk of SIDS and suffocation on couches and armchairs,[3,5,6,31,32] infants should not be fed on a couch or armchair when there is a high risk that the parent might fall asleep.

   d. Epidemiologic studies have not demonstrated any bed-sharing situations that are protective against SIDS or suffocation. Furthermore, not all risks associated with bed-sharing, such as parental fatigue, can be controlled. Therefore, the American Academy of Pediatrics (AAP) does not recommend any specific bed-sharing situations as safe. Moreover, there are specific circumstances that, in epidemiologic studies, substantially increase the risk of SIDS or suffocation while bed-sharing. In particular, it should be stressed to parents that they avoid the following situations at all times:

      i. Bed-sharing when the infant is younger than 3 months, regardless of whether the parents are smokers or not.[5,7,31–34]

      ii. Bed-sharing with a current smoker (even if he or she does not smoke in bed) or if the mother smoked during pregnancy.[5,6,34–36]

      iii. Bed-sharing with someone who is excessively tired.

      iv. Bed-sharing with someone who has or is using medications (eg, certain antidepressants, pain medications) or substances (eg, alcohol, illicit drugs) that could impair his or her alertness or ability to arouse.[7,37]

      v. Bed-sharing with anyone who is not a parent, including other children.[3]

      vi. Bed-sharing with multiple persons.[3]

      vii. Bed-sharing on a soft surface such as a waterbed, old mattress, sofa, couch, or armchair.[3,5,6,31,32]

      viii. Bed-sharing on a surface with soft bedding, including pillows, heavy blankets, quilts, and comforters.[3,38]

   e. It is prudent to provide separate sleep areas and avoid co-bedding for twins and higher-order multiples in the hospital and at home.[39]

4. Keep soft objects and loose bedding out of the crib to reduce the risk of SIDS, suffocation, entrapment, and strangulation.

   a. Soft objects, such as pillows and pillow-like toys, quilts, comfort-

ers, and sheepskins, should be kept out of an infant's sleeping environment.[40–45]

b. Loose bedding, such as blankets and sheets, might be hazardous and should not be used in the infant's sleeping environment.[3,6,46–51]

c. Because there is no evidence that bumper pads or similar products that attach to crib slats or sides prevent injury in young infants and because there is the potential for suffocation, entrapment, and strangulation, these products are not recommended.[52,53]

d. Infant sleep clothing that is designed to keep the infant warm without the possible hazard of head covering or entrapment can be used.

5. Pregnant women should receive regular prenatal care—There is substantial epidemiologic evidence linking a lower risk of SIDS for infants whose mothers obtain regular prenatal care.[54–57]

6. Avoid smoke exposure during pregnancy and after birth—Both maternal smoking during pregnancy and smoke in the infant's environment after birth are major risk factors for SIDS.

a. Mothers should not smoke during pregnancy or after the infant's birth.[1,58–61]

b. There should be no smoking near pregnant women or infants. Encourage families to set strict rules for smoke-free homes and cars and to eliminate secondhand tobacco smoke from all places in which children and other nonsmokers spend time.[62,63]

c. The risk of SIDS is particularly high when the infant bedshares with an adult smoker.[5,6,34–36]

7. Avoid alcohol and illicit drug use during pregnancy and after birth—There is an increased risk of SIDS with prenatal and postnatal exposure to alcohol or illicit drug use.

a. Mothers should avoid alcohol and illicit drugs periconceptionally and during pregnancy.[64–70]

b. Parental alcohol and/or illicit drug use in combination with bed-sharing places the infant at particularly high risk of SIDS.[7,37]

8. Breastfeeding is recommended.

a. Breastfeeding is associated with a reduced risk of SIDS.[71–73] If possible, mothers should exclusively breastfeed or feed with expressed human milk (ie, not offer any formula or other non–human milk–based supplements) for 6 months, in alignment with recommendations of the AAP.[74]

b. The protective effect of breastfeeding increases with exclusivity.[73] However, any breastfeeding has been shown to be more protective against SIDS than no breastfeeding.[73]

9. Consider offering a pacifier at nap time and bedtime—Although the mechanism is yet unclear, studies have reported a protective effect of pacifiers on the incidence of SIDS.[3,7,32] The protective effect persists throughout the sleep period, even if the pacifier falls out of the infant's mouth.

a. The pacifier should be used when placing the infant for sleep. It does not need to be reinserted once the infant falls asleep. If the infant refuses the pacifier, he or she should not be forced to take it. In those cases, parents can try to offer the pacifier again when the infant is a little older.

b. Because of the risk of strangulation, pacifiers should not be hung around the infant's neck. Pacifiers that attach to infant clothing should not be used with sleeping infants.

c. Objects such as stuffed toys, which might present a suffocation or choking risk, should not be attached to pacifiers.

d. For breastfed infants, delay pacifier introduction until breastfeeding has been firmly established,[74] usually by 3 to 4 weeks of age.

e. There is insufficient evidence that finger-sucking is protective against SIDS.

10. Avoid overheating—Although studies have revealed an increased risk of SIDS with overheating,[75–78] the definition of overheating in these studies varied. Therefore, it is difficult to provide specific room-temperature guidelines for avoiding overheating.

a. In general, infants should be dressed appropriately for the environment, with no more than 1 layer more than an adult would wear to be comfortable in that environment.

b. Parents and caregivers should evaluate the infant for signs of overheating, such as sweating or the infant's chest feeling hot to the touch.

c. Overbundling and covering of the face and head should be avoided.[79]

d. There is currently insufficient evidence to recommend the use of a fan as a SIDS risk-reduction strategy.

11. Infants should be immunized in accordance with recommendations of the AAP and the Centers for Disease Control and Prevention—There is no evidence that there is a causal relationship between immunizations and SIDS.[80] Indeed, recent evidence suggests that immunization might have a protective effect against SIDS.[81–83] Infants should also be seen for regular well-child checks in accordance with AAP recommendations.

12. Avoid commercial devices marketed to reduce the risk of SIDS—These devices include wedges, positioners, special mattresses, and special sleep surfaces. There is no evidence that these devices reduce the risk of SIDS or suffocation or that they are safe.

    a. The AAP concurs with the US Food and Drug Administration and Consumer Product Safety Commission that manufacturers should not claim that a product or device protects against SIDS unless there is scientific evidence to that effect.

13. Do not use home cardiorespiratory monitors as a strategy to reduce the risk of SIDS—Although cardiorespiratory monitors can be used at home to detect apnea, bradycardia, and, when pulse oximetry is used, decreases in oxyhemoglobin saturation, there is no evidence that use of such devices decreases the incidence of SIDS.[84–87] They might be of value for selected infants but should not be used routinely. There is also no evidence that routine in-hospital cardiorespiratory monitoring before discharge from the hospital can identify newborn infants at risk of SIDS.

14. Supervised, awake tummy time is recommended to facilitate development and to minimize development of positional plagiocephaly.

    a. Although there are no data to make specific recommendations as to how often and how long it should be undertaken, supervised, awake tummy time is recommended on a daily basis, beginning as early as possible, to promote motor development, facilitate development of the upper body muscles, and minimize the risk of positional plagiocephaly.[88]

    b. Diagnosis, management, and other prevention strategies for positional plagiocephaly, such as avoidance of excessive time in car safety seats and changing the infant's orientation in the crib, are discussed in detail in the recent AAP clinical report on positional skull deformities.[88]

15. Health care professionals, staff in newborn nurseries and neonatal intensive care nurseries, and child care providers should endorse the SIDS risk-reduction recommendations from birth.[89–91]

    a. Staff in NICUs should model and implement all SIDS risk-reduction recommendations as soon as the infant is clinically stable and significantly before anticipated discharge.

    b. Staff in newborn nurseries should model and implement these recommendations beginning at birth and well before anticipated discharge.

    c. All physicians, nurses, and other health care professionals should receive education on safe infant sleep.

    d. All child care providers should receive education on safe infant sleep and implement safe sleep practices. It is preferable that they have written policies.

16. Media and manufacturers should follow safe-sleep guidelines in their messaging and advertising.

    Media exposures (including movie, television, magazines, newspapers, and Web sites), manufacturer advertisements, and store displays affect individual behavior by influencing beliefs and attitudes.[89,91] Media and advertising messages contrary to safe-sleep recommendations might create misinformation about safe sleep practices.[92]

17. Expand the national campaign to reduce the risks of SIDS to include a major focus on the safe sleep environment and ways to reduce the risks of all sleep-related infant deaths, including SIDS, suffocation, and other accidental deaths. Pediatricians, family physicians, and other primary care providers should actively participate in this campaign.

    a. Public education should continue for all who care for infants, including parents, child care providers, grandparents, foster parents, and babysitters, and should include strategies for overcoming barriers to behavior change.

    b. The campaign should continue to have a special focus

on the black and American Indian/Alaskan Native populations because of the higher incidence of SIDS and other sleep-related infant deaths in these groups.

c. The campaign should specifically include strategies for increasing breastfeeding while decreasing bed-sharing and eliminating tobacco smoke exposure.

d. These recommendations should be introduced before pregnancy and ideally in secondary school curricula for both boys and girls. The importance of maternal preconceptional health and avoidance of substance use (including alcohol and smoking) should be included in this training.

e. Safe-sleep messages should be reviewed, revised, and reissued at least every 5 years to address the next generation of new parents and products on the market.

18. Continue research and surveillance on the risk factors, causes, and pathophysiological mechanisms of SIDS and other sleep-related infant deaths, with the ultimate goal of eliminating these deaths entirely.

a. Education campaigns need to be evaluated, and innovative intervention methods need to be encouraged and funded.

b. Continued research and improved surveillance on the etiology and pathophysiological basis of SIDS should be funded.

c. Standardized protocols for death-scene investigations should continue to be implemented. Comprehensive autopsies that include full external and internal examination of all major organs and tissues (including the brain), complete radiographs, metabolic testing, and toxicology screening should be performed. Training about how to conduct comprehensive death-scene investigation offered to medical examiners, coroners, death-scene investigators, first responders, and law enforcement should continue, and resources for maintaining training and conduct of these investigations need to be allocated. In addition, child death reviews, with involvement of pediatricians and other primary care providers, should be supported and funded.

d. Improved and widespread surveillance of SIDS and SUID cases should be implemented and funded.

e. Federal and private funding agencies should remain committed to all aspects of the aforementioned research.

LEAD AUTHOR

Rachel Y. Moon, MD

TASK FORCE ON SUDDEN INFANT DEATH SYNDROME, 2010–2011

Rachel Y. Moon, MD, Chairperson
Robert A. Darnall, MD
Michael H. Goodstein, MD
Fern R. Hauck, MD, MS

CONSULTANTS

Marian Willinger, PhD – *Eunice Kennedy Shriver National Institute for Child Health and Human Development*
Carrie K. Shapiro-Mendoza, PhD, MPH – *Centers for Disease Control and Prevention*

STAFF

James Couto, MA

ACKNOWLEDGMENTS

The task force acknowledges the contributions provided by others to the collection and interpretation of data examined in preparation of this report. The task force is particularly grateful for the report submitted by Dr Suad Wanna-Nakamura (Consumer Product Safety Commission).

abstract

FREE

Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death occurring during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from being only SIDS-focused to focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths including SIDS. The recommendations described in this report include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunization, consideration of a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in this technical report. The recommendations are published in the accompanying "Policy Statement—Sudden Infant Death Syndrome and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment," which is included in this issue (www.pediatrics.org/cgi/doi/10.1542/peds.2011-2220). *Pediatrics* 2011;128:e1341–e1367

METHODOLOGY

Literature searches using PubMed were conducted for each of the topics in this technical report and concentrated on articles published since 2005 (when the last policy statement[1] was published). In addition, to provide additional information regarding sleep-environment hazards, a white paper was solicited from the US Consumer Product Safety Commission (CPSC).[2] Strength of evidence for recommendations[3] was determined by the task force members. Draft versions of the policy statement[4] and technical report were submitted to relevant committees and sections of the American Academy of Pediatrics (AAP) for review and comment. After the appropriate revisions were made, a

final version was submitted to the AAP Executive Committee and Board of Directors for final approval.

SUDDEN INFANT DEATH SYNDROME AND SUDDEN UNEXPECTED INFANT DEATH: DEFINITIONS AND DIAGNOSTIC ISSUES

Sudden Infant Death Syndrome and Sudden Unexpected Infant Death

Sudden infant death syndrome (SIDS) is a cause assigned to infant deaths that cannot be explained after a thorough case investigation that includes a scene investigation, autopsy, and review of the clinical history.[5] Sudden unexpected infant death (SUID), also known as sudden unexpected death in infancy (SUDI), is a term used to describe any sudden and unexpected death, whether explained or unexplained (including SIDS), that occurs during infancy. After case investigation, SUIDs can be attributed to suffocation, asphyxia, entrapment, infection, ingestions, metabolic diseases, and trauma (accidental or nonaccidental). The distinction between SIDS and other SUIDs, particularly those that occur during an observed or unobserved sleep period (sleep-related infant deaths), such as accidental suffocation, is challenging and cannot usually be determined by autopsy alone. Scene investigation and review of the clinical history are also required. A few deaths that are diagnosed as SIDS are found, after further specialized investigations, to be attributable to metabolic disorders or arrhythmia-associated cardiac channelopathies.

Although standardized guidelines for conducting thorough case investigations have been developed,[6] these guidelines have not been uniformly adopted across the more than 2000 US medical examiner and coroner jurisdictions.[7] Information from emergency responders, scene investigators, and caregiver interviews can provide additional evidence to assist death certifiers (ie, medical examiners and coroners) in accurately determining the cause of death. However, death certifiers represent a diverse group with varying levels of skills and education as well as diagnostic preferences. Recently, much attention has been focused on reporting differences among death certifiers. At one extreme, some certifiers have abandoned using SIDS as a cause-of-death explanation.[7] At the other extreme, some certifiers will not classify a death as suffocation in the absence of a pathologic marker of asphyxia at autopsy (ie, pathologic findings diagnostic of oronasal occlusion or chest compression[8]), even with strong evidence from the scene investigation that suggests a probable accidental suffocation.

US Trends in SIDS, Other SUIDs, and Postneonatal Mortality

To monitor trends in SIDS and other SUIDs nationally, the United States classifies diseases and injuries according to the *International Classification of Diseases* (ICD) diagnostic codes. This classification system is designed to promote national and international comparability in the assignment of cause-of-death determinations; however, this system might not provide the optimal precision in classification desired by clinicians and researchers. In the United States, the National Center for Health Statistics assigns a SIDS diagnostic code (ICD-10 R95) if the death is classified with terminology such as SIDS (including presumed, probable, or consistent with SIDS), sudden infant death, sudden unexplained death in infancy, sudden unexpected death in infancy, or sudden unexplained infant death on the certified death certificate. A death will be coded as "other ill-defined and unspecified causes of mortality" (ICD-10 R99) if the cause of the death is reported as unknown or unspecified. A death is coded as "accidental suffocation and strangulation in bed" (ASSB) (ICD-10 W75) when the terms "asphyxia," "asphyxiated," "asphyxiation," "strangled," "strangulated," "strangulation," "suffocated," or "suffocation" are reported, along with the terms "bed" or "crib." This code also includes deaths while sleeping on couches and armchairs.

Although SIDS was defined somewhat loosely until the mid-1980s, there was minimal change in the incidence of SIDS in the United States until the early 1990s. In 1992, in response to epidemiologic reports from Europe and Australia, the AAP recommended that infants be placed for sleep in a nonprone position as a strategy for reducing the risk of SIDS.[9] The "Back to Sleep" campaign was initiated in 1994 under the leadership of the National Institute of Child Health and Human Development as a joint effort of the Maternal and Child Health Bureau of the Health Resources and Services Administration, the AAP, the SIDS Alliance (now First Candle), and the Association of SIDS and Infant Mortality Programs.[10] The Eunice Kennedy Shriver National Institute of Child Health and Human Development began conducting national surveys of infant care practices to evaluate the implementation of the AAP recommendation. Between 1992 and 2001, the SIDS rate declined, and the most dramatic declines occurred in the years immediately after the first nonprone recommendations, consistent with the steady increase in the prevalence of supine sleeping (Fig 1).[11] The US SIDS rate declined from 120 deaths per 100 000 live births in 1992 to 56 deaths per 100 000 live births in 2001, representing a decrease of 53% over 10 years. However, from 2001 to 2006 (the latest year from which data are available), the rate has remained constant (Fig 1). In 2006, 2327 infants

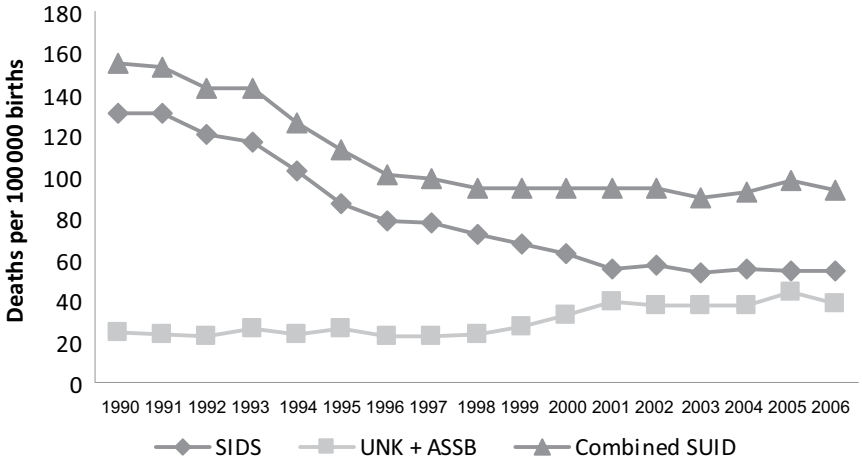

FIGURE 1
Trends in SIDS and other SUID mortality: United States 1990–2006. UNK indicates ill-defined or unspecified deaths.

died from SIDS. Although SIDS rates have declined by more than 50% since the early 1990s, SIDS remains the third-leading cause of infant mortality and the leading cause of postneonatal mortality (28 days to 1 year of age).

The all-cause postneonatal death rate has followed a trend similar to the SIDS rate: there was a 29% decline from 1992 to 2001 (from 314 to 231 per 100 000 live births). From 2001 until 2006, postneonatal mortality rates have also remained fairly unchanged (from 231 to 224 per 100 000 live births); the average decline is 3%.[12]

Several recent studies have revealed that some deaths previously classified as SIDS are now being classified as other causes of infant death (eg, accidental suffocation and other ill-defined or unspecified causes).[13,14] Since 1999, much of the decline in SIDS rates might be explained by increasing rates of these other causes of SUID, particularly over the years 1999–2001.[13,15] A notable change is in deaths attributable to ASSB. Between 1984 and 2004, ASSB infant mortality rates more than quadrupled, from 2.8 to 12.5 deaths per 100 000 live births,[15] which represents 513 infant deaths attributed to ASSB in 2004 compared with 103 in 1984.

Sleep Position

The apparent leveling of the previously declining SIDS rate is occurring coincident with a slowing in the reduction of the prevalence of prone positioning. The prevalence of supine sleep positioning, as assessed from an ongoing national sampling, increased from 13% in 1992 to 72% in 2001. From 2001 until 2010, the prevalence of supine sleep positioning has been fairly stagnant (prevalence in 2010: 75%).[11]

The 1998 and 2005 AAP policy statements and the Back to Sleep campaign not only addressed the importance of back sleeping but also provided recommendations for other infant care practices that may reduce the risk of SIDS and other sleep-related infant deaths.[1,9] Unfortunately, the ability to measure the prevalence of these other risk factors is limited by lack of data. Death certificates are useful for monitoring trends in SIDS mortality, but the circumstances and events that lead to death are not captured in vital statistics data.[16] The Centers for Disease Control and Prevention recently began to pilot a SUID case registry that will provide supplemental surveillance information about the sleep environment at the time of death, infant health history, and the comprehensiveness of the death scene investigation and autopsy. These factors will better describe the circumstances surrounding SIDS and other sleep-related infant deaths and assist researchers in determining the similarities and differences between these deaths.

Racial and Ethnic Disparities

SIDS mortality rates, similar to other causes of infant mortality, have notable racial and ethnic disparities (Fig 2).[17] Despite the decline in SIDS in all races and ethnicities, the rate of SIDS in non-Hispanic black (99 per 100 000 live births) and American Indian/Alaska Native (112 per 100 000 live births) infants was double that of non-Hispanic white infants (55 per 100 000

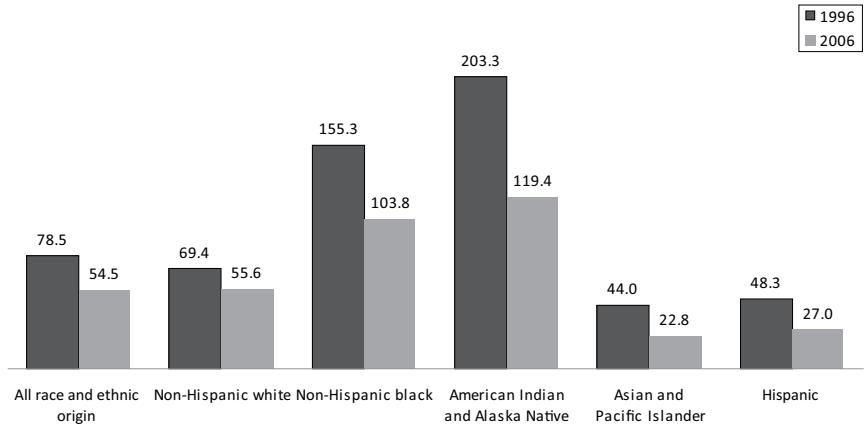

FIGURE 2

live births) in 2005 (Fig 2). SIDS rates for Asian/Pacific Islander and Hispanic infants were nearly half the rate for non-Hispanic white infants. Furthermore, similar racial and ethnic disparities have been seen with deaths attributed to both ASSB (Fig 3) and ill-defined or unspecified deaths (Fig 4). Differences in the prevalence of supine positioning and other sleep-environment conditions among racial and ethnic populations might contribute to these disparities.[17] The prevalence of supine positioning in 2010 among white infants was 75%, compared with 53% among black infants (Fig 5). The prevalence of supine sleep positioning among Hispanic and Asian infants was 73% and 80%, respectively.[11] Parent-infant bed-sharing[18–20] and use of soft bedding are also more common among black families

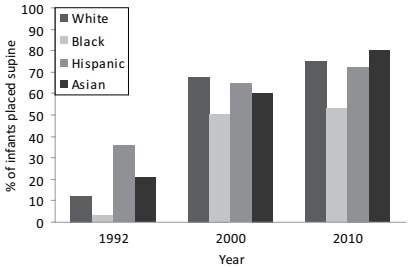

FIGURE 5

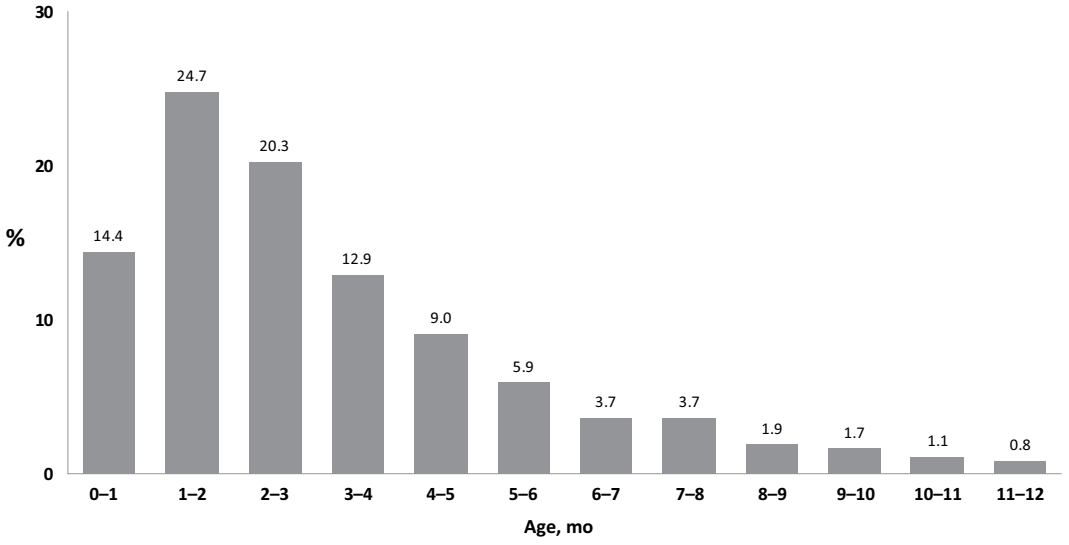

FIGURE 7
Percent distribution of deaths caused by ASSB according to age at death: United States, 2004–2006.

than among other racial/ethnic groups.[21,22] Additional work in promoting appropriate infant sleep position and sleep-environment conditions is necessary to resume the previous rate of decline (observed during the 1990s) for SIDS and all-cause postneonatal mortality.

Age at Death

Ninety percent of SIDS cases occur before an infant reaches the age of 6 months. The rate of SIDS peaks between 1 and 4 months of age. Although SIDS was once considered a rare event during the first month of life, in 2004–2006, nearly 10% of cases coded as SIDS occurred during the first month. SIDS is uncommon after 8 months of age (Fig 6).[14] A similar age distribution is seen for ASSB (Fig 7).

Seasonality of SIDS

A pattern in seasonality of SIDS is no longer apparent. SIDS deaths have historically been observed more frequently in the colder months, and the fewest SIDS deaths occurred in the warmest months.[23] In 1992, SIDS rates had an average seasonal change of 16.3%, compared with only 7.6% in 1999,[24] which is consistent with reports from other countries.[25]

PATHOPHYSIOLOGY AND GENETICS OF SIDS

A working model of SIDS pathogenesis includes a convergence of exogenous triggers or "stressors" (eg, prone

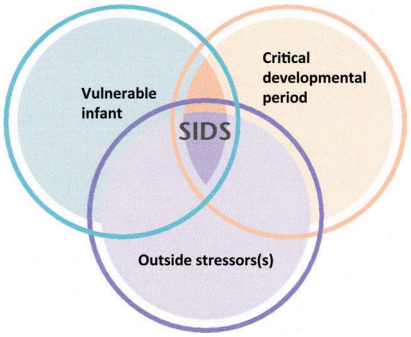

FIGURE 8
Triple-risk model for SIDS.[26]

sleep position, overbundling, airway obstruction), a critical period of development, and dysfunctional and/or immature cardiorespiratory and/or arousal systems (intrinsic vulnerability) that lead to a failure of protective responses (see Fig 8).[26] Convergence of these factors ultimately results in a combination of progressive asphyxia, bradycardia, hypotension, metabolic acidosis, and ineffectual gasping, leading to death.[27] The mechanisms responsible for dysfunctional cardiorespiratory and/or arousal protective responses remain unclear but might be the result of in utero environmental conditions and/or genetically determined maldevelopment or delay in maturation. Infants who die from SIDS are more likely to be born at low birth weight or growth restricted, which suggests an adverse intrauterine environment. Other adverse in utero environmental conditions include exposure to nicotine or other components of cigarette smoke and alcohol.

Recent studies have explored how prenatal exposure to cigarette smoke may result in an increased risk of SIDS. In animal models, exposure to cigarette smoke or nicotine during fetal development alters the expression of the nicotinic acetylcholine receptor in areas of the brainstem important for autonomic function,[28] alters the neuronal excitability of neurons in the nucleus tractus solitarius (a brainstem region important for sensory integration),[29] and alters fetal autonomic activity and medullary neurotransmitter receptors.[30] In human infants, there are strong associations between nicotinic acetylcholine receptor and serotonin receptors in the brainstem during development.[31] Prenatal exposure to tobacco smoke attenuates recovery from hypoxia in preterm infants,[32] decreases heart rate variability in preterm[33] and term[34] infants, and abolishes the normal relationship between heart rate and gestational age at birth.[33] Moreover, infants of smoking mothers exhibit impaired arousal patterns to trigeminal stimulation in proportion to urinary cotinine levels.[35] It is important to note also that prenatal exposure to tobacco smoke alters the normal programming of cardiovascular reflexes such that there is a greater-than-expected increase in blood pressure and heart rate in response to breathing 4% carbon dioxide or a 60° head-up tilt.[36] These changes in autonomic function, arousal, and cardiovascular reflexes might all increase an infant's vulnerability to SIDS.

Brainstem abnormalities that involve the medullary serotonergic (5-hydroxytryptamine [5-HT]) system in up to 70% of infants who die from SIDS are the most robust and specific neuropathologic findings associated with SIDS and have been confirmed in several independent data sets and laboratories.[37–40] This area of the brainstem plays a key role in coordinating many respiratory, arousal, and autonomic functions and, when dysfunctional, might prevent normal protective responses to stressors that commonly occur during sleep. Since the Task Force on Sudden Infant Death Syndrome report in 2005, more specific abnormalities have been described, including decreased 5-HT_{1A} receptor binding, a relative decrease in binding to the serotonin transporter, and increased numbers of immature 5-HT neurons in regions of the brainstem that are important for autonomic function.[41] These findings are not confined to nuclei containing 5-HT neurons but also include relevant projection sites. The most recent study report described in these same regions decreased tissue levels of 5-HT and tryptophan hydroxylase, the synthesizing enzyme for serotonin, and no evidence of excessive serotonin degradation as assessed by levels of 5-hydroxyindoleacetic acid (the main metabolite of serotonin) or ratios of 5-hydroxyindoleacetic acid to serotonin.[30] A recent article described a significant association between a decrease in medullary 5-HT_{1A} receptor immunoreactivity and specific SIDS risk factors, including tobacco smoking.[40] These data confirm results from earlier studies in humans[39,41] and are also consistent with studies in piglets that revealed that postnatal exposure to nicotine decreases medullary 5-HT_{1A} receptor immunoreactivity.[42] Animal studies have revealed that serotonergic neurons located in the medullary raphe and adjacent paragigantocellularis lateralis play important roles in many autonomic functions including the control of respiration, blood pressure, heart rate, thermoregulation, sleep and arousal, and upper airway patency. Engineered mice with decreased numbers of 5-HT neurons and rats or piglets with decreased activity secondary to 5-HT_{1A} autoreceptor stimulation have diminished ventilator responses to carbon dioxide, dysfunctional heat production and heat-loss mechanisms, and altered sleep architecture.[43] These studies linked SIDS risk factors with possible pathophysiology.

There is no evidence of a strong heritable contribution for SIDS. However, genetic alterations have been observed that may increase the vulnera-

bility to SIDS. Genetic variation can take the form of common base changes (polymorphisms) that alter gene function or rare base changes (mutations) that often have highly deleterious effects. Several categories of physiologic functions relevant to SIDS have been examined for altered genetic makeup. Genes related to the serotonin transporter, cardiac channelopathies, and the development of the autonomic nervous system are the subject of current investigation.[44] The serotonin transporter recovers serotonin from the extracellular space and largely serves to regulate overall serotonin neuronal activity. Results of a recent study support those in previous reports that polymorphisms in the promoter region that enhance the efficacy of the transporter (L) allele seem to be more prevalent in infants who die from SIDS compared with those reducing efficacy (S)[45]; however, at least 1 study did not confirm this association.[46] It has also been reported that a polymorphism (12-repeat intron 2) of the promoter region of the serotonin transporter, which also enhances serotonin transporter efficiency, was increased in black infants who died from SIDS[44] but not in a Norwegian population.[45]

It has been estimated that 5% to 10% of infants who die from SIDS have novel mutations in the cardiac sodium or potassium channel genes that result in long QT syndrome as well as in other genes that regulate channel function.[44] A recent report described important new molecular and functional evidence that implicates specific *SCN5A* (sodium channel gene) β subunits in SIDS pathogenesis.[47] The identification of polymorphisms in genes pertinent to the embryologic origin of the autonomic nervous system in SIDS cases also lends support to the hypothesis that a genetic predisposition contributes to the etiology of SIDS. There have also been a number of reports of polymorphisms or mutations in genes that regulate inflammation,[48,49] energy production,[50–52] and hypoglycemia[53] in infants who died from SIDS, but these associations require more study to determine their importance.

ISSUES RELATED TO SLEEP POSITION

The Supine Sleep Position Is Recommended for Infants to Reduce the Risk of SIDS; Side Sleeping Is Not Safe and Is Not Advised

The prone or side sleep position can increase the risk of rebreathing expired gases, resulting in hypercapnia and hypoxia.[54–57] The prone position also increases the risk of overheating by decreasing the rate of heat loss and increasing body temperature compared with infants sleeping supine.[58,59] Recent evidence suggests that prone sleeping alters the autonomic control of the infant cardiovascular system during sleep, particularly at 2 to 3 months of age,[60] and can result in decreased cerebral oxygenation.[61] The prone position places infants at high risk of SIDS (odds ratio [OR]: 2.3–13.1).[62–66] However, recent studies have demonstrated that the SIDS risks associated with side and prone position are similar in magnitude (OR: 2.0 and 2.6, respectively)[63] and that the population-attributable risk reported for side sleep position is higher than that for prone position.[65,67] Furthermore, the risk of SIDS is exceptionally high for infants who are placed on their side and found on their stomach (OR: 8.7).[63] The side sleep position is inherently unstable, and the probability of an infant rolling to the prone position from the side sleep position is significantly greater than rolling prone from the back.[65,68] Infants who are unaccustomed to the prone position and are placed prone for sleep are also at greater risk than those usually placed prone (adjusted OR: 8.7–45.4).[63,69,70] Therefore, it is critically important that every caregiver use the supine sleep position for every sleep period.

Despite these recommendations, the prevalence of supine positioning has remained stagnant for the last decade.[71] One of the most common reasons that parents and caregivers cite for not placing infants supine is fear of choking or aspiration in the supine position.[72–80] Parents often misconstrue coughing or gagging, which is evidence of a normal protective gag reflex, for choking or aspiration. Multiple studies in different countries have not found an increased incidence of aspiration since the change to supine sleeping.[81–83] There is often particular concern for aspiration when the infant has been diagnosed with gastroesophageal reflux. The AAP supports the recommendations of the North American Society for Pediatric Gastroenterology and Nutrition, which state that infants with gastroesophageal reflux should be placed for sleep in the supine position, with the rare exception of infants for whom the risk of death from gastroesophageal reflux is greater than the risk of SIDS[84]—specifically, infants with upper airway disorders for whom airway protective mechanisms are impaired, which may include infants with anatomic abnormalities, such as type 3 or 4 laryngeal clefts, who have not undergone antireflux surgery. Elevating the head of the infant's crib while the infant is supine is not effective in reducing gastroesophageal reflux[85,86]; in addition, this elevation can result in the infant sliding to the foot of the crib into a position that might compromise respiration and, therefore, is not recommended.

The other reason often cited by parents for not using the supine sleep position is the perception that the infant is uncomfortable or does not sleep

well.[72–80] An infant who wakes frequently is normal and should not be perceived as a poor sleeper. Physiologic studies have found that infants are less likely to arouse when they are sleeping in the prone position.[87–95] The ability to arouse from sleep is an important protective physiologic response to stressors during sleep,[96–100] and the infant's ability to sleep for sustained periods might not be physiologically advantageous.

Preterm Infants Should Be Placed Supine as Soon as Possible

Infants born prematurely have an increased risk of SIDS,[101,102] and the association between prone sleep position and SIDS among low birth weight infants is equal to, or perhaps even stronger than, the association among those born at term.[69] Therefore, preterm infants should be placed supine for sleep as soon as their clinical status has stabilized. The task force supports the recommendations of the AAP Committee on Fetus and Newborn, which state that hospitalized preterm infants should be placed in the supine position for sleep by 32 weeks' postmenstrual age to allow them to become accustomed to sleeping in that position before hospital discharge.[103] Unfortunately, preterm and very low birth weight infants continue to be more likely to be placed prone for sleep after hospital discharge.[104,105] Preterm infants are placed prone initially to improve respiratory mechanics[106,107]; although respiratory parameters are no different in the supine or prone positions in preterm infants who are close to discharge,[108] both infants and their caregivers likely become accustomed to using the prone position, which makes it more difficult to change. One study of NICU nurses found that only 50% of nurses place preterm infants supine during the transition to an open crib, and more than 20% never place preterm infants supine or will only place them supine 1 to 2 days before discharge.[109] Moreover, very prematurely born infants studied before hospital discharge have longer sleep duration, fewer arousals from sleep, and increased central apneas while in the prone position.[88] The task force believes that neonatologists, neonatal nurses, and other health care professionals responsible for organizing the hospital discharge of infants from NICUs should be vigilant about endorsing SIDS risk-reduction recommendations from birth. They should model the recommendations as soon as the infant is medically stable and significantly before the infant's anticipated discharge. In addition, NICUs are encouraged to develop and implement policies to ensure that supine sleeping and other safe sleep practices are modeled for parents before discharge from the hospital.

Newborn Infants Should Be Placed Supine Within the First Few Hours After Birth

Practitioners who place infants on their sides after birth in newborn nurseries continue to be a concern. The practice likely occurs because nursery staff believe that newborn infants need to clear their airways of amniotic fluid and may be less likely to aspirate while on their sides. No evidence that such fluid will be cleared more readily while in the side position exists. Finally, and perhaps most importantly, if parents observe health care professionals placing infants in the side or prone position, they are likely to infer that supine positioning is not important[110] and, therefore, might be more likely to copy this practice and use the side or prone position at home.[77,80,111] The AAP recommends that infants be placed on their backs as soon as they are ready to be placed in a bassinet.

Once an Infant Can Roll From the Supine to Prone and From the Prone to Supine Position, the Infant Can Be Allowed to Remain in the Sleep Position That He or She Assumes

Parents and caregivers are frequently concerned about the appropriate strategy for infants who have learned to roll over, which generally occurs at 4 to 6 months of age. As infants mature, it is more likely that they will roll. In 1 study, 6% and 12% of 16- to 23-week-old infants placed on their backs or sides, respectively, were found in the prone position; among infants aged 24 weeks or older, 14% of those placed on their backs and 18% of those placed on their sides were found in the prone position.[112] Repositioning the sleeping infant to the supine position can be disruptive and might discourage the use of supine position altogether. Although data to make specific recommendations as to when it is safe for infants to sleep in the prone position are lacking, the AAP recommends that these infants continue to be placed supine until 1 year of age. If the infant can roll from supine to prone and from prone to supine, the infant can then be allowed to remain in the sleep position that he or she assumes. To prevent suffocation or entrapment if the infant rolls, soft or loose bedding should continue to be removed from the infant's sleep environment. Some caregivers use such bedding to prevent an infant from rolling, but this bedding could cause suffocation and entrapment. Parents can be reassured by the information that the incidence of SIDS begins to decline after 4 months of age (Fig 6).

Supervised, Awake Tummy Time on a Daily Basis Can Promote Motor Development and Minimize the Risk of Positional Plagiocephaly

Positional plagiocephaly, or plagiocephaly without synostosis (PWS), can be associated with supine sleeping position (OR: 2.5).[113] It is most likely to result if the infant's head position is not varied when placed for sleep, if the infant spends little or no time in awake, supervised tummy time, and if the infant is not held in the upright position when not sleeping.[113–115] Children with developmental delay and/or neurologic injury have increased rates of PWS, although a causal relationship has not been demonstrated.[113,116–119] In healthy normal children, the incidence of PWS decreases spontaneously from 20% at 8 months to 3% at 24 months of age.[114] Although data to make specific recommendations as to how often and how long tummy time should be undertaken are lacking, supervised tummy time while the infant is awake is recommended on a daily basis. Tummy time should begin as early as possible to promote motor development, facilitate development of the upper body muscles, and minimize the risk of positional plagiocephaly. The AAP clinical report on positional skull deformities[120] provides additional detail on the prevention, diagnosis, and management of positional plagiocephaly.

SLEEP SURFACES

Infants Should Sleep in a Safety-Approved Crib, Portable Crib, Play Yard, or Bassinet

Cribs should meet safety standards of the CPSC, Juvenile Product Manufacturers Association, and the ASTM International (formerly the American Society for Testing and Materials), including those for slat spacing, snugly fitting and firm mattresses, and no drop sides.[121] The AAP recommends the use of new cribs, because older cribs might no longer meet current safety standards, might have missing parts, or might be incorrectly assembled. If an older crib is to be used, care must be taken to ensure that there have been no recalls on the crib model, that all of the hardware is intact, and that the assembly instructions are available.

For some families, use of a crib might not be possible for financial reasons or space considerations. In addition, parents might be reluctant to place the infant in the crib because of concerns that the crib is too large for the infant or that "crib death" (ie, SIDS) only occurs in cribs. Alternate sleep surfaces, such as portable cribs/play yards and bassinets might be more acceptable for some families, because they are smaller and more portable. Local organizations throughout the United States can help to provide low-cost or free cribs or play yards. If a portable crib/play yard or bassinet is to be used, it should meet the following CPSC guidelines: (1) sturdy bottom and wide base; (2) smooth surfaces without protruding hardware; (3) legs with locks to prevent folding while in use; and (4) firm, snugly fitting mattress.[121] In addition, other AAP guidelines for safe sleep, including supine positioning and avoidance of soft objects and loose bedding, should be followed. Mattresses should be firm and should maintain their shape even when the fitted sheet designated for that model is used, such that there are no gaps between the mattress and the side of the bassinet, playpen, portable crib, or play yard. Only mattresses designed for the specific product should be used. Pillows or cushions should not be used as substitutes for mattresses or in addition to a mattress. Any fabric on the sides or a canopy should be taut and firmly attached to the frame so as not to create a suffocation risk for the infant. Portable cribs, play yards, and bassinets with vertical sides made of air-permeable material may be preferable to those with air-impermeable sides.[122] Finally, parents and caregivers should adhere to the manufacturer's guidelines regarding maximum weight of infants using these products.[122,123] If the product is a combination product (eg, crib/toddler bed), the manual should be consulted when the mode of use is changed.

There are no data regarding the safety of sleepers that attach to the side of an adult bed. However, there are potential safety concerns if the sleeper is not attached properly to the side of the adult bed or if the infant moves into the adult bed. Therefore, the task force cannot make a recommendation for or against the use of bedside sleepers. In addition, infants should not be placed for sleep on adult-sized beds because of the risk of entrapment and suffocation.[124] Portable bed rails (railings installed on the side of the bed that are intended to prevent a child from falling off of the bed) should not be used with infants because of the risk of entrapment and strangulation.[125]

Car Seats and Other Sitting Devices Are not Recommended for Routine Sleep at Home or in the Hospital, Particularly for Young Infants

Some parents let their infants sleep in a car seat or other sitting device. Sitting devices include but are not restricted to car seats, strollers, swings, infant carriers, and infant slings. Parents and caregivers often use these devices, even when not traveling, because they are convenient. One study found that the average young infant spends 5.7 hours/day in a car seat or similar sitting device.[126] However, there are multiple concerns about using sitting devices as a usual infant sleep location. Placing an infant in such devices can potentiate gastro-

esophageal reflux[127] and positional plagiocephaly. Because they still have poor head control and often experience flexion of the head while in a sitting position, infants younger than 1 month in sitting devices might be at increased risk of upper airway obstruction and oxygen desaturation.[128–132] In addition, there is increasing concern about injuries from falls resulting from car seats being placed on elevated surfaces.[133–137] An analysis of CPSC data revealed 15 suffocation deaths between 1990 and 1997 resulting from car seats overturning after being placed on a bed, mattress, or couch.[136] The CPSC also warns about the suffocation hazard to infants, particularly those who are younger than 4 months, who are carried in infant sling carriers.[138] When infant slings are used for carrying, it is important to ensure that the infant's head is up and above the fabric, the face is visible, and that the nose and mouth are clear of obstructions. After nursing, the infant should be repositioned in the sling so that the head is up and is clear of fabric and the adult's body.

BED-SHARING

Room-Sharing Without Bed-Sharing Is Recommended

The terms "bed-sharing" and "cosleeping" are often used interchangeably, but they are not synonymous. Cosleeping is when parent and infant sleep in close proximity (on the same surface or different surfaces) so as to be able to see, hear, and/or touch each other.[139,140] Cosleeping arrangements can include bed-sharing or sleeping in the same room in close proximity.[140,141] Bed-sharing refers to a specific type of cosleeping when the infant is sleeping on the same surface with another person.[140] Because the term cosleeping can be misconstrued and does not precisely describe sleep arrangements, the AAP recommends use of the terms "room-sharing" and "bed-sharing."

The AAP recommends the arrangement of room-sharing without bed-sharing, or having the infant sleep in the parents' room but on a separate sleep surface (crib or similar surface) close to the parents' bed. There is evidence that this arrangement decreases the risk of SIDS by as much as 50%[64,66,142,143] and is safer than bed-sharing[64,66,142,143] or solitary sleeping (when the infant is in a separate room).[53,64] In addition, this arrangement is most likely to prevent suffocation, strangulation, and entrapment, which may occur when the infant is sleeping in the adult bed. Furthermore, room-sharing without bed-sharing allows close proximity to the infant, which facilitates feeding, comforting, and monitoring of the infant.

Parent-infant bed-sharing is common. In 1 national survey, 45% of parents responded that they had shared a bed with their infant (8 months of age or younger) at some point in the preceding 2 weeks.[19] In some racial/ethnic groups, the rate of routine bed-sharing might be higher.[18–20] There are often cultural and personal reasons why parents choose to bed-share, including convenience for feeding (breastfeeding or with formula) and bonding. In addition, many parents might believe that their own vigilance is the only way that they can keep their infant safe and that the close proximity of bed-sharing allows them to maintain vigilance, even while sleeping.[144] Some parents will use bed-sharing specifically as a safety strategy if the infant sleeps in the prone position[21,144] or if there is concern about environmental dangers such as vermin and stray gunfire.[144]

Parent-infant bed-sharing continues to be highly controversial. Although electrophysiologic and behavioral studies have offered a strong case for its effect in facilitating breastfeeding[145,146] and although many parents believe that they can maintain vigilance of the infant while they are asleep and bed-sharing,[144] epidemiologic studies have shown that bed-sharing can be hazardous under certain conditions.[147–150] Bed-sharing might increase the risk of overheating,[151] rebreathing[152] or airway obstruction,[153] head covering,[152,154–156] and exposure to tobacco smoke,[157] which are all risk factors for SIDS. A recent meta-analysis of 11 studies that investigated the association of bed-sharing and SIDS revealed a summary OR of 2.88 (95% confidence interval [CI]: 1.99–4.18) with bed-sharing.[158] Furthermore, bed-sharing in an adult bed not designed for infant safety exposes the infant to additional risks for accidental injury and death, such as suffocation, asphyxia, entrapment, falls, and strangulation.[159,160] Infants, particularly those in the first 3 months of life and those born prematurely and/or with low birth weight, are at highest risk,[161] possibly because immature motor skills and muscle strength make it difficult to escape potential threats.[158] In recent years, the concern among public health officials about bed-sharing has increased, because there have been increased reports of SUIDs occurring in high-risk sleep environments, particularly bed-sharing and/or sleeping on a couch or armchair.[162–165]

There Is Insufficient Evidence to Recommend Any Bed-Sharing Situation in the Hospital or at Home as Safe; Devices Promoted to Make Bed-Sharing "Safe" Are Not Recommended

Epidemiologic studies have not found bed-sharing to be protective against SIDS and accidental suffocation for any subgroups of the population. It is acknowledged that there are some cultures for which bed-sharing is the norm and SIDS rates are low, but there

are other cultures for which bed-sharing is the norm and SIDS rates are high. In general, the bed-sharing practiced in cultures with low SIDS rates is often different from that in the United States and other Western countries (eg, with firm mats on the floor, separate mat for the infant, and/or absence of soft bedding). It is statistically much more difficult to demonstrate safety (ie, no risk) in small subgroups. Breastfeeding mothers who do not smoke and have not consumed alcohol or arousal-altering medications or drugs are 1 such subgroup. Furthermore, not all risks associated with bed-sharing (eg, parental fatigue) can be controlled. The task force, therefore, believes that there is insufficient evidence to recommend any bed-sharing situation in the hospital or at home as safe. In addition, there is no evidence that devices marketed to make bed-sharing "safe" (eg, in-bed cosleepers) reduce the risk of SIDS or suffocation or are safe. Such devices, therefore, are not recommended.

There Are Specific Circumstances in Which Bed-Sharing Is Particularly Hazardous, and It Should Be Stressed to Parents That They Avoid the Following Situations at All Times

The task force emphasizes that certain circumstances greatly increase the risk with bed-sharing. Bed-sharing is especially dangerous when 1 or both parents are smokers (OR: 2.3–17.7)[64,65,158,166,167]; when the infant is younger than 3 months (OR: 4.7–10.4), regardless of parental smoking status[64,66,143,158,168,169]; when the infant is placed on excessively soft surfaces such as waterbeds, sofas, and armchairs (OR: 5.1–66.9)[62,64,65,143,169]; when soft bedding accessories such as pillows or blankets are used (OR: 2.8–4.1)[62,170]; when there are multiple bed-sharers (OR: 5.4)[62]; and when the parent has consumed alcohol (OR: 1.66).[66,171] There is also a higher risk of SIDS when the infant is bed-sharing with someone who is not a parent (OR: 5.4).[62]

A retrospective series of SIDS cases indicated that mean maternal body weight was higher for bed-sharing mothers than for non–bed-sharing mothers.[172] The only case-control study to investigate the relationship between maternal body weight and bed-sharing did not find an increased risk of bed-sharing with increased maternal weight.[173]

Infants May Be Brought Into the Bed for Feeding or Comforting but Should Be Returned to Their Own Crib or Bassinet When the Parent Is Ready to Return to Sleep

The risk of bed-sharing is higher the longer the duration of bed-sharing during the night.[64,65,167,169] Returning the infant to the crib after bringing him or her into the bed for a short period of time is not associated with increased risk.[65,169] Therefore, if the infant is brought into the bed for feeding, comforting, and bonding, the infant should be returned to the crib when the parent is ready for sleep. Because of the extremely high risk of SIDS, accidental suffocation, and entrapment on couches and armchairs,[62,64,65,143,169] infants should not be fed on a couch or armchair when there is high risk that the parent may fall asleep.

It Is Prudent to Provide Separate Sleep Areas and Avoid Cobedding for Twins and Higher-Order Multiples in the Hospital and at Home

Cobedding of twins and other infants of multiple gestation is a frequent practice, both in the hospital setting and at home.[174] However, the benefits of cobedding twins and higher-order multiples have not been established.[175–177] Twins and higher-order multiples are often born prematurely and with low birth weight, so they are at increased risk of SIDS.[101,102] Furthermore, there is increased potential for overheating and rebreathing while cobedding, and size discordance might increase the risk of accidental suffocation.[176] Most cobedded twins are placed on their sides rather than supine.[174] Finally, cobedding of twins and higher-order multiples in the hospital setting might encourage parents to continue this practice at home.[176] Because the evidence for the benefits of cobedding twins and higher-order multiples is not compelling and because of the increased risk of SIDS and suffocation, the AAP believes that it is prudent to provide separate sleep areas for these infants to decrease the risk of SIDS and accidental suffocation.

BEDDING

Pillows, Quilts, Comforters, Sheepskins, and Other Soft Surfaces Are Hazardous When Placed Under the Infant or Loose in the Sleep Environment

Bedding is used in infant sleep environments for comfort and safety.[178] Parents and caregivers who perceive that infants are uncomfortable on firm surfaces will often attempt to soften the surface with blankets and pillows. Parents and caregivers will also use pillows and blankets to create barriers to prevent the infant from falling off the sleep surface (usually an adult bed or couch) or to prevent injury if the infant hits the crib side. However, such soft bedding can increase the potential of suffocation and rebreathing.[54,56,57,179–181] Pillows, quilts, comforters, sheepskins, and other soft surfaces are hazardous when placed under the infant[62,147,182–187] or left loose in the infant's sleep area[62,65,184,185,188–191] and can increase SIDS risk up to fivefold independent of sleep position.[62,147] Several reports have also described that

in many SIDS cases, the heads of the infants, including some infants who slept supine, were covered by loose bedding.[65,186,187,191] It should be noted that the risk of SIDS increases 21-fold when the infant is placed prone with soft bedding.[62] In addition, soft and loose bedding have both been associated with accidental suffocation deaths.[149] The CPSC has reported that the majority of sleep-related infant deaths in its database are attributable to suffocation involving pillows, quilts, and extra bedding.[192,193] The AAP recommends that infants sleep on a firm surface without any soft or loose bedding. Pillows, quilts, and comforters should never be in the infant's sleep environment. Specifically, these items should not be placed loose near the infant, between the mattress and the sheet, or under the infant. Infant sleep clothing that is designed to keep the infant warm without the possible hazard of head covering or entrapment can be used in place of blankets; however, care must be taken to select appropriately sized clothing and to avoid overheating. If a blanket is used, it should be thin and tucked under the mattress so as to avoid head or face covering. These practices should also be modeled in hospital settings.

Wedges and Positioning Devices Are not Recommended

Wedges and positioning devices are often used by parents to maintain the infant in the side or supine position because of claims that these products reduce the risk for SIDS, suffocation, or gastroesophageal reflux. However, these products are frequently made with soft, compressible materials, which might increase the risk of suffocation. The CPSC has reports of deaths attributable to suffocation and entrapment associated with wedges and positioning devices. Most of these deaths occurred when infants were placed in the prone or side position with these devices; other incidents have occurred when infants have slipped out of the restraints or rolled into a prone position while using the device.[2,194] Because of the lack of evidence that they are effective against SIDS, suffocation, or gastroesophageal reflux and because there is potential for suffocation and entrapment, the AAP concurs with the CPSC and the US Food and Drug Administration in warning against the use of these products. If positioning devices are used in the hospital as part of physical therapy, they should be removed from the infant sleep area well before discharge from the hospital.

Bumper Pads and Similar Products Are not Recommended

Bumper pads and similar products that attach to crib slats or sides are frequently used with the thought of protecting infants from injury. Initially, bumper pads were developed to prevent head entrapment between crib slats.[195] However, newer crib standards that require crib slat spacing to be less than 2⅜ inches have obviated the need for crib bumpers. In addition, infant deaths have occurred because of bumper pads. A recent report by Thach et al,[196] who used CPSC data, found that deaths attributed to bumper pads were from 3 mechanisms: (1) suffocation against soft, pillow-like bumper pads; (2) entrapment between the mattress or crib and firm bumper pads; and (3) strangulation from bumper pad ties. However, the CPSC believes that there were other confounding factors, such as the presence of pillows and/or blankets, that might have contributed to many of the deaths in this report.[2] Thach et al[196] also analyzed crib injuries that might have been prevented by bumper pad use and concluded that the use of bumper pads only prevents minor injuries. A more recent study of crib injuries that used data from the CPSC National Electronic Injury Surveillance System concluded that the potential benefits of preventing minor injury with bumper pad use were far outweighed by the risk of serious injury such as suffocation or strangulation.[197] In addition, most bumper pads obscure infant and parent visibility, which might increase parental anxiety.[195] There are other products that attach to crib sides or crib slats that claim to protect infants from injury. However, there are no published data that support these claims. Because of the potential for suffocation, entrapment, and strangulation and lack of evidence to support that bumper pads or similar products that attach to crib slats or sides prevent injury in young infants, the AAP does not recommend their use.

PRENATAL AND POSTNATAL EXPOSURES (INCLUDING SMOKING AND ALCOHOL)

Pregnant Women Should Seek and Obtain Regular Prenatal Care

There is substantial epidemiologic evidence that links a lower risk of SIDS for infants whose mothers obtain regular prenatal care.[198–200] Women should seek prenatal care early in the pregnancy and continue to obtain regular prenatal care during the entire pregnancy.

Smoking During Pregnancy, in the Pregnant Woman's Environment, and in the Infant's Environment Should Be Avoided

Maternal smoking during pregnancy is a major risk factor in almost every epidemiologic study of SIDS.[201–204] Smoke in the infant's environment after birth is a separate major risk factor in a few studies,[202,205] although separating this variable from maternal smoking before birth is problematic. Thirdhand smoke refers to residual contamination from tobacco smoke after the cigarette has been extinguished[206]; there is no research to date on the signifi-

cance of thirdhand smoke with regards to SIDS risk. Smoke exposure adversely affects infant arousal[207–213]; in addition, smoke exposure increases risk of preterm birth and low birth weight, both of which are risk factors for SIDS. The effect of tobacco smoke exposure on SIDS risk is dose-dependent. Aside from sleep position, smoke exposure is the largest contributing risk factor for SIDS.[149] It is estimated that one-third of SIDS deaths could be prevented if all maternal smoking during pregnancy were eliminated.[214,215] The AAP supports the elimination of all tobacco smoke exposure, both prenatally and environmentally.[216,217]

Avoid Alcohol and Illicit Drug Use During Pregnancy and After the Infant's Birth

Several studies have specifically investigated the association of SIDS with prenatal and postnatal exposure to alcohol or illicit drug use, although substance abuse often involves more than 1 substance and it is difficult to separate these variables from each other and from smoking. However, 1 study of Northern Plains American Indians found that periconceptional maternal alcohol use (adjusted OR: 6.2 [95% CI: 1.6–23.3]) and maternal first-trimester binge drinking (adjusted OR: 8.2 [95% CI: 1.9–35.3])[218] were associated with increased SIDS risk independent of prenatal cigarette smoking exposure. Another study from Denmark, which was based on prospective data about maternal alcohol use, also found a significant relationship between maternal binge drinking and postneonatal infant mortality, including SIDS.[219]

Postmortem studies of Northern Plains American Indian infants revealed that prenatal cigarette smoking was significantly associated with decreased serotonin receptor binding in the brainstem. In this study, the association of maternal alcohol drinking in the 3 months before or during pregnancy was of borderline significance on univariate analysis but was not significant when prenatal smoking and case-versus-control status were in the model.[39] However, this study had limited power for multivariate analysis because of its small sample size. One study found an association of SIDS with heavy alcohol consumption in the 2 days before the death.[220] Although some studies have found a particularly strong association when alcohol consumption occurs in combination with bed-sharing,[64–66,221] other studies have not found interaction between bed-sharing and alcohol to be significant.[167,222]

Studies investigating the relationship of illicit drug use and SIDS have focused on specific drugs or illicit drug use in general. In utero exposure to opiates (primarily methadone and heroin) has been shown in retrospective studies to be associated with an increased risk of SIDS.[223,224] With the exception of 1 study that did not show increased risk,[225] population-based studies have generally shown an increased risk with in utero cocaine exposure.[226–228] However, these studies did not control for confounding factors. A prospective cohort study found the SIDS rate to be significantly increased for infants exposed in utero to methadone (OR: 3.6 [95% CI: 2.5–5.1]), heroin (OR: 2.3 [95% CI: 1.3–4.0]), methadone and heroin (OR: 3.2 [95% CI: 1.2–8.6]), and cocaine (OR: 1.6 [95% CI: 1.2–2.2]), even after controlling for race/ethnicity, maternal age, parity, birth weight, year of birth, and maternal smoking.[229] In addition, a meta-analysis of studies that investigated an association between in utero cocaine exposure and SIDS found an increased risk of SIDS to be associated with prenatal exposure to cocaine and illicit drugs in general.[230]

BREASTFEEDING

Breastfeeding Is Recommended

Earlier epidemiologic studies were not consistent in demonstrating a protective effect of breastfeeding on SIDS*; some studies found a protective effect,[67,239,240] and others did not.† Because many of the case-control studies demonstrated a protective effect of breastfeeding against SIDS in univariate analysis but not when confounding factors were taken into account,[62,184,198,231,238] these results suggested that factors associated with breastfeeding, rather than breastfeeding itself, are protective. However, newer published reports support the protective role of breastfeeding on SIDS when taking into account potential confounding factors.[243–245] Studies do not distinguish between nursing and expressed human milk. In the Agency for Healthcare Research and Quality's "Evidence Report on Breastfeeding in Developed Countries,"[243] multiple outcomes, including SIDS, were examined. Six studies were included in the SIDS-breastfeeding meta-analysis, and in both unadjusted and adjusted analysis, ever breastfeeding was associated with a lower risk of SIDS (summary OR: 0.41 [95% CI: 0.28–0.58]; adjusted summary OR: 0.64 [95% CI: 0.51–0.81]). The German Study of Sudden Infant Death, the largest and most recent case-control study of SIDS, found that exclusive breastfeeding at 1 month of age halved the risk of SIDS (adjusted OR: 0.48 [95% CI: 0.28–0.82]). At all ages, control infants were breastfed at higher rates than SIDS victims, and the protective effect of partial or exclusive breastfeeding remained statistically significant after adjustment for confounders.[244] A recent meta-analysis that included 18 case-control studies revealed an unadjusted summary OR for any breast-

*Refs 62, 65, 67, 184, 198, and 231–239.
†Refs 62, 184, 198, 231, 238, 241, and 242.

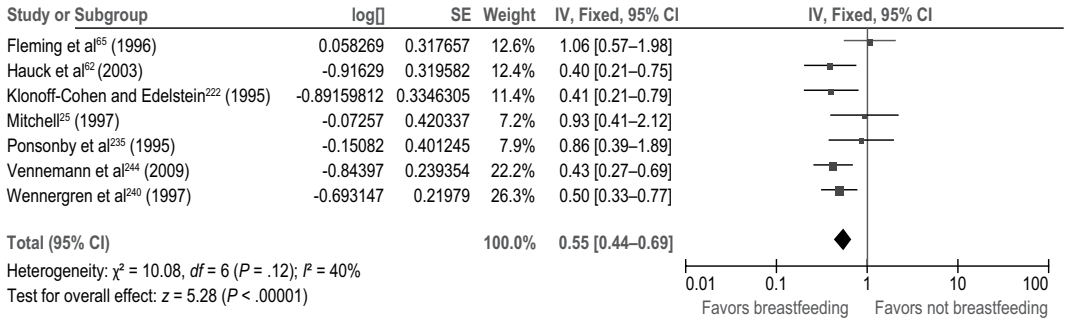

FIGURE 9
Multivariable analysis of any breastfeeding versus no breastfeeding. log[ ] indicates logarithm of the OR; weight, weighting that the study contributed to the meta-analysis (according to sample size); IV, fixed, 95% CI: fixed-effect OR with 95% CI.[245]

feeding of 0.40 (95% CI: 0.35–0.44). Seven of these studies provided adjusted ORs, and on the basis of these studies, the pooled adjusted OR remained statistically significant at 0.55 (95% CI: 0.44–0.69) (Fig 9).[245] The protective effect of breastfeeding increased with exclusivity, with a univariable summary OR of 0.27 (95% CI: 0.24–0.31) for exclusive breastfeeding of any duration.[245]

Currently in the United States, 73% of mothers initiate breastfeeding, and 42% and 21% are still breastfeeding at 6 and 12 months, respectively.[246] Non-Hispanic black mothers are least likely to initiate or to still be breastfeeding at 6 and 12 months (54%, 27%, and 12%, respectively), whereas Asian/Pacific Islander mothers initiate and continue breastfeeding more than other groups (81%, 52%, and 30%, respectively). Rates for initiating and continuing breastfeeding at 6 and 12 months for non-Hispanic white mothers are 74%, 43%, and 21%; rates for Hispanic mothers are 80%, 45%, and 24%; and rates for American Indian/Alaskan Native mothers are 70%, 37%, and 19%, respectively.

Physiologic sleep studies have found that breastfed infants are more easily aroused from sleep than their formula-fed counterparts.[247,248] In addition, breastfeeding results in a decreased incidence of diarrhea, upper and lower respiratory infections, and other infectious diseases[249] that are associated with an increased vulnerability to SIDS and provides overall immune system benefits from maternal antibodies and micronutrients in human milk.[250,251] Exclusive breastfeeding for 6 months has been found to be more protective against infectious diseases compared with exclusive breastfeeding to 4 months of age and partial breastfeeding thereafter.[249]

If a Breastfeeding Mother Brings the Infant Into the Adult Bed for Nursing, the Infant Should Be Returned to a Separate Sleep Surface When the Mother Is Ready for Sleep

Several organizations promote the practice of mother-infant bed-sharing (ie, sleeping in the same bed) as a way of facilitating breastfeeding.[142,252,253] Breastfeeding is a common reason given by mothers for bed-sharing with their infants.[254] Studies have found an association between bed-sharing and longer duration of breastfeeding, but their data cannot determine a temporal relationship (ie, it is not known whether bed-sharing promotes breastfeeding or if breastfeeding promotes bed-sharing, or if women who prefer 1 practice are also likely to prefer the other).[255] Although bed-sharing may facilitate breastfeeding, it is not essential for successful breastfeeding.[256,257] Furthermore, 1 case-control study found that the risk of SIDS while bed-sharing was similar regardless of breastfeeding status, which indicates that the benefits of breastfeeding do not outweigh the increased risk associated with bed-sharing.[258]

PACIFIER USE

Consider Offering a Pacifier at Nap Time And Bedtime

Several studies[62,66,167,231,259–262] have found a protective effect of pacifiers on the incidence of SIDS, particularly when used at the time of last sleep. Two meta-analyses revealed that pacifier use decreased the risk of SIDS by 50% to 60% (summary adjusted OR: 0.39 [95% CI: 0.31–0.50][263]; summary unadjusted OR: 0.48 [95% CI: 0.43–0.54][264]). Two later studies not included in these meta-analyses reported equivalent or even larger protective associations.[265,266] The mechanism for this apparent strong protective effect is still unclear, but lowered arousal thresholds, favorable modification of autonomic control during sleep, and maintaining airway patency during sleep have been proposed.[247,267–270] It is common for the pacifier to fall from the mouth soon after the infant falls asleep; even so, the protective effect persists throughout that sleep period.[247,271] Two studies have shown that pacifier use is most protective when used for all sleep periods.[169,266] However, these studies also

showed increased risk of SIDS when the pacifier was usually used but not used the last time the infant was placed for sleep; the significance of these findings is yet unclear.

Although some SIDS experts and policy-makers endorse pacifier use recommendations that are similar to those of the AAP,[272,273] concerns about possible deleterious effects of pacifier use have prevented others from making a recommendation for pacifier use as a risk reduction strategy.[274] Although several observational studies[275–277] have found a correlation between pacifiers and reduced breastfeeding duration, the results of well-designed randomized clinical trials indicated that pacifiers do not seem to cause shortened breastfeeding duration for term and preterm infants.[278,279] The authors of 1 study reported a small deleterious effect of early pacifier introduction (2–5 days after birth) on exclusive breastfeeding at 1 month of age and on overall breastfeeding duration (defined as any breastfeeding), but early pacifier use did not adversely affect exclusive breastfeeding duration. In addition, there was no effect on breastfeeding duration when the pacifier was introduced at 1 month of age.[280] A more recent systematic review found that the highest level of evidence (ie, from clinical trials) does not support an adverse relationship between pacifier use and breastfeeding duration or exclusivity.[281] The association between shortened duration of breastfeeding and pacifier use in observational studies likely reflects a number of complex factors such as breastfeeding difficulties or intent to wean.[281] A large multicenter, randomized controlled trial of 1021 mothers who were highly motivated to breastfeed were assigned to 2 groups: mothers advised to offer a pacifier after 15 days and mothers advised not to offer a pacifier. At 3 months, there were no differences in breastfeeding rates between the 2 groups; 85.8% of infants in the offer-pacifier group were exclusively breastfeeding compared with 86.2% in the not-offered group.[282] The AAP policy statement on breastfeeding and the use of human milk includes a recommendation that pacifiers can be used during breastfeeding, but implementation should be delayed until breastfeeding is well established.[283]

Some dental malocclusions have been found more commonly among pacifier users than nonusers, but the differences generally disappeared after pacifier cessation.[284] In its policy statement on oral habits, the American Academy of Pediatric Dentistry states that nonnutritive sucking behaviors (ie, fingers or pacifiers) are considered normal for infants and young children and that, in general, sucking habits in children to the age of 3 years are unlikely to cause any long-term problems.[285] There is an approximate 1.2- to 2-fold increased risk of otitis media associated with pacifier use, particularly between 2 and 3 years of age.[286,287] The incidence of otitis media is generally lower in the first year of life, especially the first 6 months, when the risk of SIDS is the highest.[288–293] However, pacifier use, once established, may persist beyond 6 months, thus increasing the risk of otitis media. Gastrointestinal infections and oral colonization with *Candida* species were also found to be more common among pacifier users than nonusers.[289–291]

The literature on infant digit-sucking and SIDS is extremely limited. Only 1 case-control study from the Netherlands has reported results.[262] This study did not find an association between usual digit-sucking (reported as "thumb-sucking") and SIDS risk (OR: 1.38 [95% CI: 0.35–1.51]), but the wide CI suggests that there was insufficient power to detect a significant association.

OVERHEATING, FANS, AND ROOM VENTILATION

Avoid Overheating and Head Covering in Infants

There is clear evidence that the risk of SIDS is associated with the amount of clothing or blankets on an infant and the room temperature.[182,218,294,295] Infants who sleep in the prone position have a higher risk of overheating than do supine sleeping infants.[182] It is unclear whether the relationship to overheating is an independent factor or merely a reflection of the increased risk of SIDS and suffocation with blankets and other potentially asphyxiating objects in the sleeping environment. Head covering during sleep is of particular concern. In a recent systematic review, the pooled mean prevalence of head covering among SIDS victims was 24.6% compared with 3.2% among control infants.[154] It is not known whether the risk associated with head covering is attributable to overheating, hypoxia, or rebreathing.

There has been some suggestion that room ventilation may be important. One study found that bedroom heating, compared with no bedroom heating, increases SIDS risk (OR: 4.5),[235] and another study has also demonstrated a decreased risk of SIDS in a well-ventilated bedroom (windows and doors open) (OR: 0.4).[296] In 1 study, the use of a fan seemed to reduce the risk of SIDS (adjusted OR: 0.28 [95% CI: 0.10–0.77]).[297] However, because of the possibility of recall bias, the small sample size of controls using fans ($n = 36$), a lack of detail about the location and types of fans used, and the weak link to a mechanism, this study's results should be interpreted with caution. On the basis of available data, the task force cannot make a recommendation on the use

of a fan as a SIDS risk-reduction strategy.

SWADDLING

Although Swaddling May Be Used as a Strategy to Calm the Infant and Encourage Use of Supine Position, There Is Not Enough Evidence to Recommend It as a Strategy for Reducing the Risk of SIDS

Many cultures and newborn nurseries have traditionally used swaddling, or wrapping the infant in a light blanket, as a strategy to soothe infants and, in some cases, encourage sleep in the supine position. Swaddling, when done correctly, can be an effective technique to help calm infants and promote sleep.[298] Some have argued that swaddling can alter certain risk factors for SIDS, thus reducing the risk of SIDS. For instance, it has been suggested that the physical restraint associated with swaddling may prevent infants placed supine from rolling to the prone position.[299] One study's results suggested a decrease in SIDS rate with swaddling if the infant was supine,[182] but it was notable that there was an increased risk of SIDS if the infant was swaddled and placed in the prone position.[182] Although a recent study found a 31-fold increase in SIDS risk with swaddling, the analysis was not stratified according to sleep position.[171] Although it may be more likely that parents will initially place a swaddled infant supine, this protective effect may be offset by the 12-fold increased risk of SIDS if the infant is either placed or rolls to the prone position when swaddled.[182,300] Moreover, there is no evidence that swaddling reduces bed-sharing or use of unsafe sleep surfaces, promotes breastfeeding, or reduces maternal cigarette smoking.

There is some evidence that swaddling might cause detrimental physiologic consequences. For example, it can cause an increase in respiratory rate,[301] and tight swaddling can reduce the infant's functional residual lung capacity.[299,302,303] Tight swaddling can also exacerbate hip dysplasia if the hips are kept in extension and adduction.[304–307] This is particularly important, because some have advocated that the calming effects of swaddling are related to the "tightness" of the swaddling. In contrast, "loose" or incorrectly applied swaddling could result in head covering and, in some cases, strangulation if the blankets become loose in the bed. Swaddling may also possibly increase the risk of overheating in some situations, especially when the head is covered or the infant has an infection.[308,309] However, a recent study found no increase in abdominal skin temperature when infants were swaddled in a light cotton blanket from the shoulders down.[302]

Impaired arousal has often been postulated as a mechanism that contributes to SIDS, and several studies have investigated the relationship between swaddling, arousal, and sleep patterns in infants. Physiologic studies have demonstrated that, in general, swaddling decreases startling,[301] increases sleep duration, and decreases spontaneous awakenings.[310] Swaddling also decreases arousability (ie, increases cortical arousal thresholds) to a nasal pulsatile air-jet stimulus, especially in infants who are easily arousable when not swaddled but less so in infants who have high arousal thresholds when not swaddled.[301] One study found decreased arousability in infants at 3 months of age who were not usually swaddled and then were swaddled but found no effect on arousability in routinely swaddled infants.[301] In contrast, another group of investigators showed decreased arousal thresholds[310] and increases in autonomic (subcortical) responses[311] to an auditory stimulus when swaddled. Thus, although swaddling clearly promotes sleep and decreases the number of awakenings, the effects on arousability to an external stimulus remain unclear. There is accumulating evidence, however, that there are only minimal effects of routine swaddling on arousal. In addition, there have been no studies investigating the effects of swaddling on arousal to more relevant stimuli such as hypoxia or hypercapnia.

In summary, it is recognized that swaddling is one of many child care practices that can be used to calm infants and promote sleep. However, there is insufficient evidence to recommend routine swaddling as a strategy for reducing the incidence of SIDS. Moreover, as many have advocated, swaddling must be correctly applied to avoid possible hazards such as hip dysplasia, head covering, and strangulation. It is important to note that swaddling does not reduce the necessity to follow recommended safe sleep practices.

IMMUNIZATIONS AND SIDS

Infants Should Be Immunized in Accordance With Recommendations of the AAP and Centers for Disease Control and Prevention

The incidence of SIDS peaks at a time when infants are receiving numerous immunizations. Case reports of a cluster of deaths shortly after immunization with diphtheria-tetanus-pertussis in the late 1970s created concern of a possible causal relationship between vaccinations and SIDS.[312–315] Case-control studies were performed to evaluate this temporal association. Four of the 6 studies found no relationship between diphtheria-tetanus-pertussis vaccination and subsequent SIDS,[316–319] and results of the other 2 studies suggested a temporal relationship but only in specific subgroup anal-

ysis.[320,321] In 2003, the Institute of Medicine of the National Academy of Sciences reviewed available data and concluded that "[t]he evidence favors rejection of a causal relationship between exposure to multiple vaccinations and SIDS."[322] Additional subsequent large population case-control trials consistently have found vaccines to be protective against SIDS[323–325]; however, confounding factors (social, maternal, birth, and infant medical history) might account for this protective effect.[326] It also has been theorized that the decreased SIDS rate immediately after vaccination was attributable to infants being healthier at time of immunization, or "the healthy vaccinee effect."[327] Recent illness would both place infants at higher risk of SIDS and make them more likely to have immunizations deferred.[328]

Recent studies have attempted to control for confounding by social, maternal, birth, and infant medical history.[323,325,328] In a meta-analysis, Vennemann et al[328] found a multivariate summary OR for immunizations and SIDS to be 0.54 (95% CI: 0.39–0.76), which indicates that the risk of SIDS is halved by immunization. The evidence continues to show no causal relationship between immunizations and SIDS and suggests that vaccination may have a protective effect against SIDS.

HOME MONITORS, SIDS, AND APPARENT LIFE-THREATENING EVENTS

There Is no Evidence That Apparent Life-Threatening Events Are Precursors to SIDS, and Infant Home Monitors Should Not Be Used as a Strategy for Preventing SIDS

For many years it was believed that apparent life-threatening events were the predecessors of SIDS, and home apnea monitors were used as a strategy for preventing SIDS.[329] However, there is no evidence that home monitors are effective for this purpose.[330–333] The task force concurs with the AAP Committee on Fetus and Newborn, which has recommended that infant home monitoring not be used as a strategy to prevent SIDS, although it can be useful for some infants who have had an apparent life-threatening event.[334]

POTENTIAL TOXICANTS AND SIDS

There Is no Evidence Linking Various Toxicants to SIDS

Many theories link various toxicants and SIDS. Currently, no studies have substantiated a causal relationship between metals, such as silver, cadmium, cobalt, lead, or mercury, and SIDS.[335–337] Although an ecological study found correlation of the maximal recorded nitrate levels of drinking water with local SIDS rates in Sweden,[338] no case-control study has demonstrated a relationship between nitrates in drinking water and SIDS. Furthermore, an expert group in the United Kingdom analyzed data pertaining to a hypothesis that SIDS is related to toxic gases, such as antimony, phosphorus, or arsenic, being released from mattresses[339,340] and found the toxic-gas hypothesis to be unsubstantiated.[341] Finally, 2 case-control studies found that wrapping mattresses in plastic to reduce toxic gas emission did not protect against SIDS.[191,342]

HEARING SCREENS

Newborn Hearing Screens Should Not Be Used as a Screening Test for SIDS

A single, small, retrospective case-control study examined the use of newborn transient evoked otoacoustic emission hearing screening tests as a tool for identifying infants at subsequent risk of SIDS.[343] Infants who subsequently died from SIDS did not fail their hearing tests but, compared with controls, showed a decreased signal-to-noise ratio score in the right ear only (at frequencies of 2000, 3000, and 4000 Hz). Methodologic concerns have been raised about the validity of the study methods used in this study,[344,345] and these results have not been substantiated by others. A larger but non–peer-reviewed report of hearing screening data in Michigan revealed no relationship between hearing screening test results and SIDS cases.[346] Until additional data are available, hearing screening should not be considered as a valid screening tool for determining which infants might be at subsequent risk of SIDS. Furthermore, an increased risk of SIDS should not be inferred from an abnormal hearing screen result.

EDUCATIONAL INTERVENTIONS

Educational and Intervention Campaigns Are Often Effective in Altering Practice

Intervention campaigns for SIDS have been extremely effective, especially with regard to avoidance of prone positioning.[347] Furthermore, there is evidence that primary care–based educational interventions, particularly those that address caregiver concerns and misconceptions about safe sleep recommendations, can be effective in altering practice. For instance, addressing concerns about infant comfort, choking, and aspiration while the infant is sleeping prone is helpful.[348,349] Similar interventions for improving behavior of medical and nursing staff and child care providers have shown that these professionals have similar concerns about the supine sleep position.[350–353] Primary care providers should be encouraged to develop quality improvement initiatives to improve

adherence with safe sleep recommendations among their patients.

MEDIA MESSAGES

Media and Manufacturers Should Follow Safe Sleep Guidelines in Their Messaging and Advertising

A recent study found that, in magazines targeted toward childbearing women, more than one-third of pictures of sleeping infants and two-thirds of pictures of infant sleep environments portrayed unsafe sleep positions and sleep environments.[354] Media exposures (including movie, television, magazines, newspapers, and Web sites), manufacturer advertisements, and store displays affect individual behavior by influencing beliefs and attitudes. Frequent exposure to health-related media messages can affect individual health decisions,[355,356] and media messages have been quite influential in decisions regarding sleep position.[77,80] Media and advertising messages contrary to safe sleep recommendations may create misinformation about safe sleep practices. Safe sleep messages should be reviewed, revised, and reissued at least every 5 years to address the next generation of new parents and products on the market.

RECOMMENDATIONS

The AAP's recommendations for a safe infant sleeping environment to reduce the risk of both SIDS and other sleep-related infant deaths are specified in the accompanying policy statement.[4]

LEAD AUTHOR

Rachel Y. Moon, MD

TASK FORCE ON SUDDEN INFANT DEATH SYNDROME, 2010–2011

Rachel Y. Moon, MD, Chairperson
Robert A. Darnall, MD
Michael H. Goodstein, MD
Fern R. Hauck, MD, MS

CONSULTANTS

Marian Willinger, PhD – *Eunice Kennedy Shriver National Institute for Child Health and Human Development*
Carrie K. Shapiro-Mendoza, PhD, MPH – *Centers for Disease Control and Prevention*

STAFF

James Couto, MA

ACKNOWLEDGMENTS

The task force acknowledges the contributions provided by others to the collection and interpretation of data examined in preparation of this report. The task force is particularly grateful for the report submitted by Dr Suad Wanna-Nakamura (CPSC) and for the assistance of Sarah McKinnon, PhD, MPH, and Cristina Rodriguez-Hart, MPH, with the statistics and graphs.

Committee on Injury and Poison Prevention

Skateboard and Scooter Injuries

ABSTRACT. Skateboard-related injuries account for an estimated 50 000 emergency department visits and 1500 hospitalizations among children and adolescents in the United States each year. Nonpowered scooter-related injuries accounted for an estimated 9400 emergency department visits between January and August 2000, and 90% of these patients were children younger than 15 years. Many such injuries can be avoided if children and youth do not ride in traffic, if proper protective gear is worn, and if, in the absence of close adult supervision, skateboards and scooters are not used by children younger than 10 and 8 years, respectively.

ABBREVIATION. CPSC, US Consumer Product Safety Commission.

OVERVIEW

In the past decade, there has been a resurgence in recreational skateboarding, and with it, there has been an increased number of injuries. In 1996, an estimated 5.8 million children and adolescents younger than 18 years in the United States had participated in skateboarding, and an estimated 750 000 had done so at least weekly.[1] During the past 25 years, the annual incidence of skateboard-related injuries peaked at 150 000 in 1977 and subsequently decreased to 16 000 in 1983. This decrease was likely related to decreased skateboard activity. More recently, with increasing popularity of the sport, the number of injured individuals younger than 20 years has increased from an estimated 24 000 in 1994 to approximately 51 000 in 1999.[2] In 1997, 1500 children required hospitalization for an injury sustained while skateboarding, and in most cases, the injury was to the head.

According to the US Consumer Product Safety Commission (CPSC), approximately 90% of all children and adolescents treated for skateboard-related injuries in 1999 were males.[2] The ankle, wrist, and face were the 3 most common areas injured, accounting for 38% of all injuries treated. Only 5% were severe (defined as concussions or internal injuries), whereas moderate injuries (long bone fractures or dislocations) accounted for 31%. Deaths were rare. Of those children injured seriously enough to require hospitalization at a children's hospital or pediatric trauma center, 25% were hit by a motor vehicle.[3]

Nonpowered lightweight scooters have become very popular in just a short time. These are made of lightweight aluminum with small, low-friction wheels similar to those on in-line skates. They weigh less than 10 lb and can be folded to enhance portability. Preliminary data from the CPSC indicate that an estimated 9400 people (94% younger than 15 years) were injured while using nonpowered scooters between January and August 2000. Injury frequency increased considerably during the summer months. Children younger than 8 years accounted for 31% of those injured. Approximately one third of all injuries were fractures or dislocations. Head and face injuries accounted for 29% of all injuries, whereas wrist, elbow, lower arm, and knee injuries together accounted for 34%.

The CPSC recommends that children younger than 8 years not use scooters without close supervision.[4] The CPSC further recommends that all riders use a helmet that meets their standards as well as knee and elbow pads. Children should not ride scooters on streets, at night, or on any surfaces that have water, sand, gravel, or dirt.[5]

Young children may be at high risk of injury from skateboards and scooters because their judgment of their own skills and strength is often poor, as is their ability to judge foot or vehicular traffic. Their center of gravity is higher than that of older children and adults, their neuromuscular system is not well developed, and they are not sufficiently able to protect themselves from injury. For these developmental reasons, children younger than 5 years should not ride skateboards, and those between 6 and 10 years of age should be closely supervised while skateboarding. Children younger than 8 years are at greater risk of scooter injuries than are older children and should not use them.

At the time this policy statement was developed, the increase in use of skateboards and scooters was too new for the effectiveness of these recommendations to be assessed. These preliminary recommendations were based on studies concerning the effectiveness of protective gear for in-line skating and bicycling. More time will need to pass to determine whether the popularity of skateboards and scooters will increase or wane and to assess the effectiveness of recommendations.

The American Academy of Pediatrics recommends the following:

1. Children younger than 10 years[6] should not use skateboards without close supervision by an adult or responsible adolescent. Children younger than 5 years should not use skateboards[7]; instead, parents and pediatricians should encourage them to

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

undertake activities that are more developmentally appropriate.
2. Skateboards must never be ridden in or near traffic, regardless of traffic volume.
3. "Skitching a ride," or holding on to the side or rear of a moving vehicle while riding a skateboard, should never be done. It is particularly dangerous because the rider cannot accommodate a sudden stop or swerve of the vehicle.
4. Pediatricians should advise parents, teachers, and others to strongly recommend that all skateboarders wear a helmet and other protective gear (including wrist guards, elbow pads, and knee pads) to prevent or reduce the severity of injuries resulting from falls.[8] Use of protective clothing, such as gloves, is not sufficient.[9] The helmet should be a bicycle helmet that complies (and is so labeled) with the CPSC standard[10] or a multisport helmet that complies with the N-94 standard established by the Snell Memorial Foundation.[11] The N-94 standard requires that helmets pass multiple impact tests to the back during laboratory testing.
5. Communities should continue to develop skateboarding parks and encourage youth to practice there. These parks are preferred to home-constructed ramps and jumps, because they are more likely to be monitored for safety and separate the skateboarder from pedestrian and motor vehicle traffic. Existing guidelines for such parks should be standardized.[12]
6. Until additional information is available, pediatricians should counsel parents on the use of nonpowered scooters according to the following CPSC recommendations[4]:
   - Children younger than 8 years should not ride scooters without close adult supervision.
   - Children should not ride scooters in streets, in traffic, or at night.
   - Children should wear helmets, knee pads, and elbow pads while using scooters.
7. The Academy strongly emphasizes the need to monitor the amount and nature of nonpowered scooter use and resultant injuries.

Committee on Injury and Poison Prevention

Snowmobiling Hazards

ABSTRACT. Snowmobiles continue to pose a significant risk to children younger than 15 years and adolescents and young adults 15 through 24 years of age. Head injuries remain the leading cause of mortality and serious morbidity, arising largely from snowmobilers colliding, falling, or overturning during operation. Children also were injured while being towed in a variety of conveyances by snowmobiles. No uniform code of state laws governs the use of snowmobiles by children and youth. Because evidence is lacking to support the effectiveness of operator safety certification and because many children and adolescents do not have the required strength and skills to operate a snowmobile safely, the recreational operation of snowmobiles by persons younger than 16 years is not recommended. Snowmobiles should not be used to tow persons on a tube, tire, sled, or saucer. Furthermore, a graduated licensing program is advised for snowmobilers 16 years and older. Both active and passive snowmobile injury prevention strategies are suggested, as well as recommendations for manufacturers to make safer equipment for snowmobilers of all ages.

ABBREVIATIONS. NEISS, National Electronic Injury Surveillance System; CPSC, US Consumer Product Safety Commission; AAP, American Academy of Pediatrics.

The popularity of snowmobiles in the snowbelt has increased[1–3] along with their size and speed. The National Electronic Injury Surveillance System (NEISS) of the US Consumer Product Safety Commission (CPSC) reported that there has been no decline in snowmobile injuries during the past 10 years. The average annual number of snowmobile injuries treated in emergency departments in 1997 and 1998 was more than 10 000. Of these injuries, 10% occurred in children younger than 15 years, and another 25% occurred in adolescents and young adults 15 through 24 years of age. Between January 1992 and December 1997, the Death Certificate Data Files of the CPSC recorded 51 deaths in children younger than 16 years that were directly attributable to snowmobiles. This number is almost certainly an undercount. The CPSC does not routinely acquire death certificates involving collisions with licensed motor vehicles.

For both the number of reported deaths and injuries, males were 3 times more likely than females to be the victims. Head injuries were the leading cause of injury and death.[3–5] Most deaths and serious injuries occurred as a result of the operators striking fixed objects, such as a tree, cable or wire, or another vehicle.[3] Children younger than 16 years were injured or killed when they fell from their snowmobiles, had the vehicle roll over them, or crashed the snowmobile into other snowmobiles, vehicles, or stationary objects (D. Tinsworth, written communication, January 21, 2000). Near-drowning events in children younger than 16 years were infrequent, and only 1 child drowned after encountering thin ice, in contrast to the prominence of drowning as a cause of death for older teenagers and adults.[4,5] Frostbite and hypothermia, recognized hazards,[6,7] were reported infrequently. Other injuries occurred during loading and unloading the snowmobile and when the body of the operator struck different parts of the snowmobile during sudden stops. Burns associated with refueling also have been documented.

More than 50 children in the NEISS sample were injured while being towed when their sled, tube, tire, or saucer overturned, struck an object, or was hit by another vehicle. In general, children younger than 8 years who were injured or killed from incidents involving snowmobiles tended to be passengers on snowmobiles or sleds.

Other problems associated with snowmobile operation that were reported in the literature include hearing loss from prolonged exposure to excess engine noise[8] and white finger syndrome arising from the effects of cold weather and hand/arm vibration from the handlebars of the snowmobiles.[9] Common factors identified in other studies and contributing to snowmobile incidents include operator error, speeding, traveling on inappropriate terrain, nighttime operation, and alcohol use.[1,5,10–12]

Most, but not all, states require that off-road vehicles be registered. Many states require a valid driver's license to operate a snowmobile on public lands or, where permitted, on roads. Some states mandate that children and youth be directly supervised or accompanied by an adult on the snowmobile or have successfully completed an approved snowmobile safety course. Such certification not only allows for children as young as 8 years to ride alone in some states but also permits certificate holders who are 14 years and older to serve as substitutes for adults to supervise inexperienced and noncertified child operators. In some states, there are no age restrictions. A few states have made helmets mandatory for operators younger than 16 years. Snowmobiling on private property is exempt from restrictions.[3]

Evidence is lacking that operator safety certifica-

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

tion courses adequately educate children and youth to operate snowmobiles safely. The influence of sanctioned courses on snowmobile-related injuries to individuals younger than 16 years has not been assessed. In jurisdictions where this option is available, scientifically rigorous evaluations should be performed.

RECOMMENDATIONS

Previous American Academy of Pediatrics (AAP) recommendations[13] have been updated.

Recommendations for children younger than 16 years include the following:

1. Recreational operation of snowmobiles is inappropriate for children and younger adolescents. Children younger than 16 years should not operate snowmobiles. Furthermore, children younger than 6 years do not have the strength or stamina to be transported safely as passengers on snowmobiles. Winter recreational activities for children should be developmentally appropriate.
2. Advertisements that promote snowmobiling should not be directed toward young adolescents, and advertisements should not depict young adolescents driving snowmobiles.

Recommendations for the protection of snowmobilers 16 years and older include the following:

1. Graduated licensing for snowmobile operators is recommended, consistent with the AAP policy on graduated licensing for motor vehicle drivers.[14] Although no direct evidence exists for the effectiveness of graduated licensing on teenage motor vehicle operators of snowmobiles, graduated licensing has been shown to be effective in reducing motor vehicle-related deaths among teenagers. Newly licensed operators should be restricted to snowmobiling during daylight hours on groomed trails only, with zero tolerance for alcohol consumption. To operate a snowmobile safely, persons should acquire a learner's permit by taking a state-sanctioned course.
2. Snowmobilers should travel at safe speeds, especially on unfamiliar or rugged terrain where hazards, such as difficult-to-see barbed wire, may be encountered. A speed-limiting governor, to limit the maximum speed, is suggested for newly licensed operators.
3. Irrespective of age, snowmobilers should avoid the use alcohol or other drugs before or during the operation of a snowmobile. Adults should reinforce this message by setting a good example.
4. Snowmobilers should wear well-insulated protective clothing, including goggles and waterproof snowmobile suits, gloves, and rubber-bottomed boots. All drivers and passengers should wear helmets approved by Snell or another standards organization for use while operating motorized vehicles such as motorcycles and snowmobiles. Operators should carry a first aid kit, a survival kit that includes flares, and if practical, a cellular phone. Snowmobilers should travel in groups of 2 or more and only on designated, marked trails away from roads, waterways, railroads, and pedestrian traffic. The weather forecast should be checked before snowmobiling. Operators should know the signs of hypothermia and regularly check for frostbite.
5. Snowmobilers should avoid snowmobiling on ice if they are uncertain about its thickness or condition. The condition of the trails also should be determined, and where appropriate, avalanche danger should be ascertained.
6. Snowmobilers should not carry more than 1 passenger. Headlights and taillights should be on at all times to improve the visibility of the snowmobile to other vehicle operators.
7. Use of a saucer, tube, tire, sled, or skis to pull someone behind a snowmobile is not recommended. If the need should arise to tow a person, the risk of injury is reduced by using a sled or cutter attached to the snowmobile by a rigid bar connection. The driver should travel at a slow speed over level terrain away from trees, rocks, and other vehicles, and a spotter should be used to watch the individual(s) being towed.
8. Snowmobiles must be well-maintained. Appropriate precautions should be taken by persons when fueling snowmobiles to avoid burns and when loading snowmobiles on and off trailers to prevent strains and crush injuries.

Recommendations for manufacturers include the following:

1. Snowmobile manufacturers should incorporate mechanical enhancements such as seating and handlebar design to improve rider comfort and safety, as well as to reduce hand-arm vibration to minimize white finger syndrome and numbness. Manufacturers should also attenuate sound levels generated by snowmobiles, improve headlight luminance, and add a Global Positioning System device (overhead satellites provide exact current latitudes and longitudes) to all snowmobiles. Manufacturers are urged to improve snowmobile braking, steering, and stability. Emission standards for snowmobiles should be improved.
2. Helmet designs need to be improved to minimize visor fogging and improve hearing protection. Safety standards for snowmobile helmets should be developed, and snowmobile helmets should be formally certified. Helmet manufacturers should consider adding features, such as built-in radio channels for communication and weather monitoring.

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on School Health

Soft Drinks in Schools

ABSTRACT. This statement is intended to inform pediatricians and other health care professionals, parents, superintendents, and school board members about nutritional concerns regarding soft drink consumption in schools. Potential health problems associated with high intake of sweetened drinks are 1) overweight or obesity attributable to additional calories in the diet; 2) displacement of milk consumption, resulting in calcium deficiency with an attendant risk of osteoporosis and fractures; and 3) dental caries and potential enamel erosion. Contracts with school districts for exclusive soft drink rights encourage consumption directly and indirectly. School officials and parents need to become well informed about the health implications of vended drinks in school before making a decision about student access to them. A clearly defined, district-wide policy that restricts the sale of soft drinks will safeguard against health problems as a result of overconsumption.

BACKGROUND AND INFORMATION

Overweight

Overweight is now the most common medical condition of childhood, with the prevalence having doubled over the past 20 years. Nearly 1 of every 3 children is at risk of overweight (defined as body mass index [BMI] between the 85th and 95th percentiles for age and sex), and 1 of every 6 is overweight (defined as BMI at or above the 95th percentile).[1] Complications of the obesity epidemic include high cholesterol, high blood pressure, type 2 diabetes mellitus, coronary plaque formation, and serious psychosocial implications.[2–6] Annually, obesity-related diseases in adults and children account for more than 300 000 deaths and more than $100 billion per year in treatment costs.[7–9]

Soft Drinks and Fruit Drinks

In the United States, children's daily food selections are excessively high in discretionary, or added, fat and sugar.[10–15] This category of fats and sugars accounts for 40% of children's daily energy intake.[10] Soft drink consumers have a higher daily energy intake than nonconsumers at all ages.[16] Sweetened drinks (fruitades, fruit drinks, soft drinks, etc) constitute the primary source of added sugar in the daily diet of children.[17] High-fructose corn syrup, the principle nutrient in sweetened drinks, is not a problem food when consumed in smaller amounts, but each 12-oz serving of a carbonated, sweetened soft drink contains the equivalent of 10 teaspoons of sugar and 150 kcal. Soft drink consumption increased by 300% in 20 years,[12] and serving sizes have increased from 6.5 oz in the 1950s to 12 oz in the 1960s and 20 oz by the late 1990s. Between 56% and 85% of children in school consume at least 1 soft drink daily, with the highest amounts ingested by adolescent males. Of this group, 20% consume 4 or more servings daily.[16]

Each 12-oz sugared soft drink consumed daily has been associated with a 0.18-point increase in a child's BMI and a 60% increase in risk of obesity, associations not found with "diet" (sugar-free) soft drinks.[18] Sugar-free soft drinks constitute only 14% of the adolescent soft drink market.[19] Sweetened drinks are associated with obesity, probably because overconsumption is a particular problem when energy is ingested in liquid form[20] and because these drinks represent energy added to, not displacing, other dietary intake.[21–23] In addition to the caloric load, soft drinks pose a risk of dental caries because of their high sugar content and enamel erosion because of their acidity.[24]

Calcium

Milk consumption decreases as soft drinks become a favorite choice for children, a transition that occurs between the third and eighth grades.[12,15] Milk is the principle source of calcium in the typical American diet.[11] Dairy products contain substantial amounts of several nutrients, including 72% of calcium, 32% of phosphorus, 26% of riboflavin, 22% of vitamin B_{12}, 19% of protein, and 15% of vitamin A in the US food supply.[25] The percent daily value for milk is considered either "good" or "excellent" for 9 essential nutrients depending on age and gender. Intake of protein and micronutrients is decreased in diets low in dairy products.[19,26] The resulting diminished calcium intake jeopardizes the accrual of maximal peak bone mass at a critical time in life, adolescence.[27] Nearly 100% of the calcium in the body resides in bone.[27] Nearly 40% of peak bone mass is accumulated during adolescence. Studies suggest that a 5% to 10% deficit in peak bone mass may result in a 50% greater lifetime prevalence of hip fracture,[28] a problem certain to worsen if steps are not taken to improve calcium intake among adolescents.[29]

STATEMENT OF PROBLEM

Soft drinks and fruit drinks are sold in vending machines, in school stores, at school sporting events, and at school fund drives. "Exclusive pouring rights" contracts, in which the school agrees to promote one brand exclusively in exchange for money, are being signed in an increasing number of school districts across the country,[30] often with bonus incentives tied to sales.[31] Although they are a new phenomenon, such contracts already have provided schools with more than $200 million in unrestricted revenue.

Some superintendents, school board members, and principals claim that the financial gain from soft drink contracts is an unquestioned "win" for students, schools, communities, and taxpayers.[31,32] Parents and school authorities generally are uninformed about the potential risk to the health of their children that may be associated with the unrestricted consumption of soft drinks. The decision regarding which foods will be sold in schools more often is made by school district business officers alone rather than with input from local health care professionals.

Subsidized school lunch programs are associated with a high intake of dietary protein, complex carbohydrates, dairy products, fruits, and vegetables.[16] The US Department of Agriculture, which oversees the National School Lunch Program, is concerned that foods with high sugar content (especially foods of minimal nutritional value, such as soft drinks) are displacing nutrients within the school lunch program, and there is evidence to support this.[26]

There are precedents for using optimal nutrition standards to create a model district-wide school nutrition policy,[33] but this is not yet a routine practice in most states. The discussion engendered by the creation of such a policy would be an important first step in establishing an ideal nutritional environment for students.

RECOMMENDATIONS

1. Pediatricians should work to eliminate sweetened drinks in schools. This entails educating school authorities, patients, and patients' parents about the health ramifications of soft drink consumption. Offerings such as real fruit and vegetable juices, water, and low-fat white or flavored milk provide students at all grade levels with healthful alternatives. Pediatricians should emphasize the notion that every school in every district shares a responsibility for the nutritional health of its student body.
2. Pediatricians should advocate for the creation of a school nutrition advisory council comprising parents, community and school officials, food service representatives, physicians, school nurses, dietitians, dentists, and other health care professionals. This group could be one component of a school district's health advisory council. Pediatricians should ensure that the health and nutritional interests of students form the foundation of nutritional policies in schools.
3. School districts should invite public discussion before making any decision to create a vended food or drink contract.
4. If a school district already has a soft drink contract in place, it should be tempered such that it does not promote overconsumption by students.
   - Soft drinks should not be sold as part of or in competition with the school lunch program, as stated in regulations of the US Department of Agriculture.[34]
   - Vending machines should not be placed within the cafeteria space where lunch is sold. Their location in the school should be chosen by the school district, not the vending company.
   - Vending machines with foods of minimal nutritional value, including soft drinks, should be turned off during lunch hours and ideally during school hours.
   - Vended soft drinks and fruit-flavored drinks should be eliminated in all elementary schools.
   - Incentives based on the amount of soft drinks sold per student should not be included as part of exclusive contracts.
   - Within the contract, the number of machines vending sweetened drinks should be limited. Schools should insist that the alternative beverages listed in recommendation 1 be provided in preference over sweetened drinks in school vending machines.
   - Schools should preferentially vend drinks that are sugar-free or low in sugar to lessen the risk of overweight.
5. Consumption or advertising of sweetened soft drinks within the classroom should be eliminated.

CLINICAL REPORT

Special Requirements of Electronic Health Record Systems in Pediatrics

Guidance for the Clinician in Rendering Pediatric Care

S. Andrew Spooner, MD, MS, and the Council on Clinical Information Technology

ABSTRACT

Some functions of an electronic health record system are much more important in providing pediatric care than in adult care. Pediatricians commonly complain about the absence of these "pediatric functions" when they are not available in electronic health record systems. To stimulate electronic health record system vendors to recognize and incorporate pediatric functionality into pediatric electronic health record systems, this clinical report reviews the major functions of importance to child health care providers. Also reviewed are important but less critical functions, any of which might be of major importance in a particular clinical context. The major areas described here are immunization management, growth tracking, medication dosing, data norms, and privacy in special pediatric populations. The American Academy of Pediatrics believes that if the functions described in this document are supported in all electronic health record systems, these systems will be more useful for patients of all ages.

INTRODUCTION

Child health care providers often find that clinical information systems have limited usefulness in pediatrics,[1,2] because they seem to be designed for adult care. For the purposes of this report, we use the definition of the electronic health record (EHR) system proposed by the Institute of Medicine:

> "An EHR system includes (1) longitudinal collection of electronic health information for and about persons, where health information is defined as information pertaining to the health of an individual or health care provided to an individual; (2) immediate electronic access to person- and population-level information by authorized, and only authorized, users; (3) provision of knowledge and decision-support that enhance the quality, safety, and efficiency of patient care; and (4) support of efficient processes for health care delivery. Critical building blocks of an EHR system are the electronic health records (EHR) maintained by providers. . .and by individuals (also called personal health records)."[3]

The definition proposed by the Institute of Medicine is functional in nature. It assumes that an EHR system must provide these features to be of value. Even for child health care providers, this definition is valid, and this set of features is likely to provide value to most practitioners. However, as has been noted previously,[2] when viewed from the perspective of the child health care provider, these features may fall short either in the details of how they are implemented or by omitting functions that are more routine in pediatric care than in any other primary care practice. This report provides a look at these key functional requirements through the lens of the child health care provider and augments these requirements with

the additional functions that child health care providers use in their daily practice of medicine. This report focuses on the clinical functions of the EHR system operated by the health care provider, as opposed to the more administrative functions in the practice-management system (such as appointment management, insurance eligibility determination, and billing). However, it is assumed that the EHR system in the pediatric setting is fully connected to the practice-management system through an appropriate interface or through software integration of the 2 systems.

PEDIATRIC FUNCTIONS

In 2001, the American Academy of Pediatrics (AAP) published a description of the features that would be desirable in a clinical information system to be used in pediatrics.[2] Almost none of these features were purely pediatric. For example, that statement called for medication dosing by weight and for opportunities to record information about guardianship. There are certainly instances of medication dosing by body weight in adult medicine, and many adults have guardians. Yet, these features are vastly more important in pediatrics, so it is appropriate to refer to them as "pediatric functions." Several of these functions that are of critical importance to pediatric practice are discussed in greater detail here. Others are of less general importance but have been identified as desirable by members of the Pediatrics Data Standards Special Interest Group of Health Level Seven (HL7),[4] an international health data standards development organization in which the AAP participates (www.hl7.org).

CRITICAL PEDIATRIC EHR FUNCTIONAL AREAS

There are some functional areas that are so critical to the care of infants, children, and adolescents that their absence results in the system impeding quality pediatric care.

Immunization Management

Recording Immunization Data

The ability to record multiple immunizations efficiently is critical for pediatric health maintenance activities. State and federal regulations add a complexity to the process of recording immunization administration that is absent for medications. Systems designed to record adult immunizations and other medications naturally allow the practitioner to record data such as the manufacturer, lot number, date, site, route of administration, and expiration date. The nature of immunization practices in children adds some requirements to this list, in particular, data required by the Vaccines for Children (VFC) program[5] and the National Childhood Vaccine Injury Act (NCVIA) of 1986 (42 USC §§300aa-1–300aa-34).[6,7] The VFC program, a federal program by which eligible children are provided vaccine at no charge, requires providers to maintain a separate stock of vaccine, to assess eligibility for the program, and to submit reports to the program. All of these activities require support from the information system used to track immunization data. The NCVIA has numerous implications for immunization data recording. Among these is the requirement to deliver to the parent (or equivalent health decision-maker) a vaccine information statement (VIS) and to record when it was given and which version of the VIS was given. The NCVIA also mandates that health care providers report adverse events associated with vaccines; although this applies equally to adult providers, automation of this reporting capability would be of particular interest to child health care providers, who give the bulk of vaccines. The Centers for Disease Control and Prevention's National Immunization Program (www.cdc.gov/nip) specifies these information-management requirements in detail. EHR systems also need to manage the record of consent for vaccine administration. Vaccine refusal[8] by a parent or patient requires the recording of refusal reasons and recording of which refused vaccines were offered.

Linking to Immunization Information Systems

Most states and several local jurisdictions have electronic immunization-information systems or registries.[9–11] The EHR should allow interoperability with these systems, including the ability to download, upload, and synchronize a child's immunization history. Some technical standards already exist for immunization information system functions and communications with them.[12,13]

Immunization Decision Support

Systems for encoding rules about which immunizations are due and when they are projected to be due in the future have been in existence for years.[14] For an EHR system to fully support pediatric practice, it must be able to take previous immunization data and derive, at the point of care, logical conclusions about the currency of immunization and recommend the appropriate immunizations. This functionality requires an understanding of the individual antigens present in each vaccine and analysis of when, in what form, and at what age in the child's life each antigen was—or was supposed to be—administered. There may also be local variations in this functionality based on local epidemiology. These functions might be built into the system or be derived from immunization registries or third-party programs accessed via a network. If the logic is built into the EHR system itself, there should be a way to easily update the logic to reflect changes to immunization rules and to handle new vaccines and new antigen combinations.

Growth Tracking

Graphical Representation

Child health care providers make important judgments about a child's health by visual inspection of a plot of a child's body measurements (usually weight, height, head circumference, BMI) over time. Plots show the progression of measured values over time against curves of predicted growth or percentile curves. Ideally, the visual plot should be visible at the top level of an individual record or require minimal effort for viewing. The EHR system should allow the representation of percentile curves from a usual source (Centers for Disease Control and Prevention [www.cdc.gov/growthcharts]) or other sources that may provide these curves for special populations.[15] The system should allow magnification ("zooming") of the plot to allow inspection of areas of the plot in which measurements have been frequently made. Users ought to be able to derive growth-velocity data from 2 selected data points. The system should distinguish height from length. Also, the system should accommodate corrections for preterm birth in the graphical display of body measurements.

Percentile Calculations

In addition to representation of body measurements, the percentile value of any particular body measurement against a defined distribution is desirable. Such percentile values should be calculated and displayed at the time of data entry. Percentile values should also be available for decision-support functions of the EHR system.

Medication Dosing

Dosing by Body Weight

The predominant method for calculating pediatric drug dosages is to compute them on the basis of body weight. When a current body weight is available, the EHR system should be able to incorporate it into the prescribing process and suggest doses on the basis of accepted references. Failing this, the EHR system should make weight visible in all displays associated with drug dosing. When a current body weight is not available, the system should react to this appropriately by requesting its input. For medications that require adjustment of dose as the child's weight increases, the intended dosage per unit of body weight should be recordable and maintained as an aspect of the prescription. Systems should be able to determine if a body weight obtained in the past is too old to be used in decision support (eg, last month's weight would be appropriate for an adolescent but not a neonate). Entries of height, weight, and head circumference should be checked against age-based norms so that users can be warned of possible errors. As in adult care, medication dosing by body surface area or ideal weight should also be available; however, the equations for the estimation of body surface area and ideal body weight in children are different from those in adult care.

Dose-Range Checking

With or without dosing decision support, an EHR system should be able to check drug doses posthoc by using accepted pediatric references and advise the user when no pediatric references exist.

Rounding to Safe and Convenient Doses

Many medications for infants and young children are supplied in liquid form. Because parents and other caregivers must measure a volume of liquid for each dose of medication, child health care providers must compute a volume for each dose, round it to a convenient volume, and spend time educating caregivers on the proper volume to administer. EHR systems that facilitate prescribing should support prescriptions expressed in the volume of drug to be administered and avoid expressing the prescription solely in terms of the mass of the drug.

Age-Based Dosing Decision Support

For the case in which dosing guidelines or formulary benefits vary with age or gestational age,[16] the system should incorporate those data into its decision support.

Dosing for the School Day

Pediatricians must often write prescriptions in which the medication is divided in 2 labeled packages—one for home administration and one for administration during the day at school, child care, or another care setting. EHR systems should provide the capability to generate instructions to the pharmacy to dispense a medication in this way.

Patient Identification

Newborn Identification

Although many EHR systems depend on the use of a government-issued identification number (usually the Social Security number), newborn infants do not receive these numbers for a significant period of time after birth. EHR systems should allow the registration of patients without such identifiers and allow retrieval of information on the basis of any temporary identifiers that may be used.

Prenatal Identifiers

An EHR system that allows storage of prenatal data (eg, from a fetal imaging procedure) should allow the logical connection of these data to the postnatal record once the child's record is established in the system.

Name Changes

Infants undergo name changes because of changes in family structure or the need to change the temporary

name assigned at the birth hospital. Because clinical data are connected to the old names, EHR systems need to support retrieval of data via search on previous names.

Ambiguous Sex

In the case of a child with ambiguous genitalia, an EHR system ought to allow the assignment of sex as unknown and to operate normally until the sex of the patient is assigned.

Norms for Pediatric Data

Numeric Data

Norms for almost all numeric data (such as laboratory results, body measurements, scores on standardized assessments, and vital signs) change as the child grows. For many of these data, norms change continuously with age, so it is insufficient to provide merely a handful of normative ranges. Developers should assume that all numeric data collected in a pediatric context have changing norms over the lifespan and should provide ways of flagging abnormal values at any age. Percentile values and *z* scores (number of SDs from the mean) should be available for those few data for which the distributions are known, such as height, weight, head circumference, and BMI.

Nonnumeric Data

Whenever an EHR system distinguishes normal from abnormal in nonnumeric data (eg, flagging the presence of a physical sign as abnormal), it should consider age in the interpretation of normality. For example, if "unable to feed self" is considered to be a universally abnormal finding in the interpretation of a functional assessment, then the system is not taking the functional capabilities of young children into account.

Complex Normative Relationships

Not all normative data are based solely on age. In the case of blood pressure, normative values are determined by age (to the nearest month), gender, and height percentile.[17] Similarly, peak flow meter norms depend on age, height, and gender.[18] Methods for flagging abnormal values that are based on age alone are insufficient for blood pressure and peak expiratory flow and may be insufficient for other measurements in pediatric patients.

Gestational Age

For neonates, chronologic age (expressed simply as the time since birth) is insufficient for medication-prescribing decision support, normative ranges for laboratory data, normative definitions for physical examination findings, and guideline-application support. Gestational age, chronologic age, and corrected age are each unique and important ways to present age of a neonate[16]; EHR systems need to record each of these expressions for age and allow for their use in decision support.

Privacy

Adolescent Privacy

Laws about age of consent vary from state to state[19] and according to presenting problem.[20–22] Adolescents who present for treatment of mental health disorders, for example, may consent to their treatment at an earlier age than the age of majority in most states.[19,23] Some states also have laws regarding parental notification whereby interpretation is based on the patient's age and presenting problem.[24] Practices that serve adolescents typically have policies with respect to what portion of an adolescent's care should be handled with special privacy protections (eg, in some jurisdictions, the adolescent must give explicit permission for the parent to review his or her records). These privacy protections may require the flagging of protected information. Therefore, EHR systems should support privacy policies that vary by age and according to presenting problem and diagnosis and be flexible enough to handle the policies of individual practices. Furthermore, if an EHR system handles record-keeping for consent for treatment, it should provide for the recording of assent for treatment (from an underaged adolescent or child) combined with parental informed permission[25,26] as well as consent for treatment (from an adolescent) combined with a record of parental involvement.[25] The separation of the patient's consent and the parent's or guardian's consent is particularly important in the area of testing for drugs of abuse.[27] Pregnancy is another area in which the records of patient and parental consent, assent, and permission may be less straightforward than in adult care.[28]

Children in Foster or Custodial Care

When a child is removed from the care of his or her parents, as in the case of foster care, complex issues of confidentiality of medical information arise.[29] Licensed foster parents may consent to routine medical and dental treatment for minors placed with them pursuant to a court order or with the voluntary consent of the person having the legal custody of the minor. The pediatrician should document the authority of a foster parent to give consent to medical treatment by obtaining a copy of the court order. Parents who no longer have custody may still have the right to access their children's medical records and be involved with health care decisions unless their parental rights have been terminated. EHR systems that purport to manage consent for treatment and information access will need to be able to record these details.

Consent by Proxy

Children often present for nonurgent health care in the company of an adult who is not the custodial parent or

guardian. The best way to prevent confusion about consent for care in this situation is to record the custodial parents' wishes as to which adult can consent to which child's care and under what limitations.[30] EHR systems that manage consent for treatment should support this sort of data-recording.

Adoption

Records of children who are undergoing adoption proceedings or who have been adopted may need special privacy handling, as in a case where state law offers special protections for the identity of adoptees. The EHR systems should allow flagging of these data for special privacy protection. In some states, the preadoption record may need to be separated entirely from any postadoption record by using 2 distinct patient identities.

Guardianship

The identity of a child's guardian and guarantor, although most commonly the parent, can become complicated outside the bounds of the "typical" 2-parent household. The EHR system must provide the flexibility to indicate the broad variety of adults in the child's life who may play some role in medical or financial decision-making. The system should draw a distinction between the patient's guardian and his or her financial guarantor. In those cases in which a court has appointed a guardian for a minor, the ability of the guardian to consent to medical treatment depends on the type of treatment being sought and the scope of authority the court has granted. If more than routine care is required, the pediatrician should document the authority of the guardian to give consent by obtaining a copy of the official certified letters of guardianship. The EHR system should support this record-keeping.

Emergency Treatment

When EHR systems support the recording of consent and assent for treatment, they should be flexible enough to allow for the emergency treatment of minors, in which the parent or legal guardian may be absent, and the usual procedures for consent must change.[20]

PEDIATRIC TERMINOLOGY

Some of the barriers that child health care providers encounter in the application of EHR systems relate not to functions of the system but to the inappropriate terminology used to express concepts (eg, physical examination findings, developmental milestones, diagnoses) in the EHR system's user interface. These terminology systems differ from systems such as the *International Classification of Diseases, 9th Edition, Clinical Modification*,[31] which is used to encode diagnoses for insurance claims. Rather, these terminology systems are used to allow the precise encoding of clinical concepts by the user in lieu of free text.[32] EHR systems generally use a terminology developed by a third party or by the EHR system developers themselves. A complete treatment of special terminology requirements is outside the scope of this report. The AAP and its members should advocate for the inclusion in these systems of historical findings, psychosocial risk factors, family structural details, social history, physical examination findings, developmental problems, behavioral issues, congenital syndromes, and diagnoses of particular importance to pediatrics. The US government's Consolidated Health Informatics Initiative,[33] which specifies which terminology system should be used in which clinical domain within government-sponsored health-information systems, should help focus the advocacy effort of the AAP. It is important to note, however, that no health-information system directly managed by the US federal government deals primarily with children.

DATA PRECISION

There is a broad category of functionality that may limit an EHR system's usefulness in pediatric practice: the ability to handle data at an appropriate numeric precision and graphical resolution. For example, body weight to the nearest gram is commonly accepted as an appropriate precision in neonatal facilities. As another example, an EHR system may present growth curves of height, weight, and head circumference, complete with appropriate normative curves for comparison. However, if those curves are available in only 1 graphical resolution, measurements obtained frequently (daily weight measurements, weekly head circumference measurements, etc) may become impossible to analyze visually. Age in the newborn nursery should be expressed in units at least down to the hour, if not to the minute. The units for age (days, weeks, months, years) need to grow with the age of the child, as appropriate. Developers of EHR systems should consider how the small changes in numeric data that one sees in the care of young patients affect data-recording and display.

OTHER PEDIATRIC FUNCTIONS

This report outlines the major areas of functionality that are relatively more important in pediatric care than in adult care. There are, of course, many other functions that are important, such as the ability to:

- archive and manage patient data for a statutorily defined period of time;
- provide educational materials that are appropriate to both parents and children and at varying reading levels;
- create pedigree diagrams;
- display age at all times throughout the user interface;
- select age-based documentation templates and order sets on the basis of a patient's age;

- indicate whether a guideline applies to a patient on the basis of age; and
- indicate the source of patient data, especially when the source is not the patient or the parent (eg, the school teacher or child care worker).

PEDIATRIC EHR SYSTEM FUNCTIONALITY STANDARDS

HL7 is an organization that was founded in 1987 to set international standards for how health information is exchanged between information systems. It expanded its scope beyond data interchange to include specifications for EHR system functions through its Electronic Health Record Technical Committee. The Electronic Health Record Technical Committee, which was founded in 2001, published its first balloted standard for EHR system functions in 2004.[34] This standard is being used as the basis for the EHR system certification process specified by the federal Office of the National Coordinator for Health Information Technology (created by Executive Order 13335, April 28, 2004, and authorized by Congress [FR Doc No. 05-16446, Filed August 18, 2005]). The purpose of certification is to set a minimum level of functionality that EHR systems will have to meet to qualify for special treatment, such as participation in pay-for-performance programs.[35,36] By contract with the Office of the National Coordinator for Health Information Technology, the Certification Commission for Health Information Technology (CCHIT [www.cchit.org]) is charged with establishing a certification process by which EHR system software may be declared eligible for pay-for-performance incentives designed to promote care facilitated by an information system. The CCHIT has several pediatricians working on its committees to ensure that pediatric functions are incorporated into the certification process. As of this writing, patient-care scenarios of the CCHIT that were designed to test functionality exclude infants. The HL7 Pediatric Data Standards Special Interest Group is working with the HL7 Electronic Health Record Technical Committee to ensure that the pediatric functions mentioned in this statement are included in the HL7 EHR functional model and, therefore, will become a part of EHR system certification processes in the future. The current EHR system functional model may be obtained from the HL7 Web site (www.hl7.org).

THE FUTURE OF THE PEDIATRIC EHR SYSTEM

In the wake of the rapid uptake of EHR systems in the years since the first AAP statement,[37,38] national groups have expressed increased interest in standardizing the features of EHR systems and certifying their functions.[39] Child health care providers want to be sure that pediatric functions, terminology, and data precision are built into these standards and certification processes. They want this not only to make their own systems more effective in improving the health of children but also to make all EHR systems more useful for patients of all ages. The AAP is working proactively to ensure that knowledgeable pediatricians who can thoroughly explain child health care issues are invited to address the groups that set these standards. This report should serve as a guide for these efforts to represent the interests of child health care providers and present a guide to individual practitioners who are evaluating a given system's ability to perform in the pediatric environment.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Spectrum of Noninfectious Health Effects From Molds

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Environmental Health

ABSTRACT

Molds are eukaryotic (possessing a true nucleus) nonphotosynthetic organisms that flourish both indoors and outdoors. For humans, the link between mold exposure and asthma exacerbations, allergic rhinitis, infections, and toxicities from ingestion of mycotoxin-contaminated foods are well known. However, the cause-and-effect relationship between inhalational exposure to mold and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) requires additional investigation. Pediatricians play an important role in the education of families about mold, its adverse health effects, exposure prevention, and remediation procedures.

BACKGROUND

Outdoors, fungi break down organic matter such as fallen leaves and dead trees and are ecologically beneficial. The most common outdoor molds are *Cladosporium* species, *Aspergillus* species, *Penicillium* species, *Alternaria* species, *Candida* species, *Botrytis* species, and *Helminthosporium* species. The most prevalent indoor molds in nonproblem homes are *Cladosporium* species, *Penicillium* species, *Alternaria* species, *Streptomyces* species, *Epicoccum* species, and *Aspergillus* species.[1] Indoors, molds usually are not a problem unless the spores encounter persistently humid or wet areas, at which point colonies begin to grow. Household areas such as air conditioners, basements, bathrooms, crawl spaces, pillows, refrigerator seals, sinks, shower grout, windowsills, and other places where standing water occurs are potential problem areas. Leaks in roofs, water-damaged walls, potted plants, or even pet urine can contribute to mold growth. Carpeting, ceilings, paneled or hollow walls, and wicker or straw baskets are other potential reservoirs if moisture accumulates.

Exposures to mold vary, reflecting regional differences, local climate (humidity and wind), home construction, use of varying heating and cooling systems, humidifiers, dehumidifiers, and air-filtering devices. Outdoor factors such as shade, organic debris near the home, and landscape maintenance also influence indoor mold concentrations. Air filters and dust control can decrease airborne concentrations of molds in the indoor environment.

Molds have the potential to cause a variety of adverse health effects. They affect health by both immune- and non–immune-related mechanisms. Immunologically, molds produce allergens that may lead to immunoglobulin E–mediated responses such as allergic rhinitis/conjunctivitis and asthma. Less common responses include allergic bronchopulmonary aspergillosis, allergic fungal sinusitis, and hypersensitivity pneumonitis. Nonimmune effects include infection, irritation

of mucous membranes, and reactions from toxins (mycotoxins). When mycotoxin-producing molds contaminate food products, the ingested mycotoxins can adversely affect specific target organs including the central nervous system, the gastrointestinal tract, and the kidneys. Certain mycotoxins have also been associated with hepatocellular carcinoma in persons infected with hepatitis B virus. Serious health problems from mold ingestion are very rare and tend to occur mainly in the agricultural setting.

Inhaled mycotoxins have been linked with acute idiopathic pulmonary hemorrhage (AIPH) in infants. The first report suggesting a relationship between AIPH and the mold *Stachybotrys* species came from Cleveland, Ohio, in the 1990s.[2] The Institute of Medicine (IOM) conducted a comprehensive review of the literature on the adverse health effects of mold.[3] The authors concluded that there was insufficient evidence to determine if mold exposure to *Stachybotrys* species was associated with AIPH in part because of problems with data collection and lack of available, standardized tools for exposure assessment. The IOM recommended further surveillance and additional research. Although the causal association between AIPH in infants has not been firmly established, the Cleveland study, additional case series, case reports from independent sources, and basic scientific studies in animal models have provided some evidence of plausibility. Epidemiologic studies suggest that exposure to secondhand cigarette smoke may be an additional risk factor. Ongoing work in toxicology and epidemiology will provide further insight into these issues in the future. The Centers for Disease Control and Prevention (CDC) is continuing surveillance for AIPH in metropolitan areas in states with the highest prevalence. Several systematic reviews are available,[3–5] and the accompanying technical report[6] (available online) describes mold-related clinical effects in more detail.

In addition to the adverse health effects associated with exposures to mold, there are health risks associated with living in damp indoor environments.[7–11] These risks include respiratory symptoms such as wheezing, coughing, and hay fever. The IOM study found sufficient evidence of an association between mold and other agents in damp indoor environments and upper and lower respiratory tract symptoms, as well as asthma symptoms in sensitized persons. However, there was insufficient information to determine if mold exposure was associated with the development of asthma. Similarly, no conclusions could be drawn for an association with neuropsychiatric symptoms, skin rashes, or rheumatologic illnesses.

PREVENTION/REMEDIATION

Mold spores are ubiquitous in the environment, and it is impossible to keep mold spores completely out of the house. The challenge is to keep the spores from colonizing and growing. Therefore, the key to mold control is moisture control. The aforementioned water-prone household areas should be kept as dry as possible. Actions that will help reduce indoor air humidity and prevent condensation include venting appliances that produce moisture (clothes dryers and stoves) to the outside and using a bathroom fan or opening a window when showering or bathing. When there is inadequate bathroom ventilation, using a towel to wipe shower walls and using a fan or space heater for a short period of time may diminish excessive moisture accumulation. Dehumidifiers can be used to reduce humidity to a target level of less than 50%. Bathrooms and basements should be left uncarpeted. Organic materials kept indoors, such as plants, wood, or paper products, can accumulate excess moisture and can serve as potential reservoirs of mold growth. Because outdoor molds are easily tracked inside, leaves should be discarded. Parents should be aware that playing on or near piles of leaves exposes their children to increased levels of mold spores. This increased exposure could contribute to increased symptoms among children with asthma/allergies. Condensation on pipes and ductwork within interior and exterior structure walls are other potential problem areas. Insulating cold water pipes and increasing the air temperature may help.

Remediation of water-damaged items from previous flooding or rainwater is needed to prevent mold amplification and its potential effects of upper respiratory irritation, allergic sensitization, and/or exacerbation of underlying mold allergy; remediation will also reduce the risk of structural damage to the building. Timely (within 24 hours) water cleanup and removal of water-damaged items after a flood are important.

Currently, there is insufficient information to reliably state what levels of mold exposure can result in adverse health effects and to specify what levels constitute a "dampness problem." Additional research is needed in this area to find a dose-response relationship that can help predict what the adverse health consequences of mold are. Environmental sampling may be useful to identify the source if there is a suspicion of mold (eg, musty odor) but no visible mold growth. It may also be necessary for diagnosis and treatment of mold-related illnesses, insurance purposes, or litigation. Consultation with pediatric experts in pulmonary medicine, allergy/immunology, environmental health, or physicians with expertise in occupational environmental health may be helpful in the interpretation of such environmental data.

If environmental sampling for mold is done, it should be performed by professionals, such as industrial hygienists or indoor environmental quality consultants, who have expertise in evaluating indoor mold/dampness problems. Although no formal certification process for mold evaluation exists, guidelines are available.[12–14]

Reliable air sampling can be expensive and requires

expertise and specialized equipment. If air sampling is conducted, an outdoor air sample should be collected at the same time for comparison. In general, the levels and types of molds should be similar indoors (in nonproblem buildings) and outdoors. Higher indoor concentrations of mold, a predominance of one type, or a difference in types of molds found indoors versus outdoors suggest an indoor mold problem.

Assays to detect mycotoxins and microbial volatile organic compounds in environmental samples and blood have been developed and can serve as important tools for researchers studying pathogenesis of disease. However, the tests, including immunoassays for mold, have not been standardized for clinical use, and it is not clear what levels are associated with health effects.[15]

The US Environmental Protection Agency (EPA) and the CDC offer practical guidelines for mold control and cleanup in the home setting (available at www.cdc.gov/health/mold.html or by calling 800-438-4318). According to current EPA guidelines, individuals can usually clean up mold-contaminated areas less than 10 ft.[2] If there has been extensive water damage, mold growth covers more than 10 ft,[2] the heating, ventilating, and air conditioning (HVAC) system is involved, or the water and/or mold damage was caused by sewage or flood water, consider hiring a professional and consulting the EPA guide "Mold Remediation in Schools and Commercial Buildings."[16]

Mold abatement can be difficult, and use of biocides, such as sodium hypochlorite (eg, household bleach), is controversial. Some experts believe that bleach merely decolorizes mold and that dead mold is still allergenic. However, recent evidence suggests that there is loss of skin-test reactivity to the treated mold in some sensitized individuals.[17] The CDC recommends removal of mold growth from hard surfaces with commercial products, soap and water, or a bleach solution of 1 cup of bleach to 1 gallon of water.[18] This approach is recommended for use on nonporous materials such as tile floors, countertops, metal objects, plastic, glass, and other hard nonabsorbent materials. Concrete and brick surfaces may also be cleaned this way. In general, mold may be difficult to remove from porous materials such as carpet, drywall, or wood products, and bleach (and other cleaning products) may affect the structural integrity of the material. With extensive water and mold damage, porous materials are best discarded. When deciding to use bleach for mold remediation, its accessibility and affordability must also be taken into account. If bleach is used, it should not be combined with ammonia or other household cleaning products, and the area should be well ventilated during use. Guidelines are also available from the CDC (1600 Clifton Rd, Atlanta, GA 30333 or online at the aforementioned Web address). More detailed information on mold cleanup after flooding is also available.[19]

HUMIDIFIERS

Many parents use cool mist humidifiers or vaporizers when children have colds or when the air is dry in winter. These devices, if not properly cleaned, can serve as reservoirs for mold growth. In addition, increased humidity can contribute to increased dust mite populations and mold in the indoor environment. A systematic review in the *Cochrane Database of Systematic Reviews* assessed the effects of inhaling heated water vapor in the treatment of the common cold by comparing symptoms, viral shedding, and nasal resistance after a naturally or experimentally induced common cold.[20] Three of the 6 identified trials showed slight benefit on the symptoms of the common cold; however, neither viral shedding nor viral titers decreased. Therefore, the benefit in symptoms must be balanced with the risk of increased growth and exposure to house dust mites and mold with increased humidity. If used, they should be used for a limited period of time, and they must be cleaned frequently to prevent mold growth and according to the manufacturers' instructions.

AIR CLEANERS

People with allergies and asthma may use air cleaners to decrease concentrations of mold spores in the air. Different air-filtration systems are available that remove particles (including mold spores) from the air, including electrostatic filters/precipitators, and high-efficiency particulate air (HEPA) filters.[21] Certain air cleaners, often called "air purifiers," emit large amounts of ozone and should be avoided. These ozone generators, often advertised as purifiers that cleanse the air of microbes, can produce high concentrations of ozone in an indoor environment, and the EPA and other regulatory agencies have cautioned against their use.[22,23] Filters on central forced-air systems and furnaces should be changed periodically according to the manufacturers' recommendations. Upgrading to a medium-efficiency filter (rated at 20%–50% efficiency at removing particles between 0.3 and 10 μm) will improve air quality and is economical. Electrostatic filters/precipitators in central furnace and air conditioning systems may be beneficial for airborne particles but are only effective when turned on. Room HEPA filters are also beneficial. However, they only work in a single room, and the noise generated may not be acceptable.

RECOMMENDATIONS TO PEDIATRICIANS

1. Because there are established health hazards, inquire about the presence of mold as part of a "healthy-home" inventory. Questions about a child's environment are basic to a comprehensive pediatric health history.[24] Questions can be incorporated during visits for health supervision or sick visits. Asking about a child's environment should be routine for children

with common illnesses, such as allergic rhinitis/conjunctivitis and asthma, as well as for those with less common illnesses, such as hypersensitivity pneumonitis.

2. Provide guidance to parents of all children about:
   a. the adverse health effects of mold exposure, especially the causal relationship between mold and allergic illness and respiratory symptoms; and
   b. preventing and reducing mold exposure in the immediate indoor and outdoor environments.
3. Educate families on mold remediation. Visible signs of mold growth (eg, discolored patches or cottony or speckled growth on walls or furniture, evidence of dampness or water damage or an earthy musty odor in a particular area) suggest a damp environment and mold growth. In areas where flooding has occurred, prompt cleaning (within 24 hours) of walls and other flood-damaged items is necessary to prevent mold growth. Testing the environment for specific molds is usually not necessary. In general, individuals can perform mold cleanup for areas less than 10 ft.[2]
4. When treating an infant with AIPH, inquire about mold and water damage in the home. Report cases of AIPH to state health departments. Although a causal relationship between AIPH and damp, moldy indoor environments has not been firmly established, the knowledge is incomplete at this time. Therefore, it is prudent to recommend that parents of infants with AIPH try to find and eliminate sources of chronic moisture and mold growth before the child returns to the home. Avoidance of exposure to secondhand cigarette smoke is always recommended, but especially in cases of AIPH.
5. Be aware that there are no uniformly accepted, valid, quantitative environmental sampling methods or serologic tests to assess exposures to mold and other agents associated with damp indoor environments. There are also no accepted valid airborne levels of mold that predict adverse health effects.
6. Be aware that there is currently no method to test humans for toxigenic mold exposure.[25]
7. Be aware that mold-contaminated foods (especially grains) can contain harmful amounts of mycotoxins. The US Department of Agriculture has set allowable limits in certain food items and has some routine monitoring in place to prevent harmful ingestion of mycotoxin-contaminated foods. Inquire about dietary history if a mycotoxin-induced illness is suspected.

RECOMMENDATIONS TO GOVERNMENT

1. Support research to determine the effects of molds on human health, such as:
   a. ongoing surveillance of the prevalence of AIPH in infants; and
   b. longitudinal studies on the effects of indoor mold exposure in early childhood on the development of asthma and other respiratory illnesses.
2. Support research to improve methods for quantitative assessment of exposures to indoor molds for use in further epidemiologic studies. Promote research in investigating links between exposures to indoor molds and adverse health effects.
3. Support research to determine fungal biological markers in diagnostic tests.
4. Recommend that remediation of water damage in homes and other buildings be performed promptly. Educate landlords and individuals responsible for building maintenance that damp buildings are unhealthy. They should not wait for medical complaints before starting remediation.
5. Routinely test and publish toxin limits in food and beverages.
6. The CDC, EPA, and building-management–related government agencies should continue to develop and promote education and training programs to improve efforts to avoid or reduce dampness and dampness-related health risks. Targeted programs should be developed for the general public, health professionals, and people involved in design, construction, management, and building maintenance.
7. Outdoor air mold and pollen concentrations should be monitored more extensively and added to the Air Quality Index (http://airnow.gov). The government should encourage and support programs such as the National Allergy Bureau, which monitors and reports outdoor mold and pollen counts (www.aaaai.org/nab).
8. Promote lay public education programs that properly inform US citizens about what the proven and, more importantly, unproven health effects of mold exposure are.

TECHNICAL REPORT

Spectrum of Noninfectious Health Effects From Molds

Lynnette J. Mazur, MD, MPH, Janice Kim, MD, PhD, MPH, the Committee on Environmental Health

ABSTRACT

Molds are multicellular fungi that are ubiquitous in outdoor and indoor environments. For humans, they are both beneficial (for the production of antimicrobial agents, chemotherapeutic agents, and vitamins) and detrimental. Exposure to mold can occur through inhalation, ingestion, and touching moldy surfaces. Adverse health effects may occur through allergic, infectious, irritant, or toxic processes. The cause-and-effect relationship between mold exposure and allergic and infectious illnesses is well known. Exposures to toxins via the gastrointestinal tract also are well described. However, the cause-and-effect relationship between inhalational exposure to mold toxins and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) is controversial and requires additional investigation. In this report we examine evidence of fungal-related illnesses and the unique aspects of mold exposure to children. Mold-remediation procedures are also discussed.

doi:10.1542/peds.2006-2829

Key Words
mold exposure, health effects, allergies, hypersensitivity pneumonitis, mycotoxins, hemosiderosis, water damage, remediation, prevention

Abbreviations
Ig—immunoglobulin
ABPA—allergic bronchopulmonary aspergillosis
AFS—allergic fungal sinusitis
RAST—radioallergosorbent test
OR—odds ratio
CT—computed tomography
CF—cystic fibrosis
VOC—volatile organic compound
MVOC—microbial volatile organic compound
FAO—Food and Agriculture Organization of the United Nations
WHO—World Health Organization
DON—4-deoxynivalenol
CFU—colony-forming unit(s)
CI—confidence interval
CDC—Centers for Disease Control and Prevention
AIPH—acute idiopathic pulmonary hemorrhage
IOM—Institute of Medicine
SBS—sick building syndrome
EPA—Environmental Protection Agency

BACKGROUND

Neither plant nor animal, fungi are a group of eukaryotic (possessing a true nucleus) nonphotosynthetic microorganisms. The almost 100 000 recognized fungal species include mildews, molds, mushrooms, puffballs, rusts, slime molds, smuts, truffles, and yeast. Molds are multicellular fungi that grow as a mass of branching, interlacing filaments (hyphae) known as a mycelium. Although the terms mold and fungi are commonly interchanged, all molds are fungi but not all fungi are molds.

Outdoors, fungi break down organic matter such as fallen leaves and dead trees and are ecologically beneficial. Indoors, molds usually are not a problem unless the spores encounter persistently humid or wet areas, and then colonies begin to grow. Mold flourishes in many household areas such as air conditioners, basements, bathrooms, crawl spaces, ground floors, refrigerator seals, sinks, shower grout, windowsills, and other places where standing water occurs. Leaks in roofs, water-damaged walls, damp basements, plant pots, or even pet urine contribute to mold growth. Carpeting, ceilings, paneled or hollow walls, pillows, and wicker or straw baskets may serve as reservoirs for mold proliferation if there is moisture accumulation.

Exposure to mold varies, reflecting regional differences; the effect of the local climate (humidity and wind); home construction; and use of varying heating and cooling, humidifying, dehumidifying devices, and air-filtering devices. Outdoor factors such as shade, organic debris near the home, and landscape maintenance also influence indoor concentrations. Indoor characteristics such as electrostatic

filters and dust control are associated with lower levels of mold-spore isolation. Because typical urban residents spend more than 90% of their time indoors, there is potential for exposure to mold when homes are contaminated.[1]

The most common outdoor molds are *Cladosporium* species, *Aspergillus* species, *Penicillium* species, *Alternaria* species, *Candida* species, *Botrytis* species, and *Helminthosporium* species. The most prevalent indoor molds in nonproblem homes are *Cladosporium* species, *Penicillium* species, *Alternaria* species, *Streptomyces* species, *Epicoccum* species, and *Aspergillus* species.[2]

In children and adults, molds have the potential to adversely affect health by both immune- and non–immune-related mechanisms (Table 1). The cell walls of fungi are formed of chitin (acetylglucosamine polymers), β-1(1–3)-D-glucans, polysaccharides and mucopolysaccharides, waxes, and pigments. The glucans are endotoxin-like substances that may be irritating and stimulate the immune system. During growth, fungi produce and release new enzymes and secondary metabolites that can be allergenic (eg, enzymes), irritating (eg, volatile metabolites), or toxic for other forms of life (eg, mycotoxins and antimicrobial agents).

Immunologically, molds produce allergens that may lead to sneezing, runny nose, red eyes, and other manifestations. Nonimmune effects include irritation of mucous membranes, infection, and reactions from toxic (mycotoxins) or microbial (endotoxins) byproducts. The scope of toxin-mediated effects is controversial and is being widely studied and debated in medical, scientific, insurance, and legal circles.

The purpose of this technical report is to describe mold-related clinical illness in children and to summarize the evidence of health effects in damp, moldy environments. Assessment of exposures to mold and prevention strategies will be presented. The infectious complications of fungi are beyond the scope of this article.

IMMUNE-MEDIATED HEALTH EFFECTS OF MOLD EXPOSURE

Type I reactions are mediated by immunoglobulin (Ig) E and are the basis of most allergic reactions, including immune responses, to mold exposure. The main types of IgE-mediated responses are allergic rhinitis/conjunctivitis and asthma. Other less common immune-mediated responses are allergic bronchopulmonary aspergillosis (ABPA), allergic fungal sinusitis (AFS), and hypersensitivity pneumonitis.

TABLE 1 **Noninfectious Health Effects Associated With Exposure to Molds**

Immune
Allergic rhinitis/conjunctivitis
Asthma
Hypersensitivity pneumonitis
ABPA
AFS
Nonimmune
Irritant symptoms
Inhalation fever (humidifier fever, organic dust toxic syndrome)
AIPH in infants
Toxin-mediated diseases (primarily associated with ingestions of nuts or grains contaminated with toxigenic molds)

Allergic Rhinitis

In the pediatric population, as many as 10% of children and 20% to 30% of adolescents have allergic rhinitis, and the prevalence is increasing.[3] The most common adverse health effect associated with mold exposure is allergic rhinitis. Fungi belonging to the group Deuteromycotina (*Fungi imperfecti*), particularly *Alternaria* species and *Cladosporium species*, are the most commonly studied. The second National Health and Nutrition Examination Survey noted that the most prevalent fungal IgE antibody was for *Alternaria* species (7%).[4] Studies suggest that the fungal cell wall component β-D-glucan may play a role in altering the host immune response to antigens leading to development of a T-helper type 2 or proallergenic-type response (interleukins 4 and 5, which preferentially enhance IgE synthesis and eosinophil differentiation) in the host.[5] Mold exposure is a strong irritant factor and worsens symptoms of any preexisting allergic disease in the same manner as other specific irritants such as tobacco smoke, ozone, or cold air.

The Joint Task Force on Practice Parameters in Allergy, Asthma, and Immunology has published guidelines for the diagnosis and treatment of allergic rhinitis.[6] The principal symptoms of allergic rhinitis are sneezing, rhinorrhea, and/or nasal blockage. The diagnosis requires the correlation of symptoms with a history of exposure to an allergen and in vitro demonstration of IgE antibodies by allergy skin tests or a radioallergosorbent test (RAST) for specific IgE antibodies in blood. However, the sensitivity and specificity of skin testing with mold antigens is poor. Commercially available fungal extracts are mixtures of soluble materials from spores, mycelia, cellular metabolites, and cytoplasm. Therefore, the panel of fungal allergen extracts available to clinicians may not accurately reflect the true mold-exposure profile in most indoor environments. Furthermore, cross-reactivity between different fungal extracts clearly exists, but to what extent is not known. Determination of mold-specific IgE antibodies (RAST, enzyme-linked immunosorbent assay) is costly. RASTs and related tests have lower sensitivity as well.

Asthma

The National Asthma Education Program's expert panel report defines asthma as "a lung disease with the following characteristics: 1) airway obstruction that is reversible; 2) airway inflammation; and 3) increased airway responsiveness to a variety of stimuli."[7] The panel states that the prevalence of asthma is approximately 10% in

the pediatric population and that it continues to increase. Asthma and allergic rhinitis frequently coexist, and there is evidence of a connection between allergic rhinitis and asthma. A cohort study of college freshmen with and without allergic rhinitis showed that allergic rhinitis almost tripled the risk (10.5% vs 3.6%) for the development of new asthma over the 20-year follow-up period.[8] The National Health and Nutritional Examination Survey report showed that when a skin-test result was positive for *Alternaria* species, the odds ratio (OR) of having asthma was 5.[4]

There is increasing evidence that fungi are an important environmental trigger for asthma exacerbations. High levels of basidiospores in the environment have been associated with asthma exacerbations in New Orleans, Louisiana.[9] Positive bronchial challenges in individuals with positive skin-test results have been noted with *Alternaria* species, *Basidiomycetes* species, *Cladosporium* species, *Penicillium* species, and others.[10,11] A case-control study investigated 11 young patients with asthma who experienced respiratory arrest (2 fatal cases) in seasons when high levels of *Alternaria* spores are present. Of the 11 patients, 10 had positive *Alternaria* skin-test results, compared with 31% of the controls, suggesting that *Alternaria* exposure was a risk factor for respiratory arrest.[12] Epidemiologic studies also suggest an association between dampness and mold in homes and asthma symptoms[13–17]; this association will be discussed further in "Health Risks Associated With Damp Indoor Environments."

In addition to airborne fungi, certain skin organisms (dermatophytes) can cause sensitization and antigen exposure in some patients with asthma. One study reported patients with asthma, chronic fungal skin infection, and immediate hypersensitivity to *Trichophyton* species. Patients demonstrated both upper and lower airway sensitization to dermatophyte antigens after bronchial and nasal challenge.[18] The diagnosis and treatment of asthma are well described in the National Asthma Education Program's expert panel report.[7]

Hypersensitivity Pneumonitis

Hypersensitivity pneumonitis, or extrinsic allergic alveolitis, is a group of immunologically mediated lung diseases in which the repeated inhalation of certain antigens provokes a hypersensitivity reaction with granulomatous inflammation and fibrosis in the gas-exchanging portion of the lung. Causative agents of hypersensitivity pneumonitis include bacteria (eg, thermophilic actinomycetes), fungi (eg, *Trichosporon cutaneum*), animal proteins (eg, avian), and chemicals (eg, diisocyanates). These antigens are typically less than 3 μm in diameter and are easily inhaled into the distal bronchial tree and alveoli, where they are cleared via the local lymphatic drainage into the hilar nodes, which induces an IgG antibody response. Antibody alone is not sufficient to cause disease; cytotoxic delayed hypersensitivity involving $CD8^+$ cytotoxic lymphocytes is required. A type III reaction is suggested by the presence of precipitating antibody to the offending antigen, immune complex deposition, and activation of the complement cascade, the resulting C5 activates macrophages. A type IV reaction is suggested by an increased percentage of T lymphocytes in bronchoalveolar lavage fluid, with a strong predominance of $CD8^+$ lymphocyte subsets, a low CD4-to-CD8 T-lymphocyte ratio, and the presence of granulomas on lung biopsy. Hypersensitivity pneumonitis must be distinguished from a number of nonallergic, inflammatory reactions such as "inhalation fevers," toxic alveolitis, and organic dust toxic syndrome, which is also associated with the inhalation of high levels of organic dust.

Genetics may play an important role in determining susceptibility to the development of hypersensitivity pneumonitis, because only a small proportion of exposed persons is ultimately affected. Studies have shown an association between HLA types A2 W15 and DQw3 and hypersensitivity pneumonitis.[19,20]

The prevalence of hypersensitivity pneumonitis in children is unknown. In a review of 86 pediatric cases of hypersensitivity pneumonitis, 17% were mold related; the mean age was 10 years, and the youngest patient was 8 months old.[21] Table 2 lists the fungal agents associated with hypersensitivity pneumonitis in childhood.[22]

The 3 stages of hypersensitivity pneumonitis development are acute lymphocytic infiltration, subacute granuloma formation, and chronic fibrosis. Subacute and chronic presentations are more common in children; the acute form is more common in adults.

In the acute form, symptoms of hypersensitivity pneumonitis mimic influenza (fever, myalgias, arthralgias, dyspnea, and cough, occasionally with cyanosis); these symptoms occur a few hours after exposure and resolve in 12 to 24 hours without specific treatment. Physical examination reveals an ill-appearing child with fever, dyspnea, and bibasilar crackles. Chest radiographic findings include poorly defined micronodules found predominantly in the upper and middle lung fields. High-resolution computed tomography (CT) demonstrates ground-glass attenuation of the lung fields.

In the subacute stage of hypersensitivity pneumonitis, there is an insidious onset of exertional dyspnea and fatigue. Cough can occur several days to weeks after exposure. The patient might have a subacute or chronic course, interspersed with acute exacerbations related to intermittent or seasonal exposure to the antigen(s).

The chronic form is characterized by insidious and progressive development of dyspnea and pulmonary fibrosis in a patient who has not experienced acute symptoms. The most common symptoms are exercise intolerance, cough, weight loss, and fever. On physical examination, approximately two thirds of these patients

TABLE 2 **Fungal Agents Associated With Hypersensitivity Pneumonitis**

Agent	Disease	Source
Thermoactinomyces vulgaris	Farmer's lung	Plant mold
Thermoactinomyces sacchari	Bagassosis	Sugarcane residue
Alternaria species	Woodworker's lung	Wood mold
Aspergillus clavatus	Malt worker's lung	Grain mold
Aspergillus species	Tobacco worker's lung	Tobacco mold
	Greenhouse lung	Greenhouse soil
Aureobasidium pullulans	Sequoiosis	Sequoia dust mold
Botrytis cinerea	Winegrower's lung	Grape mold
Candida albicans	Sax lung	Saxophone mouthpiece
Cephalosporium species	Basement lung	Contaminated basement (sewage/mold)
Cladosporium species	Hot-tub lung	Ceiling mold
Cryptostroma corticale	Maple-bark disease	Maple bark mold
	Greenhouse lung	Greenhouse soil
Epicoccum nigrum	Shower-curtain lung	Shower mold
Penicillium casei	Cheese washer's lung	Cheese mold
Penicillium chrysogenum	Woodworker's lung	Wood dust mold
Penicillium frequentans	Suberosis	Cork mold
Penicillium species	Domiciliary pneumonitis	House mold
Pullularia fungus	Sauna taker's disease	Sauna mold
Stachybotrys species	Domiciliary pneumonitis	House mold
Trichosporon cutaneum[a]	Summer-type hypersensitivity pneumonitis	Mold in Japanese homes
Mixed ameba, fungi, and bacteria	Air-conditioner lung	Cold mist and other humidifiers
	Ventilation pneumonitis	

[a] Association with HLA-DQw3.

have crackles and one third have digital clubbing. Chest radiographs show interstitial infiltrates with varying degrees of fibrosis and possible honeycomb appearance. The following criteria are considered essential for the diagnosis:

1. symptoms compatible with hypersensitivity pneumonitis;
2. evidence of exposure to appropriate antigen by history or detection of antibody in serum and/or bronchoalveolar lavage;
3. findings compatible with hypersensitivity pneumonitis on chest radiograph or high-resolution CT;
4. bronchoalveolar lavage lymphocytosis (40%–80%) with a predominance of CD4 (acute) or CD8 (chronic) T lymphocytes (if bronchoalveolar lavage is performed);
5. pulmonary histologic changes compatible with hypersensitivity pneumonitis (if open or video-assisted lung biopsy has been performed); and
6. positive "natural challenge" (reproduction of symptoms and laboratory abnormalities after exposure to the suspected agent).

Minor criteria include bibasilar crackles, decreased diffusing capacity, and arterial hypoxemia.

Confirmation of the diagnosis requires 4 major and 2 minor criteria and the exclusion of other diseases with similar symptoms and signs.[23] Despite the term "hypersensitivity," hypersensitivity pneumonitis is not associated with increased concentrations of IgE or eosinophils in the blood or lung. However, test results for rheumatoid factor are often positive. Treatment consists of antigen avoidance in all cases and steroid therapy in severe cases. There has been 1 case report of resolution of symptoms after installation of filters in an air-conditioning system, which lowered mold-colony counts.[24,25] The overall prognosis for children with hypersensitivity pneumonitis is excellent. In the 67 pediatric cases of hypersensitivity pneumonitis with reported outcomes, 65 children improved or became asymptomatic, 1 patient worsened, and 1 patient died.[21]

Allergic Bronchopulmonary Aspergillosis

ABPA is an immunologically mediated lung disease that occurs primarily in patients with asthma and cystic fibrosis (CF). *Aspergillus fumigatus* represents the most common etiologic agent, but other causative fungi include *Aspergillus flavus*, *Aspergillus niger*, *Aspergillus terreus*, *Candida* species, *Curvularia* species, *Dreschlera* species, and *Penicillium* species. The alveolar deposition rate is highest for agents approximately 3 μm in size, such as *Acremonium* species, *Aspergillus* species, and *Penicillium* species. The fungi are not invasive but rather colonize the respiratory tract. The resultant hypersensitivity reactions are both IgE mediated (type I) and IgG mediated (type III). Estimated prevalences of ABPA range from 0.25% to 0.8% in children with asthma and 7% to 11% in children with CF.[26]

Asthma is usually present 5 to 10 years before the diagnosis, and the presence of atopy (allergic skin-test reactivity and hay fever) increases the risk. The clinical

course is characterized by recurrent acute episodes with intervening remission. Symptoms range from acute recurrent asthma exacerbations with wheeze, cough, and chest radiographic infiltrates to generalized systemic features of fever, anorexia, headache, and malaise. Abnormal sputum production occurs in more than half of patients and is characterized by solid chunks of "dirty-green–" to beige-colored sputum plugs. In addition to recurrent wheezing, long-standing illness may lead to digital clubbing and bronchiectasis. Characteristic radiographic patterns for bronchiectasis include the "gloved finger" and "toothpaste" shadows, air fluid levels from dilated central bronchi, and tramline shadows (edematous bronchial walls).[27,28] CT is the most sensitive tool for the detection of bronchiectasis.[29]

The Rosenberg criteria for ABPA are the most widely used and remain the diagnostic standard:

1. asthma or CF with peripheral blood eosinophilia;
2. immediate cutaneous reactivity to *A fumigatus*;
3. precipitating (IgG) antibodies to *A fumigatus*;
4. elevated serum-specific IgE antibodies to *A fumigatus*;
5. elevated total serum IgE (>500 IU/mL);
6. peripheral blood eosinophilia ($>1.0 \times 10^9$/L);
7. pulmonary infiltrates (or history of) on chest radiographs; or
8. central bronchiectasis.

Not all of the criteria are needed for diagnosis. The first 5 are essential, and having 6 is generally required to confirm the diagnosis. However, continued diagnostic testing may be required for months to years to fulfill all of the criteria. In addition, a positive sputum culture for *A fumigatus* is not essential for the diagnosis, because up to 40% of patients have negative cultures.[30]

Corticosteroids modulate inflammation and immunologic reactivity and are the mainstay of treatment. The use of antifungal agents to decrease the fungal burden arising from colonization remains controversial.[31]

Allergic Fungal Sinusitis

The combination of nasal polyposis, crust formation, and sinus cultures yielding a fungal agent is known as AFS. It is estimated that approximately 5% to 10% of patients with chronic rhinosinusitis have AFS. In a review of 263 cases, 168 yielded positive fungal cultures. Of these, 87% were organisms of dematiaceous genera (*Bipolaris*, *Curvularia*, *Exserohilum*, *Alternaria*, *Drechslera*, *Helminthosporium*, and *Fusarium*); only 13% yielded *Aspergillus*.[32] AFS is similar in pathophysiology to ABPA. First, an atopic host is exposed to fungi through normal nasal respiration, thus providing an initial antigenic stimulus. Type I (IgE)– and type III (immune complex)–mediated reactions then trigger an eosinophilic inflammatory response. The resulting inflammation leads to obstruction of the sinus ostia, which may be accentuated by anatomic factors such as septal deviation or turbinate hypertrophy, resulting in stasis within the sinuses. The end result is an allergic mucin that fills the involved sinuses. The clinical presentation may be dramatic, giving rise to visual loss, facial dysmorphia, or complete nasal obstruction. Alternatively, patients may present with chronic sinusitis and nasal polyposis with a gradual increase in production of nasal crusts. Pain is uncommon. Physical findings may include exophthalmus, facial dysmorphia, or intracranial extension. The production of allergic mucin is characteristic of AFS. Grossly, allergic fungal mucin is thick, tenacious, and highly viscous in consistency; its color may vary from light tan to brown or dark green. This characteristic appearance has lead to the use of such descriptive terms as "peanut butter" and "axle grease." There is no consensus concerning diagnostic criteria for AFS. Medical treatment of AFS requires long-term immunotherapy and/or corticosteroids and fungistatic antimicrobial agents (oral and/or topical). Surgical removal of all fungal mucin is a crucial component.[33]

NON–IMMUNE-MEDIATED HEALTH EFFECTS

Irritation

Volatile organic compounds (VOCs) produced by fungi can provoke symptoms in susceptible individuals in a manner similar to nonmold irritants such as tobacco smoke, formaldehyde, or ozone. Symptoms of exposure to microbial VOCs (MVOCs) can include eye, nose, and throat irritation; headache; and fatigue. MVOCs are low molecular weight alcohols, aldehydes, and ketones. The principal volatile compound produced by many molds is 1-octen-3-ol, which has a characteristic mushroom odor. The MVOC 2-octen-1-ol may account for the musty odor of many molds; geosmin (1,10 dimethyl-9 decalol), produced by *Aspergillus versicolor*, has a characteristic earthy odor. The human nose is very sensitive to mold odors, often more so than current analytical instruments. Animal data indicate that the median lethal dose of many of these compounds is high,[34] but inhalation may provoke acute respiratory responses that range from a feeling of stuffiness to frank wheezing. The effects of prolonged low-level exposure are not known.

Inhalation Fever (Humidifier Fever and Organic Dust Toxic Syndromes)

Inhalation fever (influenza-like, self-limited syndromes including humidifier fever and organic dust toxic syndromes) have been reported in occupational or agricultural settings after acute exposures to high concentrations of microbial agents including bacteria, fungi, and associated microbial byproducts.[35] Humidifier fever is a flu-like illness occurring a few hours after exposure to aerosols generated from forced air-conditioning and hu-

midifier systems. Symptoms include fever, headache, chills, myalgia, and, less prominently, pulmonary symptoms. It usually subsides within 24 hours without residual effects. The high attack rate and the short-term effects may indicate that toxins or endotoxin-like reactions are involved. The onset occurs after intense exposure in a single day, but tachyphylaxis occurs on frequent repeated exposures. Hence, humidifier fever is sometimes called "Monday fever," because symptoms occur only on the first day back to work despite similar antigen exposure throughout the week. The pathogenesis of humidifier fever is not completely understood but has been related to excessive growth of microorganisms in humidifier reservoirs, air conditioners, and aquaria. Microorganisms implicated include amoebas, bacteria, fungi, and parasites.[36]

Similarly, organic dust toxic syndrome is a self-limited inhalation fever syndrome occurring after the inhalation of organic dusts from moldy or damp silage, hay, or other agricultural dusts or contaminated wood chips from mulching. Clinically, fever, chills, cough, minimal dyspnea, chest tightness, myalgias, malaise, nausea, and headache occur 4 to 12 hours after exposure. Symptoms of eye and mucous membrane irritation and dry cough are often reported during the acute exposure. It is postulated that organic dust toxic syndrome results from endotoxin-like reactions to high doses of microbial byproducts.[35]

More severe acute lung injury after exposure to damp and moldy organic materials in an agricultural setting also has been reported. The syndrome of toxin-related acute lung injury includes prominent respiratory symptoms, radiographic infiltrates on chest radiographs, and hypoxemia. In 1 case report, a patient developed acute pulmonary edema, presumably resulting from a severe organic dust toxic syndrome reaction or other toxin-mediated injury caused by fungal byproducts, after exposure to high levels of *Penicillium* species contaminating moldy oranges in a storehouse.[35]

Mycotoxins and Associated Health Effects of Mycotoxin Exposure

The fungi that produce mycotoxins are called "toxigenic fungi." The amount, if any, and type of mycotoxin produced depends on a complex and poorly understood interaction of factors that include (1) species of fungus, (2) genetic pattern of the particular strain of the species, (3) maturity of the colony, (4) available food source, (5) amount of water available, (6) temperature, (7) light amounts and wavelengths, (8) presence or absence of competition, (9) presence or absence of specific gases, (10) presence or absence of essential metals, and (11) other unknown factors. Thus, it does not necessarily follow from the presence of a toxigenic species that mycotoxins are present.

Mycotoxins are primarily found in spores and have been identified in the spores of *Acremonium* species, *Alternaria* species, *Aspergillus* species, *Cladosporium* species, *Cylindrocarpon* species, *Fusarium* species, *Mycothecium* species, *Penicillium* species, *Pithomyces* species, *Stachybotrys* (*S atra*, *S alternans*, or *S chartarum*), and *Trichoderma* species (see Table 3 for mycotoxin-producing molds and their health effects). Routes of exposure include ingestion, inhalation, and skin contact. Because mycotoxin-producing molds are lipid soluble, they are easily absorbed via the airways or through the skin. By convention, the term "mycotoxin" excludes mushroom toxins; therefore, the hallucinogenic toxins such as lysergic acid will not be discussed.

Toxic effects from the ingestion of moldy foods have been known for centuries. Although "St Anthony's fire" was described in the Middle Ages, it was not until the 19th century that the chemicals responsible for ergot poisoning were isolated. The fungus *Claviceps purpurea*

TABLE 3 **Mycotoxin-Producing Molds and Their Health Effects**

Fungus	Mycotoxin	Adverse Health Effect
Alternaria alternate	Tenuazonic acid	Hepatotoxic and nephrotoxic, hemorrhagic
Aspergillus flavus	Aflatoxins	Hepatotoxic, carcinogenic
Aspergillus fumigatus	Fumitremorgens	Tremorgenic
Aspergillus nidulans	Sterigmatocystin	Hepatotoxic, carcinogenic
Aspergillus ochraceus	Ochratoxin A	Hepatotoxic and nephrotoxic, carcinogenic
Cladosporium species	Epicladosporic acid	Immunosuppressive
Fusarium moniliforme	Fumonisins	Neurotoxic, hepatotoxic and nephrotoxic
Fusarium poae	T-2 toxin	Hemorrhagic and immunosuppressive
Fusarium sporotrichioides	Trichothecenes	Causes alimentary tract aleukia (nausea, vomiting)
Penicillium expansum	Patulin	Nephrotoxic and carcinogenic
	Citrinin	
Penicillium griseofulvum	Griseofulvin	Hepatotoxic, carcinogenic, teratogenic
Pithomyces chartarum	Sporidesmin	Hepatotoxic; causes photosensitization, eczema
	Phylloerythrin	
Stachybotrys chartarum	Satratoxins toxins	Immunosuppressive, hematotoxic
	Verrucarins	Inflammatory, immunosuppressive
	Roridins	Causes dermatitis; hematotoxic, hemorrhagic

grows on rye and contains a number of toxic alkaloids (eg, ergotamine and ergonovine), which are used in the treatment of migraine headaches or as uterine stimulants. The epidemic form of ergotamine poisoning attributable to the ingestion of contaminated rye is rarely seen. Ingestion of 1 g of ergot has been fatal; ergotamine has caused gangrene in doses of 10 mg/day. Circulatory changes are attributable both to prolonged vasoconstriction and to intimal hyperplasia and thrombosis. Symptoms of acute or chronic ergotamine poisoning include vomiting, diarrhea, burning abdominal pain, severe muscle pains, ischemic peripheral gangrene, headache, psychotic behavior, muscle tremors, convulsions, and coma. Treatment is based on symptoms and includes the use of vasodilators and analgesic agents.

Because mycotoxins are natural contaminants of food sources, they cannot be totally eliminated before consumption. The following mycotoxins have well-described adverse health effects.[37]

Aflatoxins

Aflatoxins are produced by certain strains of *Aspergillus* species. They were first discovered after an epidemic that killed 100 000 turkeys in the 1960s. The toxin was found in moldy Brazilian peanuts that were included in the feed. Later, these naturally occurring mycotoxins were discovered in barley, corn, other nuts, and wheat. The maximum concentrations of aflatoxins allowed in food are set by the US Food and Drug Administration. The limits for food and milk are 20 and 0.5 parts per billion (ppb), respectively. Levels up to 300 ppb are allowed in feed for livestock and poultry. A recent outbreak of aflatoxin-related jaundice in Kenya resulted from widespread contamination of locally grown maize, which occurred during storage of the maize under damp conditions. Of the 317 cases, the case fatality rate was 39%. The level of toxin in food samples ranged from 20 to 8000 ppb.[38]

Citrinin

Citrinin is found in the *Penicillium* species. It typically contaminates barley, corn, rye, and wheat. Adverse health effects include fatty infiltration and necrosis of the liver and nephrotoxicity. Because this mycotoxin is destroyed by food processing, there are no Food and Drug Administration regulations or guidelines.

Fumonisins

Fumonisins are produced by *Fusarium* species. They are commonly found in corn and are detectable in tortilla flour. They have been implicated in equine leukoencephalomalacia. The mechanism of action involves the inhibition of the sphingolipid synthesis, resulting in disruption of sphingomyelin. In humans, no toxic effects have been described, but there may be an association with the development of esophageal carcinoma. The Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) recommend a maximum tolerable intake at 2 μg/kg of body weight per day.

Ochratoxins

Ochratoxins have been isolated from *Aspergillus* and *Penicillium* species and are found in barley, cocoa, coffee, corn, soybeans, and wheat. They inhibit protein synthesis and produce most of their adverse affects in the gastrointestinal tract and kidneys. The FAO/WHO recommend a tolerable weekly intake of 100 μg/kg. Suggested tolerance levels for infant cereals and foods are 5 and 1 μg/kg, respectively.

Patulin

Patulin is produced by *Aspergillus* and *Penicillium* species and other mold species that grow in fruits such as apples, grapes, and pears. Because it is carcinogenic in animals, there are concerns about the possibility of carcinogenicity in children who drink large amounts of fruit juice, especially apple juice. There is a recommended limit of 50 μg/kg of patulin in apple juice and cider. Sulfur dioxide, a common food preservative for dry foods and juices, degrades the toxin.

Trichothecenes

Trichothecenes are metabolites that are produced by a number of fungi including *Fusarium*, *Mycothecium*, *Stachybotrys*, *Trichoderma*, and *Cephalosporium* species. There are almost 150 natural trichothecenes, of which at least 40 are mycotoxins. They are found in crops and animal feed (particularly hay and straw) contaminated with *Fusarium* species. Levels in the range of 0.5 to 40 mg/kg of T-2 toxin, 4-deoxynivalenol (DON), and nivalenol are detected in corn, peanuts, rice, and wheat. In commercial foods, such as corn, flour, popcorn, potato, wheat flour, breakfast cereals, and infant food, trichothecene levels are much lower, in the range of 0.03 to 0.5 mg/kg.

There are 4 main groups of trichothecenes. Group A includes the highly toxic T-2 toxin and diacetoxyscirpenol. Group B includes DON and nivalenol. Group C is produced by *Baccharis megapotamica* and is the least common. Group D includes roridins produced by *Mycothecium roridum*, verrucarin produced by *Mycothecium verrucaria*, and satratoxins produced by *S chartarum*. Only group D trichothecenes are produced by *S chartarum*. Setting tolerance levels for trichothecenes is difficult because of the mixtures of toxins with different toxicities. The FAO/WHO Joint Expert Committee recommends a provisional maximum tolerable daily intake of 1 μg/kg for DON and 60 μg/kg for T-2 toxin. *S chartarum* has gained recent media attention as the "toxic mold." *S chartarum* is a shiny, black mold that grows only on water-soaked cellulose. It is unusual to find it indoors because of the chronic waterlogged condition necessary

for its growth. Thus, the black mold commonly found on bathroom tile and grout is not *Stachybotrys*. In addition to the trichothecenes, *S chartarum* isolates can produce a number of other mycotoxins (Table 4).

CLINICAL EFFECTS LINKED TO *Stachybotrys* MYCOTOXINS

The first reported cases of stachybotryotoxicosis in humans occurred in the 1940s. Russians who handled contaminated hay or slept on straw-filled mattresses experienced dermatitis, pain and inflammation of the mucous membranes, burning nasal passages, tightness of the chest, bloody rhinitis, cough, fever, headache, and fatigue. Later studies reported similar symptoms in individuals exposed to *S chartarum*.[39,40] A case-control study by Johanning et al[40] was the first investigation of *Stachybotrys*-associated complaints and building-related illness. Comprehensive testing of immunologic indices using a test battery developed by the National Institute for Occupational Safety and Health to detect immunomodulation from exposure to xenobiotics was used to study the red and white blood cell systems, serum chemistry, immune function, and Ig antibodies. Results showed that the workers with direct contact with moldy materials or working in locations with the highest airborne *Stachybotrys* levels (range: 116 to more than 20 000 colony-forming units [CFU]) required temporary or permanent removal because of severely increased symptoms after return to the building with *Stachybotrys* contamination as compared with unexposed controls. Fingertip skin inflammation in 3 women handling moldy horticulture pots made of recycled paper that had visible black masses of *Stachybotrys conidia* as well as *Chaetomium perithecia* and other fungi has been reported. The illness, described as painful, inflamed efflorescences at the fingertips, followed by scaling, was attributed to the effects of a mycotoxin. However, no tests were performed to determine the etiologic agent or the mechanism (allergic or irritant contact dermatitis, toxicity, or infection).[41]

TABLE 4 ***Stachybotrys* Toxins**

Macrocyclic Trichothecenes	Enzymes
3 acetyl-deoxynivalenol	β -Glucanase
Citrinin	1,3-Endoglucanases
DON	Farnesyl-protein transferase
Diacetoxyscirpenol	Sesquiterpenes
Isosatratoxins F, G, S, and H	SMTP-3, SMTP-4, SMTP-5, and SMTP-6
Kampanols	Stachybocins A, B, and C
Nivalenol	Stachybotramide
Phenylspirodrimanes (9)	Stachybotrin C
Roridin A	Staplabin
Satratoxins F, G, and H	Staplabin analogs: SMTP-7 and SMTP-8
T-2 tetraol	Triprenyl phenol metabolites
T-2 toxin	
Verrucarin A	
Verrucarol	
Vomitoxin	

Idiopathic Pulmonary Hemorrhage

The first cluster of idiopathic pulmonary hemorrhage in infants was reported from Greece in the 1980s.[42] Other reported clusters of the illness have been reported throughout the United States, but the first report to implicate *S chartarum* was a community-based case-control study in Cleveland, Ohio.[43] Investigators found an association between exposure to water-damaged buildings and *S chartarum* with acute pulmonary hemorrhage/hemosiderosis in infants. The calculated OR was 16.25 (95% confidence interval [CI]: 2.55 to infinity). Case infants were also more likely to have had close relatives with pulmonary hemorrhage (OR: 33.14; 95% CI: 5.10 to infinity). In addition, 50% of the case infants experienced recurrent pulmonary hemorrhage after returning to their homes.[43] Of note, the OR associated with exposure to cigarette smoke in the cases was 7.9. Also of note was that none of the children had been breastfed. A study by Etzel et al[44] revealed a greater than 4-fold increase in all fungi and a more than 10-fold increase in *S chartarum* concentrations in case homes compared with control homes. The high prevalence of *S chartarum* in the Cleveland cluster-area homes (65%) was unusual; other studies in North America have detected it in less than 3% of homes. Other toxin-producing species were identified, including *A versicolor*, *Penicillium aurantiogriseum*, and *Penicillium chrysogenum*, but the differences between case and control homes for these molds were not significant. To test for interaction with environmental tobacco smoke, a multivariate matched analysis assessed the impact of *S chartarum* concentration and exposure to environmental tobacco smoke, finding an OR of 21 (95% CI: 1.07 to 7.5×10^6), for an increase of 10 U in the mean concentration of *S chartarum* in the presence of environmental tobacco smoke.[44,45] Reexamination of these data years later led the Centers for Disease Control and Prevention (CDC) to conclude that "a possible association between acute pulmonary hemorrhage/hemosiderosis in infants and exposure to molds, specifically, *S chartarum*, was not proven."[46] When 1 outlier case was excluded, the OR dropped from 9.8 to 1.5. Although the OR was lower, it remained significant (OR: 1.5; 95% CI: 1.1 to 2.5). Problems with the data collection (oversampling of air samples from case homes) and nonstandardized methods to generate artificial aerosols for sampling (vacuuming carpets and pounding on furnace ducts and furniture) were noted, leaving the hypothesis unproven. However, additional cases from ongoing surveillance in Cleveland continue to show an association between acute idiopathic pulmonary hemorrhage (AIPH) and water-damaged homes in conjunction with exposure to cigarette smoke.[47] A recent study of toxin production by the fungal isolates in victims' homes was performed. Isolates of *S chartarum* and *Memnoniella echinata* (a fungus closely related to *S chartarum*) were isolated from homes of the case infants and then ana-

lyzed both for cytotoxicity and specific toxins. The most common toxins were satratoxin H and roridin, and the results showed that the levels of cytotoxicity correlated with the levels of these trichothecenes. However, there was no relationship between cytotoxicity and the origin of the isolate (a case home or a control home).[48]

Case reports from other cities have also been published.[49,50] A report from Kansas City, Missouri, described a 1-month-old male with pulmonary hemorrhage.[49] Questioning of the family identified a recent water leak in the home after hail damage to the roof. The leak occurred in a closet of the bedroom where the infant slept. The mother also smoked cigarettes. *Stachybotrys* spores were collected from the infant's bedroom, along with several other mold species. High quantities of several potent trichothecenes were detected. The mycotoxins roridin and satratoxins were also identified. It is hypothesized that these toxins interfere with synthesis of type IV collagen and other endothelial basement membrane components, leading to increased capillary fragility and hemorrhage. It is postulated that infants are particularly sensitive to the effects of the toxins because of their rapid lung growth.[49]

S chartarum was first isolated from a patient in a case report by Elidemir et al.[51] The mold was isolated from bronchoalveolar lavage of a 7-year-old boy with a 2-year history of chronic, nonproductive cough accompanied by intermittent low-grade fever, malaise, fatigue, and decreased appetite. His bronchoalveolar lavage showed 26% hemosiderin-laden macrophages and grew *S chartarum*. *S chartarum* was also recovered from the child's water-damaged farm home. Within a month of relocating to his grandmother's house, his cough resolved, his appetite improved, and his weight increased by 2 kg.

Because the relationship among idiopathic pulmonary hemorrhage, pulmonary hemorrhage, and AIPH in infants is not clearly understood in terms of rate, etiology, and risk factors, the CDC formed a working group for the investigation and surveillance of infants with AIPH.[52] The group recommended a case definition for AIPH in infants and a plan for retrospective surveillance for AIPH in infants. The definition of a case of AIPH in an infant uses the term "pulmonary hemosiderosis" as a pathologic finding to denote the possible occurrence of pulmonary hemorrhage and not to describe a clinical syndrome. CDC criteria for a confirmed case of AIPH include pulmonary hemorrhage in a previously healthy infant younger than 1 year with a gestational age of more than 32 weeks, no history of problems that might cause pulmonary hemorrhage, and a condition that meets all of the following 3 criteria:

1. abrupt or sudden onset of overt bleeding or obvious evidence of blood in the airway, including epistaxis, hemoptysis, or frank blood in the airway below the larynx at visualization, not caused by any medical procedure (eg, laryngoscopy or intubation) or identification of hemosiderin-laden macrophages (>20% of pulmonary macrophages containing hemosiderin on bronchoalveolar lavage or biopsy specimen); a source of bleeding from the nose and oropharynx should be ruled out at the time of admission;
2. severe-appearing illness leading to acute respiratory distress or respiratory failure resulting in hospitalization in a PICU or NICU with intubation and mechanical ventilation; and
3. diffuse unilateral or bilateral pulmonary infiltrates visible on radiographs or CT of the chest; chest radiographic or CT findings should be documented within 48 hours of examination of the infant.

A previously healthy infant should:

1. have been discharged from the hospital after birth with an uneventful course before the occurrence of bronchoalveolar hemorrhage;
2. have neither never been previously intubated nor required respiratory support with oxygen;
3. not have evidence of physical abuse;
4. not have any abnormality identified on admission that would explain the bleeding; and
5. not have neonatal medical problems that can cause pulmonary hemorrhage.

Less stringent criteria define probable and suspected cases.

Currently, the CDC is in the process of a retrospective review for AIPH among infants in metropolitan areas in states with the highest death rates and with 100 or more deaths associated with pulmonary hemorrhage among infants from 1979 to the present.

Experimental animal models of *Stachybotrys* mycotoxicosis in mice are limited. In 1 study, intranasal exposure to spores of *S chartarum* containing satratoxins caused severe intraalveolar, bronchiolar, and interstitial inflammation with hemorrhagic exudation.[53]

The Institute of Medicine (IOM) conducted a comprehensive review of the literature on the adverse health effects of mold and dampness in indoor spaces, including the literature on *Stachybotrys* species and pulmonary hemorrhage.[54] They concluded that there was insufficient evidence to determine if mold exposure to *Stachybotrys* species was associated with AIPH, in part because of problems with data collection and lack of available, standardized tools for exposure assessment. The IOM recommended further surveillance and additional research.

In summary, although the causal association between AIPH in infants has not been firmly established, the Cleveland study, additional case series, case reports from independent sources, and basic scientific studies in ani-

mal models have provided some evidence of plausibility. Epidemiologic studies suggest that exposure to secondhand cigarette smoke may be an additional risk factor. Ongoing work in toxicology and epidemiology will provide more insight in the future.

CLINICAL EFFECTS LINKED TO OTHER MYCOTOXINS

Neurologic Toxicity

Ingestion of 3-nitropropionic acid produced by *Arthrinium* species is thought to cause "moldy sugarcane" or "kodua" poisoning. Symptoms include dystonia, convulsion, carpopedal spasm, and coma.[55] Cyclopiazonic acid produced by *Penicillium* species and *Aspergillus* species has also been linked to kodua poisoning. Clinically, patients have somnolence, tremors, and giddiness.[56] Other fungal components, such as VOCs, may produce neurologic effects. There is no evidence of neurologic injury associated with inhalation of mycotoxins. Patients, their parents, and clinicians have raised concerns regarding potential neurotoxicity from mold exposure, and the scant literature has been reviewed.[57]

Gastrointestinal Toxicity

Mold-contaminated food products are known to cause nausea, vomiting, abdominal pain, and diarrhea when ingested. High concentrations of trichothecenes destroy skin layers and cause acute necrosis. The mucosa of the mouth, esophagus, and intestine can be affected, and necrosis and inflammation can occur.[55,58]

Renal Toxicity

Ochratoxins (found in cereals, coffee, bread, and meat) produced by *Penicillium* species and *Aspergillus* species are associated with Balkan endemic nephropathy.[37]

Teratogenic Effects

Zearalenone produced by *Fusarium* species (F-2 toxin) possesses estrogenic activity and causes infertility and fetal malformations in animal models. Human studies have not been performed.

Cancer

Studies performed in Asia and Africa have shown that chronic consumption of aflatoxins in food increases the risk of developing hepatocellular carcinoma. However, coinfection with hepatitis B virus is an important synergistic factor that affects the carcinogenicity of aflatoxins.[59] There is no evidence linking inhaled mycotoxins to human malignancy.

SICK BUILDING SYNDROME

Sick building syndrome (SBS) was originally defined by the WHO as an excess prevalence of work-related irritations of the skin and mucous membranes and other symptoms reported by workers in modern office buildings.[60] Clinical features typically include eye, nose, and throat problems, dermatitis, drowsiness, difficulty in concentrating, headache, and fatigue. Chemical contaminants, bioaerosols, poor ventilation, odor perception, thermal comfort, and psychological factors have been suggested as causal factors. Some have suggested that the term SBS be abandoned for its lack of clarity. "Nonspecific building-related illness" as a new term has been proposed by some experts. Although individual symptoms of SBS have been associated with damp, moldy environments, the constellation of symptoms together has not been systematically evaluated in epidemiologic studies.

HEALTH RISKS ASSOCIATED WITH DAMP INDOOR ENVIRONMENTS

In the previous sections we have discussed the clinical spectrum of noninfectious health effects associated with exposures to mold; however, the pediatrician may be asked what the scientific evidence is for health risks associated with living in damp indoor environments. In the past 10 to 20 years, numerous epidemiologic studies have reported on health effects attributed to damp or moldy indoor environments or mycotoxins, and these findings were reviewed.[7,13,14,61]

In one of the first epidemiologic studies, Brunekreef et al[62] found associations between self-reported mold exposures and respiratory symptoms (wheeze, cough, hay fever) in a survey of more than 4600 US children (7–11 years of age). After taking into account other home environmental factors such as environmental tobacco smoke, the adjusted OR for wheeze was 1.79 (95% CI: 1.44 to 2.32). A Canadian survey of more than 13 000 children found associations between wheeze and cough and self-reported dampness or mold (adjusted OR: 1.89; 95% CI: 1.61 to 2.20).[15] Among the more recent studies, in a prospective cohort of 849 infants with a family history of asthma, investigators found associations between measures of mold exposure (reported persistent mold or mildew in previous 12 months or air concentrations of *Penicillium* species and humidifier use) and cough and wheezing.[63,64] In a case-control study of 272 children, there was an increased risk of allergic sensitization among those in homes with a high level of mold spores in the winter (as determined by dust collection), even after adjusting for dust mite levels, especially in children who had lived in the same home since birth.[65] Many of the larger studies were cross-sectional surveys, often with self-reported symptoms and exposures, and could be subject to bias. However, an analysis of a subset that used surveyor assessment of a damp environment found associations between respiratory systems (eg, cough and wheeze) and the presence of mold.[13] Taken together, Bornehag et al[13] found that large surveys and smaller case-control studies with more objective surveyor assessments found a consistent increase

in risk of respiratory symptoms among those who lived in a damp environment.

Dampness can be associated with dust mites and bacterial growth. However, associations between "dampness" and health have been found in areas with little dust mite exposure (eg, in northern Scandinavia) or after taking mite exposure into account in the analysis.[13]

Because of increasing public concern regarding health effects of mold spurred, in part, by reports of cases of pulmonary hemorrhage in infants in Cleveland linked to *Stachybotrys* species and a great deal of attention in the mass media, the CDC asked the IOM to conduct a comprehensive review of the scientific literature regarding the relationship between damp or moldy indoor environments and adverse health effects.

The authors of the IOM report (summarized in Table 5) found sufficient evidence of an association between mold and other agents in damp indoor environments and upper and lower respiratory tract symptoms, as well as asthma symptoms in sensitized persons.[54] There was insufficient information to determine if mold exposure was associated with the development of asthma. Similarly, the IOM reported that there was insufficient evidence to determine if mold exposure to *S chartarum* was associated with idiopathic infantile pulmonary hemorrhage because of the limitations of previous epidemiologic studies.[43–46] The IOM report also noted that other conditions reported with a damp indoor environment, including constitutional or neuropsychiatric symptoms, skin rashes, and rheumatologic diseases, were poorly studied, and no conclusions could be drawn.

Although inhalation fevers have been reported in occupational or agricultural settings after acute exposures to high concentrations of fungal agents, it would be very unusual to have concentrations of bioaerosols comparable to those experienced in inhalation/humidifier fever in most homes or public buildings. However, the IOM report noted that physicians should consider the syndrome in cases of highly contaminated indoor environments.[54] As noted previously, although individual symptoms of SBS have been associated with damp moldy environments, the constellation of symptoms together has not been systematically evaluated in epidemiologic studies. The authors of another systematic review of the literature reviewed 13 studies on fungi, mycotoxins, and the indoor environment and also concluded that there is inadequate evidence to support a causal relationship between symptoms or illness among building occupants and exposure to mycotoxins.[66]

Similarly, the American College of Occupational and Environmental Medicine review and policy statement on "Adverse Human Health Effects of Molds in the Indoor Environment" concluded that "current scientific evidence does not support the proposition that human health has been adversely affected by inhaled mycotoxins in the home, school, or office environment."[67]

There are few data assessing the health benefits of decreasing exposure to damp environments. A before-and-after intervention study in the Pacific Northwest examined health-related complaints in 37 building occupants before and after relocation from a water-damaged building.[68] The health survey revealed a high prevalence of multiple symptoms, with a predominance of neurobehavioral (fatigue, headache, and difficulty concentrating) and upper respiratory tract complaints. Public health officials were contacted and conducted a walk-through evaluation of the building. They found evidence of moisture incursion throughout the building. Mold odors were detected, and *S chartarum* was isolated from the baseboard of one of the walls. The authors concluded that the toxigenic mold was likely to be present within all the wet walls of the building and that symptoms reported by building occupants were consistent with toxigenic mold exposure. They strongly recommended that the occupants be relocated. Comparison of symptoms before and after relocation showed that most symptoms were significantly less prevalent after relocation ($P < .0001$). The majority (70%) described their overall health as "better" since relocation, and equal proportions (15%) described their overall health as "same" and "worse." A causal relationship between the symptoms and the toxigenic fungi is difficult to prove because of the study design and the subjective nature of self-reported symptoms.

TABLE 5 Findings of the IOM Report: Association Between Health Outcomes and the Presence of Mold or Other Agents in Damp Indoor Environments

Sufficient evidence of an association
Upper respiratory tract symptoms (nasal and throat)
Wheeze
Cough
Asthma symptoms in sensitized persons
Hypersensitivity pneumonitis in sensitized persons
Limited or suggested evidence of an association
Lower respiratory tract illness (eg, pneumonia, frequent colds) in children
Inadequate or insufficient evidence to determine whether an association exists
Dyspnea
Skin symptoms
Asthma development
Gastrointestinal tract problems
Airflow obstruction (in otherwise healthy persons)
Fatigue
Chronic obstructive pulmonary disease
Neuropsychiatric symptoms
Inhalation fevers (nonoccupational exposures)
Cancer
Lower respiratory illness in otherwise healthy adults
Reproductive effects
AIPH in infants
Rheumatologic and other immune diseases

ASSESSMENT, REMEDIATION, AND PREVENTION

Assessing Exposures to Indoor Mold

The diagnosis of mold-related illness and issues related to exposure as a cause of disease is problematic. Because of our incomplete knowledge of what agents in damp indoor environments (and what amount of exposure) contribute to health effects, there are no uniformly accepted, valid, quantitative environmental sampling methods or serologic tests to assess exposures to mold and other agents associated with damp indoor environments. Because of uncertainties in the exposure assessments used in health studies, federal and state regulatory agencies have not established health-based guidelines for exposure limits for indoor biological agents (ie, what air concentrations of mold spores are unlikely to cause health risk). Sampling cannot be used to check a building's compliance, because no federal mold guidelines exist. In this section, we summarize the available exposure-assessment methods, discuss their limitations, and provide some practical guidelines for the practicing physician. *Guidance for Clinicians on the Recognition and Management of Health Effects of Mold Exposure and Moisture Indoors* provides an excellent discussion of environmental assessment strategies (see "Resource for Pediatricians").

Environmental Assessment and Sampling

Methods for sampling of indoor fungi were recently reviewed and include visual inspection, bulk or surface sampling (eg, culturing pieces of damp or discolored wallboard), and air sampling.[69] Air sampling may include measurement of total spore concentration (number of spores per m^3) or viable (ie, culturable) spore concentration (CFU/m^3). Air fungal capturing devices may have a variation of up to 1000-fold between specimens obtained from the same source. Single samples from either the suspected or control area cannot provide scientifically meaningful conclusions because of the lack of statistical and practical significance. Some texts suggest at least 16 samples over 4 time periods.[70,71]

Burge[70] has suggested some rules of thumb as evidence of mold overgrowth in the indoor environment (although proposed levels are not necessarily associated with symptoms): (1) more than 200 CFU/m^3 of air or 500 spores per m^3*; (2) a CFU count 10 times higher than a noncomplaint environment; (3) CFU counts exceeding those outdoors by order of magnitude (10×); and (4) a single fungus accounting for more than half of the total. However, the criteria proposed by Burge need additional evaluation.

To date, the majority of population-based epidemiologic studies have used questionnaires regarding signs of dampness (eg, visible mold, recent water damage, musty smell, etc) as measures of exposure or inspections with trained investigators, but these methods are difficult to quantify. Recently, studies have begun to quantify exposures to mold with environmental sampling of air or dust for spores or fungal byproducts, including toxins. There is a clear need for establishing consistent methods for quantifying indoor exposures to mold for use in future health studies. Thus, the Environmental Protection Agency (EPA) and other environmental agencies have not set numeric standards for indoor concentrations of mold or mold spores regarding the levels at which adverse health impacts are associated.

Another inherent limitation of the interpretation of environmental sampling is that the sampling is conducted over a limited period (ie, snapshot of potential exposure), and measurements are often made after the development of illness or symptoms. Because production and release of mold spores and mycotoxins vary substantially, depending on physiologic and environmental factors, exposure measurements may not always track with past exposures.

Another complicating fact is that multiple species of molds are usually found in damp indoor environments; for example, exclusive exposure to *Stachybotrys* species is rare. Many fungi known to produce toxins, allergens, and irritant chemical compounds are usually found in large numbers in buildings with water problems and fungal contamination. Thus, attributing causation to one particular mold species from epidemiologic studies alone may be problematic.

Although results of environmental sampling should be interpreted with caution, the clinical and epidemiologic evidence to date suggests that damp, moldy indoor environments are unhealthy, and we outline a practical approach for assessing mold in the indoor environment in Table 6. Additional clinical evaluation tools for the recognition and management of mold and moisture-related illnesses are available (http://oehc.uchc.edu/clinser/indoor.htm).

Should I Test for Mold? What Tests Should I Order?

In clinical practice, extensive documentation of indoor fungal growth may not be necessary, depending on concerns of the occupants. Visible signs of mold growth (eg, discolored patches or cottony or speckled growth on walls or furniture, evidence of dampness or water damage or an earthy musty odor in a particular area) suggest a damp environment and mold growth. If a child with persistent asthma symptoms is sensitized to mold and there is visible mold growth in the home, efforts should be focused on cleanup and addressing the moisture problem to prevent recurrence. Additional documentation of mold exposure with sampling is not necessary.

*Spores per m^3 is the unit of measurement for total spores (both viable and nonviable); CFU/m^3 measures viable spores only. Spores per m^3 is a better indicator of potential mycotoxin exposure, assuming that mold spores contain mycotoxins.

TABLE 6 **Guidelines for Pediatricians Considering Possible Illness Related to Damp, Moldy Indoor Spaces**

When to consider indoor mold-related illness[a]
Chronic respiratory symptoms of unclear etiology
Poorly controlled asthma, perennial allergic rhinitis, or chronic sinusitis
Respiratory symptoms or recurrent influenza-like symptoms in a moldy environment
Suspected or diagnosed hypersensitivity pneumonitis, ABPA, or fungal sinusitis
Unexplained pulmonary hemorrhage, especially in infants
Assessing exposures to molds: helpful questions
Have you seen any mold or mildew on walls, floors, ceilings, or carpets, including your basement (evidence of discolored patches or cottony or speckled growth on walls or furniture)?
Have you noticed a musty or earthy smell indoors?
Has the home been flooded?
Is there any water-damaged wood or cardboard in the house?
Has there been a roof or plumbing leak, standing water in the home or areas with chronic dampness/moisture, including the basement?
Is there often condensation (fog) on the inside of the windows and/or cold inside surfaces?
Have humidifiers or air-conditioner drip pans been checked for mold overgrowth?
Are symptoms better away from the house?
Describe your basement dwellings and conditions at school or other places where you routinely spend time.
Environmental assessment
Work with an experienced industrial hygienist or investigator.
Methods: visual inspection, bulk sampling, and air sampling of visible or culturable fungal spores.
Serologic testing may be helpful in some settings.[a]

[a] Physicians should also consider and rule out other possible non–mold-related etiologies. For symptoms attributable to mycotoxin ingestion, see text.

Environmental inspection and sampling may be useful to identify the source if there is a suspicion of mold (eg, musty odor) but no visible mold growth. In addition, environmental inspection and sampling for mold may be necessary as part of the diagnostic evaluation and treatment plan when certain medical conditions are being considered (eg, hypersensitivity pneumonitis, ABPA, or acute pulmonary hemorrhage in infants). Environmental sampling for mold may also be necessary for insurance purposes or litigation. Consultation with pediatricians who have expertise in pulmonary medicine, allergy/immunology, or environmental health or physicians who have expertise in occupational environmental health may be helpful.

If environmental sampling for mold is done, the study should be performed by professionals, such as industrial hygienists or indoor air-quality consultants, who have expertise in evaluating indoor mold/dampness problems. An industrial hygienist and contractor may work together to identify the moisture problem and conduct sampling. There is currently no formal certification process for mold evaluation; however, guidelines for appropriate evaluation have been outlined.[72,73]

In addition to visual inspection, bulk sampling (culturing materials [eg, wood, particle board suspected of mold contamination]) may be used to document whether materials are contaminated. Surface sampling (cultured swabs of surfaces) may be used to document whether discoloration on surfaces is the result of fungal growth. Reliable air sampling can be expensive and requires expertise and specialized equipment. If air sampling is conducted, an outdoor air sample should be collected at the same time for comparison. In general, the levels and types of fungi found indoors (in nonproblem buildings) should be similar to those found outdoors. Exceptions may occur (eg, when there are extremely low concentrations of mold spores outdoors after a snowfall). Higher concentrations of fungal spores, a predominance of one type of fungal spores, or a difference in types of fungi found in indoor versus outdoor air samples suggest an indoor mold problem.

Other assays to detect fungi, mycotoxins, and MVOCs in environmental samples have been developed. One caveat is that the half-life of the important mycotoxins, such as the trichothecenes, is several hours, and individuals present for medical evaluation long after the acute exposure. Thus, current mycotoxin assays of blood specimens or environmental samples can serve as important tools for researchers studying pathogenesis of disease; however, the tests have not been standardized for clinical use, and it is not clear at which levels health effects are associated.

Laboratory Tests for Human Exposure to Molds or Toxins

Because fungi produce antigenic proteins that can lead to an immunologic response, medical evaluations of people concerned about exposures to mold or fungi may include laboratory testing. Trout et al[74] recently reviewed the role of immunoassay for fungal antibodies in evaluating patients in various clinical settings. The authors concluded that immunoassays are a useful adjunct to a complete evaluation, but in general, the assays

should not be used as the only means of primary assessment. Problems include lack of standardized fungal extracts and cross-reactivity among fungal species. Although the immunoassays are suggestive of exposure to mold or fungi (which are widespread in nature), the current assays cannot specify when the exposure occurred or reliably identify the particular type of mold or fungus involved. Because of these limitations, results of the immunoassays must be interpreted in the context of the clinical setting and other supporting diagnostic tests.

Thus, detection of IgE specific to common outdoor molds by skin testing or serologic testing indicates sensitization and is supportive of fungal allergies or allergy in general. However, a positive test result does not necessarily mean that the agent is the cause of the patient's symptoms. Similarly, detection of antibody by precipitin testing is often used to confirm exposure to a suspected antigen in an evaluation for hypersensitivity pneumonitis. However, asymptomatic farmers and pigeon breeders may have positive precipitin test results.[75] Conversely, some patients with clinically confirmed hypersensitivity pneumonitis will have negative antibody test results, presumably because of poorly standardized antigens, low concentrations of IgG, or incorrect identification of the causative agent.

Currently, no tests can reliably determine if a person was exposed to *S chartarum* mold, its toxins, or other molds commonly found in damp environments. A few physicians have used immunoassays to determine if their patients have been exposed to *S chartarum* mold. However, these immunoassays for *S chartarum* have not been proven to be valid for use in clinical evaluation. For instance, an isotype-specific immunoassay developed for IgE, IgG, and IgA to *S chartarum* is cross-reactive with antibodies to *A fumigatus* and *Alternaria alternata*, 2 common outdoor fungi.[74]

In 1 small study, Barnes et al[76] found IgE and IgG directed against *S chartarum* in a general population in Kansas City, Missouri. Enzyme immunoassay indicated that 65 (49.2%) of 132 serum samples tested contained IgG against *S chartarum*, and 13 (9.4%) of 139 serum samples tested contained IgE against *S chartarum*, suggesting either that *S chartarum* antibodies developed without history of overt clinical disease or that the presence of *S chartarum* may be a false-positive result. Furthermore, persons who become ill after exposure to *S chartarum* may not develop IgG or IgE anti-*Stachybotrys* antibodies.

Presence of antibodies to hemolysin produced by *S chartarum* has been suggested as a biomarker of exposure to *S chartarum*.[77] However, additional studies are needed to determine the sensitivity and specificity of testing for these antibodies.[74] A discussion of the possible misinterpretation of *Stachybotrys* serology is available.[78]

Prevention

It is impossible to keep mold spores out of the house. They come in through windows and doors, and humans and pets bring them in from the outside. The challenge is to keep the spores from colonizing and growing. Therefore, the key to mold control is moisture control. Actions that will help reduce indoor air humidity and prevent condensation include venting appliances that produce moisture (clothes dryers and stoves) to the outside and using a bathroom fan or opening a window when showering or bathing. When there is inadequate bathroom ventilation, using a towel to wipe shower walls and turning a fan or space heater on for a short period of time may diminish excessive moisture accumulation. Dehumidifiers can be used in areas with consistently elevated humidity levels, with a target humidity level of less than 50%. Dehumidifiers reduce ambient humidity but do not significantly reduce growth on surfaces in contact with ground water. To effectively control additional growth on damp surfaces, the water source must be eliminated. Bathrooms and basements should be left uncarpeted, and other indoor organic sources such as plants, wood, and paper products should be eliminated. Outdoors, fallen leaves can harbor mold and should be collected and discarded in a timely fashion. Parents should be aware that playing on or near piles of leaves exposes their children to increased levels of mold spores. This increased exposure could contribute to increased symptoms among children with asthma/allergies.

Actions that will help prevent condensation include reducing humidity; increasing ventilation by opening doors or using fans; covering cold surfaces, such as cold water pipes, with insulation; and increasing the air temperature.

Air Cleaners

People with allergies and asthma may use certain air cleaners such as air-filtration units, electrostatic precipitators, and ozone generators to eliminate bacteria, mold, and chemical contaminants from the air. Filters on central forced-air systems and furnaces should be changed periodically, according to the manufacturers' recommendations. Upgrading to a medium-efficiency filter (rated at 20%–50%) will improve air quality and is economical. Electrostatic filters/precipitators in central furnace and air-conditioning systems may be beneficial for airborne particles but are only effective when turned on. Room high-efficiency particulate air (HEPA) filters may be beneficial. However, they only work in a single room, and the noise generated may not be acceptable.

Ozone generators often advertised as "air purifiers" are touted to cleanse the air of microbes. However, ozone-producing air-cleaning devices may produce indoor concentrations of ozone high enough to reduce lung function. A study conducted by the EPA ran an

ozone generator in a test home at its maximum setting. When the room's air was sampled, ozone levels were found exceeding 0.3 ppm. This level is equal to a stage 1 smog alert, when local air-pollution–control districts advise the public to avoid some outdoor activities. These levels far exceed some states' ambient 1-hour standard for ozone of 0.09 ppm. High ozone effectively destroys microbes in water; however, air levels must reach extremely hazardous levels (50–100 times the outdoor air-quality standards) to be effective. Other electronic air cleaners, such as electrostatic precipitators and ionizers, produce ozone as a byproduct, and certain units generate potentially unhealthy levels. These devices should be cleaned and maintained regularly to minimize ozone emissions.[79]

Air-cleaning devices such as air-filtration units and electrostatic precipitators have the capacity, in theory, to remove airborne spores. However, their effectiveness in decreasing air concentrations of spores in damp indoor spaces and decreasing respiratory symptoms are unproven.

Humidifiers

Many parents use cool-mist humidifiers or vaporizers when children have colds or when the air is dry in winter. A systematic review in the *Cochrane Database of Systematic Reviews* assessed the effects of inhaling heated water vapor in the treatment of the common cold by comparing symptoms, viral shedding, and nasal resistance after a naturally or experimentally induced common cold.[80] Six randomized trials with 319 participants were identified. The results supported the use of warm-vapor inhalations in the common cold in terms of relief of symptoms (OR: 0.31 [95% CI: 0.16 to 0.60]; relative risk: 0.56 [95% CI: 0.4 to 0.79]). Results on symptom score indices were equivocal, but none demonstrated a worsening of scores. There was no evidence of decreased viral shedding measured by virus isolation in nasal secretions or measurement of viral titers in nasal washings from the treatment group. Minor adverse effects caused by thermal stress were reported in all the studies.

The potential benefit in cold symptoms must be balanced with the risk of increased growth and exposure to house dust mites and mold with increased humidity. Therefore, the general use of humidifiers should be avoided. If used for treatment of the common cold, their use should be limited, and they must be cleaned frequently to prevent mold growth and according to the manufacturers' instructions.

Remediation

Indoor water damage and/or mold overgrowth should be remediated to avoid irritant upper respiratory effects, possible sensitization to mold, possible injury from mycotoxins, and/or exacerbation of underlying mold allergy and to avoid structural damage to the building. A Finnish case-control investigation examined whether exposure to molds in the school was associated with an increased occurrence of respiratory symptoms and whether renovation of water-damaged areas affected the respiratory health of the exposed children. Results showed a significant decrease in respiratory symptoms after renovation.[81]

Who Should Perform the Cleanup?

According to current EPA guidelines, an individual can usually clean up areas less than 10 ft.[2] If there has been a lot of water damage and/or mold growth covers more than 10 ft^2; the heating, ventilation, and air conditioning (HVAC) system is involved; or the water and/or mold damage was caused by sewage or flood water, it may be wise to consider hiring a professional and consulting the EPA guide "Mold Remediation in Schools and Commercial Buildings."[82]

Cleanup Guidelines

The CDC[83] and EPA[84] (or call 800-438-4318) offer practical guidelines for cleaning up mold problems. The main way to control mold is to remove the water source and high-humidity conditions that promote spore growth. In the event of flooding, use fans or heaters to dry out the area if it has been less than 48 hours since the flood. After 48 hours, mold may already be forming on surfaces, and the use of fans would only act to disseminate them. Certain moldy materials, such as carpets and ceiling tiles, may be difficult to clean and should be discarded. When cleaning moldy areas, individuals should take precautions to limit exposure to airborne mold. In general, nonporous surfaces with mold growth can be cleaned with soap and water. Biocides are substances that can destroy living organisms, and a biocide, such as chlorine bleach, may also be used. EPA guidelines include avoiding breathing in mold or mold spores (N-95 respirator) and wearing gloves and goggles. If possible, the person with symptoms from mold exposure should not perform the cleanup.

The CDC has published extensive guidelines for mold cleanup.[85] Advice includes removal of mold growth from hard surfaces with commercial products, soap and water, or a bleach solution of 1 cup of bleach in 1 gallon of water. For extensive mold growth after the floods of Hurricane Katrina, the CDC recommendations included use of bleach.[86] Bleach is not recommended for use on porous surfaces, because its ionic structure prevents it from penetrating the materials; it also accelerates the deterioration of materials and wears down the fibers of porous materials. The use of bleach remains controversial. The debate centers, in part, on the belief that dead mold still retains its ability to trigger reactions in susceptible hosts. The first study to test the effect of allergic

individuals of mold spores treated with common household bleach found that the bleach not only kills mold but also neutralizes the mold allergens that cause mold-related health complaints. Specifically, a spray application of sodium hypochlorite–containing disinfectants onto mold-contaminated building materials killed *A fumigatus*, modified the surface characteristics of *A fumigatus conidia*, reduced recognition of *A fumigatus* mold by enzyme-linked immunosorbent assay, and resulted in loss of skin-test reactivity to the treated mold in individuals allergic to *A fumigatus*.[87]

If bleach is used, it should not be combined with ammonia or other household cleaning products, and the area should be well ventilated during use.

ADDITIONAL CONSIDERATIONS IN MEDICAL MANAGEMENT

Patient care for mold- or dampness-related illness often focuses on medical therapy, and remediation and/or environmental control of excessive mold growth is not emphasized. If remediation is not possible, removal of the patient from the environment should be seriously considered when the condition is severe or progressive over time, especially for serious illness such as hypersensitivity pneumonitis or poorly controlled asthma.

For families who rent, many housing conditions may be beyond their immediate control. Tenants have basic housing rights, and health departments and legal aid services may be able to help.[88] Pediatricians can play an important role in advocating for patients and their families by working with the local public health department and housing officials to address these issues.

CONCLUSIONS

Cause-and-effect relationships between fungal exposure and allergic disease, asthma, and hypersensitivity pneumonitis are consistently supported by epidemiologic studies. Evidence of adverse health effects of ingested mycotoxins is also abundant. However, the best evidence of a possible causal relationship between inhaled mycotoxins and respiratory illness is a single case-control study of AIPH in infants from Cleveland. Indoor dampness, by itself, seems to be associated with increased respiratory illness and symptoms, although the exact mechanism and etiologic agents are not known. Because the indoor environment is a source of many different exposures (bacteria, tobacco smoke, dampness, dust and dust mites, pet dander, and mold), it is impossible to unequivocally attribute a cause-and-effect relationship to any one specific agent. There is substantial evidence that damp, moldy environments are unhealthy, and the CDC and the EPA have developed guidelines for cleaning up the mold and fixing the moisture problem.

abstract

FREE

Sport-related concussion is a "hot topic" in the media and in medicine. It is a common injury that is likely underreported by pediatric and adolescent athletes. Football has the highest incidence of concussion, but girls have higher concussion rates than boys do in similar sports. A clear understanding of the definition, signs, and symptoms of concussion is necessary to recognize it and rule out more severe intracranial injury. Concussion can cause symptoms that interfere with school, social and family relationships, and participation in sports. Recognition and education are paramount, because although proper equipment, sport technique, and adherence to rules of the sport may decrease the incidence or severity of concussions, nothing has been shown to prevent them. Appropriate management is essential for reducing the risk of long-term symptoms and complications. Cognitive and physical rest is the mainstay of management after diagnosis, and neuropsychological testing is a helpful tool in the management of concussion. Return to sport should be accomplished by using a progressive exercise program while evaluating for any return of signs or symptoms. This report serves as a basis for understanding the diagnosis and management of concussion in children and adolescent athletes. *Pediatrics* 2010;126:597–615

INTRODUCTION

Since 1999, an extensive amount of research and media coverage has been dedicated to sport-related concussions. Young athletes pose a unique challenge, because their brains are still developing and may be more susceptible to the effects of a concussion. Even 10 years ago, a young athlete with a "ding" or low-grade concussion would have been allowed to return to sports as soon as 15 minutes after his or her symptoms had cleared. Since then, more extensive research has provided medical professionals with a better understanding of the symptomatic course and risk of potential long-term complications from concussions. As a result, management has evolved. Unfortunately, many parents, coaches, and young athletes still seem to believe that youth is a period of indestructibility. Concussion education in youth and high school sports communities is complicated by the misconception that a concussion may be "toughed out" and does not require a physician visit. Research and carefully documented experience show otherwise, although to the people who believe those misconceptions, it may seem as though the landscape of managing concussion has changed overnight.

Some organizations, such as the American College of Sports Medicine and National Athletic Trainers Association, have addressed sport-

related concussions in position statements.[1,2] Three international symposia on concussion in sport (CIS) have been held since 2001, although none focused exclusively on the pediatric athlete.[3–5] Although the Canadian Paediatric Society published guidelines on the management of the pediatric concussion, new research has been conducted since that statement.[6] This report outlines the current state of knowledge on pediatric and adolescent sport-related concussions.

DEFINITION

A clear definition of concussion requires consensus among researchers, clinicians, and patients, each of whom require a different construct for understanding the injury. Some advocate using the term "concussion," and others advocate using the term "mild traumatic brain injury" (mTBI). A recent study highlighted a general misinterpretation that an injury described as a concussion is less severe than one described as mild traumatic brain injury, which may result in a premature return to school and activity.[7] In this clinical report, we will refer to the injury as concussion.

The first of 3 international symposia on CIS was held in Vienna, Austria, in 2001.[3] From that meeting came a new consensus definition for a sport-related concussion, with minor revisions occurring in the 2 subsequent symposia held in Prague, Czech Republic, in 2004[4] and Zurich, Switzerland, in 2008.[5] The Zurich statement defined concussion as "a complex pathophysiological process affecting the brain, induced by traumatic biomechanical forces"[5] and includes 5 major features:

1. Concussion may be caused either by a direct blow to the head, face, or neck or elsewhere on the body with an "impulsive" force transmitted to the head.
2. Concussion typically results in the rapid onset of short-lived impairment of neurologic function that resolves spontaneously.
3. Concussion may result in neuropathological changes, but the acute clinical symptoms largely reflect a functional disturbance rather than a structural injury.
4. Concussion results in a graded set of clinical symptoms that may or may not involve loss of consciousness (LOC). Resolution of the clinical and cognitive symptoms typically follows a sequential course; however, it is important to note that in a small percentage of cases, postconcussive symptoms may be prolonged.
5. No abnormality on standard structural neuroimaging studies is seen in concussion.

Biokinetics and Pathophysiology

The biokinetics that induce a concussion consist primarily of acceleration-deceleration and rotational forces.[8,9] It has been proposed that greater force is required to produce an injury to the pediatric brain than to the adult brain.[10] Adults typically develop more intracranial injury in association with skull fractures than do children.[11] These findings may be related to the developing brain and skull, but it is unclear whether this model applies to sport-related concussion.

The pathophysiology of a concussion, as described from animal models, starts with a disruption of the neuronal membrane, which results in a potassium efflux to the extracellular space with a subsequent release of glutamate, an excitatory amino acid.[12] Glutamate potentiates further potassium efflux, which results in the depolarization and suppression of neuronal activity. To restore ion balance, the sodium-potassium ion pumps increase activity, which results in excessive adenosine triphosphate consumption and glucose utilization.[13] Lactate accumulates and cerebral blood flow decreases, which leads to a proposed "energy crisis."[13] A large amount of calcium also accumulates in cells, which may impair oxidative metabolism and allow for the initiation of biochemical pathways that result in cell death.[13] After the increase in glucose metabolism, there is a subsequent hypometabolic state that may persist for up to 4 weeks after injury.[14,15] Because the pathophysiology has only been established from animal models, it is still unclear whether this can be applied to the sport-related concussion.[16]

Grading Scales

There are more than 25 different published grading systems for concussions.[17] They were developed through expert opinion and rely heavily on LOC and a few symptoms, such as confusion and amnesia, to determine the severity of the concussion and subsequent return to play. The 3 concussion-grading scales most commonly used are the American Academy of Neurology,[18] Colorado Medical Society,[19] and Cantu[20,21] grading systems. In recent consensus statements, the CIS group recommended abandoning the use of grading scales and endorsed using several evaluation measures to individually guide return-to-play decisions.[3–5] In the 2004 Prague statement, the CIS group subsequently introduced the classification of concussions into simple and complex groups.[4] These groups were subsequently abandoned in the 2008 Zurich statement, because the delineation was also arbitrary and not found to be useful in managing concussion.[5] The current recommendation remains the abandonment of previous grading scales for a symptom-based approach for determination of return to play.[5]

EPIDEMIOLOGY OF CONCUSSION

It is commonly reported that 300 000 sport-related concussions occur each

year, although it was estimated in a recent review that up to 3.8 million recreation- and sport-related concussions occur annually in the United States. The large variance is attributable to original estimates including concussions that only involved LOC.[22,23] This highlights the difficulty with concussion epidemiology because of underreporting and the lack of widespread use of an injury surveillance system in youth sports.[24,25] With increasing access to recreational and organized (club and school) sports, as well as better awareness and recognition of the injury, the number of diagnosed concussions will likely increase. Because of the large numbers of participants in youth and high school sports, concussions in the pediatric and adolescent age groups account for the majority of sports-related concussions.

Concussions represent an estimated 8.9% of all high school athletic injuries.[26] Data are significantly lacking about concussions in grade school and middle school athletes, which highlights the need for more research about concussions in this younger age group.

Girls are reported to have a higher rate of concussion than boys in similar sports.[26–30] The reason for this difference is unknown, although some have theorized that female athletes have weaker neck muscles and a smaller head mass than their male counterparts.[31,32] Alternatively, male athletes may be more reluctant to report their injuries for fear of removal from competition, which may result in the incidence of concussion in boys being underestimated.[24,33]

The sport with highest risk of concussion in high school is football (Table 1).[26] In girls' sports, the rate of concussion is highest in girls' soccer and girls' basketball. Rugby, ice hockey, and lacrosse also account for higher rates of concussions but are often club sports, which limits their data inclusion in the larger high school sports epidemiologic studies.[34–37]

TABLE 1 Concussion Rates in High School Sports

Sport	Injury Rate, per 1000 Athlete Exposures
Football	0.47–1.03[a,b]
Girls' soccer	0.36[a]
Boys' lacrosse	0.28–0.34[c,d]
Boys' soccer	0.22[a]
Girls' basketball	0.21[a]
Wrestling	0.18[a]
Girls' lacrosse	0.10–0.21[c,d]
Softball	0.07[a]
Boys' basketball	0.07[a]
Boys' and girls' volleyball	0.05[a]
Baseball	0.05[a]

SIGNS AND SYMPTOMS

The signs and symptoms of concussion fall into 4 categories: physical, cognitive, emotional, and sleep (Table 2).[38] Headache is the most frequently reported symptom.[39] LOC occurs in less than 10% of concussions but is an important sign that may herald the need for further imaging and intervention.[40–42] Along with LOC, amnesia may be an important indicator of more serious injury.[40] The athlete should be evaluated for retrograde (before the event) and anterograde (after the event) amnesia by asking questions about details of events before and after the injury. The symptoms of retrograde amnesia may improve over time.[43] Often, the athlete hears peers, family, and coaches discuss events surrounding the injury and, subsequently, may falsely report remembering more about the injury. Mental fogginess may be a good predictor of a slower recovery from concussion in athletes.[44]

The signs and symptoms of concussion are similar to depression, anxiety, and attention-deficit disorders. In patients with preexisting mental health disorders, concussion may exacerbate those symptoms and make them more difficult to control. It is important to monitor this population carefully and consider altering existing care plans. Patients with learning disabilities and cognitive delays will also exhibit similar signs and symptoms, which can increase the challenge of managing their concussion.

Several factors may complicate the recognition of concussion for the athlete. Athletes may not recognize that they have concussion symptoms because of poor understanding of a concussion and its associated symptoms or from cognitive impairment from the injury itself. Symptoms may not ap-

TABLE 2 Signs and Symptoms of a Concussion

Physical	Cognitive	Emotional	Sleep
Headache	Feeling mentally "foggy"	Irritability	Drowsiness
Nausea	Feeling slowed down	Sadness	Sleeping more than usual
Vomiting	Difficulty concentrating	More emotional	Sleeping less than usual
Balance problems	Difficulty remembering	Nervousness	Difficulty falling asleep
Visual problems	Forgetful of recent information		
Fatigue	Confused about recent events		
Sensitivity to light	Answers questions slowly		
Sensitivity to noise	Repeats questions		
Dazed			
Stunned			

pear until several hours after a concussive episode.[4] In addition, young athletes may not be forthcoming with their symptoms for fear of activity restrictions.

A number of immediate motor phenomena, such as tonic posturing or convulsive movements, may accompany a concussion.[5] These immediate responses are uncommon, are generally benign, and require nothing more than standard management of the underlying concussion.[5,45] Although a brief seizure immediately after a concussive impact may not be problematic, any athlete who has a seizure after concussion should be transported emergently to a medical facility for further evaluation.

An athlete may be followed through his or her recovery with the use of the postconcussion symptom scale (Table 3). Although there are several variations, a 22-item symptom list is most commonly used. The scale is a 7-point Likert scale graded from 0 (no symptoms) to 6 (severe symptoms). An athlete may be more likely to report symptoms if given a graded scale than if asked a "yes" or "no" question. These scales have validity but have not been assessed adequately for reliability.[46,47] Results of a recent analysis of various symptom scales suggest that a 13-item checklist may be more helpful, but further research is needed to validate that recommendation.[48] Symptom scales have not been adequately studied in the grade school athlete.[47] At any age, it is important to make sure the patient understands what each symptom means and is able to complete the symptom scale independent of parental influence. Athletes with preinjury depression, sleep disturbances, and/or attention-deficit/hyperactivity disorder may not be expected to have a total score of 0 on a symptom scale before considering return to play. The evaluator must take a thorough history of the patient and account for these problems when making decisions about return to play.

TABLE 3 Postconcussion Symptom Scale (no Symptoms, 0; Moderate, 3; Severe, 6)

Headache	0	1	2	3	4	5	6
Nausea	0	1	2	3	4	5	6
Vomiting	0	1	2	3	4	5	6
Balance problems	0	1	2	3	4	5	6
Dizziness	0	1	2	3	4	5	6
Fatigue	0	1	2	3	4	5	6
Trouble falling to sleep	0	1	2	3	4	5	6
Excessive sleep	0	1	2	3	4	5	6
Loss of sleep	0	1	2	3	4	5	6
Drowsiness	0	1	2	3	4	5	6
Light sensitivity	0	1	2	3	4	5	6
Noise sensitivity	0	1	2	3	4	5	6
Irritability	0	1	2	3	4	5	6
Sadness	0	1	2	3	4	5	6
Nervousness	0	1	2	3	4	5	6
More emotional	0	1	2	3	4	5	6
Numbness	0	1	2	3	4	5	6
Feeling "slow"	0	1	2	3	4	5	6
Feeling "foggy"	0	1	2	3	4	5	6
Difficulty concentrating	0	1	2	3	4	5	6
Difficulty remembering	0	1	2	3	4	5	6
Visual problems	0	1	2	3	4	5	6

Use of the postconcussion symptom scale: The athlete should complete the form, on his or her own, by circling a subjective value for each symptom. This form can be used with each encounter to track progress toward symptom resolution. Many athletes may have some of these reported symptoms at a baseline, such as concentration difficulties in the patient with attention-deficit disorder or sadness in an athlete with underlying depression. This must be taken into consideration when interpreting the score. Athletes do not need a total score of 0 to return to play if they had symptoms before their concussion. This scale has not been validated to determine concussion severity.

Physical exertion and cognitive exertion, such as doing schoolwork, reading, playing video games, using a computer, and watching television, may worsen symptoms, although no link to long-term outcomes has been described. Athletes can develop symptoms during and after exertion, which indicates incomplete recovery.

INITIAL ASSESSMENT

On the Field

As with all acute head and neck injuries, initial assessment of the "ABCs" (airway, breathing, and circulation) and stabilization of the cervical spine are of the utmost importance. Cervical spine injury should be assumed in any athlete who is found to be unconscious after head or neck trauma. Maintaining adequate cervical spine stabilization is critical until neurologic function in all 4 limbs is evaluated and found to be intact and the athlete has no reported neck pain or cervical spine tenderness on palpation. If this evaluation cannot be accomplished or if a qualified medical professional is not available on the field, transport to an emergency facility is warranted. An athlete who was not unconscious or who quickly regained consciousness and is not suspected of having a cervical spine injury can be further evaluated on the sidelines.

Initial sideline evaluation should include an inquiry into the athlete's symptoms, a neurologic examination, and evaluation of the athlete's cognition by using one of several available sideline assessment tools, such as the Maddocks questions,[49] Standardized Assessment of Concussion (SAC),[50] Balance Error Scoring System (BESS),[51] or Sport Concussion Assessment Tool 2 (SCAT2).[5] The SCAT2 (Appendix 1) was released in the CIS Zurich statement as an enhanced version of the original SCAT introduced in the CIS Vienna statement and includes the majority of accepted sideline assessments in a comprehensive evaluation.[3,5]

The Maddocks questions are a brief set of questions to evaluate orientation as well as short- and long-term memory related to the sport and current game.[49] The questions are for sideline use only and are included in the SCAT2.[5] Examples of questions include "What team did you play last week?" and "Did the team win the last game?"

The BESS is an assessment of postural stability that is performed with the subject in 3 positions, first on a firm surface and then on a 10-cm-thick piece of foam. The 3 positions include

standing flat on both feet with hands placed on the iliac crests, standing on a single leg on the nondominant foot, and standing flat on both feet with eyes closed. Each assessment lasts 20 seconds. A score is obtained by totaling the number of errors the athlete makes over the 6 tests.[51] The BESS seems to have a practice effect and also seems to be affected not only by the environment in which the test is conducted but also by how soon after exercise the test is given.[52–55] There are concerns of intra-rater and inter-rater reliability as well as determining the most reliable components of the individual tests.[56,57] On the basis of these studies, it seems beneficial to test an athlete more than 15 minutes after cessation of exercise and in a setting in which he or she will be doing follow-up assessments, rather than on the sideline.

The SAC has been shown to have little to no practice effect.[52,53] Baseline assessments with an SAC test can be helpful in interpreting postinjury results. Any decrease from the baseline score on an SAC was found to be 95% sensitive and 76% specific for a concussion.[58] The SAC has not been validated for use in the grade school athlete.

The newer SCAT2 incorporates both the BESS and the SAC; however, the full SCAT2 evaluation has not been researched since its release with the Zurich concussion statement. Because the SCAT2 has not yet been studied, the Zurich statement authors recommended relying on the SAC score until prospective studies are conducted on the SCAT2.[5]

If a concussion is identified, the athlete should be removed from the remainder of the practice or game(s) on that day.[5] The athlete should continue to be monitored for several hours after the injury to evaluate for any deterioration of his or her condition. Referral to the emergency department is warranted if an athlete experiences repeated vomiting, severe or progressively worsening headache, seizure activity, unsteady gait or slurred speech, weakness or numbness in the extremities, unusual behavior, signs of a basilar skull fracture, or altered mental status resulting in a Glasgow Coma Score of less than 15.

In the Office/Emergency Department

When the athlete is evaluated initially in the office or emergency department after a concussion, a thorough history, including signs and symptoms as well as details of any previous head injuries; head and neck examination; neurologic examination, including gait and balance assessment (such as the BESS, Romberg test, and tandem gait); and assessment of cognitive function, including relevant portions of the SAC or SCAT2, should be performed. Although the use of terms such as a "ding" or "getting your bell rung" has been discouraged because they may minimize the severity of the injury, athletes may be more inclined to give a positive history if those terms are used.[59] The athlete should also be monitored for any deterioration of his or her condition. If there is concern for a structural brain abnormality, neuroimaging should be considered. Athletes and their parents or caregivers should be instructed which signs and symptoms to follow when at home and given clear guidelines on what would necessitate a return to the emergency department or pediatrician's office.[60] Even if an athlete's symptoms clear on the same day of the concussion and the assessment in the office or emergency department is normal, the athlete should not be allowed to return to play that same day. There is still debate about whether periodically waking the athlete during the night is necessary, because there may be more benefit from uninterrupted sleep than frequent awakenings, which may exacerbate symptoms.

NEUROIMAGING

Conventional neuroimaging is typically normal in a concussive injury. Routine imaging using computed tomography (CT) or MRI contributes little to concussion evaluation and management.[5] Although rare, a concussive blow can be associated with a cervical spine injury, skull fracture, or any of the 4 types of intracranial hemorrhage (subdural, epidural, intracerebral, or subarachnoid).[61]

Neuroimaging should be considered whenever suspicion of an intracranial structural injury exists. Signs and symptoms that increase the index of suspicion for more serious injury include severe headache; seizures; focal neurologic findings on examination; repeated emesis; significant drowsiness or difficulty awakening; slurred speech; poor orientation to person, place, or time; neck pain; and significant irritability.[38] Any patient with worsening symptoms should also undergo neuroimaging. Patients with LOC for more than 30 seconds may have a higher risk of intracranial injury, so neuroimaging should be considered for them.[60] Normal neuroimaging results in the acute phase of injury may not rule out a chronic subdural hematoma or subsequent neurobehavioral dysfunction.[61]

CT is the test of choice to evaluate for intracranial hemorrhage during the first 24 to 48 hours after injury.[62,63] It is also a superior imaging modality for detection of skull fractures.[64] CT is faster, more cost-effective, and easier to perform than MRI. Although numerous criteria have been developed to guide neuroimaging decisions after head trauma, none are sensitive and specific enough to diagnose all intracranial pathology.[65–69]

A 2010 Canadian study evaluated clinical criteria to determine who may be

at high risk of a structural brain injury identified on CT scan after a head injury.[70] Approximately 22% of the head injuries in this study were sport-related. Patients with a Glasgow Coma Scale score of less than 15 at 2 hours after injury, suspected open or depressed skull fracture, history of worsening headache, and irritability on examination were found to be at highest risk for a structural brain injury identified on a CT scan that needed neurosurgical intervention. One of the criteria for inclusion in this study was a witnessed LOC. Because LOC is noted in less than 10% of sport-related concussions, these criteria may not be applicable to all sport-related concussions.

MRI provides the ability to detect cerebral contusion, petechial hemorrhage, and white matter injury at a level superior to CT.[65] An MRI may be more appropriate if imaging is needed for an athlete 48 hours or longer after an injury and is best coordinated through the primary care or specialist physician evaluating the athlete. Newly emerging MRI modalities, such as gradient echo and perfusion and diffusion tensor imaging, are better than conventional MRI at detecting white matter alteration, especially in the pediatric population.[71,72] However, there is a paucity of research at this time that limits the clinical usefulness of these newer MRI modalities.

Functional imaging can be used to measure metabolic and hemodynamic changes in the brain.[71] Functional MRI is noninvasive and shows patterns that correlate with symptoms during concussion, such as more widespread brain activation while symptomatic compared with preinjury levels.[73] Other functional imaging modalities such as positron emission tomography (PET), magnetic resonance spectroscopy (MRS), and single-photon emission CT (SPECT) offer promise but are still in the early stages of development.[74] Functional neuroimaging will likely provide a more accurate picture of the injury and may help predict recovery better than structural neuroimaging, but further research and wider availability of this imaging modality is needed before it can be recommended.[74,75]

NEUROPSYCHOLOGICAL TESTING

Neuropsychological testing has become more commonplace in the evaluation of the athlete with concussion as a means to provide an objective measure of brain function. Neuropsychological testing is one of several tools in the assessment of an athlete with concussion but does not independently determine if an athlete has experienced a concussion or when he or she may safely return to play.[3–5] Currently, testing is performed by using one of several computerized neuropsychological tests including ANAM (Automated Neuropsychological Assessment Metrics), CogState, HeadMinder, and ImPACT (see Table 4) or through pencil-and-paper testing administered by a neuropsychologist. ANAM was initially developed for use in the military, whereas the other tests were developed specifically for sport-related concussion.

Each of the computerized tests has published data on test-retest reliability, and all have demonstrated deficits in concussed athletes compared with their baseline assessments.[76–84] One critique of the computerized tests is that the vast majority of studies have been conducted by the developers of the tests, which raises some concern for bias, because some independent study results have suggested slightly less reliable results.[85,86] A few of these computerized tests have been widely adopted at all levels of sport participation.

More rigorous pencil-and-paper testing conducted formally by a neuropsychologist is also an option, although test-retest reliability has been questioned.[87] Given the large number of athletes with concussion and relative scarcity of neuropsychologists, accessibility to these providers may often be challenging and may not be covered by insurance carriers.[88] Although the clinical neuropsychologist is often the most experienced person to interpret neuropsychological tests, nonneuropsychologists may be trained to interpret them as well, which is an important advantage of the commercially available computerized tests.[89]

If computerized or pencil-and-paper neuropsychological testing is available, ideally a baseline or preinjury test should be obtained. Baseline testing is best performed before the start of the athlete's season. Testing should be performed in a quiet environment, free of noise or distractions, while the athlete is well rested rather than immediately after exercise. Many teams and schools will administer tests in computer laboratories proctored by a

person with experience with the test, which allows for baseline testing of large groups of athletes over a short period of time.

There are no evidence-based guidelines or validated protocols about when to administer the computerized neuropsychological test after a concussion. Some administer the test while an athlete is symptomatic to provide objective data to the family and athlete regarding the injury and again when asymptomatic to help guide return to sport. Others administer the test only after an athlete has become asymptomatic to document that the athlete's cognitive function has returned to baseline. A symptomatic athlete should not be returned to play even with normal neuropsychological testing. If no baseline test is available for the athlete, his or her results can often be compared with age-established norms for the test. Interpretation of the tests should be performed by a neuropsychologist or physician who is experienced with these tests. Further research needs to be conducted to determine the optimum time and protocol for administering the computerized neuropsychological tests.

The optimum time frame for repeating baseline neuropsychological testing, if conducted, is still not well established, especially for the developing brain. A study that evaluated high school athletes with pencil-and-paper testing found stabilization of baseline scores between the 9th and 10th grades.[90] Another study of college athletes found stable scores over a 2-year period on a computerized test.[91] One must also consider that there is a lack of published baseline data in athletes younger than 12 years. There is currently no established, validated computerized neuropsychological test for the grade school athlete, although at the time of this clinical report, a computerized test for use in athletes younger than 12 years is being developed.

If an athlete is suffering from postconcussive symptoms over several months or has had multiple concussions, formal assessment by a neuropsychologist may be beneficial, specifically to identify areas for which the athlete may need academic accommodations.

MANAGEMENT

The goal of managing a young athlete with concussion is to hasten recovery by ensuring that the athlete is aware of and avoids activities and situations that may slow recovery. It is important to stress to patients and their parents to allow adequate time for full physical and cognitive recovery. Treating young athletes with a concussion is uniquely challenging, because their brains are still developing. Unfortunately, the lack of published data on the preadolescent athlete hinders evidence-based decision-making in this age group.[92] Also, there is a lack of consensus among physicians and certified athletic trainers as to how to evaluate and treat an athlete with concussion, despite widely available published guidelines.[88,93,94]

Medication Use

At the present time, there is currently no evidence-based research regarding the use of any medication in the treatment of the concussed pediatric athlete.[95] There is no evidence demonstrating the efficacy of the common use of nonsteroidal anti-inflammatory drugs (NSAIDs) or acetaminophen in alleviating the symptoms or shortening the course of an athlete's concussion. In 1 animal study, chronic administration of ibuprofen was found to worsen cognitive outcome after a traumatic brain injury.[96] It is commonly recommended that NSAIDs or aspirin be avoided immediately after a suspected head injury for fear of potentiating the risk of intracranial bleeding. Because no studies have documented any harm from use of NSAIDs after a sport-related concussion, this remains more of a theoretic risk.

Medication may be considered for those athletes with more prolonged symptoms such as difficulty concentrating, headache, sleep disturbances, and depression. Continued medication use to control concussion symptoms indicates incomplete recovery. Before considering a return to play, any medications used to reduce symptoms must be stopped and the athlete must remain symptom-free off medication.[5]

Cognitive Rest

Many athletes will report increased symptoms with cognitive activities after a concussion, which makes intuitive sense because the concussion is a functional rather than structural injury of the brain. Athletes with concussion often have difficulty attending school and focusing on schoolwork, taking tests, and trying to keep up with assignments, especially in math, science, and foreign-language classes. Reading, even for leisure, commonly worsens symptoms.

To prevent exacerbation of the athlete's symptoms and allow for continued recovery, "cognitive rest" is recommended. This rest may include a temporary leave of absence from school, shortening of the athlete's school day, reduction of workloads in school, and allowance of more time for the athlete to complete assignments or take tests. Taking standardized tests while recovering from a concussion should be discouraged, because lower-than-expected test scores may occur.[5,97] Test scores obtained while the athlete is recovering from concussion are likely not representative of true ability. Communication with school nurses, administrators, and teachers to be sure they understand these recommendations is imperative.

After reintegration into school, a student should be allowed adequate time to make up assignments, and the overall volume of make-up work should be reduced. Because students physically look well, it is not uncommon for teachers and other school officials to underestimate the difficulties that a student is experiencing and may downplay the need for cognitive rest. Education of teachers, counselors, and school administrators regarding the cognitive effects that a concussion may have on a student is important.

Other activities that require concentration and attention, including playing video games, using a computer, and viewing television, should also be discouraged, because they may exacerbate symptoms. If phonophobia is a significant symptom, exposure to loud music or the use of portable electronic music devices with headphones should be avoided. Sunglasses may be considered for athletes with significant photophobia.[98] Athletes often have slowed reaction times after a concussion and may need to avoid driving temporarily.

Physical Rest

After a concussion, all athletes should be withheld from physical exertion until they are asymptomatic at rest. With the proposed energy crisis in the brain,[13] increased energy demand in the brain from physical activity may exacerbate symptoms and has the potential to prolong recovery.[99] An athlete in the acute phase of a concussion should be restricted from physical activity. However, results of preliminary studies that evaluated patients with postconcussion syndrome have shown potential benefit from subsymptom threshold exercise training, which involves short durations of light cardiovascular activity without inducing symptoms.[100,101] Further research needs to be conducted before making formal recommendations regarding this treatment.

Broad restrictions of physical activity should be recommended, including not only the sport or activity that resulted in the concussion but also any weight training, cardiovascular training, physical education classes, and even sexual activity.[102] Leisure activities such as bike-riding, street hockey, and skateboarding should also be restricted, because they may impose a risk of additional head injury or symptom exacerbation. Assessment of mental health is also important, because a concussion may result in depression, in part from the injury itself but also from the prolonged time away from sports, difficulties in school, and sleep disturbances.

Recent Legislation

In May 2009, the state of Washington was first to pass a law regarding concussion management in young athletes. Also known as the Zackery Lystedt law, named after the then–13-year-old who sustained a serious head injury while playing football, this law requires school boards, in conjunction with the state interscholastic activity association, to develop educational materials and guidelines for athletes, coaches, and parents. The law also requires that parents and athletes sign an informed-consent form acknowledging the dangers of concussions before participation in sports. Finally, an athlete must be removed from any game if suspected of having a concussion and may not return until evaluated and given clearance to return to play from a licensed health care professional.[103] Many other states have subsequently either passed or are considering similar legislation.

RETURN TO PLAY

Determining when an athlete returns to play after a concussion should follow an individualized course, because each athlete will recover at a different pace. Under no circumstances should pediatric or adolescent athletes with concussion return to play the same day of their concussion. The phrase, "When in doubt, sit them out!" is paramount in the management of a pediatric or adolescent concussion.[3] No athlete should return to play while still symptomatic at rest or with exertion. Although the vast majority of athletes with concussion will become asymptomatic within a week of their concussion, numerous studies have demonstrated a longer recovery of full cognitive function in younger athletes compared with college-aged or professional athletes[104–108]—often 7 to 10 days or longer.[109] Because of this longer cognitive recovery period, although they are asymptomatic, there should be a more conservative approach to deciding when pediatric and adolescent athletes can return to play.

Concussion Rehabilitation

Initially proposed in 2000 by the Canadian Academy of Sport Medicine and endorsed by the CIS group in Vienna, a graded return-to-play protocol after a concussion is recommended.[3,110] This may also be referred to as "concussion rehabilitation." Once asymptomatic at rest, the athlete progresses in a stepwise fashion (Table 5) through the protocol as long as he or she remains asymptomatic. This progress may be monitored by the parent or an athletic trainer if proper instructions are given on how to proceed. Each step should take at least 24 hours, and it will take an athlete a minimum of 5 days to progress through the protocol to resume full game participation, provided symptoms do not return. A return of symptoms indicates inadequate recovery from the concussion. If symptoms return while on the protocol, once the athlete is asymptomatic again for 24 hours, the previous step may be at-

TABLE 5 Concussion Rehabilitation/Stepwise Return to Play

Rehabilitation Stage	Functional Exercise
1. No activity	Complete physical and cognitive rest
2. Light aerobic activity	Walking, swimming, stationary cycling at 70% maximum heart rate; no resistance exercises
3. Sport-specific exercise	Specific sport-related drills but no head impact
4. Noncontact training drills	More complex drills, may start light resistance training
5. Full-contact practice	After medical clearance, participate in normal training
6. Return to play	Normal game play

Each stage in concussion rehabilitation should last no less than 24 hours with a minimum of 5 days required to consider a full return to competition. If symptoms recur during the rehabilitation program, the athlete should stop immediately. Once asymptomatic after at least another 24 hours, the athlete should resume at the previous asymptomatic level and try to progress again. Athletes should contact their health care provider if symptoms recur. Any athlete with multiple concussions or prolonged symptoms may require a longer concussion-rehabilitation program, which is ideally created by a physician who is experienced in concussion management.

tempted again. Any athlete who continues to have a return of symptoms with exertion should be reevaluated by his or her health care provider. An athlete who has recovered from prolonged postconcussion syndrome or with a history of multiple concussions may need a longer period of time to progress through each step.

PREVENTION

Although preventing all concussions is unlikely, many attempts have been made to reduce the risk of concussion for athletes. These attempts include modifications to protective gear, rule changes, trying to identify athletes at risk, and continuing to educate everyone involved with youth and high school sports about the dangers of concussions.

Mouth Guards

The use of mouth guards for reducing the risk of dental trauma is well established. The role of the mouth guard in preventing concussions is more controversial. Although several studies have evaluated various mouth guards, none have conclusively demonstrated that mouth guards reduce the risk of concussion.[111–116]At this point in time, mouth guards are recommended to reduce dental trauma, but further studies are needed to evaluate their role in reducing the risk of concussions.

Helmets/Headgear

Helmets in sports have been shown in laboratory studies to reduce impact forces to the head. However, reduction in concussion incidence has not been consistently seen, despite the use of helmets. One study evaluated newer football helmet technology in high school athletes, which demonstrated a 31% decrease in relative risk and 2.3% decrease in absolute risk for sustaining a concussion.[117] Laboratory studies of a newer helmet technology suggest a potential 10% decrease in risk of reproduced concussion hits.[118] Continued technologic advances should be applauded, but further independent research and evaluation of these advances is necessary before they can be reported to reduce concussion incidence. Helmets should be assessed to meet the requirements of the National Operating Committee on Standards for Athletic Equipment for newly constructed or reconditioned helmets and should be appropriately fit for each individual athlete.

Helmets have been demonstrated to reduce concussion incidence in skiing and snowboarding and are recommended for these sports.[119–121] In a study of concussed hockey players wearing helmets with full face shields compared with half-face shield helmets, players wearing the full face shield helmet returned to play sooner, but there was no demonstrated decrease in risk or incidence of concussion between the 2 groups.[122]

Results of soccer headgear studies have revealed mild protection from concussion from players colliding heads but not from heading the ball.[123] Headgear seems to protect against soft-tissue injuries, such as lacerations, contusions, and abrasions, and is more likely to be worn by female soccer players.[123,124] Most studies have been found to have significant limitations in evaluating the potential for reducing concussions.[125] Prospective data are not currently sufficient to support recommending universal use of headgear in soccer.[126] Heading the ball in soccer is felt to be safe, if performed properly.[126] Avoiding heading does not prevent concussions.[126]

Genetic Testing

The presence of genetic markers (eg, apolipoprotein E4 gene, S-100 calcium-binding protein gene) and neuron-specific enolase have been evaluated as possible predisposing risk factors for concussion. However, the few studies conducted on younger athletes have not demonstrated significant differences in head injury characteristics or outcomes of athletes who possess these genetic markers.[127–129]At this time, genetic testing is not recommended for evaluating young athletes with concussion.

Education

Education and recognition remain the most important components of improving the care of athletes with concussions. Education should target all the key individuals involved, including athletes, parents, coaches, school administrators, athletic directors, teachers, athletic trainers, physicians, and other health care providers. Previous studies have demonstrated poor knowledge of concussion recognition

and management by players, coaches, and even clinicians.[130–133]

In 2005, the Centers for Disease Control and Prevention (CDC) published a series of concussion toolkits, titled "Heads Up," for coaches, practicing clinicians, teachers, and school counselors. These toolkits are available free from the CDC via the Internet.[134] A survey of coaches showed high satisfaction with the CDC toolkit.[135]

COMPLICATIONS

Long-term Effects

The long-term effects of concussions in athletes of all ages are cause for considerable concern. With a lack of long-term prospective studies in high school and younger athletes who sustained concussions, there are more questions than conclusive answers. An 18-year-old multisport athlete with a history of concussions from football was reported to have autopsy findings of chronic traumatic encephalopathy, previously only reported in professional football players and professional boxers.[136,137]

Athletes with 3 or more concussions are more likely to have had LOC, postevent amnesia, confusion, and 3 to 4 abnormal on-field markers of concussion.[138] Three months after a concussion, children 8 to 16 years of age have been found to have persistent deficits in processing complex visual stimuli.[139] Athletes with 2 or more concussions who had not been concussed in the previous 6 months performed similarly on neuropsychological testing as did athletes without a history of concussions who were concussed within in the previous week.[140] Compared with similar students without a history of concussion, athletes with 2 or more concussions also demonstrate statistically significant lower grade-point averages.[140] More research is needed to investigate the long-term effects of concussions at all ages of childhood and adolescence.

Second-Impact Syndrome

Second-impact syndrome occurs when an athlete who has sustained an initial head injury sustains a second head injury before the symptoms associated with the first have fully cleared. Second-impact syndrome results in cerebral vascular congestion, which often can progress to diffuse cerebral swelling and death.[141]

Although there is debate whether the cerebral swelling is attributable to 2 separate hits or a single hit, there is no question that pediatric and adolescent athletes seem to be at the highest risk of this rare condition, because all reported cases are of athletes younger than 20 years.[142] In addition, since 1945, more than 90% of the head injury–related fatalities from sports recorded by the National Center for Catastrophic Sports Injury Research occurred in athletes in high school or younger.[143] Catastrophic football head injuries are 3 times more likely to occur in high school athletes than in college athletes.[144]

Postconcussion Syndrome

A clear definition for postconcussion syndrome does not exist. The World Health Organization (WHO) established a definition of the presence of 3 or more of the following symptoms after a head injury: headache; dizziness; fatigue; irritability; difficulty with concentrating and performing mental tasks; impairment of memory; insomnia; and reduced tolerance to stress, emotional excitement, or alcohol.[145] However, the WHO definition does not specify a minimum duration of these symptoms to make the diagnosis.

Postconcussion syndrome is defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* as 3 months' duration of 3 or more of the following symptoms: fatigue; disordered sleep; headache; vertigo/dizziness; irritability or aggressiveness; anxiety or depression; personality changes; and/or apathy. Younger patients often demonstrate significant decline in school performance. Neuropsychological testing usually demonstrates difficulty in attention or memory.[146]

A recently proposed definition of postconcussive syndrome is the presence of cognitive, physical, or emotional symptoms of a concussion lasting longer than expected, with a threshold of 1 to 6 weeks of persistent symptoms after a concussion to make the diagnosis.[147]

Retirement From Sports

As with determining return to play, determining when to retire an athlete from 1 or multiple sports is often difficult for all involved. No evidence-based guidelines exist for the consideration of retiring an athlete from a sport.[148] It has been proposed that any athlete who has sustained 3 concussions in an individual season or has had postconcussive symptoms for more than 3 months should be strongly considered for a prolonged period of time away from sports.[149,150] If a clinician is not comfortable making a determination about the length of time to withhold the athlete from sports or is contemplating permanent removal from sports, referral to a specialist with expertise in sport-related concussion is recommended.

CONCLUSIONS AND GUIDANCE FOR CLINICIANS

1. Sport-related concussions are common in youth and high school sports. Limited data are available on concussions in grade school athletes, and further research is needed.
2. Concussion has many signs and symptoms, some of which overlap

with other medical conditions. LOC is uncommon, and if it lasts longer than 30 seconds, it may indicate more significant intracranial injury.

3. Results of structural neuroimaging, such as CT or MRI, generally are normal with a concussion.
4. Neuropsychological testing can be helpful to provide objective data to athletes and their families after a concussion. Neuropsychological testing is 1 tool in the complete management of a sport-related concussion and alone does not make a diagnosis or determine when return to play is appropriate.
5. Athletes with concussion should rest, both physically and cognitively, until their symptoms have resolved both at rest and with exertion. Teachers and school administrators should work with students to modify workloads to avoid exacerbation of symptoms.
6. The signs and symptoms of a concussion typically resolve in 7 to 10 days in the majority of cases. Some athletes, however, may take weeks to months to recover.
7. Any pediatric or adolescent athlete who sustains a concussion should be evaluated by a health care professional, ideally a physician with experience in concussion management, and receive medical clearance before returning to play.
8. Pediatric and adolescent athletes should never return to play while symptomatic at rest or with exertion. Athletes also should not be returned to play on the same day of the concussion, even if they become asymptomatic. The recovery course is longer for younger athletes than for college and professional athletes, and a more conservative approach to return to play is warranted.
9. The long-term effects of concussion are still relatively unknown, and further longitudinal research is needed to offer further guidance to athletes of all ages.
10. Education about sport-related concussion is integral to helping improve awareness, recognition, and management.
11. The safety and efficacy of medications in the management of sport-related concussion has not been established.
12. Retirement from contact or collision sports may be necessary for the athlete with a history of multiple concussions or with long symptomatic courses after his or her concussion.
13. New evidence-based protocols for the diagnosis and management of concussion should be incorporated into pediatric training modules and competencies.

SCAT2

Sport Concussion Assessment Tool 2

Name

Sport/team

Date/time of injury

Date/time of assessment

Age Gender M F

Years of education completed

Examiner

What is the SCAT2?[1]

This tool represents a standardized method of evaluating injured athletes for concussion and can be used in athletes aged from 10 years and older. It supersedes the original SCAT published in 2005[2]. This tool also enables the calculation of the Standardized Assessment of Concussion (SAC)[3,4] score and the Maddocks questions[5] for sideline concussion assessment.

Instructions for using the SCAT2

The SCAT2 is designed for the use of medical and health professionals. Preseason baseline testing with the SCAT2 can be helpful for interpreting post-injury test scores. Words in Italics throughout the SCAT2 are the instructions given to the athlete by the tester.

This tool may be freely copied for distribtion to individuals, teams, groups and organizations.

What is a concussion?

A concussion is a disturbance in brain function caused by a direct or indirect force to the head. It results in a variety of non-specific symptoms (like those listed below) and often does not involve loss of consciousness. Concussion should be suspected in the presence of **any one or more** of the following:

- Symptoms (such as headache), or
- Physical signs (such as unsteadiness), or
- Impaired brain function (e.g. confusion) or
- Abnormal behaviour.

Any athlete with a suspected concussion should be REMOVED FROM PLAY, medically assessed, monitored for deterioration (i.e., should not be left alone) and should not drive a motor vehicle.

Symptom Evaluation

How do you feel?

You should score yourself on the following symptoms, based on how you feel now.

	none	mild			moderate		severe
Headache	0	1	2	3	4	5	6
"Pressure in head"	0	1	2	3	4	5	6
Neck Pain	0	1	2	3	4	5	6
Nausea or vomiting	0	1	2	3	4	5	6
Dizziness	0	1	2	3	4	5	6
Blurred vision	0	1	2	3	4	5	6
Balance problems	0	1	2	3	4	5	6
Sensitivity to light	0	1	2	3	4	5	6
Sensitivity to noise	0	1	2	3	4	5	6
Feeling slowed down	0	1	2	3	4	5	6
Feeling like "in a fog"	0	1	2	3	4	5	6
"Don't feel right"	0	1	2	3	4	5	6
Difficulty concentrating	0	1	2	3	4	5	6
Difficulty remembering	0	1	2	3	4	5	6
Fatigue or low energy	0	1	2	3	4	5	6
Confusion	0	1	2	3	4	5	6
Drowsiness	0	1	2	3	4	5	6
Trouble falling asleep (if applicable)	0	1	2	3	4	5	6
More emotional	0	1	2	3	4	5	6
Irritability	0	1	2	3	4	5	6
Sadness	0	1	2	3	4	5	6
Nervous or Anxious	0	1	2	3	4	5	6

Total number of symptoms (Maximum possible 22)

Symptom severity score
(Add all scores in table, maximum possible: 22 x 6 = 132)

Do the symptoms get worse with physical activity? Y N

Do the symptoms get worse with mental activity? Y N

Overall rating

If you know the athlete well prior to the injury, how different is the athlete acting compared to his / her usual self? Please circle one response.

no different	very different	unsure

APPENDIX 1
THE SCAT2.

Cognitive & Physical Evaluation

1 Symptom score (from page 1)

22 **minus** number of symptoms ____ of 22

2 Physical signs score

Was there loss of consciousness or unresponsiveness? ☐ Y ☐ N

If yes, how long? ____ minutes

Was there a balance problem/unsteadiness? ☐ Y ☐ N

Physical signs score (1 point for each negative response) ____ of 2

3 Glasgow coma scale (GCS)

Best eye response (E)

No eye opening	1
Eye opening in response to pain	2
Eye opening to speech	3
Eyes opening spontaneously	4

Best verbal response (V)

No verbal response	1
Incomprehensible sounds	2
Inappropriate words	3
Confused	4
Oriented	5

Best motor response (M)

No motor response	1
Extension to pain	2
Abnormal flexion to pain	3
Flexion/Withdrawal to pain	4
Localizes to pain	5
Obeys commands	6

Glasgow Coma score (E + V + M) ____ of 15

GCS should be recorded for all athletes in case of subsequent deterioration.

4 Sideline Assessment – Maddocks Score

"I am going to ask you a few questions, please listen carefully and give your best effort."

Modified Maddocks questions (1 point for each correct answer)

At what venue are we at today?	0	1
Which half is it now?	0	1
Who scored last in this match?	0	1
What team did you play last week/game?	0	1
Did your team win the last game?	0	1

Maddocks score ____ of 5

Maddocks score is validated for sideline diagnosis of concussion only and is not included in SCAT 2 summary score for serial testing.

5 Cognitive assessment

Standardized Assessment of Concussion (SAC)

Orientation (1 point for each correct answer)

What month is it?	0	1
What is the date today?	0	1
What is the day of the week?	0	1
What year is it?	0	1
What time is it right now? (within 1 hour)	0	1

Orientation score ____ of 5

Immediate memory

"I am going to test your memory. I will read you a list of words and when I am done, repeat back as many words as you can remember, in any order."

Trials 2 & 3:

"I am going to repeat the same list again. Repeat back as many words as you can remember in any order, even if you said the word before."

Complete all 3 trials regardless of score on trial 1 & 2. Read the words at a rate of one per second. Score 1 pt. for each correct response. Total score equals sum across all 3 trials. Do not inform the athlete that delayed recall will be tested.

List	Trial 1	Trial 2	Trial 3	Alternative word list		
elbow	0 1	0 1	0 1	candle	baby	finger
apple	0 1	0 1	0 1	paper	monkey	penny
carpet	0 1	0 1	0 1	sugar	perfume	blanket
saddle	0 1	0 1	0 1	sandwich	sunset	lemon
bubble	0 1	0 1	0 1	wagon	iron	insect
Total						

Immediate memory score ____ of 15

Concentration

Digits Backward:

"I am going to read you a string of numbers and when I am done, you repeat them back to me backwards, in reverse order of how I read them to you. For example, if I say 7-1-9, you would say 9-1-7."

If correct, go to next string length. If incorrect, read trial 2. One point possible for each string length. Stop after incorrect on both trials. The digits should be read at the rate of one per second.

		Alternative digit lists		
4-9-3	0 1	6-2-9	5-2-6	4-1-5
3-8-1-4	0 1	3-2-7-9	1-7-9-5	4-9-6-8
6-2-9-7-1	0 1	1-5-2-8-6	3-8-5-2-7	6-1-8-4-3
7-1-8-4-6-2	0 1	5-3-9-1-4-8	8-3-1-9-6-4	7-2-4-8-5-6

Months in Reverse Order:

"Now tell me the months of the year in reverse order. Start with the last month and go backward. So you'll say December, November ... Go ahead"

1 pt. for entire sequence correct

Dec-Nov-Oct-Sept-Aug-Jul-Jun-May-Apr-Mar-Feb-Jan 0 1

Concentration score ____ of 5

[1] This tool has been developed by a group of international experts at the 3rd International Consensus meeting on Concussion in Sport held in Zurich, Switzerland in November 2008. The full details of the conference outcomes and the authors of the tool are published in British Journal of Sports Medicine, 2009, volume 43, supplement 1.
The outcome paper will also be simultaneously co-published in the May 2009 issues of Clinical Journal of Sports Medicine, Physical Medicine & Rehabilitation, Journal of Athletic Training, Journal of Clinical Neuroscience, Journal of Science & Medicine in Sport, Neurosurgery, Scandinavian Journal of Science & Medicine in Sport and the Journal of Clinical Sports Medicine.

APPENDIX 1
Continued.

6 Balance examination

This balance testing is based on a modified version of the Balance Error Scoring System (BESS)[6]. A stopwatch or watch with a second hand is required for this testing.

Balance testing

"I am now going to test your balance. Please take your shoes off, roll up your pant legs above ankle (if applicable), and remove any ankle taping (if applicable). This test will consist of three twenty second tests with different stances."

(a) Double leg stance:
"The first stance is standing with your feet together with your hands on your hips and with your eyes closed. You should try to maintain stability in that position for 20 seconds. I will be counting the number of times you move out of this position. I will start timing when you are set and have closed your eyes."

(b) Single leg stance:
"If you were to kick a ball, which foot would you use? [This will be the dominant foot] *Now stand on your non-dominant foot. The dominant leg should be held in approximately 30 degrees of hip flexion and 45 degrees of knee flexion. Again, you should try to maintain stability for 20 seconds with your hands on your hips and your eyes closed. I will be counting the number of times you move out of this position. If you stumble out of this position, open your eyes and return to the start position and continue balancing. I will start timing when you are set and have closed your eyes."*

(c) Tandem stance:
*"Now stand heel-to-toe with your **non-dominant foot** in back. Your weight should be evenly distributed across both feet. Again, you should try to maintain stability for 20 seconds with your hands on your hips and your eyes closed. I will be counting the number of times you move out of this position. If you stumble out of this position, open your eyes and return to the start position and continue balancing. I will start timing when you are set and have closed your eyes."*

Balance testing – types of errors

1. Hands lifted off iliac crest
2. Opening eyes
3. Step, stumble, or fall
4. Moving hip into > 30 degrees abduction
5. Lifting forefoot or heel
6. Remaining out of test position > 5 sec

Each of the 20-second trials is scored by counting the errors, or deviations from the proper stance, accumulated by the athlete. The examiner will begin counting errors only after the individual has assumed the proper start position. **The modified BESS is calculated by adding one error point for each error during the three 20-second tests. The maximum total number of errors for any single condition is 10.** If a athlete commits multiple errors simultaneously, only one error is recorded but the athlete should quickly return to the testing position, and counting should resume once subject is set. Subjects that are unable to maintain the testing procedure for a minimum of **five seconds** at the start are assigned the highest possible score, ten, for that testing condition.

Which foot was tested: ☐ Left ☐ Right
(i.e. which is the **non-dominant** foot)

Condition	Total errors
Double Leg Stance (feet together)	of 10
Single leg stance (non-dominant foot)	of 10
Tandem stance (non-dominant foot at back)	of 10
Balance examination score (30 **minus** total errors)	of 30

7 Coordination examination

Upper limb coordination

Finger-to-nose (FTN) task: *"I am going to test your coordination now. Please sit comfortably on the chair with your eyes open and your arm (either right or left) outstretched (shoulder flexed to 90 degrees and elbow and fingers extended). When I give a start signal, I would like you to perform five successive finger to nose repetitions using your index finger to touch the tip of the nose as quickly and as accurately as possible."*

Which arm was tested: ☐ Left ☐ Right

Scoring: 5 correct repetitions in < 4 seconds = 1

Note for testers: Athletes fail the test if they do not touch their nose, do not fully extend their elbow or do not perform five repetitions. Failure should be scored as 0.

Coordination score of 1

8 Cognitive assessment

Standardized Assessment of Concussion (SAC)

Delayed recall

"Do you remember that list of words I read a few times earlier? Tell me as many words from the list as you can remember in any order."

Circle each word correctly recalled. Total score equals number of words recalled.

List	Alternative word list		
elbow	candle	baby	finger
apple	paper	monkey	penny
carpet	sugar	perfume	blanket
saddle	sandwich	sunset	lemon
bubble	wagon	iron	insect

Delayed recall score of 5

Overall score

Test domain	Score
Symptom score	of 22
Physical signs score	of 2
Glasgow Coma score (E + V + M)	of 15
Balance examination score	of 30
Coordination score	of 1
Subtotal	**of 70**
Orientation score	of 5
Immediate memory score	of 5
Concentration score	of 15
Delayed recall score	of 5
SAC subtotal	**of 30**
SCAT2 total	**of 100**
Maddocks Score	**of 5**

Definitive normative data for a SCAT2 "cut-off" score is not available at this time and will be developed in prospective studies. Embedded within the SCAT2 is the SAC score that can be utilized separately in concussion management. The scoring system also takes on particular clinical significance during serial assessment where it can be used to document either a decline or an improvement in neurological functioning.

Scoring data from the SCAT2 or SAC should not be used as a stand alone method to diagnose concussion, measure recovery or make decisions about an athlete's readiness to return to competition after concussion.

APPENDIX 1
Continued.

Athlete Information

Any athlete suspected of having a concussion should be removed from play, and then seek medical evaluation.

Signs to watch for

Problems could arise over the first 24-48 hours. You should not be left alone and must go to a hospital at once if you:

- Have a headache that gets worse
- Are very drowsy or can't be awakened (woken up)
- Can't recognize people or places
- Have repeated vomiting
- Behave unusually or seem confused; are very irritable
- Have seizures (arms and legs jerk uncontrollably)
- Have weak or numb arms or legs
- Are unsteady on your feet; have slurred speech

Remember, it is better to be safe.
Consult your doctor after a suspected concussion.

Return to play

Athletes should not be returned to play the same day of injury. When returning athletes to play, they should follow a stepwise symptom-limited program, with stages of progression. For example:

1. rest until asymptomatic (physical and mental rest)
2. light aerobic exercise (e.g. stationary cycle)
3. sport-specific exercise
4. non-contact training drills (start light resistance training)
5. full contact training after medical clearance
6. return to competition (game play)

There should be approximately 24 hours (or longer) for each stage and the athlete should return to stage 1 if symptoms recur. Resistance training should only be added in the later stages.
Medical clearance should be given before return to play.

Additional comments

Concussion injury advice (To be given to concussed athlete)

This patient has received an injury to the head. A careful medical examination has been carried out and no sign of any serious complications has been found. It is expected that recovery will be rapid, but the patient will need monitoring for a further period by a responsible adult. Your treating physician will provide guidance as to this timeframe.

If you notice any change in behaviour, vomiting, dizziness, worsening headache, double vision or excessive drowsiness, please telephone the clinic or the nearest hospital emergency department immediately.

Other important points:

- **Rest and avoid strenuous activity for at least 24 hours**
- **No alcohol**
- **No sleeping tablets**
- **Use paracetamol or codeine for headache. Do not use aspirin or anti-inflammatory medication**
- **Do not drive until medically cleared**
- **Do not train or play sport until medically cleared**

Guidance for the Clinician in Rendering Pediatric Care

Clinical Report—Sports Drinks and Energy Drinks for Children and Adolescents: Are They Appropriate?

abstract

FREE

Sports and energy drinks are being marketed to children and adolescents for a wide variety of inappropriate uses. Sports drinks and energy drinks are significantly different products, and the terms should not be used interchangeably. The primary objectives of this clinical report are to define the ingredients of sports and energy drinks, categorize the similarities and differences between the products, and discuss misuses and abuses. Secondary objectives are to encourage screening during annual physical examinations for sports and energy drink use, to understand the reasons why youth consumption is widespread, and to improve education aimed at decreasing or eliminating the inappropriate use of these beverages by children and adolescents. Rigorous review and analysis of the literature reveal that caffeine and other stimulant substances contained in energy drinks have no place in the diet of children and adolescents. Furthermore, frequent or excessive intake of caloric sports drinks can substantially increase the risk for overweight or obesity in children and adolescents. Discussion regarding the appropriate use of sports drinks in the youth athlete who participates regularly in endurance or high-intensity sports and vigorous physical activity is beyond the scope of this report. *Pediatrics* 2011;127:1182–1189

Sports and energy drinks are a large and growing beverage industry now marketed to children and adolescents for a variety of uses. Marketing strategies for sports drinks suggest optimization of athletic performance and replacement of fluid and electrolytes lost in sweat during and after exercise, and marketing strategies for energy drinks purport a boost in energy, decreased fatigue, enhanced concentration, and mental alertness. Sports drinks are different products than energy drinks; therefore, the terms should not be used interchangeably. Sports drinks are flavored beverages that often contain carbohydrates, minerals, electrolytes (eg, sodium, potassium, calcium, magnesium), and sometimes vitamins or other nutrients. Although the term "energy" can be perceived to imply calories, energy drinks typically contain stimulants, such as caffeine and guarana, with varying amounts of carbohydrate, protein, amino acids, vitamins, sodium, and other minerals.

With children and adolescents, careful consideration is necessary when selecting a beverage to hydrate before, during, or after exercise and outside of physical activity to prevent excessive sugar and caloric intake that may encourage dental erosion, overweight, and obesity.[1]

COMMITTEE ON NUTRITION AND THE COUNCIL ON SPORTS MEDICINE AND FITNESS

KEY WORDS

sport drinks, energy drinks, obesity, caffeine

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Pediatric athletes can benefit from using sports drinks that contain carbohydrates, protein, or electrolytes[2]; however, for the average child engaged in routine physical activity, the use of sports drinks in place of water on the sports field or in the school lunchroom is generally unnecessary. Stimulant-containing energy drinks have no place in the diets of children or adolescents.[3] Excessive regular consumption of carbohydrate-containing beverages increases overall daily caloric intake without significant additional nutritional value. Therefore, frequent consumption adversely affects the appropriate balance of carbohydrate, fat, and protein intakes needed for optimal growth, development, body composition, and health. This report defines and categorizes selected popular sports and energy drinks, reviews their contents, and examines the evidence for and against the use of sports and energy drinks in children and adolescents. Recommendations are provided for counseling patients, parents, government policy-makers, and administrators who run both school programs and youth sports organizations with regard to appropriate use of sports drinks. It is not intended to be a guide for the use or effectiveness of these drinks in children and adolescents involved in competitive endurance, repeated-bout sports (such as tournaments in which the athlete may have prolonged exposure to a hot, humid environment or be subjected to prolonged, repetitive exercise, often without adequate recovery time in between competitions), or other prolonged vigorous physical activities, because these uses have been reviewed elsewhere.[4]

DEVELOPMENT OF THIS REPORT

The American Academy of Pediatrics Committee on Nutrition (CON) and Council on Sports Medicine and Fitness (COSMF) conducted a thorough review of the literature from 2000 to 2009. Various approaches were used, including numerous PubMed searches. Reference lists from related studies, reviews, editorials, and position statements from other professional organizations were used. Search terms included sports drinks, energy drinks, children, and adolescents. The recent Institute of Medicine report on school health[3] and position statements on this subject from the American Dietetic Association and American College of Sports Medicine[2] were reviewed for this report. Comments were solicited from committees, sections, and councils of the American Academy of Pediatrics; 7 entities responded. For recommendations for which high levels of evidence are absent, the expert opinions and suggestions of the CON, the COSMF, and other groups/authorities consulted were taken into consideration in development of this clinical report.

DEFINITION AND CATEGORIZATION OF SPORTS DRINKS VERSUS ENERGY DRINKS

Sports drinks are beverages that may contain carbohydrates, minerals, electrolytes, and flavoring and are intended to replenish water and electrolytes lost through sweating during exercise. In contrast, the term "energy drink" refers to a very different type of beverage. Today's energy drinks also contain substances that act as nonnutritive stimulants, such as caffeine, guarana, taurine, ginseng, L-carnitine, creatine, and/or glucuronolactone, with purported ergogenic or performance-enhancing effects. Tables 1 and 2 list some popular commercially available sports drinks and energy drinks and their respective contents.

COMPONENTS OF SPORTS AND ENERGY DRINKS AND THEIR INDICATIONS

Water

Water is an essential part of the daily diet. Adequate hydration is necessary for maintaining normal cardiovascular, thermoregulatory, and many other physiologic functions during exercise and routine daily activity. In children, maturation and body size are the primary determinants of the necessary daily water intake. The quantity of water needed to maintain a euvolemic state is influenced by a number of fac-

Selection of the specific energy drinks listed was based on the most commonly available products at the time this report was under development.
[a] The amount was not specified on the nutritional content label.

tors such as diet, medications, illnesses, and chronic health conditions. With exercise, daily water needs can increase quickly and dramatically on the basis of environmental conditions (eg, heat, humidity, sun exposure), exercise time and intensity, heat-acclimatization state, and individual sweat rates. Therefore, a deliberate increase in water intake is frequently required during exercise to avoid significant dehydration and related health consequences such as heat illness.[5]

Dehydration is caused by a mismatch between body water loss (through sweating, respiration, urine production, and fecal loss), and water intake. Significant dehydration can be associated with premature fatigue, impaired sports performance, cognitive changes, possible electrolyte abnormalities (sodium deficit), and increased risk of heat illness.[6,7] Effective management of hydration, which optimizes performance and minimizes risk of heat illness in the setting of prolonged vigorous sports participation, is complex and beyond the scope of this report. Children and adolescents should be taught to drink water routinely as an initial beverage of choice as long as daily dietary caloric and other nutrient (eg, calcium, vitamins) needs are being met. Water is also generally the appropriate first choice for hydration before, during, and after most exercise regimens. Children should have free access to water, particularly during school hours.[1,2]

Carbohydrates

Carbohydrates are the most important source of energy for an active child or adolescent. However, daily carbohydrate intake must be balanced with adequate intake of protein, fat, and other nutrients. In general, there is little need for carbohydrate-containing beverages other than the recommended daily intake of fruit juice and low-fat

milk. However, for youth who exercise with prolonged vigorous intensity, blood glucose becomes an increasingly important energy source as muscle glycogen stores decrease and the use of circulating (blood) carbohydrates rises, which results in a need to supply an ongoing carbohydrate energy substrate to avert fatigue and maintain performance. The use of a carbohydrate-containing beverage by a child or adolescent in this situation is the most appropriate use of a commercial sports drink. The carbohydrate content of sports and energy drinks varies widely. Sports drinks contain 2 to 19 g of carbohydrates (glucose and fructose forms) per serving (240 mL [8 oz]), and the carbohydrate content of energy drinks ranges from 0 to 67 g per serving. The caloric content of sports drinks is 10 to 70 calories per serving, and the caloric content of energy drinks ranges from 10 to 270 calories per serving (Tables 1 and 2). Excessive intake of carbohydrate-containing beverages beyond what is needed to replenish the body during or after prolonged vigorous exercise is unnecessary and should be discouraged.[8] Sports and energy drinks are not indicated for use during meals or snacks as a replacement for low-fat milk or water. Excessive caloric intake can result from routine dietary intake of carbohydrate-containing beverages such as sports drinks, energy drinks, or soft drinks. This excessive caloric intake can substantially increase the risk for overweight and obesity in children and adolescents and should be avoided.[1,2]

Caffeine and Other Stimulants

Many children and adolescents perceive the need to increase or boost energy levels. The body's need for energy in the form of carbohydrate and other dietary fuel sources is best provided through balanced nutrition. Energy drinks often provide carbohydrate, but the primary source of energy in these drinks is caffeine—one of the most popular stimulants taken today. It is unfortunate that many young people knowingly ingest large amounts of caffeine in a variety of forms despite the fact that regular intake has many noted negative health effects.

Caffeine has been shown to enhance physical performance in adults by increasing aerobic endurance and strength, improving reaction time, and delaying fatigue.[9–11] However, these effects are extremely variable, dose dependent, and, most importantly, have not been studied in children and adolescents. Ergogenic effects have been reported with doses of 3 to 6 mg/kg. Some athletes who desire to achieve performance enhancement may voluntarily reach daily caffeine intakes of up to 13 mg/kg of body weight.

Caffeine is absorbed by all body tissues. It is structurally similar to adenosine and, thus, can bind in its place to cell membrane receptors, which results in a subsequent block of adenosine's actions. The effects of caffeine on various organ systems include increases in heart rate, blood pressure, speech rate, motor activity, attentiveness, gastric secretion, diuresis, and temperature. Sleep disturbances or improved moods are considered variable and individualized effects.[12–17] Caffeine can increase anxiety in those with anxiety disorders,[17] and it is known also to play a role in triggering arrhythmias.[18]

There is heightened awareness of the risks of caffeine use, abuse, and even toxicity in children and adolescents.[19,20] In 2005, the American Association of Poison Control Centers reported more than 4600 calls received for questions regarding caffeine. Of these calls, 2600 involved patients younger than 19 years, and 2345 patients required treatment, although the number of pediatric patients who required treatment was not defined.[21,22] Energy drinks contain large and varied amounts of caffeine, often much more per serving than cola. Parents and children should be cautioned about the difficulties in being aware of how much caffeine is ingested depending on the product and the serving size, as differentiated from the product size. The actual caffeine content for many energy drinks is not easily identified on product packaging or via the Internet. The total amount of caffeine contained in some cans or bottles of energy drinks can exceed 500 mg (equivalent to 14 cans of common caffeinated soft drinks) and is clearly high enough to result in caffeine toxicity.[23] A lethal dose of caffeine is considered to be 200 to 400 mg/kg.[24]

Additional concerns regarding the use of caffeine in children include its effects on the developing neurologic and cardiovascular systems[14] and the risk of physical dependence and addiction. Because of the potentially harmful adverse effects and developmental effects of caffeine, dietary intake should be discouraged for all children.[14,20] Avoidance of caffeine in young people poses a great societal challenge because of the widespread availability of caffeine-containing substances and a lack of awareness of potential risks. The primary dietary source of caffeine for children is soft drinks, which contain approximately 24 mg per serving (240 mL [8 oz]).[25] Ellison et al[26] reported that children 6 to 10 years old ingested caffeine on an average of 8 of 10 days. Other authors have reported variable caffeine intakes of up to 16 mg/day by 7- to 8-year-olds, 24 mg/day by 9- to 10-year-olds, and 37.4 mg/day by 5- to 18-year-olds.[27] Symptoms of caffeine withdrawal include headache, fatigue, decreased alertness, drowsiness, difficulty concentrating, decreased desire to socialize, flulike symptoms, irritability, depressed

mood, muscle pain or stiffness, and nausea or vomiting.[28]

Guarana

Guarana is a plant extract that contains caffeine.[29] It is marketed to increase energy, enhance physical performance, and promote weight loss. One gram of guarana is equal to approximately 40 mg of caffeine.[30] Thus, the presence of guarana in an energy drink is a cause for concern, because it increases the total caffeine level in the beverage.[31]

Electrolytes

Electrolytes (primarily sodium and potassium) are often found in sports and energy drinks (Tables 1 and 2). Sodium content varies from approximately 25 to 200 mg, and potassium content generally ranges from 30 to 90 mg per serving (240 mL [8 oz]). For most children and adolescents, daily electrolyte requirements are met sufficiently by a healthy balanced diet; therefore, sports drinks offer little to no advantage over plain water.[32] During or after participation in short training or competition sessions, athletes generally do not need supplemental electrolyte replacement. However, caution should be taken with athletes who are inappropriately restricting their dietary sodium or who drink excessive amounts of water, because they may be more susceptible to serious electrolyte abnormalities. Electrolyte-replacement requirements in the setting of prolonged vigorous exercise or in excessively hot or humid conditions vary widely because of large variations in sweat rates. Severe electrolyte abnormalities that occur in each of these settings are serious and potentially life-threatening situations and are discussed in detail elsewhere.[5,32]

Amino Acids/Protein

Specific amino acids are added to some sports and energy drinks (Table 2). Protein has been shown to enhance muscle recovery when ingested promptly after exercise; accordingly, a small subset of sports drinks that contain protein or amino acids are often marketed as "muscle-recovery drinks." The ingestion of protein (the major source of amino acids) should occur throughout the day as part of a normal diet to allow the body free access to necessary amino acids. Most children and adolescents who eat a well-balanced diet easily get their recommended daily allowance of protein (1.2–2.0 g of protein per kg), even those who are engaged in regular sports activities.[33] If a food source of protein is unavailable, an amino acid–containing sports drink can be used immediately after prolonged vigorous exercise for muscle recovery. Low-fat milk is a good option for use as a postexercise protein-recovery drink. The optimal ratio of carbohydrate/protein intake is likely individual and is affected by personal tolerance, dietary practices, metabolism, and exercise type and duration.

Additional, heavily marketed effects of specific amino acids in sports and energy drinks have not been supported by appropriate clinical trials. Enhanced immune function (glutamine), vasodilatation (arginine), enhanced lipolysis (L-carnitine, which is not technically an amino acid), and caffeine-potentiating effects (taurine) are among the most commonly described.[34–36] Taurine does have an inotropic effect on cardiac muscle similar to that of caffeine.[24] Like caffeine, taurine has physiologic effects on the intracellular calcium concentration in smooth muscles that may cause coronary vasospasm.[37] In general, the use of amino acids in energy drinks in place of traditional dietary sources is not supported by the scientific literature and, therefore, is discouraged for children and adolescents. Use of stimulant-containing energy drinks with or without amino acid supplementation is always discouraged.

Vitamins and Minerals

Many sports and energy drinks contain several B vitamins, vitamin C, calcium, and magnesium. There is no advantage to consuming these vitamins and minerals in drinks, because they can be easily obtained from a well-balanced diet. For further details, see the *Pediatric Nutrition Handbook*.[1]

HARMFUL DENTAL EFFECTS OF SPORTS AND ENERGY DRINKS

Dental Erosion

Dental erosions from sports and energy drinks are of concern in children and adolescents. Bartlett et al[38] found enamel erosion in 57% of 11- to 14-year-olds in a cluster sample of adolescents. Most sports and energy drinks have a pH in the acidic range (pH 3–4). A pH this low is associated with enamel demineralization.[39] Citric acid is frequently included in sports and energy drinks and has been found to be highly erosive, because its demineralizing effect on the enamel continues even after the pH has been neutralized.[40]

Extent of Use and Misuse

Sports and energy drink consumption by children and adolescents is widespread and continues to grow. O'Dea[41] studied 78 adolescents and found that 56.4% used sports drinks and 42.3% consumed energy drinks during the 2 weeks before the survey. Adolescents consumed these products for various reasons including good taste, quenched thirst, and extra energy needed to improve sports performance. Most notably, the adolescents did not differentiate between sports and energy drinks and cited the same benefits for both beverages. None of the adolescents surveyed mentioned potential problems referable to the

consumption of these beverages, and they did not distinguish use on the basis of the degree of athletic participation.[41]

Physically active children and adolescents and their parents are often unaware of the additional nutrient and fluid needs relative to exercise. Sports drinks have an important, specific role in the diet of young athletes who are engaged in prolonged vigorous sports activity—primarily to rehydrate and replenish carbohydrate, electrolytes, and water lost during exercise.[2] However, confusion about energy by young people can lead to unintentional ingestion of energy drinks when their goal is simply to rehydrate and replenish carbohydrate, electrolytes, and water with sports drinks. Using energy drinks instead of sports drinks for rehydration can result in ingestion of potentially large amounts of caffeine or other stimulant substances and the adverse effects previously described. Of additional concern is the intentional use of energy drinks by adolescents who desire stimulant effects to combat fatigue and increase energy during sports and school activities. Advertisements that target young people are contributing to the confusion rather than effectively distinguishing between sports and energy drinks. Furthermore, marketing fails to identify appropriate sources and amounts of energy substrate that should be consumed by children and adolescents.[42]

ASSESSMENT OF USE/MISUSE IN THE OFFICE

As part of each yearly checkup, it is important for pediatric health care providers to review a patient's nutritional status (food and fluid intake) and quantify physical activity. Routine questions that specifically address the use of sports and energy drinks are recommended. Parents may be unaware of their use, or they may, in fact, promote their use, which opens the door to provide education about these drinks for both patients and their parents. Frequent consumption of energy drinks may identify students at risk of substance use and/or other health-compromising behavior.[43] Education on proper dietary and sleep habits may help combat fatigue in adolescents and may decrease the common "stimulant-seeking behaviors."

Stimulant toxicity should be reported to local poison control centers. The ability to use tracking methods for sources of stimulant substances, such as energy drinks, will improve our understanding of dietary habits and facilitate the development of appropriate public health measures to prevent misuse and abuse.[19]

Given the current epidemic of childhood overweight and obesity, we recommend the elimination of calorie-containing beverages from a well-balanced diet, with the exception of low-fat or fat-free milk, because it contains calcium and vitamin D, which are particularly important for young people.

SPORTS AND ENERGY DRINKS ARE NOT INDICATED AS NORMAL FLUID CONSUMPTION IN SCHOOLS

Sales of sports and energy drinks in schools are increasing. Having agreed voluntarily to phase out full-calorie sodas from schools by the 2009–2010 school year, beverage manufacturers are heavily promoting sports drinks as a healthier alternative. In 2006, sports drinks were the third-fastest growing beverage category in the United States, after energy drinks and bottled water, according to the trade journal *Beverage Digest*.[44] The trade group representing beverage manufacturers reported that sports drinks increased their market share in schools from 14.6% in 2004 to 20% in the 2006–2007 school year. During the same period, the market share for full-calorie sodas decreased from 39.9% to 29.8%.[44]

A few school districts have already fought policy battles over sports drinks, and Connecticut became the first, and so far only, state to have passed legislation barring sports drinks and enhanced waters in schools.[45] Bills have been introduced in the US Congress to set new nutritional standards for the foods and drinks that schools sell to students outside cafeterias.[45]

In April 2007, the Institute of Medicine published a report titled *Nutrition Standards for Foods in Schools*,[3] in which it recommended a healthier eating environment for children and adolescents in this country. Relevant to sports and energy drinks, its recommendations for schools included:

- limit sugars in food and drink;
- have water available at no cost;
- restrict carbonated, fortified, or flavored waters;
- restrict sports drinks to use by athletes only during prolonged, vigorous sports activities;
- prohibit energy drink use, even for athletes; and
- prohibit the sale of caffeinated products in school.

CLINICAL IMPLICATIONS: GUIDANCE FOR THE PEDIATRICIAN

Regarding consumption of sports and energy drinks by children and adolescents, the pediatrician is encouraged to:

- Improve the education of children and adolescents and their parents in the area of sports and energy drinks. This education must highlight the difference between sports drinks and energy drinks and their associated potential health risks.

- Understand that energy drinks pose potential health risks primarily because of stimulant content; therefore, they are not appropriate for children and adolescents and should never be consumed.
- Counsel that routine ingestion of carbohydrate-containing sports drinks by children and adolescents should be avoided or restricted. Intake can lead to excessive caloric consumption and an increased risk of overweight and obesity as well as dental erosion.
- Educate patients and families that sports drinks have a specific limited function for child and adolescent athletes. These drinks should be ingested when there is a need for more rapid replenishment of carbohydrates and/or electrolytes in combination with water during periods of prolonged, vigorous sports participation or other intense physical activity.
- Promote water, not sports or energy drinks, as the principal source of hydration for children and adolescents.

abstract

Accurately defining and reporting perinatal deaths (ie, fetal and infant deaths) is a critical first step in understanding the magnitude and causes of these important events. In addition to obstetric health care providers, neonatologists and pediatricians should know the current US definitions and reporting requirements for live births, fetal deaths, and infant deaths. Correct identification of these vital events will improve our local, state, and national data so that these deaths can be better addressed and reduced. *Pediatrics* 2011;128:177–181

INTRODUCTION

Perinatal mortality comprises the combination of fetal deaths and neonatal deaths. In the United States in 2005, the fetal mortality rate for gestations of at least 20 weeks (6.2 fetal deaths per 1000 live births and fetal deaths)[1] was similar to the infant mortality rate (6.9 infant deaths per 1000 live births).[2] Depending on the definition used, fetal mortality contributes to approximately 40% to 60% of perinatal mortality. Understanding the etiologies of these events and predicting risk begins with accurately defining cases; the collection and analysis of reliable statistical data are an essential part of in-depth investigations on local, state, and national levels.

Fetal and infant deaths occur within the clinical practice of several types of health care providers. Although obstetric practitioners report fetal deaths, certain situations can occur during a delivery in which viability or possibility of survival is unclear; the pediatrician or neonatologist may attend the delivery to assess the medical condition of the fetus or infant, assess previable gestational age, provide care as indicated, and report a subsequent infant death, if it occurs. Incorrectly defining and reporting fetal deaths and early infant deaths may contribute to misclassification of these important events and result in inaccurate fetal and infant mortality rates.[3] Within this context, the American Academy of Pediatrics provides definitions and reporting requirements of fetal death, live birth, and infant death in an effort to emphasize that neonatologists and pediatricians play an important role in recording accurate and timely information surrounding these events. This role includes making the determination of the specific vital event during delivery, recording information surrounding the event on the appropriate certificate or report in compliance with state-specific requirements, and ensuring completeness and accuracy of the information, including the underlying cause of death when known. Although guidance for these definitions is provided elsewhere,[4–6] it may not be readily available to pediatricians in the delivery room.

Both the collection and use of information about fetal, infant, and perinatal deaths have been hampered by lack of understanding of differences in definitions, statistical tabulations, and reporting requirements among providers and state, national, and international bodies. Distinctions can and should be made between the definition of an event and the reporting requirements for the event. The definition indicates the meaning of a term (eg, live birth, fetal death). A reporting requirement is that part of the defined event for which reporting is mandatory.

DEFINITIONS

A fetus is defined from 8 weeks after conception until term while in the uterus. An infant is live born and younger than 365 days of age. Challenges in consistent definitions of fetal and infant death mostly stem from perception of viability, which should not change the definition of the event. In other words, an extremely preterm infant born at 16 weeks' gestation may be defined as a live birth but is not currently viable outside of the womb. On the basis of international standards set by the World Health Organization,[7] the National Center for Health Statistics of the Centers for Disease Control and Prevention defines live birth, fetal death, infant death, and perinatal death as follows.[4]

Live Birth

The complete expulsion or extraction from the mother of a product of human conception, irrespective of the duration of pregnancy, which, after such expulsion or extraction, breathes or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, regardless of whether the umbilical cord has been cut or the placenta is attached. Heartbeats are to be distinguished from transient cardiac contractions; respirations are to be distinguished from fleeting respiratory efforts or gasps.

Fetal Death

Death before the complete expulsion or extraction from the mother of a product of human conception, irrespective of the duration of pregnancy, that is not an induced termination of pregnancy. The death is indicated by the fact that, after such expulsion or extraction, the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles. Heartbeats are to be distinguished from transient cardiac contractions; respirations are to be distinguished from fleeting respiratory efforts or gasps.

For statistical purposes, fetal deaths are further subdivided as "early" (20–27 weeks' gestation) or "late" (≥28 weeks' gestation). The term "stillbirth" is also used to describe fetal deaths at 20 weeks' gestation or more. Fetuses that die in utero before 20 weeks' gestation are categorized specifically as miscarriages.

Infant Death

A live birth that results in death within the first year (<365 days) is defined as an infant death. Infant deaths are further subdivided as early neonatal (<7 days), late neonatal (7–27 days), neonatal (<28 days), or postneonatal (28–364 days).

Perinatal Death

Perinatal death is not a reportable vital event, per se, but is used for statistical purposes. Perinatal deaths refer to fetal deaths and live births with only brief survival (days or weeks) and are grouped on the assumption that similar factors are associated with these losses. Three definitions of perinatal deaths are in use:

- Perinatal death, definition I, includes infant deaths that occur at less than 7 days of age and fetal deaths with a stated or presumed period of gestation of 28 weeks or more.
- Perinatal death, definition II, includes infant deaths that occur at less than 28 days of age and fetal deaths with a stated or presumed period of gestation of 20 weeks or more.
- Perinatal death, definition III, includes infant deaths that occur at less than 7 days of age and fetal deaths with a stated or presumed gestation of 20 weeks or more.

From national and international perspectives, perinatal deaths have important implications for both public health and clinical interventions. However, the interpretations of these definitions vary globally on the basis of cultural perspectives, clinical definitions of viability, and availability of information. The National Center for Health Statistics currently classifies perinatal deaths according to the first 2 definitions. Definition I is used by the National Center for Health Statistics and the World Health Organization to make international comparisons to account for variability in registering births and deaths between 20 and 27 weeks' gestation.[8] However, definition II is more inclusive and, hence, is more appropriate for monitoring perinatal deaths throughout gestation, because the majority of fetal deaths occur before 28 weeks' gestation.

REPORTING REQUIREMENTS

In the United States, states and independent reporting areas (ie, New York City, Washington DC, and the US territories) register the certificates of live birth, death, and fetal death. These certificates/reports include clinical information. Challenges in consistent reporting of fetal death, in particular, stem from the variation in reporting requirements among states.[9] Recommended definitions and reporting requirements are issued through the

TABLE 1 Reporting Requirements for Fetal Death According to State or Reporting Area, 2005

Criteria	State/Reporting Area
Gestational age criteria only	
All periods	Arkansas, Colorado, Georgia, Hawaii, New York,[a] Rhode Island, Virginia, Virgin Islands
≥16 wk	Pennsylvania
≥20 wk	Alabama, Alaska, California, Connecticut, Florida, Illinois, Indiana, Iowa, Maine, Maryland,[b] Minnesota, Nebraska, Nevada, New Jersey, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Texas, Utah, Vermont,[c] Washington, West Virginia, Wyoming
≥5 mo	Puerto Rico
Both gestational age and birth weight criteria	
≥20 wk or ≥350 g	Arizona, Idaho, Kentucky, Louisiana, Massachusetts, Mississippi, Missouri, New Hampshire, South Carolina, Wisconsin, Guam
≥20 wk or ≥400 g	Michigan
≥20 wk or ≥500 g	District of Columbia
Birth weight criteria only	
≥350 g	Delaware,[d] Kansas, Montana[d]
≥500 g	New Mexico, South Dakota, Tennessee[e]

[a] Includes New York city, which has separate reporting.
[b] If gestational age is unknown, weight of ≥500 g.
[c] If gestational age is unknown, weight of ≥400 g, ≥15 oz.
[d] If weight is unknown, ≥20 weeks' completed gestation.
[e] If weight is unknown, ≥22 completed weeks' gestation.
Data source: National Center for Health Statistics, National Vital Statistics Reports.

Model State Vital Statistics Act and Regulations (the Model Law).[10,11] The Model Law recommends fetal death reporting for deaths that occur at 350 g or more or, if the weight is unknown, of 20 completed weeks' gestation or more. However, states have the authority to register these vital events and might not necessarily follow the Model Law, which results in differences in birth weight and gestational age criteria for reporting fetal deaths (Table 1). States also vary in the quality of the data reported, which includes missing data.[9]

All live births, regardless of gestational age, are reported as vital record events. Infant deaths involve both the reporting of a live birth event and a death event using a certificate of live birth and a certificate of death, respectively. Information from the certificate of live birth, including demographic information, selected maternal risk factors, maternal labor and delivery information, and infant weight and gestational age, are linked to information on the infant death certificate to include cause-of-death information. The fetal death certificate or report, a single document, includes maternal demographic information, selected maternal risk factors, labor and delivery information, and information about the fetus to include weight, gestational age, and cause of death. Accurate completion of these vital records is important for generating accurate data to determine the magnitude and causes of fetal, infant, and perinatal deaths.

PRACTICAL CONSIDERATIONS

A flow diagram for the determination of appropriate reporting of perinatal deaths was developed by the National Association for Public Health Statistics and Information Systems (Fig 1). The diagram delineates the sequence of reporting and can be used in delivery rooms to appropriately report perinatal events. Induced termination of pregnancy is included in the flow diagram but is beyond the scope of this report.

In the circumstance of delivery events in which the fetus is of uncertain viability, if the infant is determined to be a live birth, the event is reported regardless of birth weight, length of gestation, survival time, or other clinical information (eg, Apgar scores). If fetal death is determined, the event should be reported by the obstetric health care provider on the basis of state criteria and should include both birth weight and gestational age. The appropriate use of these definitions should be reflected in the medical record. Fetal deaths should not be assigned Apgar scores or be admitted to the nursery or NICU. Although the actual evaluation and management of fetal and infant death is beyond the scope of this guidance and has been reported elsewhere,[12] a postmortem examination of the fetus or infant and placenta should be conducted whenever possible.

In summary, the accurate and timely reporting of live birth and fetal and infant death is the cornerstone of perinatal mortality data. Because reducing fetal and infant mortality is among the nation's health goals, accurate definitions of these events are essential for understanding causes and researching potential solutions.

RECOMMENDATIONS

1. Physicians should accurately define and report vital events as follows:
   - Live birth: The complete expulsion or extraction from the mother of a product of human conception, irrespective of the duration of pregnancy, which, after such expulsion or extraction, breathes or shows any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, regardless of whether the umbilical cord has been cut or the placenta is attached. Heartbeats are to be distinguished from transient cardiac contractions; respirations are to be distinguished from fleeting respiratory efforts or gasps.
   - Fetal death: Death before the complete expulsion or extraction

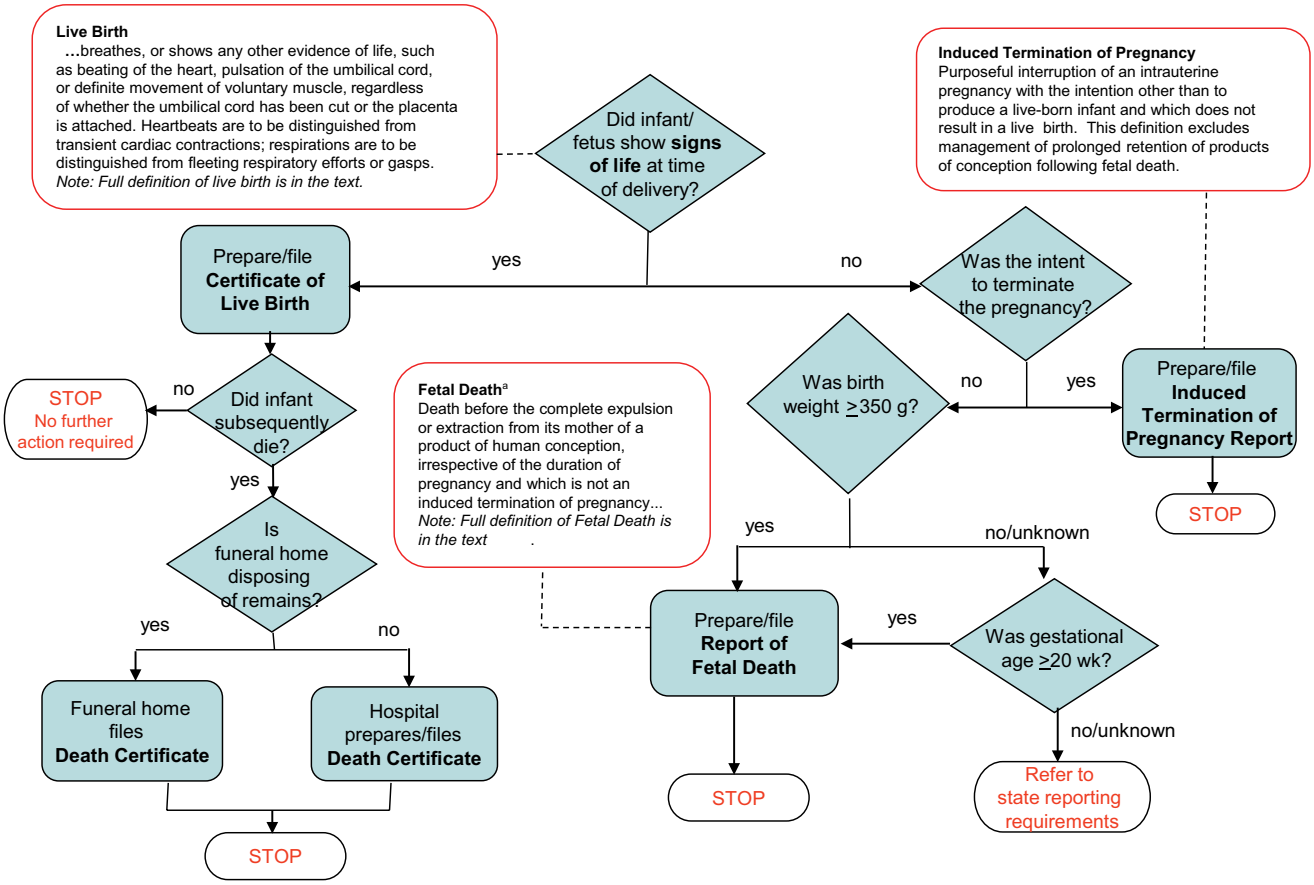

FIGURE 1

Hospital guidelines for reporting live births, infant deaths, fetal deaths, and induced terminations of pregnancy. [a] For most states, a report of fetal death is required when the birth weight is 350 g or greater or the gestational age is 20 weeks or older. Adapted with permission from the National Association for Public Health Statistics and Information Systems (www.naphsis.org).

from the mother of a product of human conception, irrespective of the duration of pregnancy, that is not an induced termination of pregnancy. The death is indicated by the fact that, after such expulsion or extraction, the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles. Heartbeats are to be distinguished from transient cardiac contractions; respirations are to be distinguished from fleeting respiratory efforts or gasps.

- Infant death: A live birth that results in death within the first year (<365 days).

2. Physicians should obtain accurate information on state law to ensure that the fetal death certificate/report is filed according to state requirements.
3. Physicians should obtain accurate information to complete reporting of live births, infant deaths, and fetal deaths (in support of obstetrician reporters) to include pertinent demographic information, maternal medical history, and fetal or infant diagnoses. An autopsy of the fetus or infant and examination of the placenta should be performed when possible.

POLICY STATEMENT

State Children's Health Insurance Program Achievements, Challenges, and Policy Recommendations

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Child Health Financing

ABSTRACT

This policy statement reviews the impressive progress of the State Children's Health Insurance Program since its enactment in 1997 and identifies outstanding challenges and state and federal policy recommendations. The American Academy of Pediatrics urges Congress to reauthorize SCHIP to strengthen its historic gains. The following set of recommended strategies for reauthorization pertain to funding, eligibility and enrollment, coverage, cost sharing, payment and provider-network capacity, and quality performance.

INTRODUCTION

The State Children's Health Insurance Program (SCHIP), enacted in 1997 as Title XXI of the Social Security Act (Pub L No. 105–33), has achieved remarkable progress in its brief history. As a result of SCHIP, health insurance has been extended to millions of children from low-income families, and rates of uninsurance among this population have declined by 2.2 million, from 23% in 1997 to 14.4% in 2004.[1] Access to health care has been vastly improved.[2] Specifically, because of SCHIP, more children have a medical home, more children receive preventive care and immunizations, and fewer children have an unmet need for dental care.[2–7] Family satisfaction and quality of care have also improved significantly under SCHIP.[4,7] Income and racial/ethnic gaps in health insurance coverage and access to care have also narrowed.[8] SCHIP also has had positive spillover effects on the Medicaid program.[9] As a result of SCHIP outreach, millions of potentially eligible but uninsured children have been enrolled in Medicaid.[10] Eligibility-determination processes have been simplified, and coordination between SCHIP and Medicaid has become increasingly effective.[2] The landmark SCHIP legislation allowed states to design their SCHIP programs as expansions of Medicaid, as separate non-Medicaid programs, or as combinations of the two. Unlike Medicaid, SCHIP is not an entitlement. It is capped at the amount that is funded by Congress and the states. States were able to pursue different approaches for offering the most comprehensive, affordable coverage possible for near-poor children and their families. SCHIP is important now more than ever because of concerns about the increased numbers of children with obesity, diabetes, mental health disorders, asthma, and other chronic conditions and the importance of ensuring that these children will be given timely and continuous access to health care services over the span of childhood and adolescence.

Despite the program's widely acknowledged success and popularity, several

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

outstanding challenges have been identified by SCHIP officials, enrolled families, participating pediatricians and other health care professionals, and health service researchers. These challenges pertain to (1) ensuring adequate funding, (2) extending the reach of SCHIP to all potentially eligible children and to more uninsured children and families at higher income levels, (3) improving benefit coverage in non-Medicaid plans, (4) maintaining affordable premiums and other forms of cost sharing, (5) providing adequate payments and strengthening provider-network capacity, and (6) improving quality performance. This policy statement identifies recommended strategies in each of these 6 areas, which the American Academy of Pediatrics (AAP) believes will further the program's success in the next decade.

BACKGROUND

In 2005, SCHIP programs provided health insurance to 4 million children nationwide.[11] States selected different approaches to provide health insurance under SCHIP; 21 states created a combination Medicaid and non-Medicaid program, 18 states created a non-Medicaid program, and 17 states and territories and the District of Columbia created a Medicaid program.[12] In 27 states and the District of Columbia, eligibility levels are established at the congressional target of 200% of the federal poverty level (FPL), and in 13 states, eligibility has been extended to children with family incomes above 200% of the FPL. Eligibility extends up to 300% of the FPL in 5 states (Connecticut, Maryland, Missouri, New Hampshire, and Vermont) and 350% of the FPL in 1 state (New Jersey).

The original funding-allocation formula for SCHIP, which will expire in 2007, is based on each state's share of low-income children, its share of low-income uninsured children, and the state's cost of providing health care services. Funds not spent by states within an allotted time are redistributed to other states according to a specific formula. Unfortunately, in fiscal year 2007, 17 states face SCHIP funding shortfalls that amount to approximately $1 billion according to the Center on Budget and Policy Priorities.[13] Shortfalls occurred because of the size of the population of uninsured children, the growth in the population of children from low-income families, the growing instability of employment-based health insurance, and inflation.

In addition to the very serious federal budget shortfalls, since 2001 states have experienced significant budget shortfalls that have adversely affected their ability to sustain their SCHIP programs. The most common cost-cutting response has been to limit outreach and enrollment; few states have actually lowered eligibility or benefits or imposed significantly higher cost-sharing requirements.[14] These cost-cutting actions resulted in a first-ever dip in enrollment in 2003.[15]

The scope of coverage for SCHIP programs in the 39 states that are offering a non-Medicaid plan to some or all of their SCHIP enrollees, although not as comprehensive as Medicaid coverage, still (with few exceptions) far exceeds benefits in employer-sponsored health insurance plans.[16] Similarly, although premium rates, copayments, and other dollar limits impose financial burdens for some families, they are still markedly less than those in private health insurance plans, and families consider them reasonable and affordable.[17]

Provider payment rates, however, are generally low—well below commercial rates—and in many states are at the same level as Medicaid rates. Medicaid professional fees were estimated to be approximately 70% of Medicare rates in 2004 according to the 2006 AAP Pediatric Medical Cost Model developed by actuaries at Reden & Anders.[18]

The AAP recommends the following improvements to strengthen SCHIP:

1. Ensure adequate funding

   - Establish a new funding-formula approach that relies on a combination of national and state data that does not penalize states for successfully enrolling uninsured children, that takes into account state variations in the costs of providing care, and that extends the period during which redistributed funds can be spent.
   - Set the budget baseline for SCHIP at a rate significantly higher than the level set in law for the final year of SCHIP's initial authorization to avoid future budget shortfalls.

2. Extend eligibility and enrollment

   - Establish a performance-based outreach fund that rewards states that are more successful in enrolling uninsured children who are eligible for public coverage.
   - Continue to improve on administrative simplification to facilitate enrollment and reenrollment, including shortened forms, streamlined verification requirements, online enrollment, and renewal assistance. In addition, grant states the flexibility to automatically enroll children into SCHIP (and Medicaid) on the basis of findings of other means-tested programs such as the Supplemental Nutrition Program for Women, Infants, and Children (WIC), the National School Lunch Program, and the Food Stamp Program.
   - Encourage presumptive eligibility for all children by allowing health care professionals and designated agencies to grant eligibility for up to 60 days while a child goes through the enrollment process. In addition, encourage states to adopt 12-month continuous eligibility for SCHIP-enrolled (and Medicaid-enrolled) children.

- Allow households with children in both Medicaid and SCHIP to enroll in the same program to ensure continuity among siblings with their pediatric medical home.
- Encourage expansion of SCHIP to include adolescents 19 through 21 years of age and allow emancipated minors eligibility for SCHIP on the basis of their own income. In addition, eliminate eligibility restrictions for dependents of state employees if they qualify on the basis of income.
- Encourage higher income eligibility levels (>200% of the FPL) and discontinue the practice of counting family assets to extend eligibility to more uninsured children.[19]
- Offer SCHIP buy-in options for children whose family incomes are above their state's SCHIP eligibility level but who do not have access to or cannot afford comprehensive private health insurance.
- Allow states to cover legal immigrant children who enter the United States on or after August 1996. These children, under the 1996 Welfare Law, are ineligible for Medicaid and SCHIP coverage during their first 5 years in the United States. Other complex rules restrict legal immigrant children from gaining public coverage until they are citizens.
- Allow states to draw down Medicaid/SCHIP matching funds when employers pay for a share of the cost of coverage for children of low-income families enrolled in Medicaid or SCHIP.
- Encourage waiver applications of the Centers for Medicare and Medicaid Services to expand SCHIP coverage for uninsured pregnant women and parents if states have already maximized comprehensive coverage and full enrollment of children.

3. Support comprehensive coverage
   - Preserve Medicaid benefit coverage in states with Medicaid SCHIP programs.
   - Encourage states to adopt SCHIP benefit packages that are consistent with the AAP policy statement "Scope of Health Care Benefits for Children From Birth Through Age 21,"[20] including oral health services, the full range of mental health services, and substance abuse treatment. Preventive care, immunization standards, and periodicity schedules also should be consistent with current AAP requirements. In addition, definitions of medical necessity should adhere to AAP recommendations.[21]
   - Extend eligibility for the Vaccines for Children Program to all children enrolled in non-Medicaid SCHIP programs.
   - Eliminate the prohibition against partial benefit packages to allow states with non-Medicaid SCHIP programs to provide additional wrap-around coverage to children, especially those with special health care needs who have inadequate private health insurance.
4. Maintain affordable coverage
   - Eliminate differences in copayments and coinsurance for physical and mental health services.
   - Adopt cost-sharing policies that do not shift cost to pediatricians, hospitals, and other health care professionals and do not deter the use of medically necessary services. Deductibles and coinsurance should not be used; rather, cost sharing should be in the form of income-adjusted premiums and copayments.
   - Maintain policy that requires all preventive services under SCHIP to be exempt from cost sharing.
5. Improve provider payments and network capacity
   - Establish payment rates under SCHIP for pediatric services that are at least equal to the most current Medicare RBRVS (Resource-Based Relative Value Scale) rates.
   - Ensure adequate payment when new vaccines and other new technologies are introduced. Under capitated arrangement, states should ensure that provisions are made to reimburse physicians for all vaccine-related overhead costs (vaccine product-acquisition and administration costs) of the new vaccines until new contracts are negotiated. In addition, physicians should receive payment for the expenses associated with the administration of each vaccine.
   - Adopt financial incentives for medical homes, especially in the care of children with special needs, including chronic care management, child and family education, and coordination and consultation with pediatric specialists and other support services.
   - Provide financial incentives for pediatric practices that adopt quality-performance goals.
   - Recognizing the dearth of pediatric subspecialists nationwide, encourage the inclusion of pediatric subspecialists, and the academic medical centers in which they practice, in managed care plan networks, and encourage coordination and communication between pediatric subspecialists and primary care practitioners.
   - Identify new mechanisms to designate and support safety net providers, including office-based pediatric practices and hospitals that specialize in the care of children, who serve a certain proportion of publicly insured children.

- Ensure medical home and pediatric subspecialty network continuity in SCHIP and Medicaid when children switch managed care plans and when children switch between the 2 sources of coverage.

6. Strengthen quality performance

   - Adopt a consistent conceptual framework (eg, the framework of the Institute of Medicine) to assess health care quality across SCHIP programs that takes into account the unique features of child health and health care.[22] Performance goals for states and the plans with which they contract should consist of short-term and long-term health care outcomes, including monitoring eligibility thresholds and projected enrollment volume, program retention, access to medical care, assessments of process and outcomes of pediatric care, and family and provider satisfaction.
   - Improve the collection and analysis of individual-level enrollment data and claims-based utilization data.
   - Involve pediatricians, pediatric subspecialists, pediatric mental health professionals, pediatric dentists, and other pediatric clinicians and families, including those who represent special populations, in continuously reviewing and evaluating each state's SCHIP.
   - Expand funding support for SCHIP evaluations and allow greater access to state data for research.
   - Measures should be appropriate for children's health. Any effort to measure quality should take into account the unique features of child health and health care. In addition, pediatric and family representatives should be included in all measurement efforts at the national, state, and local levels.

CONCLUSIONS

SCHIP has a proud history on which to build. To achieve continued success in reducing uninsurance among children and ensuring access to high-quality pediatric care, the AAP recommends that Congress and state policy makers adopt these important recommendations.

RESIDENTS' ATTITUDES ABOUT DUTY HOURS REGULATIONS

"To better understand the perspectives of residents on the effects of the ACGME duty hours restrictions, Jennifer S. Myers, MD, and colleagues performed a multi-site survey of internal medicine and surgery residents, focusing on residents who were in training both before and after implementation of the new regulations. The survey questions were designed to elicit opinions in three areas: quality of patient care and safety, residency education, and quality of resident life. . . . Medical and surgical residents' opinions of quality of care and medical errors were similar to each other. Both groups of residents felt that the quality of care had decreased slightly after implementation of the new regulations, but that the continuity of care had decreased a great deal. They also felt that errors attributable to continuity of care had increased, but that errors related to resident fatigue had decreased. Residents felt that the new rules had created a 'shift-work' mentality among housestaff, but did not believe that the quality of program graduates had changed. In addition, they felt that their quality of life had improved substantially since the implementation of the regulations. . . . The authors note that the survey results indicate that medical errors related to fatigue might have been replaced with errors related to discontinuity of care as a result of duty hours reform. Furthermore, duty hours reform has not resulted in significantly more hours of sleep per week for residents. Residents have also reported reductions in bedside teaching and in opportunities for mentoring from attending physicians. The authors state that these unintended consequences of duty hours reductions will need to be addressed as residency programs adapt their educations programs to meet regulatory requirements."

POLICY STATEMENT

Strength Training by Children and Adolescents

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Council on Sports Medicine and Fitness

ABSTRACT

Pediatricians are often asked to give advice on the safety and efficacy of strength-training programs for children and adolescents. This statement, which is a revision of a previous American Academy of Pediatrics policy statement, defines relevant terminology and provides current information on risks and benefits of strength training for children and adolescents.

www.pediatrics.org/cgi/doi/10.1542/peds.2007-3790

doi:10.1542/peds.2007-3790

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

Key Words
children, adolescents, strength training, resistance training, Olympic weightlifting

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

STRENGTH TRAINING (ALSO known as resistance training) is a common component of sports and physical fitness programs for young people, although some adolescents may use strength training as a means to enhance muscle size for improving appearance. Strength-training programs may include the use of free weights, weight machines, elastic tubing, or an athlete's own body weight. The amount and form of resistance used and the frequency of resistance exercises are determined by specific program goals. Table 1 defines common terms used in strength training.

BENEFITS OF STRENGTH TRAINING

In addition to the obvious goal of getting stronger, strength-training programs may be undertaken to try to improve sports performance and prevent injuries, rehabilitate injuries, and/or enhance long-term health. Similar to other physical activity, strength training has been shown to have a beneficial effect on several measurable health indices, such as cardiovascular fitness, body composition, bone mineral density, blood lipid profiles, and mental health.[1,2] Recent studies have shown some benefit to increased strength, overall function, and mental well-being in children with cerebral palsy.[3,4] Resistance training is being incorporated into weight-control programs for overweight children as an activity to increase the metabolic rate without high impact. Similar to the geriatric population, strength training in youth may stimulate bone mineralization and have a positive effect on bone density.[5,6]

Multiple studies have shown that strength training, with proper technique and strict supervision, can increase strength in preadolescents and adolescents.[7,8] Frequency, mode (type of resistance), intensity, and duration all contribute to a properly structured program. Increases in strength occur with virtually all modes of strength training of at least 8 weeks' duration and can occur with training as little as once a week, although training twice a week may be more beneficial.[7–12] Appropriately supervised programs emphasizing strengthening of the core (focusing on the trunk muscles, eg, the abdominal, low back, and gluteal muscles) are also appropriate for children and theoretically benefit sports-specific skill acquisition and postural control. Unfortunately, gains in strength, muscle size, or power are lost ~6 weeks after resistance training is discontinued.[1,13]

In preadolescents, proper resistance training can enhance strength without concomitant muscle hypertrophy. Such gains in strength can be attributed to a neurologic mechanism whereby training increases the number of motor neurons that are "recruited" to fire with each muscle contraction.[11,14–16] This mechanism accounts for the increase in strength in populations with low androgen concentrations, including female individuals and preadolescent boys. In contrast, strength training augments the muscle growth that normally occurs with puberty in boys and girls by actual muscle hypertrophy.[12,14,17,18]

Strength training is a common practice in sports in which size and strength are desirable. Unfortunately, results are inconsistent regarding the translation of increased strength to enhanced youth athletic performance.[1,14,19,20] Preventive exercise (prehabilitation) refers to strength-training programs that address areas commonly subjected to overuse injuries, such as providing rotator cuff and scapular stabilization exercises preventively to reduce overuse injuries of the shoulder in overhead sports. There is limited evidence to suggest that prehabilitation may help decrease injuries in adolescents, but it is unclear whether it has the same benefit in preadolescent athletes,[1,21,22] and there is no evidence that strength training will reduce the incidence of catastrophic sports-related injuries in youth. Recent research suggested a possible reduction in sports-related anterior cruciate ligament injuries in adolescent girls

TABLE 1 **Definition of Terms**

Term	Definition
Strength training	The use of resistance methods to increase one's ability to exert or resist force. The training may include use of free weights, the individual's own body weight, machines, and/or other resistance devices to attain this goal.
Core strengthening	Focusing a strengthening program to the muscles that stabilize the trunk of the body. The training emphasizes strengthening of the abdominal, low back, and gluteal muscles as well as flexibility of muscular attachments to the pelvis, such as the quadriceps and hamstring muscles.
Set	A group of repetitions separated by scheduled rest periods (eg, 3 sets of 20 reps).
Reps	Abbreviation for repetitions.
One-rep max (1RM)	The maximum amount of weight that can be displaced in a single repetition.
Concentric contraction	The muscle shortens during contraction (eg, arm curl, leg press).
Eccentric contraction	The muscle lengthens during contraction (eg, lowering a weight).
Isometric contraction	The muscle length is unchanged during contraction (eg, wall sits: athlete holds the position of feet planted flat on ground with knees at a 90° angle and back against the wall).
Isokinetic contraction	The speed of muscle contraction is fixed through the range of motion.
Progressive resistive exercises	An exercise regimen in which the athlete progressively increases the amount of weight lifted and/or the number of repetitions. The more repetitions, the greater the work performed and the greater the endurance development. The more weight lifted, the greater the strength development.
Plyometric exercises	Repeated eccentric and concentric muscle contractions, such as jumping up onto and down from a platform.
Weightlifting	A competitive sport that involves maximum lifting ability. Weightlifting (which is sometimes called Olympic lifting) includes the "snatch" and the "clean and jerk."
Power lifting	A competitive sport that also involves maximum lifting ability. Power lifting includes the "dead lift," the "squat," and the "bench press."
Body building	A competition in which muscle size, symmetry, and definition are judged.

when strength training was combined with specific plyometric exercises.[23] Plyometric exercises enable a muscle to reach maximum strength in a relatively short time span through a combination of eccentric and concentric muscle contractions, such as jumping up onto and down from a platform.

RISKS OF STRENGTH TRAINING

Much of the concern over injuries associated with strength training come from data from the US Consumer Product Safety Commission's National Electronic Injury Surveillance System,[24] which has estimated the number of injuries connected to strength-training equipment. The data from the National Electronic Injury Surveillance System neither specify the cause of injury nor separate recreational from competitive injuries that result from lifting weights. Muscle strains account for 40% to 70% of all strength-training injuries, with the hand, low back, and upper trunk being commonly injured areas.[24,25] Most injuries occur on home equipment with unsafe behavior and unsupervised settings.[24] Injury rates in settings with strict supervision and proper technique are lower than those that occur in other sports or general recess play at school.[26,27]

Appropriate strength-training programs have no apparent adverse effect on linear growth, growth plates, or the cardiovascular system,[1,10,11,28,29] although caution should be used for young athletes with preexisting hypertension, because they may require medical clearance to reduce the potential for additional elevation of blood pressure with strength training if they exhibit poorly controlled blood pressure. Youth who have received chemotherapy with anthracyclines may be at increased risk for cardiac problems because of the cardiotoxic effects of the medications, and resistance training in this population should be approached with caution.[30] Specific anthracyclines that have been associated with acute congestive heart failure include doxorubicin, daunomycin/daunorubicin, idarubicin, and possibly mitoxantrone. Youth with other forms of cardiomyopathy (particularly hypertrophic cardiomyopathy), who are at risk for worsening ventricular hypertrophy and restrictive cardiomyopathy or hemodynamic decompensation secondary to an acute increase in pulmonary hypertension, should be counseled against weight training. Individuals with moderate to severe pulmonary hypertension also should refrain from strenuous weight training, because they are at risk for acute decompensation with a sudden change in hemodynamics.[31] Young people with Marfan syndrome with a dilated aortic root also are counseled against participation in strength-training programs. Young athletes with seizure disorders should be withheld from strength-training programs until clearance is obtained from a physician. Overweight children may appear to be strong because of their size but often are unconditioned with poor strength and would require the same strict supervision and guidance as is necessary with any resistance program.

GUIDELINES FOR STRENGTH TRAINING

A medical evaluation of the child before beginning a formal strength-training program can identify risk factors for injury and provide an opportunity to discuss previous injuries, low-back pain, medical conditions, training goals, motives for wanting to begin such a program, techniques, and expectations from both the child and the parents. Youth should be reminded that strength training is only a small part of an overall fitness or sports program. Although research supports the safety and efficacy of resistance training for children, it is not necessary or appropriate for every child. Youth who are interested in getting bigger and stronger should be discouraged from considering the use of anabolic steroids and other performance-enhancing substances and should be provided with information regarding the risks and health consequences of using such substances. More patient-friendly information on performance-enhancing substances is available at www.aap.org/family/sportsshorts12.pdf. The American Academy of

Pediatrics (AAP) strongly condemns the use of performance-enhancing substances and vigorously endorses efforts to eliminate their use among children and adolescents.[32,33]

Because balance and postural control skills mature to adult levels by ~7 to 8 years of age,[34] it seems logical that strength programs need not start before achievement of those skills. Children also should have advanced to a certain level of skill proficiency in their sport before embarking on a disciplined strength-training program for the strength to have some potential value.

Strength gains can be acquired through various types of strength-training methods and equipment; however, most strength-training machines and gymnasium equipment are designed for adult sizes and have weight increments that are too large for young children. Free weights require better balance control and technique but are small and portable, provide small weight increments, and can be used for strengthening sports-specific movements.

Explosive and rapid lifting of weights during routine strength training is not recommended, because safe technique may be difficult to maintain and body tissues may be stressed too abruptly. This restrictive concept is applied to strength training, as opposed to the competitive sport of weightlifting, which is sometimes referred to as Olympic lifting. The sport of weightlifting is distinct from common strength training, because it involves specific types of rapid lifts, such as the "snatch" and the "clean and jerk."

Prepubertal youngsters are involved in competitive weightlifting, but philosophies often vary between Western nations and Eastern European nations.[35] Limited research on weightlifting as a sport has revealed that children have participated with few injuries,[35–37] and some programs have low rates of injury because they require stringent learning of techniques before adding any weight. As with general strength training, strict supervision and adherence to proper technique are mandatory for reducing the risk for injury. Clearly, this is an area in which more research is necessary to substantiate low injury rates as more youngsters continue to be involved with competitive weightlifting. Because of the limited research regarding prepubertal injury rates in competitive weightlifting, the AAP remains hesitant to support participation by children who are skeletally immature and is opposed to childhood involvement in power lifting, body building, or use of the 1-repetition maximum lift as a way to determine gains in strength.

For the purposes of this policy statement, the research regarding strength gains and the recommendations regarding youth involved in lifting weights apply specifically to the activity of strength training as an adjunct to exercise and sports participation.

When children or adolescents undertake a strength-training program, they should begin with low-resistance exercises until proper technique is perfected. When 8 to 15 repetitions can be performed, it is reasonable to add weight in 10% increments. Increasing the repetitions of lighter resistance may be performed to improve endurance strength of the muscles in preparation for repetitive-motion sports. Exercises should include all muscle groups, including the muscles of the core, and should be performed through the full range of motion at each joint. For achievement of gains in strength, workouts need to be at least 20 to 30 minutes long, take place 2 to 3 times per week, and continue to add weight or repetitions as strength improves. Strength training >4 times per week seems to have no additional benefit and may increase the risk for an overuse injury. Proper technique and strict supervision are mandatory for safety reasons and to reduce the risk for injury. Proper supervision is defined as an instructor-to-student ratio no more than 1:10 and an approved strength-training certification, as discussed in Table 2. Proper 10- to 15-minute warm-up and cool-down periods with appropriate stretching techniques also are recommended. Guidelines have been proposed by the AAP (as follows), the American Orthopaedic Society for Sports Medicine,[38] and the National Strength and Conditioning Association.[39,40]

Young people who want to improve sports performance generally will benefit more from practicing and perfecting the skills of their sport than from strength training alone, although strength training should be part of a multifaceted approach to exercise and fitness. If long-term health benefits are the goal, then strength training should be combined with an aerobic training program.

RECOMMENDATIONS

1. Proper resistance techniques and safety precautions should be followed so that strength-training programs for preadolescents and adolescents are safe and effective. Whether it is necessary or appropriate to start such a program and which level of proficiency the youngster already has attained in his or her sport activity should be determined before a strength-training program is started.
2. Preadolescents and adolescents should avoid power lifting, body building, and maximal lifts until they reach physical and skeletal maturity.
3. As the AAP has stated previously, athletes should not use performance-enhancing substances or anabolic steroids. Athletes who participate in strength-training programs should be educated about the risks associated with the use of such substances.
4. When pediatricians are asked to recommend or evaluate strength-training programs for children and adolescents, the following issues should be considered:
   a. Before beginning a formal strength-training program, a medical evaluation should be performed by a pediatrician or family physician. Youth with uncontrolled hypertension, seizure disorders, or a history of childhood cancer and chemotherapy should be withheld from participation until additional treatment or evaluation. When indicated, a referral may be made to a pediatric or family physician sports medicine specialist who is familiar with various strength-training methods as well as risks and benefits for preadolescents and adolescents.
   b. Children with complex congenital cardiac disease (cardiomyopathy, pulmonary artery hyperten-

National Strength Professional Association (NSPA) Personal Trainer	18 y of age, adult CPR certification	Two 10-h lectures, written/practical examination, 50 MC questions, 5 practicals	2 y, 24 NSPA CEC	No	www.nspainc.com

As of 2006, instructor certifications received by the following groups are certified by the National Committee for Certifying Agencies (NCCA): National Strength and Conditioning Association, American College of Sports Medicine, American Council on Exercise, National Council on Sports & Fitness, National Academy of Sports Medicine, and the National Federation of Professional Trainers. CPR indicates cardiopulmonary resuscitation; MC, multiple choice; CEC, continuing education credits, CEU, continuing education unit.

sion, or Marfan syndrome) should have a consultation with a pediatric cardiologist before beginning a strength-training program.

c. Aerobic conditioning should be coupled with resistance training if general health benefits are the goal.

d. Strength-training programs should include a 10- to 15-minute warm-up and cool-down.

e. Athletes should have adequate intake of fluids and proper nutrition, because both are vital in maintenance of muscle energy stores, recovery, and performance.

f. Specific strength-training exercises should be learned initially with no load (no resistance). Once the exercise technique has been mastered, incremental loads can be added using either body weight or other forms of resistance. Strength training should involve 2 to 3 sets of higher repetitions (8 to 15) 2 to 3 times per week and be at least 8 weeks in duration.

g. A general strengthening program should address all major muscle groups, including the core, and exercise through the complete range of motion. More sports-specific areas may be addressed subsequently.

h. Any sign of illness or injury from strength training should be evaluated fully before allowing resumption of the exercise program.

i. Instructors or personal trainers should have certification reflecting specific qualifications in pediatric strength training. See Table 2 for the various avenues of certification and certifying organizations.

j. Proper technique and strict supervision by a qualified instructor are critical safety components in any strength-training program involving preadolescents and adolescents.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

POLICY STATEMENT

Substance Use Screening, Brief Intervention, and Referral to Treatment for Pediatricians

abstract

FREE

As a component of comprehensive pediatric care, adolescents should receive appropriate guidance regarding substance use during routine clinical care. This statement addresses practitioner challenges posed by the spectrum of pediatric substance use and presents an algorithm-based approach to augment the pediatrician's confidence and abilities related to substance use screening, brief intervention, and referral to treatment in the primary care setting. Adolescents with addictions should be managed collaboratively (or comanaged) with child and adolescent mental health or addiction specialists. This statement reviews recommended referral guidelines that are based on established patient-treatment–matching criteria and the risk level for substance abuse. *Pediatrics* 2011;128:e1330–e1340

INTRODUCTION

Although it is common for adolescents and young adults to try mood-altering chemicals, including nicotine, it is important that this experimentation not be condoned, facilitated, or trivialized by adults including parents, teachers, and health care providers. Use of alcohol and other drugs remains a leading cause of morbidity and mortality for young people in the United States.[1,2] Even the first use of alcohol or another drug can result in tragic consequences such as unintentional injury or death. All substance use involves health risks that can occur long before there is drug addiction, and teenagers seem to be particularly susceptible to health risk–taking behaviors and injuries related to alcohol, tobacco, and other drug use.[3,4] In addition, research has established that adolescence is a period of neurodevelopmental vulnerability for developing addictions; age at first use is inversely correlated with lifetime incidence of developing a substance use disorder.[4–6]

The pediatrician has a well-recognized and important professional and societal role in the prevention, detection, and management of all pediatric health risks and disorders, including tobacco, alcohol, and other drug use among children and adolescents. Consistent with *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*,[7] primary care practitioners are ideally suited for preventing problem behaviors and consistently screening for them, including the development of mental health disorders and psychosocial problems, among which are substance use and addiction. The nonuse message should be reinforced by pediatricians through clear and consistent information presented to patients, parents, and other family members

TABLE 1 Substance Use Spectrum and Goals for Office Intervention

Stage	Description	Office Intervention Goals
Abstinence	The time before an individual has ever used drugs or alcohol (more than a few sips)	Prevent or delay initiation of substance use through positive reinforcement and patient/parent education
Experimentation	The first 1–2 times that a substance is used and the adolescent wants to know how intoxication from using a certain drug(s) feels	Promote patient strengths; encourage abstinence and cessation through brief, clear medical advice and educational counseling
Limited use	Use together with ≥1 friends in relatively low-risk situations and without related problems; typically, use occurs at predictable times such as on weekends	Promote patient strengths; further encourage cessation through brief, clear medical advice and educational counseling
Problematic use	Use in a high-risk situation, such as when driving or babysitting; use associated with a problem such as a fight, arrest, or school suspension; or use for emotional regulation such as to relieve stress or depression	As stated above, plus initiate office visits or referral for brief intervention to enhance motivation to make behavioral changes; provide close patient follow-up; consider breaking confidentiality
Abuse	Drug use associated with recurrent problems or that interferes with functioning, as defined in the *DSM-IV-TR*	Continue as stated above, plus enhance motivation to make behavioral changes by exploring ambivalence and triggering preparation for action; monitor closely for progression to alcohol and other drug addiction; refer for comprehensive assessment and treatment; consider breaking confidentiality
Addiction (dependence)	Loss of control or compulsive drug use, as defined in the *DSM-IV-TR* as "dependence"	As stated above, plus enhance motivation to accept referral to subspecialty treatment if necessary; consider breaking confidentiality; encourage parental involvement whenever possible

DSM-IV-TR indicates *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision.*

while developing and maintaining a trusting patient care relationship.[8] To decrease the health burden associated with substance use and substance use disorders, the Substance Abuse and Mental Health Services Administration recommends that universal screening for substance use, brief intervention, and/or referral to treatment (SBIRT) become a part of routine health care.[9] As a group, adolescents are at the highest risk of experiencing substance use–related acute and chronic health consequences, so they are also the age group likely to derive the most benefit from universal SBIRT. Specific SBIRT tools and strategies have well-documented efficacy for adult alcohol and drug use.[10,11] More recently, developmentally appropriate tools and strategies have been designed specifically for use with adolescents.[12–15]

Experience with substances can be considered a spectrum that varies from primary abstinence to addiction. The goal of applying universal SBIRT with adolescents is to identify an individual's experience along this spectrum and institute the appropriate intervention for each adolescent at every health care visit. Table 1 outlines a conceptual framework for the adolescent substance use spectrum and provides stage-correlated goals for optimal primary care office intervention.

Incorporating SBIRT practices into the primary care routine interfaces well with structured psychosocial interview schemes in common use, such as HEADSS or SSHADESS.[16,17] Following the HEADSS acronym guides the adolescent interview through questions about home, education, activities, drug and alcohol use, sexuality, and suicide. The SSHADESS interview framework covers the same life areas and underscores resiliency by identifying the patient's perceived and realized strengths before exploring environmental context and risks. Structured tools can be easily incorporated into the written or electronic health record to remind the practitioner to conduct screening and document the results. Recent research has established that adolescents who present for either urgent or follow-up care appointments are more likely to report alcohol and drug use and other high-risk behaviors when compared with those who present for well care, so substance use screening is recommended whenever an adolescent presents for outpatient care.[18] In recognition of the challenges posed by conducting health-risk screening amid the time constraints and competing medical needs found in nearly every practice context, the National Institute on Alcohol Abuse and Alcoholism is developing an empirically based 2-question alcohol use screen as part of a guide for interdisciplinary health care personnel for assessing adolescent alcohol use and then responding to the screening results. Because alcohol use is often the first risk behavior in which adolescents engage, alcohol-only screening may be a reasonable approach when time does not permit a full psychosocial interview.[19] The expectation remains that soon thereafter a full psychosocial interview, including strengths promotion and risk screening, will be conducted during a scheduled follow-up appointment. Whenever a child or adolescent has a positive alcohol-only screening result, a full psychosocial evaluation should be conducted as soon as possible, because underage drinking is associated

with a greater likelihood of other risk behaviors.[20]

This policy statement builds on the American Academy of Pediatrics (AAP) statements on tobacco, alcohol, and other drug use by providing pediatricians with additional guidance and tools for boosting their confidence and competence in preventing, detecting, and influencing the course of adolescent substance use.[8] The SBIRT framework presented here is similar in structure to the "ask, advise, refer" recommendation for tobacco use. For detailed information about providing care for adolescents who use tobacco, see the AAP technical report "Tobacco as a Substance of Abuse."[21]

SCREENING

Screening is a procedure applied to populations and is intended to identify people with a disease, condition, or symptom. Screening does not yield a formal diagnosis but, rather, guides further decision-making. Screening an adolescent for substance use is designed to determine if the adolescent has used alcohol or other drugs in the previous 12 months and, if so, to delineate the associated level of risk.

Succinct screens for adolescent substance abuse are available and outlined in the AAP statements "Tobacco, Alcohol, and Other Drugs: The Role of the Pediatrician in Prevention, Identification, and Management of Substance Abuse"[8] and "Alcohol Use by Youth and Adolescents: A Pediatric Concern."[22] The CRAFFT screen is a validated, developmentally appropriate, brief, easy-to-use screen with good discriminative properties for determining high risk of substance use disorders in the adolescent age group treated in primary care.[12] Use of this screening tool has been researched more extensively than any other substance use screening method in the adolescent age group. As a measure of risk, each "yes" answer to the 6 CRAFFT questions is scored as 1 point, so as the score increases, there is a corresponding greater likelihood of having a substance use disorder (ie, meets the diagnostic criteria for having substance abuse or substance dependence [addiction] delineated in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*[23] [DSM-IV-TR]). Recently, the CRAFFT tool was effectively integrated into an adolescent SBIRT algorithm and toolkit produced for Massachusetts practitioners by a collaborative led by the Massachusetts Department of Public Health Bureau of Substance Abuse Services.[14] This statement will lead the practitioner through this time-efficient, research-informed adolescent SBIRT algorithm (Fig 1).

The SBIRT algorithm starts with a 2-step method of using the CRAFFT screening tool. First, the clinician asks 3 specific opening questions to determine if the adolescent has used alcohol or other drugs in the previous 12 months, and the answers to these questions determine what portion of the CRAFFT screen is indicated (Fig 1 [start at the top center]). Adolescents who answer "no" to all 3 opening questions (Fig 1, upper left) are still asked the "C" (or "car") question to determine if they have placed themselves at risk by riding with an alcohol- or drug-"influenced" or intoxicated driver. Those who answer "yes" to any of the opening questions are asked all 6 CRAFFT questions (Fig 1, upper right). This 2-step screening may be accomplished by interview with the physician or office staff or by self-administered written or electronic survey. As with all psychosocial interviews, screening for substance use is most informative when conducted confidentially without a parent or guardian present. Before screening, both patients and parents should be well informed about the confidentiality policy followed in that practice setting, including the safety-related limits that justify whether to continue or break confidentiality.[24]

BRIEF INTERVENTION

Brief intervention describes a screening outcome-responsive conversation that focuses on encouraging a patient to make healthy choices and personal behavior changes regarding risky activity such as substance use. In primary care pediatrics, the term "brief intervention" encompasses a spectrum of responses that includes providing patients who report no substance use with brief positive feedback about their ability to make healthy choices. When the screening process reveals alcohol or other drug use, the indicated brief intervention ranges from providing brief advice to using a brief negotiated interview based on motivational techniques to encourage the desired behavior change or acceptance of a referral for treatment.

Low Risk: Abstinence

Screening should be conducted whenever possible, regardless of visit type, and should always be included as part of the annual well-adolescent visit. Adolescents who report no use of tobacco, alcohol, or other drugs *and* answer "no" to the "car" question of the CRAFFT screen are at low risk of having a substance use disorder. It is important that these patients receive praise and encouragement for making smart decisions and healthy choices (Fig 1, upper left ["no to all opening questions"]).[17] Experience is showing that even a few positive words from a physician can delay initiation of alcohol use by adolescents.[25] Anticipatory guidance to avoid riding with a driver who has been drinking or using drugs is always appropriate.

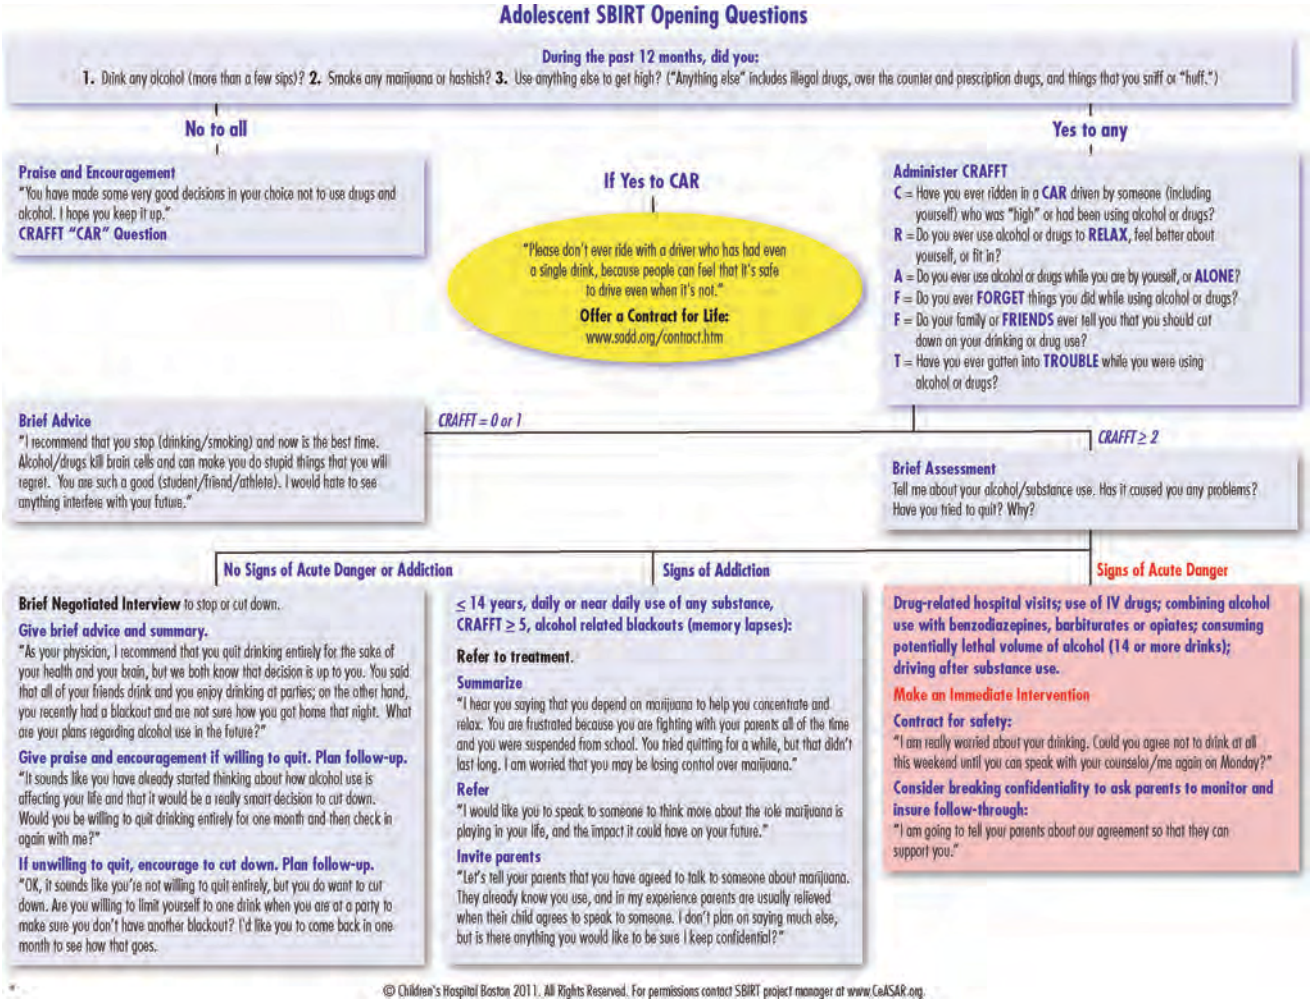

FIGURE 1
Adolescent SBIRT algorithm. (Reprinted with permission from the Adolescent Substance Abuse Program, Children's Hospital Boston.)

Driving Risk

All adolescents who report driving after alcohol or drug use or riding with a driver who has been using alcohol or drugs (ie, answer "yes" to the "car" question) should receive educational counseling regarding the associated danger (Fig 1, top-center oval). Ask adolescents to make a safety plan and commit to avoiding future driving/riding risks. The Contract for Life developed by Students Against Destructive Decisions (SADD) is a short, thought-provoking statement that can be used to facilitate development of a safety plan between an adolescent and a parent or other responsible adult.[26] This contract can be downloaded from the SADD Web site (www.saddonline.com/contract.htm). Pediatricians should consider breaking confidentiality if the adolescent cannot or will not commit to avoiding riding with a driver who has been using alcohol and/or drugs or avoiding their own alcohol or other drug use and driving—the basis for their positive response to the "car" question.

Moderate Risk: CRAFFT-Negative

Adolescents who have begun using alcohol or drugs and score 0 or 1 on the CRAFFT screen are considered at moderate risk of having substance use–associated problems (Fig 1, middle-left side). These adolescents may benefit from brief intervention consisting of both clear advice to stop alcohol and other drug use and educational counseling about the health effects of drug use (eg, "Recent research has confirmed that brain growth continues into at least the 20s, and alcohol poisons developing brain cells"). Brief intervention for adolescents in this category should also include recognition of strengths and positive personal and family attributes (eg, "You are such a good student, it would be a shame to let alcohol interfere with your education").

High Risk: CRAFFT-Positive

Adolescents who test positive on the CRAFFT screen, defined as having a

CRAFFT score of 2 or greater, are at high risk of having a substance use disorder. The middle right side of the SBIRT algorithm shows that the adolescent with a positive CRAFFT-screen result should undergo further assessment to detect whether the alcohol and/or other drug use indicates acute danger or "red flags" for addiction and to reveal the level of conviction the adolescent has for engaging in behavior change. To look for a pattern of increasing alcohol or other drug use, ask adolescents about their drug use history, their experience with any alcohol- or other drug-associated problems or troubles, and whether they have made quit attempts and why. A well-conducted assessment that encourages an adolescent to discuss problems associated with drug use and reasons for quit attempts is consistent with motivational-interviewing or motivational-enhancement techniques for supporting positive behavior change and can be the first step of brief intervention for this level of substance use.

Signs of Acute Danger

An adolescent who reports experience with certain risk behaviors, such as having a drug-related hospital visit, using intravenous drugs, combining sedatives (including alcohol, benzodiazepines, barbiturates, or opioids), consuming a potentially lethal volume of alcohol (≥14 drinks), or driving or engaging in other potentially dangerous activity after alcohol or drug use, shows clear signs of acute danger that warrant immediate intervention (Fig 1, lower-right rectangle). If any sign of addiction is also present, the corresponding lower-middle portion of the Fig 1 algorithm will guide the medically indicated action, which is treatment referral. The next step when addiction is not yet a concern is to ask the adolescent to commit to avoiding the behavior(s) and consider using a simple written contract to document this commitment. If the adolescent is unwilling or unable to commit or seems to underestimate the significance of alcohol or other drug use, consider breaking confidentiality to protect patient safety. Adolescents who choose to disclose such high-risk behaviors to a clinician might be asking for help. If breaking confidentiality is required to protect safety, discuss with the adolescent exactly what you will disclose and what you can keep confidential. Often, teens are most concerned about protecting small details (ie, which friends are involved, where they obtained substances, etc) that would have minimal impact on their immediate safety plan and can be kept confidential. Design a plan that involves the parent(s) or another responsible adult, professional counselors, and other substance abuse–related services. Schedule close follow-up to ensure patient compliance and safety.

Red Flags for Addiction

Probable substance addiction is indicated by red-flag findings, including a CRAFFT score of 2 or more in an adolescent aged 14 years or younger, daily or near-daily use of any substance, a CRAFFT score of 5 or higher, and alcohol-related blackouts (memory lapses) (Fig 1, lower-middle rectangle). Breaking confidentiality to protect patient safety is, again, a key consideration. Parents should be involved in this process whenever possible, because most adolescents will not follow through with a referral on their own. In most cases, parents will already be highly suspicious or aware of their adolescent's drug use, although they might underestimate the extent or severity. Adolescents might be willing to include their parent(s) in a discussion of recommendations, particularly if the clinician can present any concerns and recommendations in the context of positive patient and family attributes, such as mentioning the adolescent's honesty when screened or willingness to undergo further assessment. An adolescent with an addiction red flag should be referred for detailed evaluation and subspecialty treatment that is as specific to adolescents with substance use disorders as possible (see "Referral to Treatment").

No Signs of Acute Danger or Addiction

Adolescents who have had relatively minor consequences associated with their substance use should be engaged in a brief negotiated interview (BNI) based on motivational principles to encourage abstinence or risk reduction (Fig 1, lower-left rectangle). In contrast to brief advice, a BNI involves a negotiation that attempts to reduce substance use and related risk behaviors by using the negative aspects of substance use as reported by the adolescent. The BNI is based on the principles of motivational interviewing, which is a counseling approach in which a clinician encourages a patient to explore the effects of his or her current behavior on personal interests or goals. These principles align well with established pediatric medical home practices of providing confidential care and building a trust relationship and rapport. Motivational-interviewing or BNI techniques are particularly useful for adolescents who have experienced problems associated with alcohol or drug use but remain ambivalent about continued use or have not yet considered the possibility of changing their behavior. A full review of motivational interviewing is beyond the scope of this statement; interested readers are referred to the seminal work by Miller and Rollnick.[27]

Brief negotiated interviews have been used successfully to reduce both alcohol[28–30] and marijuana[31] use by adoles-

I,_____ , agree to not drink alcohol, use drugs, or take anyone else's medication for the next _____ days. I also will not provide drugs, alcohol, or prescription medications for anyone else during this time. In addition, I agree to not drive a motor vehicle while under the influence of drugs or alcohol, nor will I ride with a driver who has been drinking or using drugs.
I will come to my follow-up appointment with _____on _____.
Signed, _____

Date: _____

FIGURE 2
Abstinence challenge. (Reprinted with permission from the Adolescent Substance Abuse Program, Children's Hospital Boston.)

cents in emergency care settings. These studies all used multicomponent interventions delivered by peer health educators. To date, no study has examined the effectiveness of this type of intervention when conducted by clinicians working with adolescents in the primary care setting, although these techniques have been used and studied extensively with adult patients. We recommend that clinicians performing a BNI in primary care (1) summarize information from the assessment (see above), (2) repeat for emphasis any problems associated with substance use identified by the adolescent, and (3) ask the adolescent whether he or she would like to make changes in the future (eg, "I understand that you really enjoy smoking marijuana with your friends. On the other hand, you were suspended from the basketball team after the coach caught you with marijuana, and you are worried that having a 'record' of marijuana use might be bad for your college applications. What are your plans regarding marijuana use in the future?"). Telling adolescents who are invested in their substance use to stop using substances can trigger resistance, whereas asking about their own plans might present an opportunity for positive feedback (eg, "It sounds as if you have already thought this through. I fully support your decision to quit using for now"). When an adolescent professes interest in making a behavior change, consider asking for a signed commitment not to use alcohol or other drugs for a defined time period (Fig 2). Patients who are not willing to try complete abstinence might agree to risk reduction. In these cases, discuss concrete parameters for tracking progress.

All patients who have had a brief negotiated interview need follow-up to ensure patient compliance and safety. Adolescents who have met their goals can benefit from both a discussion of the pros and cons of their decreased substance use and reinforced motivation toward sustained behavior change. Those who were unable to meet their own goals might benefit from more extensive and individual counseling targeted specifically at substance use provided by an allied mental health professional such as a social worker or psychologist. Referral to interdisciplinary mental health professionals within the same practice setting often optimizes patient compliance. Research on the effectiveness of individual substance abuse counseling with motivational interviewing in particular has shown decreased harmful behaviors in adolescents, including decreased frequency of alcohol use and episodes of drinking and driving, alcohol-related injuries, and other problems.[29,32–36] In addition, an arm of the Cannabis Youth Treatment Study[37] revealed that motivational enhancement therapy using motivational-interviewing techniques plus cognitive behavioral therapy had greater cost-effectiveness and efficacy when compared with family therapy and psychoeducational support.

REFERRAL TO TREATMENT

Referral to treatment describes the facilitative process that provides patients identified as needing more extensive evaluation and treatment with access to appropriate services. In accordance with the SBIRT algorithm (Fig 1), signs of acute danger or red flags for addiction usually indicate the need for referral to adolescent-specific specialty care.

Addiction is a neurologically based, chronic, relapsing disorder that requires long-term management and monitoring. Any adolescent who meets the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* criteria for substance dependence should be assessed by a professional experienced with adolescent addiction.[23] Because resistance and denial (ie, lack of insight) are intrinsic to substance use disorders and are expected at this stage of the disease, the patient and/or family might be unwilling to pursue an evaluation that is clearly indicated. Despite this potential challenge, it is important for the pediatrician to remain engaged with the patient and family and supportive during discussions and decision-making about the patient's care options. Motivational-interviewing strategies can often be helpful in encouraging an adolescent and/or the family to accept a referral.

It is essential that pediatricians establish effective working relationships with alcohol and other drug treatment professionals and facilities in their communities to ensure that adolescent patients have access to treatment that is appropriate for their developmental, psychosocial, medical, and mental health needs. Adolescent patients with alcohol or other drug use disorders should be

managed collaboratively (or comanaged) with child and adolescent mental health or addiction specialists whenever possible and scheduled for medical home office visits throughout the recovery process.

Deciding where to refer an adolescent in need of treatment is often complicated by limited treatment availability and insurance-coverage complexities. In most cases, pediatricians refer adolescent patients to a mental health or addiction specialist to conduct a comprehensive biopsychosocial assessment and determine the appropriate level of care from the treatment spectrum, which ranges from outpatient substance abuse counseling to long-term residential treatment programs. In 2001, the American Society of Addiction Medicine revised its comprehensive national guidelines for placement, continued stay, and discharge for patients with alcohol and other drug problems, devised separate guidelines for adults and adolescents, and detailed 5 broad levels of care that range from early intervention to medically managed intensive inpatient treatment and correspond to addiction severity, related problems, and potential for behavior change and recovery[38] (Table 2).

An essential part of assisting the substance-using adolescent is becoming familiar with available community options, such as education and prevention services for those identified early in their substance use, or treatment modalities such as treatment-locator mechanisms and patient-treatment–matching criteria. The Center for Substance Abuse Treatment has published evidence-based treatment and assessment protocols, manuals, and facility-contact information (available at www.chestnut.org/li/apss/CSAT/protocols/index.html). To help identify treatment options throughout the country, the Substance Abuse and Mental Health Services Administration maintains a comprehensive and easy-to-use substance abuse treatment facility locator on its Web site (www.samhsa.gov/treatment/index.aspx). This site also includes both a buprenorphine physician and treatment program locator and an opioid treatment program directory. Opioid addiction and alcohol abuse are the primary indications for medication-assisted treatment in adult populations, and buprenorphine is effective for managing withdrawal of opioid-dependent adolescents and facilitating treatment completion.[39,40]

Successful addiction treatment usually involves more than 1 level of care during a long recovery process. Most patients in addiction treatment consider themselves "recovering" rather than "recovered" in recognition of their lifelong potential for relapse. Whether treatment begins in outpatient or inpatient care, it should continue at a level appropriate for the patient's recovery process, often through sequential or overlapping therapeutic levels that usually include participation in a formal structured program, 12-step self-help groups (eg, Alcoholics Anonymous, Alateen, Narcotics Anonymous), continued after-care programs, and self-help recovery work.

Medical home follow-up plays a key role for all patients in recovery. Relapse can be prevented, but because it often occurs, it should be anticipated as a potential part of the recovery process. Relapse should be viewed not as failure but as a learning opportunity important to the recovery process. Pediatricians have an important supportive role when a patient relapses and once again should initiate referral to treatment. By collaborating with addiction medicine specialists and other mental health professionals and working with the school, the family, and third-party payers, the pediatrician plays a central and essential role in the substance abuse treatment and recovery process for children and adolescents.

CRITERIA FOR THE SELECTION OF A SUBSTANCE ABUSE TREATMENT PROGRAM

The following criteria were based on Substance Abuse and Mental Health Services Administration and Center for Substance Abuse Treatment standards as optimal goals for inpatient or outpatient substance abuse treatment programs that serve the pediatric population.[41] The program will:

1. View drug and alcohol abuse as a primary disease rather than a symptom.
2. Include a comprehensive patient evaluation and developmentally appropriate management and treatment referral plan for associated medical, emotional, and behavioral problems identified.
3. Maintain rapport with the patient's pediatrician to facilitate seamless after-care and primary care follow-up.
4. Adhere to an abstinence philosophy. Drug use is a chronic disease, and a drug-free environment is essential. Tobacco use should be prohibited, and nicotine-cessation treatment should be provided as part of the overall treatment plan. Continued tobacco, alcohol, or other drug use should be viewed as a need for more treatment rather than discharge or refusal to treat.
5. Maintain a low patient-to-staff ratio.
6. Employ treatment professionals who are knowledgeable in both addiction treatment and child and adolescent behavior and development.
7. Ensure that professionally led support groups and self-help groups are integral parts of the program.

TABLE 2 Substance Use Treatment

Outpatient	
Group therapy	Group therapy is a mainstay of substance abuse treatment for adolescents with substance use disorders. It is a particularly attractive option, because it is cost-effective and takes advantage of the developmental preference for congregating with peers. However, group therapy has not been extensively evaluated as a therapeutic modality in this age group, and existing research has produced mixed results.[46,48]
Family therapy	Family-directed therapies are the best validated approach for treating adolescent substance abuse. A number of modalities have been demonstrated effective. Family counseling typically targets domains that figure prominently in the etiology of substance use disorders in adolescents: family conflict, communication, parental monitoring, discipline, child abuse/neglect, and parental substance use disorders.[46]
Intensive outpatient program	IOPs serve as an intermediate level of care for patients who have needs that are too complex for outpatient treatment but do not require inpatient services. These programs allow people to continue with their daily routine and practice newly acquired recovery skills both at home and at work. IOPs generally comprise a combination of supportive group therapy, educational groups, family therapy, individual therapy, relapse prevention and life skills, 12-step recovery, case management, and aftercare planning. The programs range from 2 to 3 h/d, 2–5 d/wk, and last 1–3 months. These programs are appealing, because they provide a plethora of services in a relatively short period of time.[49,a]
Partial hospital program	Partial hospitalization is a short-term, comprehensive outpatient program in affiliation with a hospital that is designed to provide support and treatment for patients with substance use disorders. The services offered at these programs are more concentrated and intensive than regular outpatient treatment; they are structured throughout the entire day and offer medical monitoring in addition to individual and group therapy. Participants typically attend sessions for 7 or 8 h/d, at least 5 d/wk, for 1–3 weeks. As with IOPs, patients return home in the evenings and have a chance to practice newly acquired recovery skills.[50,b]
Inpatient/residential	
Detoxification	Detoxification refers to the medical management of symptoms of withdrawal. Medically supervised detoxification is indicated for any adolescent who is at risk of withdrawing from alcohol or benzodiazepines and might also be helpful for adolescents withdrawing from opioids, cocaine, or other substances. Detoxification may be an important first step but is not considered definitive treatment. Patients who are discharged from a detoxification program should then begin either an outpatient or residential substance abuse treatment program.[47,48]
Acute residential treatment	ART is a short-term (days to weeks) residential placement designed to stabilize patients in crisis, often before entering a longer-term residential treatment program.[47] ART programs typically target adolescents with co-occurring mental health disorders.
Residential treatment	Residential treatment programs are highly structured live-in environments that provide therapy for those with severe substance abuse, mental illness, or behavioral problems that require 24-hour care. The goal of residential treatment is to promote the achievement and subsequent maintenance of long-term abstinence and equip each patient with both the social and coping skills necessary for a successful transition back into society. Residential programs are classified as short-term ($<$30 d) or long-term ($\geq$30 d). Residential programs generally comprise individual and group-therapy sessions plus medical, psychological, clinical, nutritional, and educational components. Residential facilities aim to simulate real living environments with added structure and routine to prepare patients with the framework necessary for their lives to continue drug- and alcohol-free after completion of the program.[51,c]
Therapeutic boarding school	Therapeutic boarding schools are educational institutions that provide constant supervision for their students by a professional staff. These schools offer a highly structured environment with set times for all activities; smaller, more specialized classes; and social and emotional support. In addition to the regular services offered at traditional boarding schools, therapeutic schools also provide individual and group therapy for adolescents with mental health or substance use disorders.[52,d]

IOP indicates intensive outpatient program; ART, acute residential treatment.

[d] See www.ncbi.nlm.nih.gov/books/NBK24159.

8. Maintain separate treatment groups for patients at varying developmental levels (adolescents versus young adults versus older adults).
9. Involve the entire family in the treatment, and relate to the patients and their families with compassion and concern. Strive to reunify the family whenever possible.
10. Ensure that follow-up and continuing care are integral parts of the program.
11. Offer patients an opportunity to continue academic and vocational education and assistance with restructuring family, school, and social life. Consider formal academic and cognitive skills assessment, because unidentified weaknesses might contribute to emotional factors that contribute to the substance use.
12. Keep the family apprised of costs and financial arrangements for inpatient and outpatient care and facilitate communication with managed care organizations.

13. Be located as close to home as possible to facilitate family involvement, although separation of the adolescent from the family might be indicated initially.

DUAL DIAGNOSIS

The fact that other psychiatric disorders occur with increased frequency in adolescents who use tobacco, alcohol, or other drugs raises additional diagnostic and therapeutic considerations.[42–44] This potential for dual diagnosis makes it essential for the pediatrician to be knowledgeable about the prevalence of co-occurring psychiatric diagnoses and how they manifest so that comprehensive assessment of a substance-using adolescent can include screening for any coexisting disorders and timely referral to the most suitable and effective treatment available.

BILLING AND PAYMENT ISSUES FOR PEDIATRICIANS

Time-based *Current Procedural Terminology* (CPT) codes are available specifically for tobacco use—cessation counseling and for structured alcohol/substance abuse screening and brief intervention (SBI) counseling. Medicare uses time-based G-codes for structured SBI services. Medicaid has established H-codes, which individual states must "turn on" (ie, approve) for reimbursement, although many states have not yet completed this activation process. G-codes and H-codes are located in the Healthcare Common Procedural Coding System (HCPCS) level II code set. A comprehensive fact sheet on coding substance use screening and SBIRT is available at the AAP Practice Management Online site (http://practice.aap.org/content.aspx?aid=2914), and further clarification can be addressed through the AAP coding hotline (AAPCodinghotline@aap.org) and the annually updated AAP publication *Coding for Pediatrics*.[45] Insurers differ markedly in their coding interpretation and reimbursement rates. Certain substance use diagnoses might be considered mental health disorders that require "carve-out" contract services provided by mental health specialists and are not allowable as reimbursable primary care provider services. Furthermore, physicians should be aware that when an adolescent is covered by a parent's insurance policy and the insurance company sends the policyholder an explanation of benefits that includes defined diagnostic codes, the adolescent patient's confidentiality is at risk of compromise.

RECOMMENDATIONS FOR PEDIATRICIANS

The AAP recommends that pediatricians:

1. Become knowledgeable about all aspects of SBIRT through training program curricula or continuing medical education that provide current best-practices training.
2. Become knowledgeable about the spectrum of substance use and the patterns of nicotine, alcohol, and other drug use, particularly by the pediatric population in their practice area.
3. Ensure appropriate confidentiality in care by becoming familiar and complying with state and federal regulations that govern health information privacy, including the confidential exchange of substance use and treatment information.
4. Screen all adolescent patients for tobacco, alcohol, and other drug use with a formal, validated screening tool, such as the CRAFFT screen, at every health supervision visit and appropriate acute care visits, and respond to screening results with the appropriate brief intervention.
5. Augment interpersonal communication and patient care skills by becoming familiar with motivational-interviewing techniques.
6. Develop close working relationships with qualified and licensed professionals and programs that provide the range of substance use prevention and treatment services, including tobacco cessation, that are necessary for comprehensive patient care.
7. Facilitate patient referrals through familiarity with the levels of treatment available in the area and application of the multidimensional assessment criteria to determine the intensity of services needed.
8. Make referrals to adolescent-appropriate treatment for youth with problematic use or a substance use disorder.
9. Consider throughout the SBIRT process that psychiatric disorders can co-occur in adolescents who use psychoactive substances.
10. Stay abreast of coding regulations, strategies, and updates to bill for tobacco, alcohol, and other drug use SBIRT services.
11. Advocate that heath care institutions and payment organizations provide mental health and substance use services across the pediatric/adolescent ages and developmental stages while ensuring parity, quality, and integration with primary care and other health services.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

CLINICAL REPORT

Suicide and Suicide Attempts in Adolescents

Guidance for the Clinician in Rendering Pediatric Care

Benjamin N. Shain, MD, PhD, and the Committee on Adolescence

ABSTRACT

Suicide is the third-leading cause of death for adolescents 15 to 19 years old. Pediatricians can take steps to help reduce the incidence of adolescent suicide by screening for depression and suicidal ideation and behavior. This report updates the previous statement of the American Academy of Pediatrics and is intended to assist the pediatrician in the identification and management of the adolescent at risk of suicide. The extent to which pediatricians provide appropriate care for suicidal adolescents depends on their knowledge, skill, comfort with the topic, and ready access to appropriate community resources. All teenagers with suicidal thoughts or behaviors should know that their pleas for assistance are heard and that pediatricians are willing to serve as advocates to help resolve the crisis.

INTRODUCTION

The number of adolescent deaths that result from suicide in the United States had been increasing dramatically during recent decades until 1990, when it began to decrease modestly. In 2003, there were 3988 suicides among people 15 to 24 years old; 1487 (11% of deaths) were among those 15 to 19 years old, and 2501 (13% of deaths) were among those 20 to 24 years old.[1] The true number of deaths from suicide actually may be higher, because some of these deaths may have been recorded as "accidental."[2]

From 1950 to 1990, the suicide rate for adolescents 15 to 19 years old increased by 300%,[3] but from 1990 to 2003, the rate in this age group decreased by 35%.[1] Adolescent boys 15 to 19 years old had a suicide rate that was 6 times greater than that of their female counterparts, whereas the rate of suicide attempts was twice as high among girls than among boys.[4] The ratio of attempted suicides to completed suicides among adolescents is estimated to be 50:1 to 100:1.[5] Suicide affects young people from all races and socioeconomic groups, although some groups seem to have higher rates than others. American Indian/Alaska Native males have the highest suicide rate, and black women have the lowest rate of suicide. A statewide survey of students in grades 7 through 12 found that 28.1% of bisexual and homosexual boys and 20.5% of bisexual and homosexual girls had reported attempting suicide.[6] The 2003 Youth Risk Behavior Survey of students in grades 9 through 12 in the United States indicated that during the 12 months before the survey, 28.6% of students felt sad or hopeless almost every day for at least 2 weeks in a row, 16.5% had planned a suicide attempt, 8.5% had attempted suicide, and 2.9% had made a suicide attempt that required medical attention.[4]

Firearms, used in half of completed suicides among people 15 to 19 years of age, were the leading method of suicide for boys in this age group in 2003 (54% of

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

suicides) and the second-leading method for girls (29%).[1] Suicide attempts that involve a firearm usually are fatal, because there is little chance for rescue. Firearms in the home, regardless of whether they are kept unloaded or stored locked, are associated with a higher risk of completed adolescent suicide.[7,8] In 1 study, when firearms were present in the home, each of the practices of securing the firearm (keeping it locked and unloaded) and the ammunition (keeping it locked and stored away from the firearm) were associated with reduced risk of youth shootings that resulted in unintentional or self-inflicted injury or death.[9] Parents must be warned about the lethality of firearms in the home and advised strongly to remove them from the premises or, at least, to secure them.[10] Ingestion of pills is the most common reported method of attempted suicide among adolescents.[11] However, the incidence of suicide attempts using other methods, such as hanging, is not known, because victims who do not die may not be brought for medical treatment.[11]

Youth seem to be at much greater risk from media exposure than adults and may imitate suicidal behavior seen on television.[12] Media coverage of an adolescent's suicide may lead to cluster suicides, with the magnitude of additional deaths proportional to the amount, duration, and prominence of the media coverage.[12]

ADOLESCENTS AT INCREASED RISK

Although no specific tests are capable of identifying a suicidal person, specific risk factors exist.[11,12] The clinician should use care in interpreting risk factors, however, because risk factors are common, whereas suicide is infrequent. In addition, the lack of most risk factors does not make an adolescent safe from suicide.

Fixed risk factors include family history of suicide or suicide attempts, male gender, parental mental health problems, gay or bisexual orientation, a history of physical or sexual abuse, and a previous suicide attempt. Social and environmental risk factors include the presence of firearms in the home, impaired parent-child relationship, living outside of the home (homeless or in a corrections facility or group home), difficulties in school, neither working nor attending school, social isolation, and presence of stressful life events such as legal or romantic difficulties or an argument with a parent. Personal mental health problems that predispose to suicide include depression, bipolar disorder, substance abuse or dependence, psychosis, posttraumatic stress disorder, panic attacks, and a history of aggression, impulsivity, or severe anger. More than 90% of adolescent suicide victims met criteria for a psychiatric disorder before their death. Immediate risk factors include agitation, intoxication, and a recent stressful life event. More information is available from the American Academy of Child and Adolescent Psychiatry[11] and Gould et al.[12]

INTERVIEWING THE ADOLESCENT

Primary care pediatricians should be comfortable screening for suicide and mood disorders by asking about emotional difficulties, identifying lack of developmental progress, and estimating level of distress, impairment of functioning, and level of danger to self and others. If needed, referral should then be made for appropriate mental health evaluation and treatment. This clinical report goes into more detail than is needed for this basic assessment. In areas where the resources necessary to make a timely mental health referral are lacking, pediatricians are strongly encouraged to obtain extra training and become competent in providing a more in-depth assessment.

The best way to assess for suicidal ideation is by directly asking or screening via self-report. Self-administered scales can be useful for screening, because adolescents may disclose information about suicidality on self-report that they deny in person. Scales, however, tend to be oversensitive and underspecific and lack predictive value (see the American Academy of Child and Adolescent Psychiatry practice parameter[11]). Adolescents who endorse suicidality on a scale should always be assessed clinically.

One approach to initiate a confidential inquiry into suicidal thoughts or concerns is to ask a general question such as, "Have you ever thought about killing yourself or wished you were dead?" The question is best placed in the middle or toward the end of a list of questions about depressive symptoms. Regardless of the answer to the first question, the next question should be, "Have you ever done anything on purpose to hurt or kill yourself?" If the response to either question is positive, the pediatrician should obtain more detail (eg, nature of past and present thoughts and behaviors, time frame, intent, who knows and how did they find out). Inquiry should include suicide plans ("If you were to kill yourself, how would you do it?"), whether there are firearms in the home, and the response of the family. No data indicate that inquiry about suicide precipitates the behavior. In a screening program, asking high school students about suicidal ideation and behavior did not create distress or increase suicidal ideation, even in high-risk students.[13]

The adolescent should be interviewed separately from the parent, because the patient may be more likely to withhold important information in the parent's presence. Information should also be sought from parents and others as appropriate. Although confidentiality is important in adolescent health care, for adolescents at risk to themselves or others, safety takes precedence over confidentiality; the adolescent should understand that at the onset. Pediatricians need to inform appropriate people when they believe an adolescent is at risk of suicide. As much as is possible, the sequence of events that preceded the threat should be determined, current problems and conflicts should be identified, and the

degree of suicidal intent should be assessed. In addition, pediatricians should assess individual coping resources, accessible support systems, and attitudes of the adolescent and family toward intervention and follow-up.[14]

Questions should also be asked to elicit known risk factors. In particular, all adolescents, especially any patients who show psychosocial or adaptive difficulties, should be screened regularly for symptoms of mood disorders and should be asked about suicidal ideation, physical and sexual abuse, substance use, and sexual orientation. Screening at acute care visits, when possible, is desirable, because mental health problems may manifest more strongly at these times.[15]

Care in interviewing needs to be taken, because abrupt intrusive questions could result in a reduction of rapport and a lower likelihood of the adolescent sharing mental health concerns. This is especially true during a brief encounter for an unrelated concern. Initial questions should be open-ended and relatively nonthreatening. Examples include "Aside from [already stated non–mental health concern], how have you been doing?" "Is there anything that has been stressing you lately?" "How have things been going with _ [school, friends, parents, sports]?" When possible, more detailed questions should then follow, particularly during routine care visits or when a mental health concern is stated or suspected.

Suicidal thoughts or comments should never be dismissed as unimportant. Statements such as, "You've come really close to killing yourself," may, if true, acknowledge the deep despair of the youth and communicate to the adolescent that the interviewer understands how close to acting he or she has been. Such disclosures should be met with reassurance that the patient's pleas for assistance have been heard and that help will be sought.

Serious mood disorders, such as major depressive disorder or bipolar disorder, may present in adolescents in several ways.[16] Some adolescents may come to the office with complaints similar to those of depressed adults, having symptoms such as sad or down feelings most of the time, crying spells, guilty or worthless feelings, markedly diminished interest or pleasure in most activities, significant weight loss or weight gain or increase or decrease in appetite, insomnia or hypersomnia, fatigue or loss of energy, diminished ability to think or concentrate, and thoughts of death or suicide. The clinician should also look for adolescent manifestations of symptoms (Table 1).[17] Some adolescents may present with irritability rather than depressed mood as the main manifestation. Other adolescents present with somatic symptoms such as abdominal pain, chest pain, headache, lethargy, weight loss, dizziness and syncope, or other nonspecific symptoms.[18] Others present with behavioral problems such as truancy, deterioration in academic performance, running away from home, defiance of authorities, self-destructive behavior, vandalism, alcohol or other drug abuse, sexual acting out, and delinquency.[19]

Typically, symptoms of depression, mania, or a mixed state (depression and mania coexisting or rapidly alternating) can be elicited with careful questioning but may not be immediately obvious. Mania is characterized by irritability or euphoria along with symptoms that include decreased need for sleep, talking a lot, racing thoughts, grandiosity, distractibility, agitation or increased goal-directed activity, or excessive involvement in pleasurable activity that has a high potential for painful consequences (eg, running away, sexual activity, putting self in dangerous situations).[16] Mania was once thought to occur only rarely in youth. However, approximately one fifth of all patients with bipolar disorder have their first episode during adolescence, although the prevalence in adolescents is still controversial. Developmental variations in presentation, symptomatic overlap with other disorders, and lack of clinician awareness

TABLE 1 **Depressive Symptoms and Examples in Adolescents**

Signs and Symptoms of Major Depressive Disorder	Signs of Depression Frequently Seen in Youth
Depressed mood most of the day	Irritable or cranky mood; preoccupation with song lyrics that suggest life is meaningless
Decreased interest/enjoyment in once-favorite activities	Loss of interest in sports, video games, and activities with friends
Significant weight loss/gain	Failure to gain weight as normally expected; anorexia or bulimia; frequent complaints of physical illness; eg, headache, stomach ache
Insomnia or hypersomnia	Excessive late-night TV; refusal to wake for school in the morning
Psychomotor agitation/retardation	Talk of running away from home, or efforts to do so
Fatigue or loss of energy	Persistent boredom
Low self-esteem; feelings of guilt	Oppositional and/or negative behavior
Decreased ability to concentrate; indecisive	Poor performance in school; frequent absences
Recurrent suicidal ideation or behavior	Recurrent suicidal ideation or behavior (writing about death; giving away favorite toys or belongings)

(Reprinted with permission from the *Diagnostic and Statistical Manual of Mental Disorders*. Washington, DC: American Psychiatric Association; 2000.)

have all led to underdiagnosis or misdiagnosis.[20] Red flags for mania in adolescents include episodes of rage, grossly overreacting to limit setting or other circumstances that the adolescent does not desire, and having good days and bad days. Mixed states may be particularly dangerous, because the adolescent may have hopelessness associated with depression and agitation, impulsivity, and the ability to get things done associated with mania.

MANAGEMENT OF THE SUICIDAL ADOLESCENT

Management depends on the degree of immediate and intermediate risk (see the American Academy of Child and Adolescent Psychiatry practice parameter[11] for a review and the article by Kaye et al[21] for a practical guide to pediatric mental health evaluation, treatment, and systems of care). Unfortunately, no one can accurately predict suicide, so even experts can only determine who is at higher risk. Examples of adolescents at high risk include those with a plan or recent suicide attempt with a high probability of lethality; stated current intent to kill themselves; recent suicidal ideation or behavior accompanied by current agitation or severe hopelessness; and impulsivity and profoundly dysphoric mood associated with bipolar disorder, major depression, psychosis, or a substance use disorder. An absence of factors that indicate high risk, especially in the presence of a desire to receive help and a supportive family, suggests a lower risk but not necessarily a low risk. Low risk is difficult to determine. For example, an adolescent who has taken 8 ibuprofen tablets may have thought that it was a lethal dose and may do something more lethal the next time. Alternatively, the adolescent may have known that 8 ibuprofen tablets is not lethal and took the pills as a rehearsal for a lethal attempt. In the presence of a recent suicide attempt, the lack of current suicidal ideation may also be misleading if none of the factors that led to the attempt have changed or the reasons for the attempt are not understood. The benefit of the doubt is generally on safety in the management of the suicidal adolescent.

The term "suicide gesture" should not be used, because it gives a false sense of security. "Suicide attempt" is a more appropriate term for any deliberately self-harmful behavior or action that could reasonably be expected to produce self-harm and is accompanied by some degree of intent or desire for death as well as thinking by the patient at the time of the behavior that the behavior had even a small possibility of resulting in death. In a less-than-forthcoming patient, intent may be inferred by the lethality of the behavior, such as taking a large number of pills, or by an affirmative answer to a question such as, "At the time of your action, would you have thought it okay if you had died?"

Adolescents who initially may seem at low risk, joke about suicide, or seek treatment for repeated somatic complaints may be asking for help the only way they can. Their concerns should be assessed thoroughly. Adolescents who are judged to be at low risk of suicide should still receive close follow-up, referral for a timely mental health evaluation, or both if they should have any significant degree of dysfunction or distress from emotional or behavioral symptoms.

For adolescents who seem to be at moderate or high risk of suicide or have attempted suicide, a mental health professional should be consulted immediately during the office visit. Options for immediate evaluation include hospitalization, transfer to an emergency department, or an appointment the same day with a mental health professional.

Intervention should be tailored to the adolescent's needs. Adolescents with a responsive and intact family, good peer relations and social support, hope for the future, and a desire to resolve conflicts may require only a brief crisis-oriented intervention.[22] In contrast, adolescents who have made previous attempts, exhibit a high degree of intent to commit suicide, show evidence of serious depression or other psychiatric illness, are abusing alcohol or other drugs, have low impulse control, or have families who are unwilling to commit to counseling are at high risk and may require psychiatric hospitalization and long-term psychiatric and psychologic intervention.

Although no controlled studies have been conducted to prove that admitting adolescents at high risk to a psychiatric unit saves lives,[11] the safest course of action is hospitalization, thereby placing the adolescent in a safe and protected environment. An inpatient stay will allow time for a complete medical and psychiatric or psychologic evaluation with initiation of therapy in a controlled setting. The choice of hospital unit depends on available facilities in the area, health and mental health insurance, and managed care policies. Medical units that hospitalize adolescents must be staffed to manage both the medical and psychiatric needs of suicidal adolescents.[23] Proper medical intervention and treatment are essential for stabilization and management of patients' conditions. After the adolescent's condition has been stabilized medically, a comprehensive emotional and psychosocial assessment must be completed before discharge. Inquiry should be made into the events that preceded the attempt, the adolescent's current problems, and the presence of current or previous psychiatric illness and self-destructive behavior. In addition to an in-depth psychologic evaluation of the adolescent, family members should be interviewed to obtain additional information to help explain the adolescent's suicidal thoughts or attempt. This information includes detailed questions about the adolescent's medical, emotional, social, and family history with special attention to signs and symptoms of mood disorders, stress, substance abuse, impulsivity, and anger. With parental permission and adolescent assent,

teachers and family friends also may provide useful information.

All adolescents who attempt suicide need a comprehensive outpatient treatment plan before discharge. Specific plans are needed, because adherence with outpatient therapy often is poor. Most adolescents who are examined in emergency departments and referred to outpatient facilities fail to keep their appointments. This is especially true when the appointment is made with someone other than the medical home practitioner or the person who performed the initial assessment.[24] Continuity of care, therefore, is of paramount importance. Medical home practitioners can enhance continuity and adherence by maintaining contact with suicidal adolescents even after referrals are made. All firearms should be removed from the home, because adolescents may still find access to locked guns stored in their home. Potentially lethal medication should be locked up. Vigorous treatment of the underlying psychiatric disorder is important in decreasing short-term and long-term risk. Contracting with the adolescent against suicide has not been proven effective in preventing suicidal behavior.[11] The technique may still be helpful in assessing risk in that refusal to agree to either not harm oneself or tell a specified person about intent to harm oneself is ominous.

Working with a suicidal adolescent typically provokes anxiety in those who are providing treatment. Suicide risk can only be reduced, not eliminated, and risk factors provide no more than guidance. Much of the information regarding risk factors is subjective and must be elicited from the adolescent, who may have his or her own agenda. Of course, clinicians' anxiety may be reduced with knowledge and experience. Just as importantly, clinicians need to be aware of their own anxiety to prevent interference in treatment and overreaction or underreaction.

ANTIDEPRESSANT MEDICATIONS AND SUICIDE

A complete review of the pharmacologic treatment of adolescent mood disorders is beyond the scope of this report. However, the Food and Drug Administration (FDA) directive of October 2004 and heavy media coverage make the use of antidepressant medications worth mentioning. The FDA directed pharmaceutical companies to label all antidepressant medications distributed in the United States with a black-box warning "to alert health care providers to an increased risk of suicidality (suicidal thinking and behavior) in children and adolescents being treated with these agents."[25] The FDA did not prohibit the use of these medications in youth but called on clinicians to balance increased risk of suicidality with clinical need and to monitor closely "for clinical worsening, suicidality, or unusual changes in behavior." The warning particularly stressed the need for close monitoring during the first few months of treatment and after dose changes.

The FDA advisory panel was aware that this warning could have the unintended effect of limiting access to necessary and effective treatment,[17] and reported prescriptions of antidepressants for children and adolescents decreased by 19% in the third quarter of 2004 and 16% in the fourth quarter compared with the year before.[26] Concern has been expressed that this reduction of antidepressant prescribing may be related to the 18.2% increase in US youth suicides (1737–1935) from 2003 to 2004 after a decade of steady declines.[27]

A recent example of the effectiveness of these medications in adolescents is the Treatment for Adolescents With Depression Study,[28] a large, well-designed study that found that a combination of fluoxetine and cognitive behavioral therapy led to significant clinical improvement in 71% of adolescents with major depression. This compared with improvement of 61% for fluoxetine alone, 43% for cognitive behavioral therapy alone, and 35% for placebo. Those who were treated with fluoxetine showed approximately twice the rate of self-harm adverse events compared with those who were not treated with fluoxetine.[28] However, despite adolescents with the highest suicide risk being excluded from the study, 29% of the depressed patients reported suicidal thoughts before the start of treatment. After 12 weeks of treatment, this decreased to 10% across all groups, with the combined-treatment group showing significantly more of a decrease than those in the placebo group.

The warning by the FDA was prompted by a finding that in 24 clinical trials that involved more than 4400 child and adolescent patients and 9 different antidepressant medications, spontaneously reported suicidal ideation or behavior was present in 4% of the subjects who were taking medication and 2% of the subjects who were taking a placebo. Contradictory findings of a slight reduction of suicidality, however, were found when subjects were asked at each visit about suicidal ideation and behavior. The latter method does not rely on spontaneous reports and is considered to be more reliable than event reports.[17]

Furthermore, a reanalysis of the data including 7 additional studies and using a random-effects model showed only a 0.7% increase in the risk of suicidal ideation or behavior.[29] The random-effects model is considered to provide a more conservative estimate of effect compared with the fixed-effect model used by the FDA, because it does not assume homogeneity across studies as does the fixed-effects model.

No suicides occurred during any of the studies. Suicidal ideation and behavior are common, and suicides are vastly less common, which makes it difficult to relate a change in one to a change in the other.[17] Furthermore, the 28% decrease in completed suicides in the 10- to

19-year-old age group over the past decade may be at least partly a result of the increase of youth antidepressant prescribing over the same time period. Analyzing US data by dividing the country into 588 2-digit zip-code zones showed a significant ($P < .001$) 0.23-per-100 000 annual decrease in adolescent suicide with every 1% increase in antidepressant prescribing.[30]

Regardless of whether the use of antidepressant medications changes the risk of suicide, depression is an important suicide risk factor, and careful monitoring of adolescents' mental health and behavioral status is critically important, particularly when initiating or changing treatment. The FDA warning states, "All pediatric patients being treated with antidepressants for any indication should be observed closely for clinical worsening, suicidality, and unusual changes in behavior, especially during the initial few months of a course of drug therapy, or at times of dose changes (either increases or decreases). Ideally, such observation would include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then visits every other week for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits."[31]

The American Psychiatric Association and the American Academy of Child and Adolescent Psychiatry have recommended a different monitoring approach[17] that enlists the parents or guardians in the responsibility for monitoring and individualizing the frequency and nature of monitoring to the needs of the patient and the family. This approach potentially increases the effectiveness of monitoring and provides greater flexibility, thus reducing a barrier to prescribing. Warning signs for family members to contact the prescribing physician are listed in Table 2.[17]

Patients should not abruptly stop antidepressant medications, because withdrawal effects may include agitation and increased depression. Pediatricians should convey to parents the importance of consulting with the prescribing physician before stopping medication or changing the dose.

TABLE 2 **Treatment With Antidepressant Medication: Warning Signs for Family Members to Contact the Physician**

New or more frequent thoughts of wanting to die
Self-destructive behavior
Signs of increased anxiety/panic, agitation, aggressiveness, impulsivity, insomnia, or irritability
New or more involuntary restlessness (akathesia), such as pacing or fidgeting
Extreme degree of elation or energy
Fast, driven speech
New onset of unrealistic plans or goals

SUMMARY

1. Adolescent suicide is an important public health problem.
2. Knowledge of risk factors may assist in the identification of adolescents who are at higher risk.
3. It is important to know and use appropriate techniques for interviewing potentially suicidal adolescents.
4. Mood disorders in adolescents have a variety of presentations.
5. Management options depend on the degree of suicide risk.
6. Treatment with antidepressant medications has risks and benefits.

ADVICE FOR PEDIATRICIANS

1. Ask questions about mood disorders, suicidal thoughts, sexual orientation, and other risk factors associated with suicide in routine history taking throughout adolescence, preferably at both acute care and routine care visits.
2. Recognize the medical and psychiatric needs of the suicidal adolescent and work closely with families and health care professionals involved in the management and follow-up of youth who are at risk or have attempted suicide. Develop working relationships with emergency departments and colleagues in child and adolescent psychiatry, clinical psychology, and other mental health professions to optimally manage the care of adolescents who are at risk of suicide. Because mental and physical health services are often provided through different systems of care, extra effort is necessary to ensure good communication, continuity, and follow-up through the medical home.
3. Because resources for adolescents and physicians vary by community, become familiar with local, state, and national resources that are concerned with treatment of psychopathology and suicide prevention in youth, including local hospitals with psychiatric units, mental health agencies, family and children's services, crisis hotlines, and crisis intervention centers. Have a list of relevant telephone numbers easily available in the office.
4. Educate yourself and your patients about the risks and benefits of antidepressant medications and provide reassurance that the medications are relatively safe and depression is relatively dangerous.
5. Carefully monitor patients with depression, especially after the initiation of antidepressant medication treatment and dose changes.

6. Because there is great variation among general pediatricians in training and comfort with assessing and treating patients with mental health problems, as well as in access to appropriate mental health resources, consider additional training and ongoing education in diagnosing and managing adolescent mood disorders, especially if practicing in an underserved area. Pediatricians without such skills still have an important role in screening all patients and referring patients when necessary.
7. During routine evaluations, ask whether firearms are kept in the home, and discuss with parents the increased risk of adolescent suicide with the presence of firearms. Specifically for adolescents at risk of suicide, advise parents to remove guns and ammunition from the house and secure supplies of potentially lethal medications.
8. Know the risk factors (eg, signs and symptoms of depression) associated with adolescent suicide and serve as a resource on the issue of adolescent suicide for parents, teachers, school personnel, clergy, and members of community groups who work with youth.
9. Advocate for benefit packages in health insurance plans to ensure that adolescents have access to preventive and therapeutic mental health services that adequately cover the treatment of clinically significant mental health disorders.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Supplemental Security Income (SSI) for Children and Youth With Disabilities

abstract

The Supplemental Security Income (SSI) program remains an important source of financial support for low-income families of children with special health care needs and disabling conditions. In most states, SSI eligibility also qualifies children for the state Medicaid program, providing access to health care services. The Social Security Administration (SSA), which administers the SSI program, considers a child disabled under SSI if there is a medically determinable physical or mental impairment or combination of impairments that results in marked and severe functional limitations. The impairment(s) must be expected to result in death or have lasted or be expected to last for a continuous period of at least 12 months. The income and assets of families of children with disabilities are also considered when determining financial eligibility. When an individual with a disability becomes an adult at 18 years of age, the SSA considers only the individual's income and assets. The SSA considers an adult to be disabled if there is a medically determinable impairment (or combination of impairments) that prevents substantial gainful activity for at least 12 continuous months. SSI benefits are important for youth with chronic conditions who are transitioning to adulthood. The purpose of this statement is to provide updated information about the SSI medical and financial eligibility criteria and the disability-determination process. This statement also discusses how pediatricians can help children and youth when they apply for SSI benefits. *Pediatrics* 2009;124:1702–1708

THE SUPPLEMENTAL SECURITY INCOME PROGRAM FOR CHILDREN

The Supplemental Security Income (SSI) program was established by the Social Security Amendments of 1972 (Pub L No. 92-603) and replaced several federal programs including Old-Age Assistance, Aid to the Blind, Aid to the Permanently and Totally Disabled, and other grants to the states. The SSI program makes monthly payments to people who have low income and limited resources (assets) and are 65 years or older, blind, or disabled. It was the first government program to provide cash payments for the benefit of children with disabilities. The first payments were made under SSI in January 1974. The number of child recipients of SSI has grown substantially since it was first introduced. As of December 2005, more than 1 million children younger than 18 years were eligible for SSI benefits.[1] The SSI program continues to be administered by the Social Security Administration (SSA).

The SSI program remains an important program of the federal government for children and adolescents with disabilities/special needs.[2–4] SSI is a nationwide program that:

- provides monthly cash payments based on family income and resources;
- qualifies a child for Medicaid health care benefits in most states; and
- ensures referral of children who receive SSI to state Title V children with special health care needs programs.

SSI VERSUS SOCIAL SECURITY DISABILITY INSURANCE

SSI is often confused with Social Security Disability Insurance (SSDI). The SSI program makes payments to children with disabilities/special needs who are younger than 18 years, and eligibility is based on family/individual income and assets. The definition of disability for children under SSI is different from the definition of disability for adults. SSI payments are funded through general revenues of the federal government but can be supplemented by the states. SSDI benefits are funded by Social Security (Federal Insurance Contributions Act [FICA]) taxes, which workers and self-employed people pay into the Social Security trust fund. Any child, disabled or not, can receive SSDI benefits if a parent is disabled or retired and is entitled to Social Security benefits, or if a parent dies, having worked long enough under Social Security. The child must be younger than 18 years (or 18–19 years of age and still in high school) and unmarried. For SSDI, there are no income or asset limits; however, SSDI is based on employment history and payment of Social Security taxes. An adult who was disabled before 22 years of age may be eligible for child's benefits if a parent is deceased or receiving retirement or disability benefits. The SSA considers this a "child's" benefit, because it is paid on a parent's Social Security earnings record. The disability decision is made by using the disability rules for adults. An individual who is entitled to receive SSDI benefits becomes eligible for Medicare after a 2-year waiting period. There are different listings of medical impairments that may qualify for either SSI or SSDI, although both are based on an individual's disability precluding them from gainful employment.

Approximately two thirds of US states and the District of Columbia provide Medicaid eligibility to people who are eligible for SSI benefits. In these states, the SSI application is also the Medicaid application, and eligibility for Medicaid starts the same month as that for SSI. A small number of states* use the same rules to decide eligibility for Medicaid as the SSA uses for SSI but require the filing of a separate application, and others* use their own eligibility rules for Medicaid, which are different from federal SSI rules, and a separate application for Medicaid must be filed.[5]

The last major change to the SSI program was in 1996, when the Personal Responsibility and Work Opportunity Reconciliation Act (Pub L No. 104-193) changed the definition of disability for children to require a medically determinable impairment or combination of impairments that results in marked and severe functional limitations. This legislation also removed the individualized functional assessment step from the disability-determination process, which had been in place since February 1990.

*For more information about current related laws, please contact the American Academy of Pediatrics Division of State Government Affairs (www.aap.org/advocacy/stgov.htm).

ELIGIBILITY

Disability Criteria

Under current regulations, the SSA considers a child (birth to age of 18 years) to be disabled if:

- the child has a medically determinable physical or mental impairment (or combination of impairments) that results in marked and severe functional limitations; and
- the disability has lasted or is expected to last at least 1 year or is expected to result in death (within 1 year).[6,7]

Financial/Resource Eligibility Criteria

The financial and resource eligibility criteria for SSI are complicated. Although there are general guidelines, there are many exceptions. Therefore, the information provided here should be used as a general guide. The upper income limits for eligibility for the SSI program (Table 1) are higher in most states than for other federal or state programs, such as Medicaid or a State Children's Health Insurance Program (SCHIP). There are also limits on the amount of total assets (resources), such as jewelry, savings accounts, or checking accounts, that a family can have. In 2009, the limit on assets is $2000 if 1 parent lives in the household and $3000 if 2 parents live in the household.

BENEFITS

Children on SSI receive a monthly payment based on the income of the child and other family members in the household. The federal benefit rate in 2009 is $674 per month for an individual and $1011 for a couple. The total SSI payment varies according to state, because some states supplement the federal benefit rate with state funds. SSI eligibility also automatically qualifies a child for Medicaid in most states.

TABLE 1 SSI Income Eligibility

No. of Other Children Without a Disability in Household	Maximum Earned Monthly Income, $[a]		Maximum Unearned Monthly Income, $[a]	
	1-Parent Household	2-Parent Household	1-Parent Household	2-Parent Household
0	2821	3495	1388	1725
1	3158	3832	1725	2062
2	3495	4169	2062	2399
3	3832	4506	2399	2736
4	4169	4843	2736	3073
5	4506	5180	3073	3410
6	4843	5517	3410	3747

Shown is parents' maximum monthly income (in dollars) for a child with disability to be eligible for SSI in states that do not supplement SSI payments (for the year 2008). Amounts are adjusted each year to reflect inflation. The maximum levels are higher in states that supplement SSI.

[a] Rules related to "earned" and "unearned" income are complex. A chart cannot show a maximum amount when some of the family's monthly income is earned and some is unearned. If the family's total estimated income is close to the limit for earned income, a child may still qualify for SSI.

The income eligibility requirements for SSI continue to be more liberal, in general, than those for Medicaid. Therefore, the SSI program continues to provide children with disabilities access to the health care services that they might not otherwise be able to afford.[3] In addition, the Deficit Reduction Act of 2005 included passage of the Family Opportunity Act, a long-sought program that gives states the opportunity to provide Medicaid coverage to children with special health care needs who would qualify for SSI if not for family income and/or resources. Under the Family Opportunity Act, states have the option to expand Medicaid coverage to children up to the age of 18 with family incomes up to 300% of the federal poverty level who meet the SSI disability standard but whose family income exceeds current eligibility levels. The Family Opportunity Act includes provisions that require limits on cost-sharing and interaction with employer-sponsored insurance when families have access to insurance in which the employer provides at least 50% of the costs of the annual premium.[8] Several states also exempt SSI recipients from mandated enrollment in Medicaid managed-care arrangements. In addition, all state Title V children with special health care needs programs are mandated to assist children who receive SSI in accessing health and other supportive services.

APPLICATION PROCESS

If there is any possibility that a child is eligible for SSI, the parent or guardian should apply on behalf of the child. Some states require that families apply for SSI before they will consider the child's eligibility for state programs. Table 2 provides detailed information about how families can apply for SSI benefits for a child with disabilities.

DETERMINATION OF ELIGIBILITY FOR SSI

Presumptive Disability

Presumptive disability allows payments to begin quickly when there is a very strong likelihood that the child will be found to be disabled once all the evidence is obtained. Children for whom 1 of the following conditions is alleged may meet the requirements for a presumptive-disability decision, which can be made at the local SSA office. These conditions are:

- amputation of a leg at the hip;
- total blindness;
- total deafness;
- bed confinement or immobility without use of a wheelchair, walker, or crutches as a result of a recent change in a long-standing condition, excluding recent accident or recent surgery;
- stroke (cerebral vascular accident) that occurred more than 3 months ago, and the child has continued marked difficulty in walking or using a hand or arm;
- cerebral palsy, muscular dystrophy or muscular atrophy, and marked difficulty in walking, speaking, or coordinating the hands or arms;
- Down syndrome;
- severe mental deficiency (mental retardation) in a child aged 7 years and older;
- symptomatic HIV infection;
- birth weight of less than 1200 g and an age of 1 year or younger;
- birth weight between 1200 and 2000 g related to specific gestational ages and an age of 1 year or younger;
- HIV infection, confirmed by a medical source, and the file contains form SSA-4814 or SSA-4815;
- terminal cancer/illness with a life expectancy of 6 months or less, with confirmation by telephone or in a signed statement from a physician, or in hospice care, with confirmation from a physician or knowledgeable hospice official;
- allegation of spinal cord injury causing inability to ambulate without a walker or equivalent device 2 weeks after a spinal cord injury, with confirmation from an appropriate medical professional;
- end-stage renal disease with ongoing dialysis, and the file contains a completed form CMS-2728 (End-Stage Renal Disease Medical Evidence Report-Medicare Entitlement and/or Patient Registration); or
- allegation of amyotrophic lateral sclerosis (ALS or Lou Gehrig disease).

TABLE 2 What to Tell Families About SSI Application, Disability Determination, and Appeals Procedures: SSI Citizenship and Residency Eligibility Criteria

How to apply
To apply for SSI benefits for a disabled child, parents should call the toll-free number for the SSA (1-800-772-1213) to make an appointment for a telephone interview or visit a local Social Security office to complete an application.
If parents make an appointment for a telephone interview, an SSA claims interviewer will contact them. The interviewer will provide general information to parents about the financial, medical, disability, and functional criteria used to determine SSI eligibility. This information is provided to help parents decide whether to proceed with the application process. The SSA prefers that parents use the telephone process because, according to the SSA, it is more efficient for both the parents and the SSA.
What parents need to know
The telephone line is often busy, but they should keep trying.
The SSA interviewer will gather information about family income, financial resources, and the child's citizenship/residency status.
On the basis of the above-listed information, the interviewer will indicate whether it appears that the child is financially eligible for SSI.
Financial eligibility for adults (≥18 y) is based only on what the young adult owns and/or earns; parental income/assets are not considered in the determination.
The interviewer will ask the parents if they want to file an application for the child.
They have a right to request and file an application even if it does not appear that the child qualifies financially.
They will need to be prepared to provide the interviewer with information about all the medical sources who have treated or examined the child for the alleged conditions, including their complete names, addresses, telephone numbers, and dates of treatment.
Application forms completed by telephone will be mailed to the parents' home for signature.
The telephone interviewer should not suggest that the child does (or does not) appear to meet the SSI disability criteria.
The date of the telephone interview serves as the protective filing date, so there is no loss of payments. Parents should keep a record of all contacts with the SSA, including the name, date, and telephone number (including the extension) of the person with whom they spoke.
The process of determining disability can take several months or more.
Applying at the SSA field office
If parents choose to go to a local SSA field office, they should call either the local office or the toll-free number to make an appointment. This will ensure that an SSA staff person will be available to take the application and will reduce the amount of waiting time when filing an application. If parents cannot gather all of the required information by the time of the appointment, they should still go to the SSA field office at that time to begin the application process, thus establishing a protective filing date. When the SSA has the needed information about family income and financial resources, they will determine the financial eligibility for SSI.
SSI citizenship and residency eligibility criteria
To be eligible for SSI, a child must be a US citizen or a naturalized citizen. For SSI disability purposes, a child is an individual who is younger than 18 y. Children who are authorized to remain in the United States by the Immigration and Naturalization Service may also qualify. The child must also reside in 1 of the 50 states, the District of Columbia, or the Northern Mariana Islands. Children who live in Puerto Rico, Guam, and the US Virgin Islands may be US citizens but do not meet the SSI requirements for residency. The exception is children of military personnel who are assigned to overseas duty.

The field-office staff may base presumptive disability decisions on observations they make during interviews or on the documentation from medical or other health care professionals. Medical or psychological staff of the state disability-determination services (see next section) may make such decisions with respect to any impairment, not just those listed here.

A child who has been found to be disabled under a presumptive disability decision may receive SSI payments for up to 6 months while the formal evaluation of eligibility is conducted. For the determination of a presumptive disability, the pediatrician who treats a child with 1 of these conditions should provide the parents with a statement about the diagnosis and the severity of the child's condition. Parents can request a presumptive disability decision for their child on the basis of this statement.

Disability Determination

Each state has an agency that makes disability determinations on behalf of the SSA.[5] States use a variety of names for these agencies; however, they are generically known as disability-determination services (DDSs). State DDS offices operate under federal regulations and instructions issued by the SSA. Once the representative in the SSA office determines that the child is a US citizen and appears to qualify financially, he or she sends information about the child's disability and a list of additional sources of information to the DDS office. (Additional information about citizen and residency requirements is included in Table 2.) The DDS agency uses a team that consists of a disability examiner and medical or psychological professionals to decide whether a child is eligible for SSI on the basis of the available medical and nonmedical evidence.[9,10]

The decision-making team attempts to develop a complete medical and functional history for the child for at least the 12 months preceding the application for SSI. DDS staff members do not examine the child. Information is requested from physicians, hospitals, psychologists, schools, teachers, therapists, social workers, parents, friends, relatives, the child, and anyone else who may be able to provide relevant information about the child's impairment(s) and functioning. The determination of disability by the DDS agency is based primarily on the written information submitted, especially the child's medical records. It is essential, therefore, for pediatricians and other professionals to forward appropriate records or to provide a complete, detailed summary report.

Role of the Primary Care Physician

The primary care physician, as provider of the medical home, is uniquely positioned to act as both repository for this information and facilitator for submission of the summary report. However, the role of treating physicians is to provide accurate, timely, impartial information, not to decide whether an individual is disabled. The DDS team will make the disability decision by using information from the primary care physician and many other sources. A pediatrician's medical report in support of a child's application for SSI should:

- use specific terms and include results from specific clinical tests (if they have been obtained) mentioned in the childhood Listing of Impairments from the SSA[7];
- include at least a 12-month medical history of the child;
- provide complete, detailed clinical findings (including any results of physical, intelligence, developmental, and mental status examinations);
- include complete, detailed laboratory findings (eg, blood pressure, radiographic films, and chromosome test results);
- specify the diagnosis (statement of disease or injury on the basis of signs, symptoms, and laboratory findings);
- review treatments prescribed with response and prognosis;
- state the probable duration of the impairment;
- include an assessment of the child's physical or mental abilities to function in an age-appropriate manner and to perform age-appropriate daily activities; and
- describe the nature and limiting effects of the impairment(s) on the child's ability to function in an age-appropriate manner and to perform age-appropriate daily activities.

If the available information provided by those who treat the child is insufficient for determining disability, the DDS agency can arrange and pay for a consultative examination by a treating physician or, if a treating physician is unable or unwilling to conduct the examination, by an independent physician. On the basis of all the available information, the DDS agency follows a 3-step process[11] ("sequential evaluation") to make a determination. The steps of this process and the decision criteria are described in the next paragraph. The DDS agency then informs the SSA of the decision and sends a written notification of the decision to the parents (or other applicant). If the claim is denied, the decision notice includes the reasons and provides information about the right to appeal the decision.

THE 3-STEP EVALUATION PROCESS

At step 1, the examiner determines whether the child is engaging in substantial gainful activity (SGA)—that is, working and earning more than $980/month ($1640/month for a blind individual).† If the child is engaging in SGA, the claim is denied. If the child is not engaging in SGA, the examiner goes to step 2 of the evaluation process.

At step 2, a medical or psychological consultant determines, on the basis of available documentation, whether the child has an impairment or combination of impairments that is severe. "Severe" is defined as more than a minimal or slight limitation in a child's ability to function in an age-appropriate manner. If the child's impairment is a slight abnormality or combination of slight abnormalities that causes no more than minimal functional limitations, the SSI claim is denied. If it is determined that the impairment is severe, the examiner proceeds to step 3.

At step 3, the medical or psychological consultant determines whether the child's impairment is the same as ("meets") or is medically equivalent in severity to ("equals") 1 of the conditions on the Listing of Impairments from the SSA.[7] The DDS team will find that a child's impairment (or combination of impairments) meets a listed condition only when the symptoms, signs, and laboratory findings are the same as the findings included in the criteria in the SSI listings for that impairment. If a child's impairment meets a listing, then that child is determined to be disabled and is eligible for SSI benefits. If the child's impairment does not meet a listing, the medical consultant must determine if the child's impairment is "medically equivalent in severity" to any listed impairment. If it is not, the medical consultant must determine if the child's impairment functionally equals any listed impairment by considering how the child functions compared with children of the same age without impairments.

TRANSITIONING YOUTH

SSI can be an important source of financial support and health benefits (by linked Medicaid eligibility) for young adults with disabilities. Once an individual with a disability becomes an adult at 18 years of age, the DDS agency determines his or her eligibility for SSI by using the adult definition of disability—that is, inability to perform SGA. Approximately one third of children who receive SSI will lose their SSI eligibility because of the change in disability criteria effective at 18 years of age, based on disability and financial resources. However, children with severe impairments who were not eligible for SSI as children because the family did not meet financial eligibility

†These represent 2008 income levels.

requirements often become eligible for SSI after their 18th birthday. The SSA regards individuals aged 18 years and older, even if they live with their parents, to be a household of 1 for purposes of determining financial eligibility. These individuals must meet the adult definition of disability to be found disabled. Adults on SSI are generally eligible for services through their state vocational rehabilitation agency as well as a variety of work incentives and supports, including the Medicaid Buy-In Program, which has been introduced in a number of states. Each state has at least 1 Benefits Planning and Outreach Assistance organization that can help individuals to understand SSI and SSDI benefits as well as work incentives.

RECOMMENDATIONS

Pediatricians, individually and through state chapters of the American Academy of Pediatrics, should continue efforts to make families aware of the SSI program and provide assistance with the SSI application process. Such efforts can ensure that program benefits intended for children and youth with medically eligible conditions will be received. These efforts should include:

- in conjunction with the medical home model,[12] designating at least 1 member of the office staff to remain up-to-date on SSI policies and procedures;
- making up-to-date information about the SSI program available to families;
- obtaining a copy of the Listing of Impairments from the SSA and using this document as a basis for providing specific, detailed reports to the DDS agency in support of children's applications for SSI benefits;
- promoting methods of increasing office efficiency for timely completion of reports provided to the DDS agency;
- following the Pediatric Consultative Examination Guidelines of the SSA when performing consultative examinations of children; the guidelines are available through the DDS agency ("The Green Book"[10]);
- supporting and facilitating the ongoing distribution of SSA brochures to inform professionals and families about the SSI program; and
- inviting staff members from the SSA and DDS to participate in local and statewide educational meetings and workshops organized by American Academy of Pediatrics chapters.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Clinical Report—Supporting the Health Care Transition From Adolescence to Adulthood in the Medical Home

abstract

Optimal health care is achieved when each person, at every age, receives medically and developmentally appropriate care. The goal of a planned health care transition is to maximize lifelong functioning and well-being for all youth, including those who have special health care needs and those who do not. This process includes ensuring that high-quality, developmentally appropriate health care services are available in an uninterrupted manner as the person moves from adolescence to adulthood. A well-timed transition from child- to adult-oriented health care is specific to each person and ideally occurs between the ages of 18 and 21 years. Coordination of patient, family, and provider responsibilities enables youth to optimize their ability to assume adult roles and activities. This clinical report represents expert opinion and consensus on the practice-based implementation of transition for all youth beginning in early adolescence. It provides a structure for training and continuing education to further understanding of the nature of adolescent transition and how best to support it. Primary care physicians, nurse practitioners, and physician assistants, as well as medical subspecialists, are encouraged to adopt these materials and make this process specific to their settings and populations. *Pediatrics* 2011;128:182–200

1. INTRODUCTION AND METHODOLOGY

With reasonable biological certainty, most adolescents transition to adulthood. There is much less certainty about the manner in which health care professionals support this transition. Transition planning, when present at all, can be inexplicit, incomplete, or late, and when necessary, the transfer of care to an adult medical home and to adult medical subspecialists involves more of a drift away from pediatric care rather than a clearly planned and executed handoff. In 2002, a consensus statement coauthored by the American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), and the American College of Physicians (ACP)-American Society of Internal Medicine was published, stating the importance of supporting and facilitating the transition of adolescents with special health care needs* into adulthood.[1] This statement represented the shared perspectives of health care professionals, families, youth, researchers,

*The Maternal and Child Health Bureau (MCHB) defines children and youth with special health care needs as "[t]hose who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."[21]

and policy-makers. It provided foundational guidance for health care processes that include health care planning and information exchange, for professional education and certification, and for insurance and payment reform. Its conclusions and critical steps remain widely accepted standards that have informed the development of pilot projects, model practices, and national initiatives to improve support for transitioning youth. The US Department of Health and Human Service's Maternal and Child Health Bureau (MCHB) has been instrumental in promoting the importance of seamless, effective, and comprehensive services for all youth and families during this major life transition.[2]

After nearly a decade of effort, widespread implementation of health transition supports as a basic standard of high-quality care has not been realized. To date, only limited progress can be documented in the achievement of the consensus statement's 6 critical steps. Although 2 National Surveys of Children With Special Health Care Needs indicate improvements between 2001 and 2006, there has been only limited achievement of national health policy goals related to transition.[3,4] Outcomes-related research efforts have, so far, failed to fully address the transition needs of adolescents with or without chronic conditions.[5] A recent national survey revealed that pediatricians remain poorly informed about the conclusions of the consensus statement and that most pediatric practices neither initiate transition planning early in adolescence nor offer transition-support services, which have been found to be critical for ensuring a smooth transition to the adult health care model.[6] The survey authors noted that "gaps in transition support are due in part to limited staff training; lack of an identified staff person responsible for transition; financial barriers; and anxiety on the part of pediatricians, adolescents, and their parents about planning for their future health care."[7] Other authors have cited the lack of developmentally appropriate tools for assessing child and family readiness for transition as a barrier to transition.[8,9]

The result is that many pediatricians, youth, and families have found a limited availability of adult providers with whom to arrange a smooth transition of care.[10–14] In addition, evidence indicates that many adult providers feel unprepared to care for young adults with complex chronic conditions. In some cases, there is no identified adult primary care or specialty provider to whom care can be transitioned. Lack of time, adequate payment, and training have been cited as major barriers to transition.[15] Workforce shortages exist and are anticipated to worsen for physicians and other health professionals providing care for adults of all ages. In the face of an aging population that needs care, these shortages may be an obstacle to the delivery of primary care to more young adults with or without special health care needs.[16]

Family physicians caring for youth note that no transfer of primary care will be needed; nevertheless, there is a need to implement an adult model of care; plan for the transfer of specialty care to adult medical subspecialists; and support broader transition planning that includes issues such as educational attainment, career choices, and independent living needs. Internists find it challenging to care for a child or youth with special health care needs when the youth lacks preparation to be his or her own health advocate and the referring physician sends only minimal information about the youth and/or his or her condition.[17] Despite the recent spread of the family-centered medical home model for the redesign of primary care, payment reforms for non–encounter-based services (such as transition planning and care coordination) still have not materialized to a significant degree. Finally, with relatively few model practices exemplifying high-quality transition supports, training providers in the principles of health care transition remains challenging.

When there are obstacles, there are also opportunities. The need is stronger than ever for the seamless transfer of care and personal health information from pediatric care settings to more adult settings and for all youth to function as independently as possible in promoting their own health as adults. The 2007 AAP Annual Leadership Forum designated the resolution "transitioning youth with special health care needs to adult health care" as a top-10 priority. *Bright Futures* provides a framework for anticipatory guidance throughout childhood and adolescence that encourages parental support of self-management and independent decision-making about health.[18] Explicitly planned care as the product of a partnership among health care professionals, youth, and families has become an essential characteristic of the primary care medical home for which recognition standards have become more firmly established, such as the Physician Practice Connection for the Patient-Centered Medical Home of the National Committee on Quality Assurance and the Medical Home Index of the Center for Medical Home Improvement.[19,20] Providing high-quality transition care and support may become one of the standards that both pediatric and adult primary care practices would need to meet to be recognized as a medical home and become eligible for new payment scenarios.

These new opportunities have set the stage for a reaffirmation of the principles in the original consensus state-

ment by the AAP, American Academy of Family Physicians, and American College of Physicians. All 3 professional groups also recognize the need to translate those principles into practical operational guidance for the care of all children and youth as they transition to adulthood. Although youth with special health care needs require a broader range of considerations during their transitions, all youth need education, guidance, and planning to prepare to assume appropriate responsibility for their own health and well-being in adulthood.[21] Most youth with chronic illnesses will survive into adulthood and, depending on the severity and specifics of their disability, should transition to an adult model of care. After the age of majority,† all youth deserve to be treated as adults and to experience an adult model of care, although some people may require decision-making support from a third-party proxy, such as through guardianship or power of attorney. Recent evidence has shown that higher executive function affecting impulsivity and decision-making continues to mature through the mid-20s. Older adolescents and young adults may require guided decision-making assistance from clinicians and family members as they enter adult systems of care.[22] Nevertheless, most youth will benefit from advance planning and preparation for that experience regardless of whether they remain with their pediatric provider or medical subspecialist after the age of 18.

This report assumes that it is the youth, not the clinician, who is transitioning in his or her movement from one stage of life and development to another. The actions of the youth's medical home involve not the transition of care but, rather, the transfer of some or all elements of care to an adult medical home setting or, in the case of a family medicine medical home, to an adult medical home model. The medical home visit is a different process when the patient has reached the age of majority; adult patients have specific considerations and necessitate providers' attention to new requirements such as adopting consent for treatment processes and Health Insurance Portability and Accountability Act (HIPAA)–compliant forms. Health care transfer is an element of transition and has a defined end point that may vary from patient to patient. Because both transition and transfer are influenced by environmental, socioeconomic, medical, and other factors, it is the responsibility of the medical home—in partnership with patients and their families—to coordinate efforts that ensure optimal outcomes for every patient.

The patient- and family-centered medical home model of primary care includes 3 distinct but interrelated care processes: preventive care; acute illness management; and chronic condition management (CCM). CCM constitutes an explicit and defined approach that involves planned and proactive care rooted in evidence- and consensus-based guidelines, written care plans, and active care coordination. The medical home uses a registry to track the status of its patients with special health care needs and may stratify the registry in terms of the severity or complexity of the patient's condition. Those with more complex conditions may be identified for written care plans, care coordination, and a more intense, amplified transition plan. CCM also includes an explicit approach to comanagement with medical subspecialists in which the roles of primary and specialty care are clearly articulated. (Comanagement involves an explicit and transparent process in which providers involved in a patient's care determine—in collaboration with the patient or family—which provider will be responsible for which aspects of the patient's care. Comanagement can occur between primary care providers and 1 or more medical subspecialists. It might also occur during the transfer of care from a pediatric to an adult setting.) Transition activities for youth with special health care needs should include a comanagement-transition plan that articulates the process and timing for the transfer of care from pediatric to adult medical subspecialists. (These components of CCM are described in greater detail later in this report.)

This clinical report aims to advance the practice-based implementation of planning, decision-making, and documentation processes for youth who are approaching transition, including those who have special health care needs and those who do not. It intends to provide a structure for training, continuing education, and research to further the understanding of best practices for transition of adolescents to adult care. It does not detail the activities conducted by receiving providers who accept patients into an adult model of medical home care. Because there is currently only limited outcome literature about transition, this clinical report is based on expert opinion and consensus recommendations rather than on specific evidence. The report provides a decision-making algorithm (Fig 1) for all youth, beginning at 12 years of age. The algorithm includes a branch with expanded, generic guidelines for transitioning youth with special health care needs who require CCM.[23] These chronic condition guidelines can, in turn, provide a template for later, more detailed, and specialized applications of the algorithm to specific conditions and specialty care

†The "age of majority" is a legal definition of the age at which a person is considered to be an adult. In most states, this age is 18 years; exceptions are Alabama and Nebraska (19 years) and Washington, DC, and Mississippi (21 years).

situations. These guidelines, recommendations, and resources will also be useful to the medical subspecialist engaging in the transition process; primary care providers and medical subspecialists are encouraged to make this process specific for their own needs.

Methodology

The AAP and the National Center for Medical Home Implementation (a cooperative agreement between the AAP and the MCHB) have prioritized the issue of transitioning youth from a pediatric to an adult medical home with the goal of facilitating the effective transition of all youth from pediatric to ap-

B

ALGORITHM COMPONENT	DESCRIPTIVE TEXT
Medical Home Interaction for Patients ≥12 Years of Age	***1.*** Initiate first step in the health care transition planning process at age 12.
Is the Patient 12–13 Years of Age? / Is the Patient 14–15 Years of Age? / Is the Patient 16–17 Years of Age? / Is the Patient ≥18 Years of Age?	***2a, 2b, 2c, 2d. Age Ranges.*** By age 12, conduct surveillance to assess any special health care needs. Start actual transition planning by age 14. By ages 16–17, transition planning should be well established. At age 18, initiate an adult model of care for most youth, even if there is no transfer of care. If transition planning does not occur on the schedule described by the algorithm, a concentrated effort is required (eg, special visits) to complete the process successfully.
STEP 1: Discuss Office Transitions Policy with Youth & Parents	***3a.*** Every practice should have a written transition policy that is prominently displayed and discussed with youth and families. The policy should explicitly state the practice's expectations and care process for the health care transition of their adolescent patients to an adult model of care.
STEP 2: Ensure Step 1 is Complete, then Initiate a Jointly Developed Transition Plan with Youth & Parents	***3b.*** The practice should use a standard transition plan that can be adapted for each patient's needs. This tool should include components to obtain an accurate assessment of the patient's ability to transition successfully. Providers should interview youth and family members to identify needs and assess the intentions and motivations for youth independence.
STEP 3: Ensure Steps 1 & 2 are Complete, then Review & Update Transitions Plan & Prepare for Adult Care	***3c.*** Transition plans must be reviewed regularly and updated as necessary. The provider must also perform surveillance for changes in the youth's medical status and address youth and family concerns that may warrant changes in transition goals. Failure to achieve transition-readiness goals warrants reevaluation of the existing plan and increased frequency of medical home interventions/visits. A "pretransfer" visit to the adult medical home could be conducted during the year before the transfer.
STEP 4: Ensure Steps 1, 2, & 3 are Complete, then Implement Adult Care Model* **for pediatric practices transfer to adult provider*	***3d.*** Transition to an adult model of care occurs appropriate for youth's developmental level, which is followed as appropriate by transfer to an adult medical home. Complete medical records should be delivered to the adult provider, along with a portable summary, which is also provided to the patient or guardian. For children and youth with special health care needs, direct communication between pediatric and adult providers is essential, because adult medical personnel may be unfamiliar with certain pediatric conditions.
Does Patient Have Special Health Care Needs?**	***4.*** Transition planning for children and youth with special health care needs should include specific CCM activities such as use of registries; care plans; care coordination; CCM office visits; and comanagement with medical subspecialists. Transition goals must be individualized to account for variations in the complexity of a youth's condition and in the youth's intellectual ability and guardianship status.
Incorporate Transition Planning in Chronic Condition Management	***5a.*** Youth with special health care needs require an expanded transition-planning process. Transition planning in CCM includes addressing the exchange of complex health information; competencies for self-care; transfers of specialty care; and issues related to insurance, entitlements, guardianship, and eligibility for adult services. In a medical home, such youth may have a written care plan as part of the medical record. At age 14, this plan should include a section titled "transition plan," which should be expanded and developed as the youth approaches age 18 and beyond.
Have Age-Appropriate Transitions Issues Been Addressed?	***5b.*** Use of transition-planning tools and readiness checklists facilitate the provider's ability to ensure that all age-appropriate transition issues have been addressed. Each action step must be completed in order, even if it means the provider has to schedule specific visits to initiate and complete steps missed earlier in the process to catch up before the next visit.
Initiate Follow-up Interaction	***5c.*** Focused tasks involving little detail or complexity can be addressed by the medical home care coordinator, medical provider, or other appropriate staff through telephone or electronic media. More complex issues may necessitate face-to-face office visits.
Transition Component of Interaction Complete	***6.*** The provider is finished with the transition tasks for that specific interaction or visit; transition planning is an ongoing activity that occurs at every interaction.

Continued.

propriate adult care. The Executive Committee and staff of the AAP Council on Children With Disabilities (COCWD) are leading the transitions initiative, which has received funding support from the National Center for Medical Home Implementation and the COCWD. The ultimate goal of this initiative is to help medical home providers, patients, and their families ensure a successful transition to appropriate adult care.

In 2008, the AAP convened a meeting to review and provide advice on proposed transition initiatives. Current literature and activities were highlighted, and areas in which assistance is needed for pediatric providers to properly address transitioning youth to adult care within their practice were identified. The first activity of the transitions initiative was to develop a clinical report to provide pediatric providers with the information they need to facilitate youth receiving high-quality, developmentally appropriate health care services as they transition to adulthood. A Transitions Clinical Report Authoring Group was subsequently assembled and cochaired by Drs Carl Cooley and Paul Sagerman. Other disciplines and/or groups represented on the authoring group include pediatric primary care and subspecialty physicians, adult health care providers, family members, and a young adult who recently completed his own health care transition.

These stakeholders partnered to develop this clinical report on the importance of youth receiving high-quality, developmentally appropriate health care services as they transition to adulthood. It provides practitioners with a clear time line and algorithmic protocol for succeeding in this process. A draft version of this clinical report underwent extensive peer review by committees, councils, sections, and additional groups within the AAP as

well as by external people or groups who were either identified as experts in the field or had requested the reviewing opportunity. The resulting comments were incorporated into the report, as appropriate. It is expected that all subsequent AAP transition initiatives will use the publication of this clinical report, and the guidance therein, as a foundation for education, training, and quality measurement.

2. GETTING READY FOR TRANSITION

Transition planning should be a standard part of providing care for all youth and young adults, and every patient should have a transition plan regardless of his or her specific health care needs. Successful transition involves the engagement and participation of the medical home team (physicians, nurse practitioners, physicians assistants, nurses, care coordinators), the family and other caregivers, and the individual youth collaborating in a positive and mutually respectful relationship (ie, one that honors diversity and is consistent with each family's cultural and religious beliefs). The medical home team does not engage in transition planning alone; rather, it jointly creates and implements the plan with the youth and his or her family/caregivers. The medical home team facilitates a process that is planned, smooth, and patient- and family-centered. The parents' role is to actively engage in the process and move in and out of the decision-making position as appropriate. The youth's role is to maximize his or her independence and primacy in the decision-making process to foster lifelong functioning and self-determination. The receiving adult providers also need to be identified and engaged and, as needed, to provide developmentally appropriate support for the family and young adult during the transition process. This process is described in both the algorithm and "Adult Medical Home (Receiving Provider): Roles and Responsibilities."

a. Provider Readiness

A key component of supporting the transition process is the primary care medical home having an explicit office policy that describes the practice's approach to health care transition, including the age and process at which youth shift to an adult model of care. This office policy applies to all youth (both with and without special health care needs), guides the process, and helps the youth and family members (or other caregivers) understand both their and the medical home team's roles and responsibilities. The office transition policy should be visible and readily available to patients and their families, including depicting them in brochures, posters, and/or Web-based information about the practice. This office policy should clearly describe the goal of transition as part of lifelong preparation for a successful adult life and articulate how transition planning facilitates the patient's movement from a pediatric to an adult care mode.[17] Additional components of the office policy are described later in the algorithm.

To achieve the goal of transition planning as a standard of care, the medical home team must receive training and technical assistance to implement transitions effectively and adopt transition-related practices (eg, discussing the office transition policy, assessing family and youth transition readiness, developing referral relationships in the adult care system). Adult medical homes and medical subspecialists may need to build their capacities to provide services to young adult patients, particularly those with cognitive impairments and other special health care needs. Education and clinical experience for medical home team members will provide essential skills for the successful transition of youth both with and without special needs. Issues of provider readiness are described further in "Adult Medical Home (Receiving Provider): Roles and Responsibilities."

b. Family Readiness

The medical home team members must understand and address patients' and parents' perspectives and needs during transition and recognize that this process is complex and potentially emotional for parents and other caregivers/guardians. Although families make multiple transitions during their children's lives, for many parents, the pediatrician has been a constant, and they may find transition from the known to the unknown to be stressful. This is particularly likely to be true for parents of children with special health care needs. To make the process smoother for all involved, transition planning must anticipate and address challenges that parents may face as the youth enters adulthood.

It is important for physicians and other health care professionals to engage parents and youth with education and information about their role in the transition process. This education should include information about how the health care environment changes when the youth legally becomes an adult at 18 years of age as well as differences between pediatric and adult medicine models. The provider's goals are to normalize the transition process, address the families' anxieties or questions, and foster a team approach to help facilitate the acquisition of skills and tools that the youth can use both in transition and beyond. The family members or other caregivers should be engaged and open to the process (eg, learning about any upcoming changes in health coverage), encourage autonomous decision-making

and self-care on the part of the youth, and share their questions and/or concerns with the provider as they adjust to their role shifting from primary decision-maker and caregiver to a more supportive role.

c. Youth Readiness

For transition planning to succeed, providers, and parents/caregivers must view the youth as the driver in the process and encourage the youth to assume increasing responsibility for his or her own health care to the fullest extent possible. Empowering youth through transitions fosters the development of self-management skills and tools needed for them to gain more control in, and over, their lives.[24] Although this is the case for youth both with and without special health care needs, it is particularly critical for the former, who may require a broader range of considerations during the transition process.[25]

Although this report presents optimal ages for initiating and conducting transition planning, it is never too early to begin conversations among the provider, family/caregivers, and patient about planning for the future. This is especially true for children with special health care needs. For this population, it is likely that similar conversations are occurring in the educational system regarding Individualized Education Plans (IEPs); these various conversations can reinforce and buttress one another.[25] Prioritizing and reinforcing the value of independence and decision-making as part of the transition-planning process not only reinforces such messages on the part of providers, family members/other caregivers, and the broader community but also facilitates the patient's successful transition to adult medical care and active participation in maintaining his or her own health.

3. FRAMING THE ALGORITHM

An algorithm is a finite list of steps connected by various decision-making points that can be taken to move from a known beginning to a predictable end state. As a decision-making tool, an algorithm presents clear-cut questions that, when answered, delineate standardized pathways that lead to the process's next step(s) and a desired outcome. Clinical algorithms have long been popular and effective tools for helping clinicians understand and implement a diagnostic, therapeutic, or management process. Algorithms also provide a logic model for the incorporation of processes of care into electronic health records (EHRs). Algorithms have been included recently in AAP policy documents as strategies to support health care professionals to develop a pattern and practice to address developmental concerns in children from birth through 3 years of age and to engage in early identification of children with autism spectrum disorders.[23,26]

The algorithm contained in this clinical report (Fig 1) specifies the protocol for managing the transition process; assists physicians and other health care professionals to implement the transition process; and provides a transition structure for youth and their families. It is intended for use by clinicians within a medical home setting as a "jumping-off point" for the identification of youth who have reached a point in their lives at which health care transition should be integrated as a routinely recognized part of the office visit. Individual steps along the transition process will vary from one youth to the next depending on individual patient, family/caregiver, health care professional, and community-resource factors. The transition process is best initiated by the time a child is 12 years of age and ideally should occur during a health maintenance or CCM visit. Transfer itself should occur within the 18- to 21-year age range, although it can occur earlier because some internists accept new patients at 15 years of age, particularly if they see other family members as well. Some youth may experience a variety of health care settings as they move from pediatric to adult models of care (eg, while in college or military service), but these settings are not likely to provide a comprehensive medical home. Youth should either remain in their pediatric medical home or be well established in their adult medical home while receiving episodic care in these settings.

a. Explanation of the Algorithm Components

Row 1: Medical Home Interaction

Medical Home Interaction for Patients ≥12 Years of Age

All youth, regardless of whether they have identified special health care needs, should be assessed for transition readiness. Preparation for adult life should be a routinely addressed topic for any health maintenance visit that occurs within the medical home during the adolescent years. The *Bright Futures* initiatives provide content materials on this subject matter.[20] Medical homes can provide appropriate transition services, support, and planning. Transition planning with patients and families must be initiated during an office visit to allow face-to-face communication, because the parties involved may not have previously considered this subject matter. Subsequent medical home transition-planning "interactions" may include, but not be limited to, office visits for health maintenance or acute illness, CCM visits, nursing visits, telephone or e-mail consultations, provision of office policies, and/or record reviews and updates. It is of paramount impor-

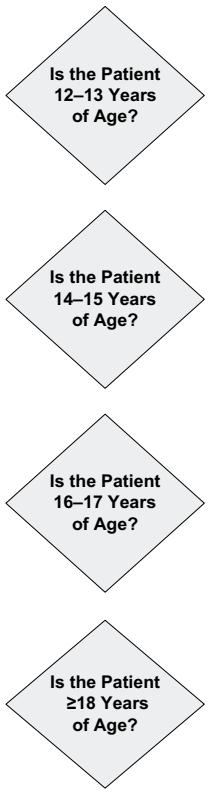
tance that the primary care medical home recognize which youth in the practice have reached the age for transition planning and prompt these families to come in for a visit to initiate the process. Each action step does not require a separate medical home visit, and multiple action steps can be addressed during a visit, although doing so requires a greater investment of time and resources.

Although opinions differ on the age for initiating the transition process, the most appropriate time is early adolescence, when youth become developmentally capable of engaging in activities regarding their personal futures. Therefore, this clinical report recommends initiating the first step in the health care transition-planning process at the age of 12, which allows sufficient time to adequately prepare patients, families, and medical providers before the youth legally becomes an adult at the age of 18. Several clinical studies have found this age to be an appropriate time to initiate the process to most successfully affect the transition's outcome.[27–29]

Children and youth with special health care needs and their families may benefit from discussions regarding adult transitioning that begin earlier than 12 years of age, depending on specific patient circumstances. Expectations for vocation, independent living, guardianship, reproduction, life expectancy, and other topics should be discussed at the earliest possible opportunity with parents and/or other appropriate caregivers if it is determined that the child's transition process will be different from that of children without special health care needs. In addition, some children with chronic medical conditions (eg, asthma or diabetes) may be introduced to developmentally appropriate self-care at ages younger than 12. The timing of these discussions must be individualized.

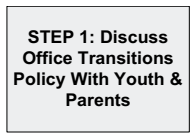
Row 2: Age Ranges

The second row of the algorithm assists health care providers in developing a practice of recognizing the need for transition for all patients 12 years or older. The use of emerging health information technology is likely to aid in this process (eg, through registries and age-related prompts). The age ranges presented in the algorithm are designed to aid the provider in assessing the most appropriate ages for implementing specific stages of transition planning. For most patients, this appropriateness is determined by age, whereas for others, it may be modified on the basis of developmental considerations. The provider's flexibility and judgment are important in this process. Actual transition planning should be initiated at the age of 14. The goal is to identify patients who are either entering or within the 14- to 15-year age range to initiate the development of a patient-specific transition plan at the child's next visit.



Row 3: Action Steps for Specific Age Ranges

Transition is a dynamic and fluid process that includes 4 major action steps. Each of the first 3 action steps (discussion of medical home transition policy, initiation of transition plan, and review/update of the transition plan) lays the foundation for the next. The fourth action step (implementation of an adult care model) prepares the youth and/or caregiver for the transfer to an adult care model. Regardless of the age at which the patient's transition process is initiated, the 4 action steps for transition planning must be accomplished in a linear fashion. For example, if transition is being initiated for a 16-year-old who presents for a health maintenance visit, steps 1 and 2 of the algorithm must be completed before moving to step 3 (the age-appropriate stage for a 16-year-old). As noted, a separate medical home visit is not required for each action step, and multiple action steps can be addressed in a single visit.



In (3a) step 1, the provider shares and discusses the office transition policy with the youth and his or her family or other caregivers. As described previously, every pediatric practice should have a well-defined policy that clearly states the expectations for the health care transition of their adolescent patients to an adult model of care. This policy should be displayed in a location where youth and their caregivers can easily read it (eg, posted in front offices and waiting rooms and described in brochures and on the practice's Web site). The policy should reflect the appropriate level of health literacy, reading and language proficiency, and cultural norms for the population the practice serves. Components of the

office transition policy include, but are not limited to:

- the expected age of patient transfer to an adult model of health care;
- the patient's responsibilities in preparing for transition;
- the parent, family, and/or caregiver responsibilities in preparing for transition; and
- the medical provider's responsibilities in preparing for transition.

In addition to posting the transitions policy, providers should provide a written copy of the office policy to all patients who are aged 12 or older and their families. Optimally, this policy is provided before a face-to-face encounter between the family/caregivers and the medical provider to allow the patient and family/caregivers sufficient time to become familiar with the policy and prepare any questions they may have before the office visit. Office policies can be given to the transitioning youth and family/caregivers while in the waiting room or be sent to their home before the visit. The delivery and discussion of the office transition policy should be documented in the patient's medical records. Medical home providers should be familiar with each of the transition policy's components to facilitate discussion and respond to questions posed during the office visit. Having a transitions policy that is presented early to the patient and family and other caregivers removes any doubt about the timing of transfer and raises awareness that the medical home will be a valuable support for those who need additional assistance.

For youth without special health care needs, no further transition-specific activities are required until the 14- to 15-year visits. For adolescents with special health care needs, however, the period from 12 to 14 years of age is likely to be spent beginning preparations for transition readiness. For this reason, during the 12- to 13-year visits, the medical home provider must identify those patients who are at risk of having a more complicated transition because of special medical, developmental, social, and/or environmental needs. Some children with particularly complex health care needs may benefit from the early implementation of a formal transition plan before the age of 14.

STEP 2: Ensure Step 1 Is Complete, Then Initiate a Jointly Developed Transition Plan With Youth & Parents

In (3b) step 2, the medical home provider initiates a transition plan that is jointly developed with the youth and his or her parents. Starting at age 14 (or before, for some children with special health care needs, as described previously), a formal transition plan should be initiated for all youth and placed in the medical record for review during future office visits. The written plan should document the youth's current readiness to assume a greater role in self-management of his or her health care, the steps to be conducted to achieve a successful transition, and the transmittal of information to the youth and family/caregivers. It forms the basis for records to be provided to the receiving provider and youth on the transfer of care between the ages of 18 and 21. Implementation and review of the transition plan can be an important measurable quality-improvement effort on the part of the medical home.

The starting point for this step is the recognition of patient capabilities and delineation of responsibilities between patient, family and other caregivers, and medical providers for overall patient care. Practices should select a readiness-assessment tool to use that can be modified for specific patient situations. Readiness tools reveal areas of both strength and weakness on which patient education can be focused to accomplish future goals in self-management. Regardless of the tool chosen, it should contain specific minimum components that provide an accurate, point-in-time assessment of the individual patient's ability to transition successfully. (These components are described below. Many readiness-assessment tools and skills checklists exist for conducting this assessment; some are listed in "Resources.")

No matter what tool is used to assess and document readiness, providers should interview family members or other caregivers and the youth independently of one another to identify needs and assess intentions and motivations for the patient's independence. The identification of special health care needs (medical or otherwise) requires the medical home to be proactive in facilitating relationships between the youth and appropriate community and/or state resources.

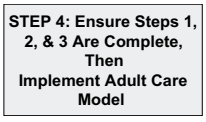
STEP 3: Ensure Steps 1 & 2 Are Complete, Then Review & Update Transitions Plan & Prepare for Adult Care

In (3c) step 3, the medical home provider reviews and updates the transition plan and works with the patient to engage in the transition process. The transition plan documentation should be reviewed on a regular basis to promote recognition by the patient, the family/caregivers, and the provider of successes and/or deficits in readiness preparation. Medical providers and caregivers can reprioritize the readiness goals with respect to changes in the youth's medical status and/or concerns on the part of the caregivers. Although the number of times this review occurs depends on the frequency of the patient's visits to the medical home, it should be conducted at least

annually. Focused efforts and intensified communication (among the patient, family members and other caregivers, and providers) may uncover systemic roadblocks or deficiencies in the patient's abilities to achieve previous expectations.

If there has been a failure to achieve transition-readiness goals, a reevaluation of the existing plan is warranted; it may be necessary to increase the frequency of medical home interventions or visits. Because 16- to 17-year-olds are significantly closer to the age of expected transfer of care to an adult model, accomplishing transition goals may not be feasible within the annual health maintenance schedule. Readiness plans will require revision on the basis of the outcome of such communication.

Successful transition requires the identification of an adult care medical home, and completion of this task is one of the most important for pediatric providers. The patient and/or family (and other caregivers) may need assistance identifying available and qualified adult care providers; when they select an adult provider, it is the pediatric medical home's responsibility to ensure appropriate communication of any and all medical needs to the receiving provider. In the final year before transfer from the pediatric medical home, the youth and family/caregivers might benefit from a visit with the potential adult provider(s) to explore the potential of a long-term relationship. Pediatric care occurring within a family medicine practice obviates the need for such a visit but not the need for preparation for an adult model of care.



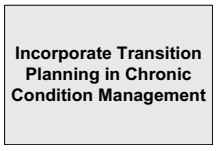
In (3d) step 4, the medical home provider implements an adult care model or affects the transfer to an adult medical home provider. After documented completion of the readiness goals in the individual youth's transition plan, the pediatric provider's role is to facilitate transfer of care to an adult medical home. For young adults with complex health care issues, direct communication between pediatric and adult providers is essential, because adult medical personnel may be unfamiliar with certain pediatric conditions.[17] For youth with complex needs, families are almost always a significant part of this conversation, because they are likely to be highly involved in not only caring for the youth but also arranging for, and supervising, others who provide care. The provider, youth, and family must jointly prepare a portable medical summary and, for children with special health care needs, a care plan, which should be delivered to the patient (or his or her legal guardian) and to the receiving provider. EHRs should also be provided to the adult provider. Medication reconciliation should be performed by the pediatric medical home before the record is transferred and by the receiving adult medical home when the record is received. (The components of this summary are described in "Implementing the Algorithm.")

Health care transition does not necessarily end with transfer. Some patients and/or caregivers may need additional support from the adult medical home to complete specific transition tasks. Providing this support through care coordination and consultation within the adult medical home optimizes the patient's self-management skills. In addition, the pediatric provider should make himself or herself available to the adult provider as a resource for any needed information or assistance during the immediate posttransfer period.

Row 4: Determination of Special Needs

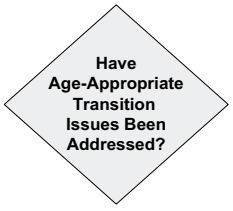
The transition process may be simpler for youth without disabilities or chronic health conditions compared with those with special health care needs. If the youth has no special health care needs, the provider's primary task is to ensure that all age-appropriate transition issues are addressed and that a smooth transfer to an adult model of care occurs. For the youth with special health care needs, the transition process should be initiated at the age of 12 and may necessitate specific CCM activities (these components are described below). The MCHB definition encompasses a wide variety of conditions and range of severities, including children with developmental disabilities and chronic illnesses as well as those with mental health and behavioral disorders.[21] The development of patient registries to aid in the identification of these children is a core component of CCM within the medical home model. An important feature of such planning is the recognition that many tasks that lead to patient self-management are beyond the capability of young adults whose medical conditions include cognitive challenges. Transition goals must be individualized to account for such variations.

Row 5: CCM and Follow-up



To the extent possible, basic transition planning and preparation for an adult

health care model should be the same for children and youth with and without special health care needs. For many children and youth with chronic medical, developmental, and/or behavioral conditions, however, an expanded process of transition planning is necessary to address the exchange of more complex health information, competencies for self-care, and the transfer of specialty care from pediatric to adult medical subspecialists. In addition, broader transitional issues related to health insurance, entitlements, guardianship, and eligibility for adult community-based services must be addressed also. In a medical home, some youth with special health care needs will have a written care plan as part of the medical record that can serve as a script for care coordination and care planning. At the age of 14, this written care plan should begin to include a section titled "transition plan"; this transition section should be developed steadily as the youth approaches the age of 18 and beyond. (Transition planning in CCM is more described fully below.)



Regardless of whether the child has special health care needs, providers should ensure that age-appropriate transition issues have been addressed at every medical home visit and that the process is on track. Use of appropriate transition-planning tools and readiness checklists will facilitate the provider's ability to answer this question. The act of "addressing" transition issues is not synonymous with the successful completion of the process, however. Identification of items in need of attention, and the formulation of plans to accomplish them, may be sufficient to complete this action step. If patients have fallen behind the transition-planning schedule, providers are likely to need to schedule a special visit to complete all of the tasks related to transition planning.

Follow-up interactions may take one of several forms. Focused tasks that involve little detail or complexity can be addressed by staff such as the medical home care coordinator or medical provider via telephone communication or electronic media (eg, secure e-mail). Larger or more complex issues may necessitate 1 or more face-to-face office visits, which should not be relegated to the next periodic health maintenance visit.

Row 6: Interaction Complete

This point does not mean that the office visit is complete or that the provider does not continue to provide care, merely that the part of the process of providing care that centers around transition planning has been completed for this specific office visit or interaction.

4. IMPLEMENTING THE ALGORITHM

Every youth who reaches the age of transition from a pediatric medical home or becomes a legal adult within his or her current medical home needs to have a basic transition plan developed through collaboration among the youth, family, and provider. Those with special health care needs require additional components specifically to address their chronic care management (see "Integrating Transition Planning Into CCM for Children and Youth With Special Health Care Needs").

a. Transition Plan Components for Every Child and Youth

There are 4 recommended components for a transition plan, each of which can be augmented by the use of specific tools to facilitate the work of the provider, youth, and family.

1. *Assess* for transition readiness. The provider, family, and youth begin by articulating realistic goals for transition and identifying new skills that will be needed by the patient to meet those goals successfully. Although it is not the main focus of the medical home, the assessment should be "person-centered" and include identification of other areas of readiness for transition into the adult world in general, including education/vocation, independent living, and patient awareness of medical needs and age-appropriate preventive care, as outlined by resources such as *Bright Futures*.[18] Numerous tools are available in the form of "readiness checklists" that allow providers to obtain a baseline idea of the current capacity of the youth, family and other caregivers, and providers to successfully achieve the outlined goals. Transition progress should be measured through periodic reassessment using the same checklists at each visit (see "Resources" for selected transition-readiness materials).
2. *Plan* a dynamic and longitudinal process for accomplishing realistic goals. The first step of transition planning is the establishment of goals that allow the youth to achieve as seamless a transition as possible. A formal, written transition plan that outlines specific actions that are necessary to meet the stated goals should be part of the patients' medical record by the

age of 14. The written transition plan should account for cultural, developmental, organizational, and contingency-related concerns. In general, categories recommended to be incorporated into the transition plan include the plan's main goal(s), identification of who within the medical home will be responsible for overseeing and/or coordinating the plan, the time line for accomplishing stated goals, the skills required by the youth to achieve maximum self-management, the families' or other caregivers' role, and an articulation of proposed financing of the youth's adult health care (see "Resources" for selected transition-planning tools).

3. *Implement* the plan through education of all involved parties and empowerment of the youth in areas of self-care. After the transition plan has been outlined and goals have been established, specific activities to ensure that the youth acquires needed skills should begin. Examples of these goals include the ability to schedule one's own medical appointments, obtain medications, have a one-on-one dialogue with a medical provider, and be familiar with one's medical history and any needed medications. Ongoing discussion of the transition plan at all health care visits is a key step in accomplishing transition goals. This should be a dynamic process that begins gradually and is continually assessed at regular intervals. The timing of these reassessments depends on the capacity of the youth and his or her family and other caregivers as well as the amount of time remaining until the anticipated transfer of care to the adult medical home. The transition-readiness checklists used during the initial assessment to establish goals (outlined previously) are the tools of choice for documenting successful accomplishment of specific goals and tasks. It is highly recommended that a medical home use the same checklists throughout the entire transition process for an individual patient to provide continuity over time and assist youth, families, and providers to stay "on track" regarding specific goals that have yet to be accomplished.

   Throughout this process, the provider should continually strengthen the partnership with the patient and family members and other caregivers by engaging in active dialogue and information-sharing to empower the youth to take on new roles, as appropriate. It is important to recognize that, at the age of maturity, the youth becomes a legal adult (except when guardianship by another person has been obtained). As a result of confidentiality laws, the youth should be seen alone unless other arrangements have been legally made. One to 2 years before the anticipated transfer of medical care, the pediatric provider should assist the youth and/or family/caregivers to identify potential adult practices, prepare the appropriate documentation for transition, and suggest that the youth interview the adult practice before making a final transfer.

4. *Document* progress to enable ongoing reassessment and movement of medical information to the receiving (adult care) provider. Many excellent tools for documenting the transition process exist, including some that can be used within an EHR system and others that are paper-based. For example, providers might place a transition front sheet on the patient's chart or use a "dashboard" tool in the patient's EHR at the age of 12. Both of these methods work well in flagging important actions that have occurred and/or need to be scheduled as part of the transition process. Regardless of the specific tool used, it should provide a flexible method for assessing the youth's readiness for transition and progress made toward that goal. Gathering relevant information to document the patient's transition progress is of paramount importance as the anticipated transfer date approaches. It is well documented that a common barrier to adult medical providers' acceptance of transitioning youth is a lack of accompanying medical documentation.[16] It is critical that medical documentation be portable and include 3 components: (1) the transition plan (see above); (2) longitudinal readiness checklists (see above), which demonstrate both successes and deficits in self-management skills; and (3) a portable medical summary. The portable medical summary contains basic medical and social data to give adult medical providers the information necessary to begin assuming care for the patient. All youth receive this portable medical summary, because the data it contains are essential topics and elements that are critical to the transition summary. Although the categories of the medical summary are appropriate for all chronic health conditions, specific information should be tailored to the patient's conditions.

b. Integrating Transition Planning Into CCM for Children and Youth With Special Health Care Needs

Transition planning applies to all children and youth and should follow the steps defined in the algorithm. The presence of chronic health conditions and/or developmental disabilities (ie,

children or youth with special health care needs) imposes specific primary care requirements on the family-centered medical home characterized as CCM. Effective CCM, in turn, demands additional considerations related to transition planning. CCM involves an explicit, planned process of coordinated, proactive care aimed at achieving the best possible clinical and functional outcomes for the individual patient and for the population of patients with chronic conditions. While following the general sequence and timing of the transition algorithm, transition planning for children or youth with special health care needs will usually be incorporated into the broader CCM process. Early in the transition-planning process, it will be important to determine whether the youth is likely to be a completely independent decision-maker as an adult or require decision-making support from a third-party proxy such as through guardianship or power of attorney. Even with these considerations in mind, it is important to plan with the youth and family/caregivers to achieve the maximum possible participation of the youth in the transition-planning process.

1. Registry. The family-centered medical home CCM process may include a registry of the practice's patients with special health care needs. The registry should be searchable on the basis of patient age so that youth who are ready for each stage of the transition process (see algorithm) can be identified. The registry might also include fields indicating which steps in the transition process are due for completion, have been completed, or are past due for completion. Additional fields unique to the transition of children or youth with special health care needs might include "discussed guardianship," "identified adult subspecialists," etc.
2. Care Plan. Some children or youth with special health care needs will have an action-oriented care plan for tracking current problems and health-related needs including what action is needed, who will be responsible, and by when the action should have occurred. When a child or youth with special health care needs enters the age group covered in the transition algorithm, the action-oriented care plan should begin to contain a transition section that will become the youth's transition plan. The incorporation of the transition plan into the general action-oriented care plan will ensure integration of transition planning with other health-related actions.
3. Care Coordination. Care coordination is one of the foundations of the family-centered medical home and assumes special importance for children or youth with special health care needs who utilize the health care system frequently and who may have multiple health care and other service providers. Those who coordinate health care for the child or youth with special health care needs will need to take into consideration the youth's transition plan and the current stage of the transition-planning process. Care coordination may be instrumental in supporting the transfer of care from various pediatric medical subspecialists to their adult specialty counterparts.
4. CCM Visits. The family-centered medical home provides periodic CCM visits that may occur in addition to health maintenance and acute illness management visits to monitor the status of patients with chronic conditions and implement/update their care plans. These CCM visits would provide the occasions for transition education and planning.
5. Comanagement. Explicit comanagement between primary care physicians and medical subspecialists ensures communication and prevents both omissions and redundancies of care. It explicitly identifies the respective roles of the primary care medical home and the medical subspecialists in a manner that is clear to each provider and the youth and family and other caregivers. The locus of management may shift from time to time between primary care and specialty care depending on the youth's age and the complexity and acuity of specific health problems. Comanagement with medical subspecialists assumes particular importance for transition planning, because it provides the framework in which to plan for and implement the transfer of care from pediatric subspecialists to adult medical subspecialists and surgical specialists. Comanagement may also be the context for a dialogue of explicit communications between the youth's medical home and the future adult medical home provider. Comanagement planning with respect to transition planning should include the timing and process for specific transfers of care in each relevant specialty area. In some cases, the plan may be to retain a pediatric subspecialist into adulthood because of the absence of appropriately qualified adult medical subspecialists.

It should be noted that some diagnosis-specific programs, including clinics for hemophilia and cystic fibrosis, have established strong programs to guide subspecialty transfer. The National Hemophilia Foundation established a nationwide network of

hemophilia diagnostic and treatment centers and, in 2003, adopted transition guidelines that provide age-related recommendations. These models and transition guidelines acknowledge that there are continuing areas for improvement such as addressing preventive health needs or promoting the adult model of decision-making by young adult patients.[30,31]

i. Components of the Transition Plan for Youth With Special Health Care Needs: Necessary Information for the Receiving Provider, Patient, and Family Members/Caregivers

In addition to the items in the transition plan for all youth (described previously), additional components should be included in transition plans and records for youth with disabilities and/or special health care needs. All transition plans should be tailored to the individual patient and his or her needs.

Additional data elements that are likely to be included in the transfer documentation for youth with special health care needs include baseline functional and neurologic status; the patient's cognitive status, including formal test results and date of administration, when possible; condition-specific emergency treatment plans and contacts; and the patient's health education history and assessment of his or her understanding regarding health conditions, treatments, and prognosis with particular attention to entry into adult life, including procreation potential and genetic information.

Information about advance directives should include an identification of the decision-maker proxy or guardian and any history of advance-directive planning. For patients with communication impairments, the transition documentation should include the patient's communication preferences and anticipated needs for accommodations in both communication and clinical care (ie, use of sign language interpreter, augmentative communication device, etc).

ii. Components of the Transition Plan for Youth With Special Health Care Needs: Assessment and Documentation of Readiness

As part of the transition-planning process, a member of the medical home team should regularly assess the patient and his or her family and other caregivers on progress toward achieving transition readiness and preparation for adult life. Interventions to address individual difficulties and/or provide extra resources should be conducted during visits. Education and empowerment techniques should be used to ensure that development of needed skills is embraced by the patient and families and continues to occur. Providers must ensure that they document both the patient's and family's progress toward successfully completing the plan's components as well as any plan revisions. A formal method should be used to document the stepwise completion of developmentally appropriate tasks required to prepare the transitioning patient for adult life. Flow sheets, registry reminders, and planned visit templates for specific ages are all possible means to do so. In addition, documentation is particularly important in certain specific areas.

Insurance Coverage

The 2010 Patient Protection and Affordable Care Act (PPACA) health care reform legislation will affect coverage, access to care, and care coordination in the short-term and/or long-term. Specific provisions of the PPACA expand children's and youth's access to coverage and ongoing care, including changes that permit children to remain on their parent's insurance until the age of 26; eliminate insurers' ability to exclude coverage on the basis of preexisting conditions; improve coverage portability; create a high-risk pool insurance for people who cannot access coverage through other sources; enhance Medicaid payment to primary care physicians; and mandate that nearly all people (including young adults) have coverage. Although these changes are likely to prove beneficial, it is likely that parents, caregivers, and transitioning youth alike will need assistance to understand this complex legislation and its impact on their lives and the transition process. In addition, PPACA provisions are to be implemented over time, and youth must be encouraged to proactively plan to avoid suffering substantial coverage gaps and/or delays in coverage because of "preexisting conditions" until 2014, when this practice is prohibited under PPACA. In addition, age eligibility and coverage requirements may vary for programs such as Title V, Medicaid, Supplemental Security Income (SSI), and Social Security Disability Income (SSDI). Youth with chronic conditions should be encouraged to evaluate future employment options that are most likely to offer insurance coverage for high-risk people (ie, employers who participate in large group plans and, thereby, spread out risk). Parental employment-based coverage limitations also vary widely; although a few plans cover adults with disabilities who are dependents of their parents, they are the exception. Because of the critical nature of insurance coverage for people with special health care needs, it is essential that providers discuss insurance issues with these patients and document plans to ensure continued coverage.

Self-Advocacy

Critical topic areas for the empowerment of youth with special health care needs include self-advocacy and

making plans about decision-making status, educational and/or employment opportunities, living arrangements, and community-inclusive opportunities. It is critical to encourage families to initiate training and decision-making opportunities for children with special health care needs at a young age. Families should receive assistance from experts in self-advocacy when considering the range of potential support, which may include personal informal advocates, power of attorney, and limited-to-full guardianship. Important resources include organizations, such as Family Voices; local chapters of The Arc; and lawyers who are experienced in disability issues. Because of the importance of self-advocacy for youth with special health care needs, it is essential that providers initiate conversations about decision-making and begin to plan advocacy support for these youth far in advance of the age of majority.

Legal Issues

The assessment of the patient's potential capacity to consent occurs as part of the ongoing CCM process. Providers should suggest goals and action steps that help youth achieve their fullest potential and participate as much as possible in assent and consent processes during their clinical care. It is critical that youth and family members and other caregivers alike understand the significant health system changes associated with the age of majority, including support-service or program-eligibility changes, selective service registration requirements, consent and confidentiality provisions, and guardianship issues. Youth and family members/caregivers need to think about how health care decisions will be made once the youth turns 18. Because of the particular importance of legal issues for youth with special health care needs, it is essential that providers ensure that both the patients and family members understand and are prepared for legal changes associated with adulthood. In addition, problems can arise when a youth is incapacitated and unable to direct his or her own care. Preparing a health care proxy or power of attorney for the young adult will avert such a situation.

Health Education

People with chronic conditions should receive periodic, updated health education about their condition. Necessary information includes an understanding of the patient's specific condition; typical disease process and prognosis; current treatment and treatment options; medication knowledge; self-assessment; and self-care issues, especially in defining emergent situations and responses. Particular attention should be paid to issues of puberty that may not have presented earlier, such as sexual expression, reproductive issues, and genetic transmission. Because of the importance of the patient's understanding his or her own condition, it is essential for providers to document that this information has been provided to, and understood by, the patient.

Caregiver's Issues

Assessment of family/caregiver adaptation is another component of the transition-readiness assessment for families of children and youth with chronic conditions. Attention should be paid to coping on the part of the youth, his or her parents and siblings, and any other appropriate family members and other caregivers. Parents and caregivers must adapt to the transition of authority from parent to youth that occurs when the youth has the capacity to accept the transfer and may experience grief if the child lacks the capacity to assume independent decision-making. For this reason, providers must be ready to help parents and caregivers cope with the life changes associated with chronic conditions as well as with transfer planning. Because these situations can be stressful for the youth and family members/caregivers alike, it is essential that providers assess patients' coping mechanisms and provide referrals for additional care, as appropriate.

5. ADULT MEDICAL HOME (RECEIVING PROVIDER): ROLES AND RESPONSIBILITIES

The transition of a young adult will make it necessary to identify an adult practice that is prepared to accept the patient and provide the full range of care and care coordination in an appropriate, patient-centered care model. Most young adults are healthy and require only the continuation of health maintenance and promotion and the availability of an adult medical home when acute illnesses arise. Yet, even the population of young adults without special health care needs includes those with adolescent-type risky behaviors, mental health issues, and reproductive health needs that require enhanced attention. Young adults with disabilities and chronic medical conditions are more vulnerable to failures in the transition of health care services and require more attention from providers and the health care system. Fundamentally, clinical hurdles and process hurdles present major challenges for a successful move to adult-oriented care for young adults with special health care needs.

The transition of a young adult necessitates the identification of an adult practice that is prepared to accept the patient and provide the full range of care and care coordination in an appropriate patient-centered care model. Shortages in the adult medical home workforce may limit future ca-

pacity to do so. Thus, clinical hurdles largely encompass deficits in education and/or experience of some adult providers to effectively care for this diverse patient population, as well as financial disincentives that limit access to adult-oriented care. The authors of several recent articles have explored the perspective of adult providers participating in the medical transition of young adults with special health care needs. Okumura et al[15] found that, when adult medical care providers were exposed to the process of transitioning young adults in the context of their residency training experiences, they were much more likely to incorporate it into their practices after residency. Anecdotally, however, these residency training experiences are not common, and many practicing physicians have learned "on the job" to manage patients with complex needs. A recent survey of internists' needs when accepting a transitioning youth revealed that education in congenital and childhood-onset conditions was critical.[17] In addition, the respondents cited the need for identified medical subspecialists to help with management decisions. Although adult medical providers have the role of assuming the care and management of these youth, they should not be expected to do so without supports that are more readily available to pediatric providers.

Caring for young adults with special health care needs may represent a challenge that some adult primary care practices are currently not prepared to meet. Further work is needed to characterize, demonstrate, and teach an adult model of care that is responsive to the particular needs of all young adults and sensitive to the specific challenges associated with providing high-quality care to young adults with specific chronic conditions (eg, autism, cerebral palsy, intellectual disability, sickle cell disease). Ideally, the health care payment system would encourage early and ongoing professional relationships with pediatric providers in anticipation of transitions and also support comanagement with pediatric primary care and medical subspecialty providers while the patient is becoming established with the adult practice. At some point, the responsibility for the transitioning young adult will become that of the adult provider, at which time, the adult provider and his or her clinical team should assume a key role in supporting the young adult and his or her family and other caregivers in finding a new balance in the adult medical setting. The transitioning youth's developmental and functional abilities may influence the transition's success. The continued involvement of the family/caregivers should be expected and encouraged during this transition period. In addition, working with the family and other caregivers and other supports to ensure adequate health care insurance and financing for these youth is a major goal of transition.

Second, process hurdles include challenges in the communication of appropriate medical records; community resources; preparation of the young adult and his or her family/caregivers to integrate into an adult-focused medical system; and issues related to payment. Adult providers should not expect a "handoff" from pediatric practices but, rather, a "handshake." Establishing collegial relationships between pediatric and adult medical providers is important for facilitating ongoing access to medical care for patients in transition. Although every transition is different, the best transitions include several core elements. Receivers (providers to whom the youth transitions for care) may reasonably expect that, as the adult medical home team, they will be provided with concise and accurate medical information about the youth and his or her condition, as described previously. In addition, receivers should ensure that:

- the responsible party for medical decision-making has been clearly identified;
- unambiguous adult consent and confidentiality policies have been explained to the patient and his or her family and other caregivers;
- communication has occurred about how the practice operates for issues such as paperwork and medication refills; and
- access to the practice for routine and after-hours care has been discussed with the patient and his or her family and other caregivers.

Although many young adult patients will transition to adult practices from pediatric-based practices, the unique relationship that many family physicians have with their patients allows for ongoing care throughout the life span. Although transfer of care many not occur in these situations, it is likely that young adults with special health care needs have pediatric subspecialists who may wish to facilitate transfer to their adult counterparts. The family physician has the special responsibility to be aware of these needs and, in some situations, to potentially play the role of both the "sender" and "receiver."

Certainly, successful transition is a test of the degree to which a practice operates within the ideals encompassed in the medical home model of care. A team approach to the challenges of transition is necessary for facilitating the level of care for which adult providers strive. Inclusion of local public health and community-based resources should be considered whenever possible to ensure that the medical home approach is followed,

particularly for vulnerable patient populations with special health care needs.

Payment for Health Care Transition Work

The steps involved in the health care transition algorithm are intended to be part of existing office visits using well-established billing codes. For youth without special health care needs, transition preparation and planning would be incorporated into regularly scheduled health maintenance visits and billed as such (Current Procedural Terminology [CPT] codes 99394 and 99395). For youth with special health care needs who have sufficient complexity to justify periodic CCM visits in addition to health maintenance visits, health care transition preparation and planning are intended to occur during a CCM visit billed as a prolonged encounter with an established patient (CPT codes 99214 or 99215). Such visits can be documented as involving counseling for more than 50% of the visit. Youth with highly complex needs may require a CCM visit in which the counseling provided is devoted entirely to transition, but these visits are still reimbursable when using the prolonged-encounter codes and the counseling rule. Activity outside of office encounters involved in the management of a youth's transition plan (whether it stands alone or is incorporated into a more general care plan for a chronic condition) constitutes "care plan oversight." Such work may involve phone calls to prospective adult primary care physicians or medical subspecialists, conversations with the youth and family regarding transition plans, or communication with community agencies integral to the transition process. These activities can be billed by using care plan oversight CPT codes 99374 (15–29 minutes) and 99375 (≥30 minutes) through which the physician can bill monthly for the cumulative time spent on care (or transition) plan oversight. Similar coding and billing options may be exercised after the transfer of care from a pediatric medical home to an adult medical home.

6. CLINICAL GUIDANCE AND FUTURE SUGGESTIONS

This report attempts to address the need for guidance to aid practitioners' implementation of youth transition planning into practice. Yet, transitions cannot occur in a vacuum. Systemic barriers that have been reported as factors that hamper clinicians from implementing needed changes include lack of training and payment for transition activities, receivers to accept these patients, research to identify best practices, and advocacy to advance the research results. Increased training on the critical skill of transitioning can be integrated into an adolescent medicine rotation in internal medicine and into the adolescent medicine and continuity clinic rotations for pediatric residents. Med-peds, pediatrics, and family medicine residencies may provide significant training opportunities in this area. Dually boarded med-ped physicians would seem ideally equipped to care for transitioning adolescents and young adults and to assist in the training of other primary care generalist physicians regarding care over this age range. Unfortunately, the med-peds workforce remains too small and is not likely to grow sufficiently to affect the health care transition of most youth and young adults.

Graduate medical education programs may also provide a forum for pediatric and adult providers to build and maintain relationships that are needed to enhance collaboration and improve communication, ultimately facilitating comanagement of complex conditions. Payment is a crucial element in the promotion of transition planning. Incorporating transition planning into CCM is a process that costs time and money and should be included in conversations about care coordination and payment. Further research is required to define best practices, clinical pathways, and cost-effectiveness for transition planning. Quality-improvement science may provide additional methodologies to inform the understanding of potential strategies. Once best practices are identified, advocacy and education efforts will need to be directed toward several areas including:

- enhanced payment for transition services;
- case-finding of those in need of transition services who are not receiving them;
- insurance coverage for patients in need of transition planning;
- standards of care and credentialing of providers;
- training for primary care physicians and medical subspecialists to promote transitions within the medical home; and
- promotion of training and clinical learning experience on transition and transfer of youth and young adults (both with and without special needs) for trainees in all medical fields.

7. CONCLUSION

A well-timed, well-planned, and well-executed transition from child- to adult-oriented health care, ideally occurring between the ages of 18 and 21, enables youth to optimize their ability to assume adult roles and activities. For this reason, transition planning should be a standard part of providing care for all youth and young adults, and every patient should have an individualized transition plan regardless of his or her specific health care

needs. The AAP, American Academy of Family Physicians, and American College of Physicians recognize that providers need assistance to accomplish this goal. Education of practicing and resident physicians in training is essential for the integration of the concepts of the patient- and family-centered medical home, the principles of transition of care, and the processes for successful transfer of care. Therefore, this clinical report provides a consensus on activities to support the practice-based implementation of transition planning for youth with and without special health care needs. It describes a series of activities designed to ensure that uninterrupted, high-quality, and developmentally appropriate health care services are available to patients moving from adolescence to adulthood. The clinical report provides a clear time line, beginning at 12 years of age, to assist providers in implementing the 4 specific activities in transition: discussing the medical home transition policy; initiating a transition plan; reviewing/updating the transition plan; and implementing an adult care model. It also includes an algorithm that specifies the protocol for managing the transition process, helps providers implement the transition process, and provides a transition structure for patients and their families. The algorithm includes a branch with expanded, generic guidelines for transitioning youth with special health care needs who require CCM. Primary care providers and medical subspecialists are encouraged to make this process specific for their own and their patients' needs.

[b]The federal Maternal and Child Health Bureau defines children with special health care needs as: "Those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally" (McPherson M, Arango P, Fox H, et al. A new definition of children with special health care needs. Pediatrics. 1998;102(1 pt 1):137–140.)

APPENDIX 1

Medical Home Interaction for Patients ≥ 12 Years of Age

1. Initiate first step in the health care transition planning process at age 12.

Is the Patient 12–13 Years of Age? | Is the Patient 14–15 Years of Age? | Is the Patient 16–17 Years of Age? | Is the Patient ≥ 18 Years of Age?

2a, 2b, 2c, 2d. Age Ranges. By age 12, conduct surveillance to assess any special health care needs. Start actual transition planning by age 14. By ages 16-17, transition planning should be well established. At age 18, initiate an adult model of care for most youth, even if there is no transfer of care. If transition planning does not occur on the schedule described by the algorithm, a concentrated effort is required (eg, special visits) to successfully complete the process.

3a. Every practice should have a written transition policy that is prominently displayed and discussed with youth and families. The policy should explicitly state the practice's expectations and care process for the health care transition of their adolescent patients to an adult model of care.

STEP 1: Discuss Office Transitions Policy with Youth & Parents

STEP 2: Ensure Step 1 Is Complete Then Initiate a Jointly Developed Transition Plan With Youth & Parents

3b. The practice should utilize a standard transition plan that can be adapted for each patient's needs. This tool should include components to obtain an accurate assessment of the patient's ability to successfully transition. Providers should interview youth and family members to identify needs and to assess the intentions and motivations for youth independence.

3c. Transitions plans must be reviewed regularly and updated as necessary. The provider must also perform surveillance for changes in the youth's medical status and address youth and family concerns that may warrant changes in transition goals. Failure to achieve transition readiness goals warrants reevaluation of the existing plan, and increased frequency of medical home interventions/visits. A "pretransfer" visit to the adult medical home could be conducted during the year before the transfer.

STEP 3: Ensure Steps 1 & 2 Are Complete, Then Review & Update Transitions Plan & Prepare for Adult Care

STEP 4: Ensure Steps 1, 2, & 3 Are Complete, Then Implement Adult Care Model[a]

[a]For pediatric practices transfer to adult provider

3d. Transition to an adult model of care occurs appropriate for youth's developmental level. This is followed as appropriate by transfer to an adult medical home. Complete medical records should be delivered to the adult provider, along with a portable summary, which is also provided to the patient or guardian. For children and youth with special health care needs, direct communication between pediatric and adult providers is essential, as adult medical personnel may be unfamiliar with certain pediatric conditions.

4. Transition planning for children and youth with special health care needs should include specific chronic condition management (CCM) activities such as: use of registries; care plans; care coordination; CCM office visits; and comanagement with medical subspecialists. Transition goals must be individualized to account for variations in the complexity of a youth's condition and in the youth's intellectual ability and guardianship status.

Does Patient Have Special Health Care Needs?[b]

Incorporate Transition Planning in Chronic Condition Management

5a. Youth with special health care needs require an expanded transition planning process. Transition planning in CCM includes addressing the exchange of complex health information; competencies for self-care; transfers of specialty care; and issues related to insurance, entitlements, guardianship, and eligibility for adult services. In a medical home, such youth may have a written care plan as part of the medical record. At age 14, this plan should include a section titled "transition plan," which should be expanded and developed as the youth approaches age 18 and beyond.

5b. Use of transition planning tools and readiness checklists facilitate the provider's ability to ensure that all age-appropriate transition issues have been addressed. Each action step must be completed in order, even if this means the provider has to schedule specific visits to initiate and complete steps missed earlier in the process in order to catch up before the next visit.

Have Age-Appropriate Transitions Issues Been Addressed?

Initiate Follow-up Interaction

5c. Focused tasks involving little detail or complexity can be addressed by the medical home care coordinator, medical provider, or other appropriate staff through telephone or electronic media. More complex issues may necessitate face-to-face office visits.

6. The provider is finished with the transition tasks for that specific interaction or visit; transition planning is an ongoing activity that occurs at every interaction.

Transitions Component of Interaction Complete

AMERICAN ACADEMY OF PEDIATRICS

Committee on Pediatric AIDS

Surveillance of Pediatric HIV Infection

ABSTRACT. Pediatric human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) surveillance should expand to include perinatal HIV exposure and HIV infection as well as AIDS to delineate completely the extent and impact of HIV infection on children and families, accurately assess the resources necessary to provide services to this population, evaluate the efficacy of public health recommendations, and determine any potential long-term consequences of interventions to prevent perinatal transmission to children ultimately determined to be uninfected as well as for those who become infected. Ensuring the confidentiality of information collected in the process of surveillance is critical. In addition, expansion of surveillance must not compromise the established, ongoing surveillance system for pediatric AIDS. An expanded pediatric HIV surveillance program provides an important counterpart to existing American Academy of Pediatrics and American College of Obstetricians and Gynecologists recommendations for HIV counseling and testing in the prenatal setting.

BACKGROUND

The goals of surveillance for pediatric human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome (AIDS) are to 1) determine the scope of the pediatric HIV epidemic and collect data on trends in the incidence of pediatric infection, 2) characterize the spectrum of disease and modes of transmission, 3) assess when children are identified in the course of their disease so that linkage with needed medical and social services can be improved, 4) project the course of the epidemic to provide needed resources, 5) evaluate the impact of public health recommendations and programs, and 6) facilitate evaluation of the impact of in utero exposure to therapies to reduce perinatal transmission on the long-term outcome of HIV-infected and uninfected children.

The Centers for Disease Control and Prevention (CDC), in conjunction with the Council of State and Territorial Epidemiologists (CSTE), has proposed expanding national surveillance for pediatric HIV infection by adding standardized, confidential reporting of HIV infection in children to the current reporting system for pediatric AIDS.[1] In 1989 and 1993, the CSTE recommended that all states conduct surveillance for HIV infection in children by instituting uniform reporting requirements under policies that maintain confidentiality and security of HIV/AIDS surveillance data. In 1995, the CSTE recommended adding pediatric HIV infection to the national public health surveillance system, and since January 1996, data on reported cases of pediatric HIV infection have been provided in *Morbidity and Mortality Weekly Report*.

Currently, >50% of states conduct confidential surveillance of HIV infection in children. Most of these states also conduct surveillance for perinatal HIV exposure (reporting of HIV antibody positivity). State and local health departments then follow up these cases to determine the child's ultimate infection status and progression to AIDS. The pediatric HIV/AIDS case report form currently allows for reporting at multiple time points for children (ie, at perinatal exposure, HIV infection determination, AIDS diagnosis, and death).

This statement reviews the purposes of the HIV/AIDS surveillance system and discusses the advantages and limitations to the public and to individual children and families of expanding HIV surveillance for children, and recommends the level of surveillance appropriate at this time.

PURPOSE OF SURVEILLANCE

A public health surveillance system should provide ongoing, systematic collection, analysis, evaluation, and dissemination of data describing and monitoring important public health events. These data are used to determine the need for public health interventions and to plan, implement, and evaluate resulting programs and actions. Surveillance systems should be simple and acceptable to those reporting the health event. The majority of cases under surveillance should be detectable in a timely manner and therefore should represent the occurrence of the health event over time and its distribution in the population.[2]

The CDC and state and local health departments have conducted surveillance for AIDS in children and adults since 1981. Such surveillance has provided essential data for characterizing the AIDS epidemic, evaluating trends in opportunistic infections such as *Pneumocystis carinii* pneumonia (PCP), allocating resources for prevention and treatment, and projecting the future impact of disease. The characterization of AIDS is empiric and captures only patients with severely symptomatic HIV infection and therefore detects only a portion of the population

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

infected. Reporting limited to AIDS patients severely underestimates resource needs for the increasing population of HIV-infected and HIV-exposed children.

DISTINGUISHING BETWEEN INDIVIDUAL TESTING AND INFECTION SURVEILLANCE

It is important to distinguish between testing of an individual and surveillance for infection or disease. HIV testing of pregnant women or their newborns that is linked to patient identifiers is performed for clinical care and should be conducted only with consent. The purpose of named HIV testing is to engage a woman in continuing care for herself and her infant. Compliance with medical care is likely to be greatest when the woman feels she has made an informed judgment regarding HIV testing for herself or her infant. The AAP and American College of Obstetricians and Gynecologists (ACOG) recommend that all pregnant women receive HIV education and counseling as part of regular prenatal care. Additionally, it is recommended strongly that HIV testing be performed in all pregnant women with their consent, with documentation in the event of refusal of testing.[3,4] HIV testing under such conditions provides direct benefit to the woman and child.

Surveillance usually has indirect benefits to the individual through general improvement in the public health. The surveillance process occurs independently of the individual patient, and is accomplished by reporting of selected conditions detected by the health care provider, along with identifiers, to local and state health departments. In recommending that any condition be deemed reportable to public health agencies, it is important to weigh the public health benefits of surveillance, the extent of provisions for confidentiality and security of the information reported on individuals, and how acceptable reporting is to providers.

RATIONALE FOR PEDIATRIC HIV INFECTION SURVEILLANCE

Early in the HIV epidemic, surveillance was limited to end-stage disease, AIDS, because an agreed-on syndrome was defined for which no diagnostic test existed and the etiology was not known. Even when diagnosis of HIV infection became possible by serologic testing, interventions were not yet identified that could change the course of the disease. Initial reports of pediatric HIV infection indicated that AIDS progressed rapidly in most HIV-infected children; the epidemic was newly recognized, and only symptomatic disease, primarily in young children, was appreciated. It was expected, therefore, that surveillance for AIDS would provide a good surrogate for evaluating the magnitude of HIV infection in children.

As it became possible to make a definitive diagnosis of infection in the absence of symptoms, it was discovered that not all children with HIV infection die in the first several years of life. Current natural history studies clearly document a bimodal age distribution for the survival of children with pediatric HIV infection. The median age at onset of HIV-related symptoms is 14 months, but the rapid progression to AIDS during the first year of age occurs in only 10% to 30% of perinatally infected infants. Most children infected do not develop AIDS until a median age of 4 to 6 years or older,[5–8] and a significant minority of infected children may survive beyond the age of 8 to 9 years without developing AIDS. [9–11]

Substantial medical and social service resources are needed for the care of children who are exposed to and infected with HIV. The CDC estimates that 12 240 HIV-infected children were living in the United States at the end of 1993, only 22% of whom had developed AIDS.[12] On an annual basis since then, an estimated additional 6500 infants have been born to HIV-infected women, 1630 of whom, in the absence of intervention, were infected each year based on an estimated 25% vertical transmission rate. Use of zidovudine during pregnancy and labor and in the neonatal period theoretically could lower the number of infected children born annually to 520, and this is recommended by the US Public Health Service (PHS) and the AAP.[13–16] However, health care resources are still required for the larger group of HIV-exposed infants for monitoring during the initial 6 weeks of zidovudine prophylaxis, initiation of prophylaxis to prevent PCP as per the current PHS recommendations,[17] and diagnostic testing during the first 6 months of age to determine infection status. Additionally, all children with in utero exposure to antiretroviral drugs require follow-up for any long-term consequences of such exposure.[16]

In recent years, various technologic and medical advances have been made in the detection and treatment of pediatric HIV infection. Current tests permit HIV infection to be diagnosed in nearly all perinatally infected infants no later than age 6 months,[18,19] and most such infants have positive virologic tests by 1 month of age. Early intervention with prophylaxis for PCP[17] has been shown to decrease the occurrence of this infection significantly and reduce early death.[20] There have been important changes in the recommendations for prophylaxis against PCP in children. Prophylaxis should start in all infants born to HIV-positive women at 4 to 6 weeks of age (which may be before infant HIV infection status has been determined definitively), and should be discontinued in children subsequently found to be uninfected continued in all HIV-infected children through at least the first year of age regardless of the $CD4^+$ lymphocyte count.[17] Antiretroviral therapy has prolonged life and, with other supportive therapeutic modalities, modified the course of disease.[21–24]

Finally, the results of AIDS Clinical Trials Group Protocol 076 indicate that a regimen of zidovudine given during pregnancy, labor, and delivery and to the newborn can reduce the risk of perinatal HIV transmission by two thirds.[13] These findings have led to PHS recommendations regarding use of zidovudine to reduce perinatal transmission[15,16] and for HIV counseling and voluntary testing of all pregnant women in the United States.[3,25] With the availability of specific interventions for the prevention and treatment of HIV infection and the complications associated with infection, surveillance for AIDS alone is

less useful for projecting resource needs and planning intervention programs.

HIV infection in children usually is indicative of HIV infection in a family unit. Regardless of the symptom status of the child, considerable health and social service resources are necessary to meet the needs of such families. Therefore, data on the numbers of children born to HIV-infected women and of HIV infection in children would have great usefulness.

IMPORTANT CONSIDERATIONS REGARDING PEDIATRIC HIV SURVEILLANCE

Surveillance of HIV-Infected and HIV-Exposed Infants

When contemplating nationwide expansion of pediatric HIV surveillance, it is important to consider whether reporting should include children who have been exposed to HIV, as well as those known to be infected. Children born to HIV-infected mothers may require evaluation for up to 18 months to determine definitively whether the child is uninfected. Continuing medical monitoring is necessary in such children, and appropriate clinical management dictates that certain interventions (eg, PCP prophylaxis) be initiated pending diagnostic evaluation. Therefore, to delineate fully the impact of HIV infection in children and estimate the medical and social service resources necessary for their care, reporting would optimally include infants of indeterminate status as well as those who are infected. Such data help evaluate the implementation and effectiveness of interventions to reduce perinatal transmission and of recommendations for prophylaxis against PCP. The ability to evaluate the potential long-term impact of such regimens on uninfected as well as HIV-infected children would be facilitated.

There are potential benefits for the mother (as well as other siblings and family members) of reporting of perinatal HIV exposure and/or pediatric HIV infection. The health department, the pediatric health care provider, and the maternal health care provider can work together to refer the mother to medical and social services for her own care, including appropriate counseling regarding HIV and its transmission, immunologic monitoring, antiretroviral treatment, prophylaxis for opportunistic infections, and evaluation of other family members for HIV infection.

Early treatment should be available to mothers and children. This will require enhancement of ambulatory specialized care in inner-city and rural areas and financial resources at local, state, and national levels to meet this obligation. Surveillance data are needed for determining resource allocation. The impact of HIV infection on children and the resultant health care requirements can be accurately determined by a surveillance system that includes reporting of children with perinatal HIV exposure as well as those with definite HIV infection and AIDS. Such data are critical to enable the most complete and reliable appraisal of current and future resource needs.

Many states have already implemented systems for surveillance of HIV-exposed infants. State and local health departments have provided information to the health care providers who report the information on their patients about referrals to available health care and social service resources for the patient and his/her family members.[26] It also has helped to evaluate the implementation of public health recommendations. Additional information from these states will be important to evaluate the usefulness of surveillance of HIV-exposed children.

Important considerations in surveillance for HIV exposure include concerns about confidentiality, particularly for the majority of infants who will be found to be uninfected. The benefits and limitations of maintaining identifiers of such uninfected children in the surveillance system need careful consideration.

Confidentiality Concerns

The confidentiality of HIV/AIDS case reports is critical in HIV/AIDS surveillance. The CDC and state health departments have policies and procedures to maintain security and confidentiality of disease surveillance records, and most states have additional specific confidentiality laws for patient-related HIV data. At the federal level, no patient names are collected and surveillance records are protected by assurance of confidentiality that prohibits the unauthorized disclosure of individual identifying information. Names are removed from patient records and unique coded identifiers are assigned, and the encrypted data are transmitted to the CDC. Federal funding for HIV/AIDS surveillance to state and local health departments is contingent on the ability of the health department to ensure the security and confidentiality of personal identifying information collected as part of surveillance activities.

The reporting of named identifiers to the state or local health department ensures that health departments can eliminate duplicate reports, provide referrals to services, and conduct follow-up to monitor the occurrence of severe illness and death. The state also can evaluate completeness of reporting by matching AIDS case registries with birth and death registries or hospital discharge records, and investigate cases of epidemiologic importance, such as those with no identified risk or unusual laboratory and clinical characteristics.

Although there are clear benefits to named reporting, a concern that it might deter individuals from undergoing HIV testing has been raised. However, a study that evaluated the impact of state reporting policies on personal plans to seek HIV testing found no evidence that such name-reporting was related to a decrease in the numbers of people reporting previous and planned HIV testing.[27] In addition, such reporting has assisted in providing public health services to newly diagnosed HIV-infected persons and in attracting increased funding for outpatient care and support services.[28]

Specific confidentiality provisions are in place to prevent disclosure of surveillance data identifiers to outside parties in all states. However, individual states maintain the authority to legislate disclosure when deemed important for public health purposes.

For example, two state legislatures have issued statutes containing confidentiality provisions, but that require notification of selected parties by the health department regarding reported cases of pediatric HIV infection or AIDS. Statutes in Illinois and South Carolina require that health department officials give notice of the identity of a reported HIV-infected child to the principal of the school in which the child is enrolled (in South Carolina, this applies only to public schools). Legislation requiring that school officials be notified of a child's HIV infection status is not consistent with published policies of a number of medical, educational, and public health organizations, including the AAP[29] and the PHS.[30] These policies evolve from the beliefs that notification of school officials by state or local public health agencies without the knowledge of the family is not consistent with the interests of children or their families, and compromises the rights of families to inform or not inform the schools.

Impact on Mothers and Families Identified Through Pediatric HIV/AIDS Reporting

All infants with perinatal exposure to HIV have HIV-infected mothers, and reporting of HIV exposure or infection in infants constitutes indirect knowledge of maternal serostatus. It has been speculated that some women might be deterred from having their infants evaluated for HIV for fear of identification of their status and potential social stigmatization. However, this has not been substantiated, and the knowledge that a regimen of zidovudine can reduce significantly the risk of perinatal HIV transmission has provided a strong impetus for pregnant women to learn their HIV infection status early in pregnancy.

Seroprevalence Surveys

Serologic testing of blood specimens that are not linked to individual patient identifiers for the purposes of surveillance has provided important information regarding the extent of the HIV epidemic. In pediatrics, because the presence of HIV antibody in the newborn reflects the infection status of the child's mother, the unlinked testing of neonatal filter paper blood specimens for HIV antibody has provided information regarding the distribution and prevalence of HIV infection in childbearing women. The population-based National HIV Survey in Childbearing Women, which was suspended by the PHS in May 1995, was used to examine HIV infection trends among women and children and to identify geographic areas in greatest need of prevention and treatment resources. Data from this survey, for example, demonstrated an increase in HIV infection among childbearing women in rural areas of the southeastern United States and was used to target and obtain funding for epidemiologic studies and prevention/service programs for these areas.[31]

With recommendations that PCP prophylaxis begin at 4 to 6 weeks of age and the discovery that zidovudine given to pregnant women and their infants can reduce significantly the risk of perinatal transmission, a few states have instituted or are considering legislation to require mandatory HIV testing of all newborns, with subsequent identification and informing of seropositive mothers. However, it is critical to recognize that testing of newborn blood specimens does not identify infected mothers early enough to permit initiation of zidovudine therapy during pregnancy to reduce perinatal transmission and therefore prevent HIV infection in children. Recognizing this, rather than mandating newborn HIV testing, a few states have passed legislation to require routine prenatal HIV education and HIV testing for all pregnant women, an approach more likely to reduce perinatal HIV infection.

The conduct of the serosurvey of childbearing women is important to evaluate trends in HIV infection in childbearing women and project resource needs. In conjunction with surveillance of HIV exposure, such a serosurvey permits evaluation of counseling and testing recommendations and validation of the efficacy of the surveillance system.[32] The PHS, AAP, and ACOG recommend that all women receive HIV education and counseling as part of their regular prenatal care. Additionally, it is strongly recommended that HIV testing be performed in all pregnant women with their consent, with documentation in the event of refusal of testing.[3,4,25] In areas in which pregnant women have been provided the opportunity to gain knowledge of their HIV serostatus, concerns about the conduct of an unlinked serosurvey would be diminished. Therefore, the AAP supports reinstitution of the serosurvey in areas in which the PHS, ACOG, and AAP recommendations for HIV counseling and testing in the prenatal setting have been implemented.

CONCLUSION

The AAP believes that there would be significant benefits to expanding surveillance for pediatric HIV infection nationwide through the addition of confidential reporting of perinatal HIV exposure and HIV infection in children to the ongoing surveillance of AIDS. However, confidentiality is crucial, and such information must be safeguarded and protected from unwarranted disclosures.

RECOMMENDATIONS

1. The AAP supports expanding HIV/AIDS surveillance in children to include reporting of HIV infection and AIDS status in all states and territories of the United States. This expansion must include appropriate safeguards for confidentiality.
2. With confidentiality provisions and adequate resources to ensure that there is no detrimental effect on ongoing surveillance for HIV infection and AIDS, the AAP supports additional expansion of HIV surveillance to include reporting of HIV-exposed infants.
3. The AAP opposes linkage of pediatric HIV infection reporting with disclosure to school and child care personnel as well as to other nonpublic health service organizations.
4. The reporting format should be simple and easy to implement for the health care community responsible for reporting to the health department.

5. The AAP reaffirms that all pregnant women should receive HIV education and counseling as part of regular prenatal care, and recommends strongly that HIV testing should be performed in all pregnant women with their consent, with documentation in the event of refusal of testing.
6. In areas in which AAP, ACOG, and PHS recommendations for HIV education, counseling, and testing in the prenatal setting have been implemented, seroprevalence surveys to determine the rate of HIV infection among childbearing women should be reimplemented.
7. Access to care for HIV-infected children and mothers is essential. However, the availability of resources to facilitate such access may depend on data documenting the extent of the problem in these populations. Therefore, expansion of HIV/AIDS surveillance should not be delayed until access problems have been resolved completely.

Swimming Programs for Infants and Toddlers

ABSTRACT. Infant and toddler aquatic programs provide an opportunity to introduce young children to the joy and risks of being in or around water. Generally, children are not developmentally ready for swimming lessons until after their fourth birthday. Aquatic programs for infants and toddlers have not been shown to decrease the risk of drowning, and parents should not feel secure that their child is safe in water or safe from drowning after participating in such programs. Young children should receive constant, close supervision by an adult while in and around water.

ABBREVIATION. AAP, American Academy of Pediatrics.

Drowning is a leading cause of unintentional injury and death in the pediatric age group. In the United States, drowning rates are the highest among children ages 1 through 2 years. In Arizona, California, Florida, and Texas, drowning is the leading cause of death in this age group.[1] Other reported medical risks to infants and toddlers that involve being in water include hypothermia,[2,3] water intoxication,[4–6] and the spread of communicable diseases.[7] Serious consequences from these medical conditions are rare and can generally be reduced by following existing guidelines published by the American Red Cross[8] and the YMCA.[9] The policy statement published in 1993 by the American Academy of Pediatrics (AAP) entitled "Drowning in Infants, Children, and Adolescents"[10] also provides an excellent review of the subject. This AAP policy statement on infant swimming programs is an update of the 1985 policy.[11]

Infant and toddler aquatic programs are popular throughout the United States. An estimated 5 to 10 million infants and preschool children participate in formal aquatic instruction programs. Infant and preschool programs have been developed by such organizations as the American Red Cross[8] and the YMCA.[9,12] These programs, which focus on aquatic adjustment and swimming readiness skills, may also include water safety instruction for parents and guardians. They provide enjoyment for parents and children but were not designed to teach children to become accomplished swimmers or to survive independently in the water. Other infant/toddler aquatic programs, however, attempt to develop water survival skills.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Regardless of the program design or focus, infant and toddler aquatic programs are unable to ensure that children will understand water hazards, use appropriate avoidance strategies, or attain program safety goals. Currently, no data are available to determine if infant and toddler aquatic programs increase or decrease the likelihood of drowning. Programs that claim to make children safe in water or safe from drowning are misrepresenting what is possible and are giving parents a false sense of security about their child's safety in the water.

Swimming skills (ie, the ability to perform standard swimming strokes) should be distinguished from water safety skills (ie, survival flotation, energy conservation "swimming," or poolside safety behavior). Without specific training, children can perform rudimentary swimming movements in the water sometime around their first birthday.[13] The types of swimming movements a young child first demonstrates are not traditional strokes, such as the front crawl, but are more basic movements similar to the dog paddle. The optimum time to master more complex skills of swimming has not been thoroughly researched and has not been determined. A recent study by Blanksby et al[14] showed that swimming skills can be acquired more readily once motor development has reached the 5-year-old level. Although some children may acquire swimming skills earlier, Parker and Blanksby[15] found that children younger than 4 years require longer instructional periods to learn skills and are limited by their neuromuscular capacity. Therefore, having children begin swimming lessons at an earlier age does not translate to a more rapid mastery of aquatic skills or a higher level of swimming proficiency compared with those taking lessons at a later age.

The effects of training on the acquisition of water survival skills in young children have been studied by Asher et al[16] In a population of children averaging 34 months of age, water survival skills were enhanced after a training program. Safety training, however, did not result in a significant increase in the poolside safety skills of these children. The correlation between measurable safety skills and risk of drowning has not been established.

For any water safety or swimming class, children learn better if they are developmentally ready, properly motivated, positively reinforced, and if the experience is enjoyable. When instruction attempts to optimize learning by reducing fear of water, children may unwittingly be encouraged to enter the water without supervision.

Regardless of an infant's or toddler's apparent

level of comfort and competence in or around water, constant close supervision by an adult is necessary to prevent drowning and near-drowning. Even a brief lapse in supervision can have tragic results.[17–20] The concept of "touch supervision" has been advocated, which requires the caregiver to be within an arm's reach or able to touch the swimmer at all times.

RECOMMENDATIONS

Until more clear-cut scientific evidence exists on the effects of infant and toddler aquatic programs, the AAP recommends the following:

1. Children are generally not developmentally ready for formal swimming lessons until after their fourth birthday.
2. Aquatic programs for infants and toddlers should not be promoted as a way to decrease the risk of drowning.
3. Parents should not feel secure that their child is safe in water or safe from drowning after participation in such programs.
4. Whenever infants and toddlers are in or around water, an adult should be within an arm's length, providing "touch supervision."
5. All aquatic programs should include information on the cognitive and motor limitations of infants and toddlers, the inherent risks of water, the strategies for prevention of drowning, and the role of adults in supervising and monitoring the safety of children in and around water.
6. Hypothermia, water intoxication, and communicable diseases can be prevented by following existing medical guidelines and do not preclude infants and toddlers from participating in otherwise appropriate aquatic experience programs.
7. Pediatricians should support data collection, drowning prevention research, and legislation aimed at reducing the risk of drowning in young children in and around water.

American Thoracic Society

Targeted Tuberculin Testing and Treatment of Latent Tuberculosis Infection

THIS OFFICIAL STATEMENT OF THE AMERICAN THORACIC SOCIETY WAS ADOPTED BY THE ATS BOARD OF DIRECTORS, JULY 1999. THIS IS A JOINT STATEMENT OF THE AMERICAN THORACIC SOCIETY (ATS) AND THE CENTERS FOR DISEASE CONTROL AND PREVENTION (CDC). THIS STATEMENT WAS ENDORSED BY THE COUNCIL OF THE INFECTIOUS DISEASES SOCIETY OF AMERICA (IDSA), SEPTEMBER 1999, AND THE SECTIONS OF THIS STATEMENT AS IT RELATES TO INFANTS AND CHILDREN WERE ENDORSED BY THE AMERICAN ACADEMY OF PEDIATRICS (AAP), AUGUST 1999.

Executive Summary

This statement provides new recommendations for targeted tuberculin testing and treatment regimens for persons with latent tuberculosis infection (LTBI) and updates previously published guidelines (1, 2). This statement is issued in recognition of the importance of these activities as an essential component of the TB Elimination Strategy promoted by the U.S. Public Health Service Advisory Council on the Elimination of Tuberculosis, and reports the deliberations of expert consultants convened by the American Thoracic Society (ATS) and Centers for Disease Control and Prevention (CDC).

Isoniazid for 6-12 mo has been the mainstay of treatment for LTBI in the United States for more than 30 yr. However, the application of isoniazid for LTBI has been limited because of poor adherence, due to the relatively long duration of treatment required, and because of concerns about toxicity. Therefore, there has been interest in the development of shorter, rifampin-based regimens as alternatives to isoniazid for the treatment of LTBI. During the past decade, a series of studies of "short-course" treatment of LTBI in persons with human immunodeficiency virus (HIV) infection has been undertaken. The results of these trials have recently become available, and the in-depth analyses of these and prior studies of isoniazid form the scientific basis of the treatment guidelines presented in this report. In addition, many changes to previous recommendations regarding testing for and treatment of LTBI are presented (Table 1).

TARGETED TUBERCULIN TESTING

Targeted tuberculin testing for LTBI is a strategic component of tuberculosis (TB) control that identifies persons at high risk for developing TB who would benefit by treatment of LTBI, if detected. Persons with increased risk for developing TB include those who have had recent infection with *Mycobacterium tuberculosis* and those who have clinical conditions that are associated with an increased risk for progression of LTBI to active TB (see Tables 2 and 3). Following that principle, targeted tuberculin testing programs should be conducted only among groups at high risk and discouraged in those at low risk. Infected persons who are considered to be at high risk for developing active TB should be offered treatment of LTBI irrespective of age.

Based on the sensitivity and specificity of the purified protein derivative (PPD) tuberculin skin test and the prevalence of TB in different groups, three cut-points have been recommended for defining a positive tuberculin reaction: ≥ 5 mm, ≥ 10 mm, and ≥ 15 mm of induration (see Table 7). For persons who are at highest risk for developing active TB if they are infected with ***M. tuberculosis*** (i.e., persons with HIV infection, who are receiving immunosuppressive therapy, who have had recent close contact with persons with infectious TB, or who have abnormal chest radiographs consistent with prior TB), ≥ 5 mm of induration is considered positive. For other persons with an increased probability of recent infection or with other clinical conditions that increase the risk for progression to active TB, ≥ 10 mm of induration is considered positive. These include recent immigrants (i.e., within the last 5 yr) from high prevalence countries; injection drug users; residents and employees of high-risk congregate settings (including health care workers with exposure to TB); mycobacteriology laboratory personnel; persons with clinical conditions such as silicosis, diabetes mellitus, chronic renal failure, leukemias and lymphomas, carcinoma of the head or neck and lung, weight loss of ≥ 10% ideal body weight, gastrectomy, and jejunoileal bypass; and children younger than 4 yr of age or infants, children, and adolescents exposed to adults in high-risk categories. For persons at low risk for TB, for whom tuberculin testing is not generally indicated, ≥ 15 mm of induration is considered positive.

TREATMENT OF LATENT TUBERCULOSIS INFECTION

In this report, treatment recommendations use an adaptation of the rating system from recent U.S. Public Health Service documents (3) that grades the strength of the recommendation (A, B, or C) and the quality of evidence supporting the recommendation (I, II, or III). Four regimens are recommended for the treatment of adults with LTBI. (See Tables 8 and 10 for detailed recommendations, dosages, and contraindications.)

This Statement is one of four Statements on the diagnosis, treatment, prevention, and control of tuberculosis. The Statement updates and revises information on the treatment of latent tuberculosis infection in (1) Treatment of tuberculosis and tuberculosis infection in adults and children. Am J. *Respir. Crit. Care Med.* 1994;149:1359–1374, and information on screening for tuberculosis in (2) Control of tuberculosis. *Am. Rev. Respir. Dis.* 1992;146:1623–1633. **For information on the treatment of tuberculosis, refer to (1). For information on management of contacts and organization of control programs, refer to (2). For information on diagnostic methods, refer to (3) Diagnostic standards and classification of tuberculosis in adults and children. Am.** *J. Respir. Crit. Core Med.* 2000;161 :**1376-I 395.**

Drugs	Duration (mo)	Interval	Rating* (Evidence)† HIV−	HIV+
Isoniarid	9	Daily	A (II)	A (II)
		Twice weekly	B (II)	B (II)
Isoniazid	6	Daily	B (I)	C (I)
		Twice weekly	B (II)	C (I)
Rifampin-pyrazinamide	2	Daily	B (II)	A (I)
	2-3	Twice weekly	C (II)	C (I)
Rifampin	4	Daily	B (II)	B (III)

* A = preferred; B = acceptable alternative; C = offer when A and B cannot be given.
† I = randomized clinical trial data; II = data from clinical trials that are not randomized or were conducted in other populations; III = expert opinion.

The isoniazid daily regimen for 9 mo is recommended because prospective, randomized trials in HIV-negative persons indicate that 12 mo of treatment is more effective than 6 mo of treatment. However, in subgroup analyses of several trials the maximal beneficial effect of isoniazid is likely achieved by 9 mo, and minimal additional benefit is gained by extending therapy to 12 mo. When compared with placebo, both 6-mo and 12-mo regimens are effective in HIV-positive patients; however, these regimens have not been compared with each other in randomized trials.

Although a 9-mo regimen of isoniazid is the preferred regimen for the treatment of LTBI, a 6-mo regimen also provides substantial protection and has been shown to be superior to placebo in both HIV-negative and HIV-positive persons. In some situations, treatment for 6 mo rather than 9 mo may provide a more favorable outcome from a cost-effectiveness standpoint. Thus, based on local conditions, health departments or providers may conclude that a 6-mo rather than a 9-mo course of isoniazid is preferred.

Both the 9-mo and 6-mo isoniazid regimens may be given intermittently (i.e., twice weekly). When isoniazid is given intermittently, it should be administered only as directly observed therapy (DOT).

The 2-mo daily regimen of rifampin and pyrazinamide is recommended on the basis of a prospective randomized trial of treatment of LTBI in HIV-infected persons that showed the 2-mo regimen to be similar in safety and efficacy to a 12-mo regimen of isoniazid. Twice-weekly treatment with rifampin and pyrazinamide for 2 or 3 mo may be considered when alternative regimens cannot be given. This intermittent regimen should always be administered as DOT. Some experts recommend that the 2-mo regimen of daily rifampin and pyrazinamide also be given by DOT, which can consist of five observed and two self-administered doses each week. In situations in which rifampin cannot be used (e.g., HIV-infected persons receiving protease inhibitors), rifabutin may be substituted.

Rifampin given daily for 4 mo is recommended on the basis of the efficacy of a similar regimen in (I) a prospective randomized trial of tuberculin-positive persons with silicosis and (2) a nonrandomized trial in persons exposed to individuals with isoniazid-resistant TB. This option may be especially useful for patients who cannot tolerate isoniazid or pyrazinamide.

Before beginning treatment of LTBI, active TB should be ruled out by history, physical examination, chest radiography, and, when indicated, bacteriologic studies.

Special considerations for treatment of LTBI apply to the following populations:

- When isoniazid is chosen for treatment of LTBI in persons with HIV infection or those with radiographic evidence of prior TB, 9 mo rather that 6 mo is recommended.
- For pregnant, HIV-negative women, isoniazid given daily or twice weekly for 9 or 6 mo is recommended. For women at risk for progression of LTBI to disease, especially those who are infected with HIV or who have likely been infected recently, initiation of therapy should not be delayed on the basis of pregnancy alone, even during the first trimester. For women whose risk for active TB is lower, some experts recommend waiting until after delivery to start treatment.
- For children and adolescents, isoniazid given either daily or twice weekly for 9 mo is the recommended regimen.
- For contacts of patients with isoniazid-resistant, rifampin-susceptible TB, rifampin and pyrazinamide given daily for 2 mo is recommended, and for patients with intolerance to pyrazinamide, rifampin given daily for 4 mo is recommended.
- For persons who are likely to be infected with isoniazid- and rifampin-resistant (multidrug) TB and who are at high risk for developing TB, pyrazinamide and ethambutol or pyrazinamide and a quinolone (i.e., levofloxacin or ofloxacin) for 612 mo are recommended. Immunocompetent contacts may be observed or treated for at least 6 mo, and immunocompromised contacts (e.g., HIV-infected persons) should be treated for 12 mo.

TABLE 1

CHANGES FROM PRIOR RECOMMENDATIONS ON TUBERCULIN TESTING AND TREATMENT OF LATENT TUBERCULOSIS INFECTION (LTBI)

Tuberculin testing

- Emphasis on targeted tuberculin testing among persons at high risk for recent LTBI or with clinical conditions that increase the risk for tuberculosis (TB), regardless of age; testing is discouraged among persons at lower risk
- For patients with organ transplants and other immunosuppressed patients (e.g., persons receiving the equivalent of ≥ 15 mg/d of prednisone for 1 mo or more), 5 mm of induration rather than 10 mm of induration as a cut-off level for tuberculin positivity
- A tuberculin skin test conversion is defined as an increase of ≥ 10 mm of induration within a 2-yr period, regardless of age

Treatment of latent tuberculosis infection

- For human Immunodeficiency virus (HIV)-negative persons, isoniarid given for 9 mo is preferred over 6-mo regimens
- For HIV-positive persons and those with fibrotic lesions on chest X-ray consistent with previous TB, isoniazid should be given for 9 mo instead of 12 mo
- For HIV-negative and HIV-positive persons, rifampin and pyrazinamide should be given for 2 mo
- For HIV-negative and HIV-positive persons, rifampin should be given for 4 mo

Clinical and laboratory monitoring

- Routine baseline and follow-up laboratory monitoring can be eliminated in most persons with LTBI, except for those with HIV infection, pregnant women (or those in the immediate postpartum period), and persons with chronic liver disease or those who use alcohol regularly
- Emphasis on clinical monitoring for signs and symptoms of possible adverse effects, with prompt evaluation and changes in treatment, as indicated

CLINICAL AND LABORATORY MONITORING

Once patients have been identified and then tested for LTBI, they should receive an initial clinical evaluation. They should also receive follow-up evaluations at least monthly (if receiving isoniazid alone or rifampin alone) and at 2, 4, and 8 wk (if receiving rifampin and pyrazinamide). This evaluation should include questioning about side effects and a brief physical assessment checking for signs of hepatitis. Patients should be ed-

ucated about the side effects associated with treatment of LTBI and advised to stop treatment and promptly seek medical evaluation when they occur.

Baseline laboratory testing is not routinely indicated for all patients at the start of treatment for LTBI (see Table 8). Patients whose initial evaluation suggests a liver disorder should have baseline hcpatic measurements of serum aspartate aminotransferase (serum glutamic oxaloacetic transaminase) (AST [SGOT]) or alanine aminotransferase (serum glutamic pyruvic transaminase) (ALT [SGPT]) and bilirubin. Baseline testing is also indicated for patients with HIV infection, pregnant women, and women in the immediate postpartum period (i.e., within 3 mo of delivery), persons with a history of chronic liver disease (e.g., hepatitis B or C, alcoholic hepatitis, or cirrhosis), persons who use alcohol regularly, and persons at risk for chronic liver disease. Baseline testing is not routinely indicated in older persons. However, such testing may be considered on an individual basis, particularly for patients who are taking other medications for chronic medical conditions. Active hepatitis and end-stage liver disease are relative contraindications to the use of isoniazid or pyrazinamide for treatment of LTBI.

Routine laboratory monitoring during treatment of LTBI is indicated for persons whose baseline liver function tests are abnormal and other persons at risk for hepatic disease. Laboratory testing may also be indicated for the evaluation of possible adverse effects that occur during the course of treatment (e.g., liver function studies for patients with symptoms compatible with hepatotoxicity or a uric acid measurement to evaluate complaints of joint pain). Some experts recommend that isoniazid should be withheld if transaminase levels exceed three times the upper limit of normal if associated with symptoms and five times the upper limit of normal if the patient is asymptomatic.

Introduction

HISTORY OF TREATMENT OF LATENT TUBERCULOSIS INFECTION AND RELEVANCE TO TUBERCULOSIS CONTROL

For more than three decades, treatment of persons with latent *Mycobacteriunz tuberculosis* infection (LTBI) to prevent the development of active disease has been an essential component of tuberculosis (TB) control in the United States (4). In the United States and other countries with a low incidence of TB, most new, active cases have occurred among persons who were once infected, contained this infection, and then later developed active TB (5). The identification and treatment of infected persons at highest risk for developing disease benefit both infected persons and susceptible persons in their communities. Until recently, isoniazid was the only drug proven effective and thus recommended for treatment of LTBI.

Shortly after isoniazid was found to be effective for the treatment of TB, clinical trials were begun to assess the ability of the drug to prevent progression of primary disease in children. When it was found that this intervention was highly effective, larger trials were begun to evaluate the drug for treatment of infected contacts of TB patients and of other persons at high risk (e.g., those with radiographic evidence of prior, untreated TB) (6). In 1965, isoniazid treatment of LTBI was first recommended for general use by the American Thoracic Society (ATS) (7). This initial statement recommended isoniazid for persons with evidence of previously untreated TB and persons with recent tuberculin skin test conversions, including all children younger than 3 yr of age with a positive tuberculin skin test. In 1967, ATS and PHS broadened the recommendations to include all persons who had had a purified protein derivative (PPD) tuberculin skin-test reaction of $\geq$ 10 mm. The recommendations stated that chemoprophylaxis is mandatory for (I) persons with inactive cases of TB who were not previously treated and their contacts, (2) persons with tuberculin skin test conversions, (3) persons with specified medical conditions, and (4) all persons younger than 20 yr of age who had had positive tuberculin skin tests (8). With widespread use of such an inexpensive drug that had "virtually no side effects," it was believed that "chemoprophylaxis [could] reduce future morbidity from TB in high risk groups by some 50 to 75 percent" (8).

However, despite this belief, the goal of reducing TB morbidity by such a substantial percentage through the administration of isoniazid was never reached. In 1970, among several thousand persons who began isoniazid treatment as a result of an outbreak of TB on Capitol Hill in the District of Columbia, 19 persons developed clinical signs of liver disease and two persons died of hepatic failure attributed to isoniazid (9). The recognition that isoniazid was associated with potentially fatal hepatitis led to the development of guidelines regarding pretreatment screening and monitoring to minimize the risk for severe complications (10). In 1974, following a study to quantify the risk for isoniazid-related hepatitis (11), guidelines for treatment of LTBI were updated. The revised guidelines excluded low-risk persons aged older than 35 yr of age as candidates for treatment (12).

Subsequent controversy over the appropriate age cut-off for these low-risk, tuberculin-positive persons ensued, with one group concluding that the risks of treatment of LTBI outweighed the benefits for young adults (13). This controversy and resulting confusion led to a decrease in the use of isoniazid for treating persons with LTBI—even persons at high risk for whom treatment was indicated (14). In 1983, the guidelines were further revised to recommend routine clinical and laboratory monitoring for persons aged older than 35 yr of age and other persons at risk for hepatotoxicity (15). Recent studies have suggested that since the advent of routine monitoring, the risk for severe hepatotoxicity has been substantially reduced (16).

Because widespread use and the potential impact of isoniazid treatment of LTBI became limited by actual and perceived toxicity and patient nonadherence because of the relatively long period of treatment required, alternatives to isoniazid were suggested (17). The introduction of rifampin, which appeared to be a better sterilizing agent than isoniazid, suggested the possibility that rifampin-based regimens might be safer, more effective, and shorter. The occurrence of the human immunodeficiency virus (HIV) epidemic and the need to evaluate the efficacy of treatment for LTBI in persons coinfected with HIV and *M. tuberculosis* led to a series of studies of short-course treatment of LTBI in HIV-infected persons (18). The results of these studies have recently become available and have contributed substantially to guidelines on treatment of LTBI in persons with HIV infection (3).

RELATIONSHIP OF TUBERCULIN TESTING TO TREATMENT OF LATENT TUBERCULOSIS INFECTION

As the rate of active TB in the United States has decreased, identification and treatment of persons with latent infection who are at high risk for active TB have become essential components of the TB elimination strategy promoted by the PHS Advisory Council on the Elimination of Tuberculosis (19). Because testing persons for infection and provision of treatment are interrelated, these recommendations include sections on program activities aimed at identifying high-risk infected persons and tuberculin skin testing, as well as recommendations on the use of new, short-course treatment regimens.

CHANGE IN NOMENCLATURE

Identification of persons with LTBI has previously been accomplished by widespread tuberculin skin testing of individuals or groups at variable risk for TB. In many situations, this screening was done with limited consideration of the risk for TB in the population(s) being tested. To focus on groups at the highest risk for TB, the term "targeted tuberculin testing" is used in these guidelines to encourage directed program activities.

Although the terms "preventive therapy" and "chemoprophylaxis" have been used for decades, they have also been confusing. "Preventive therapy" has referred to the use of a simple regimen (usually isoniazid) to prevent the development of active TB disease in persons known or likely to be infected with *M. tuberculosis,* but it rarely results in true primary prevention (i.e., prevention of infection in persons exposed to persons with infectious TB). To describe the intended intervention more accurately, this report uses the terminology "treatment of LTBI" rather than "preventive therapy" or "chemoprophylaxis." This change in nomenclature will hopefully promote greater understanding of the concept for both patients and providers, resulting in more widespread implementation of this essential TB control strategy.

Scientific Rationale

TARGETED TUBERCULIN TESTING

Groups at Risk and Risk Factors for Infection with *M. tuberculosis*

Targeted tuberculin testing for LTBI identifies persons at high risk for TB who would benefit by treatment of LTBI, if detected. Persons at high risk for TB (i.e., risk substantially greater than that of the general U.S. population) have either been infected recently with ***M. tuberculosis*** or have clinical conditions that are associated with an increased risk of progression of LTBI to active TB (Tables 2 and 3). Screening of low-risk persons and testing for administrative purposes (e.g., certification of school teachers) should be replaced by targeted testing.

Persons or groups with presumed recent M. tuberculosis ***infection.*** Persons infected with ***M. tuberculosis*** are at greatest risk for developing disease shortly after infection has occurred (Table 2). In two controlled trials examining the efficacy of treatment of LTBI among contacts of persons with active TB and among patients in mental hospitals, the tuberculin skin tests of 1472 participants in the placebo groups of the trials converted from negative to positive. Among persons whose tests converted, 19 developed disease in the first year of follow-up (12.9 cases per 1000 person-years) compared with 17 persons in the subsequent 7 yr of follow-up (1.6 cases per 1,000 person-years) (6). In a study of TB vaccines given to British schoolchildren, 2550 unvaccinated participants' tuberculin skin tests converted. Of these, 121 (4.7%) developed clinical TB within 15 yr of entry into the study: 54% developed disease during the first year after infection and 82% developed disease within 2 yr of infection (20).

In designing and planning targeted testing programs, several groups of persons can be identified as being at increased risk for being recently infected with ***M. tuberculosis.*** A high prevalence of either LTBI or active TB has been documented among close contacts of persons with infectious pulmonary TB (21); both of these characteristics are likely attributable to recent contact with infectious persons. Likewise, persons whose tuberculin skin tests convert from negative to positive within a period of 2 yr are presumed to have been infected recently.

Persons who have immigrated from areas of the world with high rates of TB have incidence rates that approach those of their countries of origin for the first several years after arrival in the United States (22). This high rate likely results from infection with *M. **tuberculosis*** in the native country before immigration and progression to disease soon after arrival in the United States. This hypothesis is supported by (I) DNA fingerprinting studies with restriction fragment length polymorphism (RFLP) interpreted to correlate with low rates of recent transmission of TB among foreign-born case patients in the United States (23) and (2) other data indicating that with time, the incidence of TB in foreign-born persons declines to approach that of the U.S. population (24).

Children, especially those younger than 5 yr of age, who have a positive tuberculin skin test are likely to be in the early stage of LTBI and are at high risk for progression to active disease, with the potential for disseminated TB (25). The risk for developing active TB is also increased in adolescents and young adults (25).

Recent U.S. studies (including RFLP studies) have helped characterize certain epidemiologically defined groups of persons with high rates of TB transmission and increased risk for being recently infected (e.g., homeless persons, those with HIV infection, and injection drug users) (23, 26). In addition, persons who reside or work in institutional settings (e.g., hospitals, homeless shelters, correctional facilities, nursing homes, and residential homes for patients with AIDS [27]) with persons at risk for TB may have an ongoing risk for acquiring TB infection. However, the risk for transmission varies greatly, and the likelihood that a specific institution is a site of transmission of ***M. tuberculosis*** can be determined only by local epidemiological data.

Clinical conditions associated with progression to active tuberculosis. HIV infection contributes most to an increased risk for progression of LTBI to active TB. Rates of progression to TB among HIV-infected persons have ranged from 35 to 162 per 1000 person-years of observation (Table 2) (28). In a prospective cohort study of persons with HIV infection in the United States, the annual risk of active TB among persons with a positive tuberculin test was 45 cases per 1000 person-years (29). Injection drug users also have an increased risk for progressing to active TB (10 cases per 1000 person-years) (30), and this risk is even greater for injection drug users coinfected with HIV and TB (76 cases per 1000 person-years) (31). These higher rates may reflect increased transmission, more recent infection in this population, and the increased risk associated with injection drug use and HIV infection.

The risk for active TB is also increased in (I) persons with pulmonary fibrotic lesions seen on chest radiographs (presumed to be from prior, untreated TB) and (2) underweight persons. Persons with fibrotic lesions on chest radiographs consistent

TABLE 2

INCIDENCE OF ACTIVE TUBERCULOSIS (TB) IN PERSONS WITH A POSITIVE TUBERCULIN TEST, BY SELECTED RISK FACTORS

Risk Factor	TB Cases/l ,000 Person-vears
Recent TB infection	
infection < 1 yr past	12.9 (6)*
Infection l-7 yr past	1.6
Human immunodeficiency virus	
(HIV) infection	35.0-l 62 (28)
Injection drug use	
HIV seropositive	76.0 (31)
HIV seronegative or unknown	10.0 (31)
Silicosis	68 (36)
Radiographic findings consistent with prior TB	2.0-I 3.6 (32-34)
Weight deviation from standard	
Underweight by ≥ 15%	2.6 (35)
Underweight by 1 0–14%	2.0
Underweight by 5–9%	2.2
Weight within 5% of standard	1.1
Overweight bv ≥ 5%	0.7

TABLE 3

RELATIVE RISK* FOR DEVELOPING ACTIVE TUBERCULOSIS (TB), BY SELECTED CLINICAL CONDITIONS

Clinical Condition	Relative Risk
Silicosis	30 (37, 38)'
Diabetes *mellitus*	2.0–4.1 (42-44)
Chronic renal failure/hemodialysis	10.0-25.3 (39-41)
Castrectomy	2-5 (45–47)
Jejunoileal bypass	27-63 (48, 49)
Solid organ transplantation	
Renal	37 (50)
Cardiac	20-74 (51, 52)
Carcinoma of head or neck	16 (53)

* Relative to control population; independent of tuberculin-test status.
† Numbers in parentheses are reference numbers.

with prior, healed TB have a risk for progression to active TB of 2.0-13.6 per 1000 person-years of observation (32-34). A study of 23,541 U.S. Naval recruits with tuberculin reactions ≥ 10 mm demonstrated that recruits who were ≥ 15% underweight from the standard weight for their height had a risk of progression to disease that was twofold that of persons who were within 5% of the standard weight for their height and more than threefold that of persons who were overweight (35).

Studies indicate that several other clinical conditions increase the risk for active TB, although participants in these studies were not stratified by tuberculin-test status (Table 3).

Tuberculin-positive persons with silicosis have an approximately 30-fold greater risk for developing TB (36-38). Persons with chronic renal failure who are on hemodialysis also have an increased risk: 10–25 times greater than the general population (3941). Persons with diabetes mellitus have a risk for developing active TB that is twofold to fourfold greater than persons without diabetes mellitus, and this risk is likely greater in persons with insulin-dependent or poorly controlled diabetes (42-44). Other clinical conditions that have been associated with active TB include gastrectomy with attendant weight loss and malabsorption (45–47), jejunoileal bypass (48, 49), renal (50) and cardiac (51, 52) transplantation, carcinoma of the head or neck (53), and other neoplasms (e.g., lung cancer, lymphoma, and leukemia [54]).

Persons receiving prolonged therapy with corticosteroids and other immunosuppressive agents may be at risk for reactivation of TB, but the exact risk is unknown (1). Because prednisone (or its equivalent) given > 15 mg/d for 2-4 wk suppresses tuberculin reactivity (55, 56), and because lower doses or those given intermittently are not associated with TB, this dose is likely the lower limit that could predispose persons to develop TB (57). Reactivation of TB is more likely to occur in persons receiving higher doses of corticosteroids for prolonged periods of time, especially in populations at high risk for TB, but specific thresholds of dose and duration that could increase the risk for TB are unknown (58). Persons who use alcohol may be at increased risk for acquiring or developing TB, but given the many other potential risk factors that commonly occur among such persons, alcohol use has been difficult to identify as a separate risk factor for TB (2, 42, 59, 60).

Operational Considerations

In ***A Strategic Plan for the Elimination of Tuberculosis in The United States,*** published by CDC in 1989 (61), the responsibility for detection and treatment of LTBI in high-risk groups was assigned directly to public health agencies. At that time, the administration of skin tests, interpretation of test results, and intensive follow-up required to ensure adherence with and to prevent side effects of isoniazid treatment were believed to be beyond the scope of most private health care providers.

However, in 1995, CDC published recommendations on targeted testing and treatment of LTBI that emphasized the importance of health departments in assisting local providers in the development, implementation, and evaluation of TB screening programs appropriate for their communities (2). This recommendation was based on the recognition that changes in the organization, delivery, and financing of health care in the United States have led to most routine tuberculin testing being done outside of the public health system (62). For example, populations that previously received clinical services, including diagnosis of LTBI, at public health clinics are now increasingly being enrolled as members of managed care organizations.

Because health departments might lack access to high-risk populations and the resources necessary to undertake targeted testing programs, the participation of other health care providers is essential to ensure the successful implementation of community efforts to prevent TB in high-risk groups. Community sites where persons at high risk may be accessed and where targeted testing programs have been evaluated include neighborhood health centers (63), jails (64), homeless shelters (65), inner-city sites (66), methadone (67) and syringe/needle-exchange programs (68), and other community-based social service organizations (69).

DIAGNOSIS OF LATENT TUBERCULOSIS INFECTION

Tuberculin Skin Testing

The tuberculin skin test is the only proven method for identifying infection with ***M. tuberculosis*** in persons who do not have TB disease. Although the available tuberculin skin-test antigens are < 100% sensitive and specific for detection of infection with ***M. tuberculosis,*** no better diagnostic methods have yet been devised. Proper use of the tuberculin skin test requires knowledge of the antigen used (tuberculin), the immunologic basis for the reaction to this antigen, the technique(s) of administering and reading the test, and the results of epidemiologic and clinical experience with the test. Detailed information on these topics is provided in the ATS/CDC Statement ***Diagnostic Standards and Classification of Tuberculosis in Adults and Children (70).***

Immunologic basis for the tuberculin reaction. Infection with ***M. tuberculosis*** produces a delayed-type hypersensitivity reaction to certain antigenic components (tuberculins) that are contained in extract of culture filtrate of the organism. Purified protein derivative (PPD) tuberculin, which is used for most skin testing, is isolated from culture filtrate by protein precipitation.

The reaction to intracutaneously injected tuberculin is a delayed-type (cellular) hypersensitivity (DTH) reaction, and infection by ***M. tuberculosis*** usually results in a DTH response to PPD tuberculin that is detectable 2-12 wk after infection (71). However, a DTH reaction to PPD tuberculin may also indicate infection with various nontuberculous mycobacteria or vaccination with Bacille Calmette-Guérin (BCG), a live attenuated mycobacterial strain derived from ***Mycobacterium bovis.*** Delayed hypersensitivity reactions to tuberculin usually begin 5-6 h after injection, reach a maximum at 48-72 h, and subside over a period of a few days, although positive reactions often persist for up to 1 wk (72).

Sensitivity and specificity of skin-test reactions. Knowledge of tuberculin-test sensitivity and specificity, as well as positive predictive value, is required to interpret skin-test reactions properly. For persons with LTBI and normal immune responsiveness, test sensitivity approaches 100% (73). However, false-positive tuberculin tests occur in persons who have been infected with nontuberculous mycobacteria and in persons who have received BCG vaccine. These false-positive reactions result in a lower specificity and a low positive predictive value in persons who have a low probability of LTBI. The general U.S. population currently has an estimated ***M. tuberculosis*** infection rate of 5–10%, and children entering school in many areas of the country have a 0.1–1% prevalence of infection. Even if the test has a specificity approaching 99%, testing of persons in such low-prevalence groups would result in most positive tests being false-positive tests (71). However, the specificity of the test is also dependent on the criterion used to define a "positive" test. The specificity can be improved by progressively increasing the reaction size that separates positive from negative reactors (at the expense of decreasing test sensitivity) (73).

Previous BCG vaccination. Intracutaneous inoculation with

BCG is currently used in many parts of the world as a vaccine against tuberculosis. Tuberculin reactivity caused by BCG vaccination generally wanes with the passage of time but can be boosted by the tuberculin skin test. Periodic skin testing may prolong reactivity to tuberculin in vaccinated persons (74). No reliable method has been developed to distinguish tuberculin reactions caused by vaccination with BCG from those caused by natural mycobacterial infections, although reactions of ≥ 20 mm of induration are not likely caused by BCG (75).

HIV infection and anergy testing. HIV-infected persons may have a compromised ability to react to tuberculin skin tests because of cutaneous anergy associated with progressive HIV immunosuppression (76). However, the usefulness of anergy testing in selecting tuberculin-negative, HIV-infected persons who might benefit from treatment of LTBI has not been demonstrated (77).

Chest Radiographs

In persons with LTBI, the chest radiograph is usually normal, although it may show abnormalities suggestive of prior TB. Previous, healed TB can produce various radiographic findings that usually differ from those associated with active TB. Dense pulmonary nodules, with or without visible calcification, may be seen in the hilar area or upper lobes. Smaller nodules, with or without fibrotic scars, are often seen in the upper lobes, and upper-lobe volume loss often accompanies these scars. Nodules and fibrotic lesions of previous, healed TB have well-demarcated, sharp margins and are often described as "hard." Bronchiectasis of the upper lobes is a nonspecific finding that sometimes occurs from previous pulmonary TB. Pleural scarring may be caused by prior TB but is more commonly caused by trauma or other infections. Nodules and fibrotic scars may contain slowly multiplying tubercle bacilli with substantial potential for future progression to active TB (32). Conversely, calcified nodular lesions (calcified granulomas) and apical or basal pleural thickening pose a lower risk for future progression to active TB.

Sputum Examinations

The presumptive diagnosis of active pulmonary TB is often made on the basis of microscopic examination of a stained sputum smear for acid-fast bacilli (AFB). Confirmation of the diagnosis usually requires identification of ***M. tuberculosis in*** culture. In asymptomatic persons with normal chest radiographs, AFB are rarely seen on sputum smear examination, and tubercle bacilli are not found in cultures of respiratory specimens. However, some HIV-infected persons with sputum culture-positive TB have been described as having normal chest radiographs.

TREATMENT OF LATENT TUBERCULOSIS INFECTION

Isoniazid

Experimental studies. Before clinical trials of isoniazid for the treatment of LTBI were begun in the United States, its efficacy was demonstrated in guinea pigs. In a study conducted by PHS, guinea pigs receiving varying doses of isoniazid were challenged with virulent tubercle bacilli (78). Those animals receiving a daily dosage of at least 5 mg/kg were protected (i.e., survival was comparable to control animals who were not challenged with the bacillus). On the basis of these studies, the dose of 5 mg/kg was chosen for clinical studies in humans.

Clinical trials in HIV-negative persons. Many randomized, controlled clinical trials of isoniazid for the treatment of LTBI were conducted in the 1950s and 1960s (6). These trials were conducted in seven countries, both industrialized and developing, and involved more than 100,000 participants at risk for TB, including children with primary TB, contacts of active case patients, persons who had had tuberculin skin reactions, institutionalized patients with mental disease, and persons with inactive TB. Most studies compared 12 mo of isoniazid with placebo. The outcomes measured in these studies included progression of primary TB, tuberculin conversion in uninfected contacts, prevention of TB in infected persons, and recurrence of disease. The effectiveness of treatment, as measured by the decrease in TB among all persons participating in these trials, varied from 25 to 92%. However, when analysis was restricted to persons who were compliant with the medication, the protective efficacy was approximately 90%. Substantial protection was conferred even if pill taking was irregular but sustained, suggesting the possibility that intermittent treatment may be efficacious.

Only one trial, conducted by the International Union Against Tuberculosis (IUAT) (32), was designed to evaluate various durations of isoniazid. In this trial, a placebo regimen was compared with isoniazid regimens lasting for 3, 6, and 12 mo among persons with fibrotic pulmonary lesions consistent with inactive TB. The 5-yr incidence rates of tuberculosis were 1.43% for placebo compared with 1.13, 0.50, and 0.36% for the 3-, 6-, and 12-mo regimens, respectively (Table 4). The rates indicated a 65% effectiveness for the 6-mo isoniazid regimen and 75% effectiveness for the 12-mo regimen; persons who received 6 mo of isoniazid had a 40% higher risk for TB compared with those who received 12 mo of therapy.

The difference in the two regimens is magnified when study subjects who received "almost all" of the monthly drug allotments for their scheduled duration of therapy and who were believed to have taken ≥ 80% of the medication each month were compared. In this subgroup, which constituted 78% of the entire study population, the resulting 5-yr incidence rates were 1.5% for persons receiving placebo compared with 1.0, 0.5, and 0.1% for the 3-, 6-, and 12-mo regimens, respectively. In this analysis, isoniazid taken for 6 mo was 69% efficacious and for 12 mo was 93% efficacious; participants on the 6-mo

regimen had a fourfold higher risk for TB than those on the 12-mo regimen. Although the incidence of TB was similar for persons with small lesions (< 2 cm^2) assigned the 6-mo and 12-mo regimens, such persons were less adherent to treatment. The 12-mo regimen provided a substantial reduction in risk compared with the 6-mo regimen among compliant persons with small lesions (Table 4).

Additional information on the efficacy and effectiveness of different lengths of therapy with isoniazid for the treatment of LTBI has been derived from a randomized study of household contacts conducted by PHS (21). Among persons believed to have taken ≥ 80% of their assigned medication during the months they took isoniazid, those who took medication for at least 10 mo experienced a 68% reduction in TB (Table 5). In contrast, among persons who took ≥ 80% of the medication for < 10 mo, only a 16% reduction in the TB rate occurred. The same data can be further examined to determine whether reduction in the rate of TB was affected more by duration of therapy or the amount of medication. The effectiveness of isoniazid decreased slightly for less compliant patients who took 40–79% of the prescribed medication during the 10-mo period (52–57% reduction compared to 68% reduction), suggesting that even an intermittent treatment regimen would be effective if taken for at least 10 mo (Table 5).

In a community-based study conducted in Bethel, Alaska (79), persons who took < 25% of the prescribed annual dose had a threefold higher risk for TB than those who took ≥ 50% of the annual dose. However, a more recent analysis of study data indicated that the efficacy decreased significantly if < 9 mo of isoniazid was taken (Figure 1) (80).

Effectiveness data from the IUAT study, published data on isoniazid-associated hepatitis, and cost information obtained from a survey of U.S. TB programs were used to assess the cost effectiveness of various durations of isoniazid (81). The cost per case of TB prevented with the 6-mo regimen was determined to be half of the cost as either the 3-mo or 12-mo regimens. This cost-effectiveness analysis was largely responsible for the widespread adoption of the 6-mo regimen of isoniazid for the treatment of LTBI in HIV-seronegative persons with normal chest radiographs (82). However, the protection conferred by taking at least 9 mo of isoniazid is greater than that conferred by taking 6 mo; it is not likely that further protection is conferred by extending the duration of treatment from 9 to 12 mo (80).

Clinical trials in HIV-positive persons. Seven randomized, controlled trials have evaluated different regimens for the treatment of LTBI infection in persons with HIV infection (Table 6). Five of these studies evaluated isoniazid regimens using comparison groups that either received a placebo or were not actively treated.

In the first study, conducted in Haiti during 19861992, 12 mo of daily isoniazid resulted in a substantial reduction in TB (83%) among tuberculin-positive persons (83). Protection was constant over the 4 yr of follow-up after treatment. Two other studies, which evaluated 6 mo of isoniazid taken daily by tuberculin-positive persons, had differing results: the drug provided a significant level of protection in Uganda (68%) (84) but did not provide a significant level of protection in Kenya (40%) (85). A fourth study evaluated a 6-mo, twice-weekly regimen of isoniazid in both tuberculin-positive and -negative persons in Zambia (86). The overall level of protection was minimal but significant (38%). Although the level of protection among tuberculin-positive persons was higher (70%), it was not significant because of the limited number of persons in this group.

The Uganda study also evaluated the 6-mo regimen of daily isoniazid in anergic persons, as did the fifth study conducted in the United States (87). In both studies, the level of protection against TB was low, and neither study demonstrated a significant level of protection.

Additional evaluations of isoniazid were conducted in tuberculin-negative persons who were not assessed for anergy (83, 85, 86). The level of protection provided by isoniazid among this population was not significant in any of the studies. Thus, for HIV-infected persons, treatment should be targeted at tuberculin-positive persons. A recently published meta-analysis of these trials supports this conclusion (88).

Safety and tolerability. In 1965, when isoniazid was first recommended in the United States for treatment of LTBI, it was not thought to cause severe toxicity. In the PHS studies conducted among TB contacts, the percentage of persons stopping treatment because of suspected drug reactions was low and approximately equivalent for the placebo and isoniazid groups (21). The occurrence of hepatitis was rare and was not assumed to be caused by isoniazid. However, studies conducted in the late 1960s suggested that isoniazid did cause hepatitis and indicated that asymptomatic increase in hepatic transaminases occurred among persons receiving the drug (89). It was not until the 1970s, when several persons receiving isoniazid for LTBI died from hepatitis, that the likelihood of isoniazid hepatitis was understood (9).

The largest and most comprehensive study of isoniazid hepatitis was conducted by PHS during 1971-1972 (11). In this survey, nearly 14,000 persons who received isoniazid were monitored for the development of hepatitis. The overall rate of probable isoniazid hepatitis was 1%, but it was age related, with no cases occurring among persons younger than 20 yr of age and the highest rate (2.3%) occurring among persons older than 50 yr of age. An association of hepatitis also was found with alcohol consumption, with rates being fourfold higher among persons consuming alcohol daily than among those who did not drink alcohol. Rates among males and females were equivalent and were lower among black males and higher among Asian males compared with rates among white males. Hepatitis rates were lower among participants in the IUAT trial, although the same positive association with age was observed (32). In the PHS surveillance study, eight deaths from hepatitis occurred among the participants, seven of which were among persons living in Baltimore. Several years after completion of the study, a review of death certificates showed a marked increase in deaths from cirrhosis during 1972 in Baltimore and surrounding counties, suggesting that another cofactor may have been associated with the cluster of deaths observed in the study (90).

A comprehensive analysis of deaths from isoniazid-associated hepatitis in the United States found that women may be at increased risk of death (91). Other reports have suggested that the risk for isoniazid-associated hepatitis may be in-

creased by the administration of the drug to pregnant women in the third trimester and the immediate postpartum period (92) or by the concomitant administration of acetaminophen (93). Although experimental evidence suggests that acetaminophen hepatotoxicity is potentiated by isoniazid (94), a more detailed study of deaths from isoniazid-associated hepatitis did not implicate acetaminophen as a factor (95).

Isoniazid-related deaths continue to be reported. However, the likelihood of this occurrence can be greatly reduced by careful monthly monitoring and stopping of medication if symptoms occur (96). In a recent study, seven of eight patients receiving a liver transplant following the development of fulminant, isoniazid-related hepatitis continued to take the drug for a least 10 d after onset of symptoms of hepatotoxicity (97).

Following the PHS surveillance study, guidelines on the use of isoniazid for the treatment of LTBI were revised to recommend that low-risk persons older than 35 year of age with reactive tuberculin skin tests not be treated, that no more than 1 mo drug supply be issued at a time, and that monthly questioning and education about signs and symptoms of hepatitis should be routine (12). The guidelines were further revised to recommend baseline and periodic liver-function tests for persons at risk for hepatotoxicity, including persons aged 35 yr of age or older (15).

More recently, a survey found that many public health TB clinics now use clinical, rather than biochemical, monitoring for hepatotoxicity during treatment of LTBI (98). Clinical monitoring is based on educating patients about the symptoms of hepatotoxicity and instructing them to stop treatment immediately if such symptoms occur and to report to the clinician for evaluation. After using clinical monitoring exclusively, one public health TB clinic reported only 11 cases of clinical hepatotoxicity (one of which required hospitalization) and no deaths among more than 11,000 persons with LTBI during isoniazid treatment over a 7-yr period (99). Based on this emerging experience with clinical monitoring, some authorities have called for the establishment of new recommendations for drug toxicity monitoring "that are congruent with established therapeutic/toxicity relationships" (98).

Recent studies of isoniazid treatment of LTBI in HIV-infected persons have demonstrated that the medication was well tolerated and not associated with substantial increases in hepatic side effects. In a recent meta-analysis of placebo-controlled trials, adverse drug reactions were slightly but not significantly more common among persons receiving isoniazid (88).

Despite the high efficacy and relative safety of isoniazid treatment for LTBI, its use has been frequently debated; much literature has been published regarding whether and when to prescribe isoniazid (13, 100–102). However, because the arguments embodied in that literature emerged more than two decades ago, in a different environmental context with different risks and contingencies, its appropriateness to current circumstances is uncertain.

Although the likelihood that a patient treated with isoniazid would develop hepatitis was low, it presented a valid argument against the use of isoniazid among persons who had no increased risk for developing active TB. Most of the arguments concerning the use of this drug, which appeared from the 1970s through the early 1980s, focused on persons at low risk for reacting to tuberculin, primarily those 35 yr of age or older who were likely at higher risk for isoniazid-associated hepatitis than younger patients.

Because the debate over whether to prescribe or withhold isoniazid for persons older than 35 yr of age at low risk for reacting to tuberculin involved a trade-off between risk for developing active TB versus risk for developing isoniazid-induced hepatitis, decision analysis was used by most investigators (103). Despite many analyses, the decision to treat persons at low risk for reacting to tuberculin at any age continued to be controversial. Although various analyses supported both sides of the debate, none of the calculated benefits of isoniazid was substantial.

Short-course Regimens

Experimental studies in animals. Because of high rates of nonadherence with the long duration of isoniazid (i.e., 612 mo) and the rare occurrence of fatal isoniazid hepatitis, short-course, rifampin-containing treatment regimens have recently been evaluated. The studies evaluating rifampin were based on data from several studies in mouse models of chronic TB. One study compared isoniazid with regimens of rifampin alone; rifampin and pyrazinamide; and isoniazid, rifampin, and pyrazinamide (104). The rifampin-only regimen sterilized lung and spleen tissues within 4 mo, and the combination of rifampin and pyrazinamide sterilized tissues within 2 mo. The isoniazid, rifampin, and pyrazinamide regimen was of intermediate efficacy, taking longer than the rifampin and pyrazinamide regimen to sterilize tissues. The isoniazid regimen had not sterilized tissues by the end of 6 mo.

The apparent superiority of the rifampin-pyrazinamide regimen over the regimen containing the same two drugs plus isoniazid might be explained by impaired absorption of rifampin when given simultaneously with other drugs in mice (105). Support for this hypothesis came from a study using a Cornell mouse model (106) that compared 6-wk regimens of rifampin, rifampin-isoniazid, rifampin-pyrazinamide, and rifampin-pyrazinamide-isoniazid, with delayed administration of rifampin when given with other drugs. The efficacy of all three regimens was similar, with trend toward a lower colony count in spleens of animals given more drugs, and lower colony counts in the lungs of mice given rifampin-isoniazid. Experimental studies have also suggested that rifabutin alone, taken daily, and rifabutin-isoniazid, taken twice weekly, may effectively treat LTBI in 3 mo (107).

Clinical trials in HIV-negative persons. The only randomized clinical trial to evaluate rifampin-containing regimens among HIV-seronegative persons was conducted in tuberculin-positive persons with silicosis in Hong Kong (36). In this study, daily regimens of 6 mo of isoniazid, 3 mo of rifampin, or 3 mo of isoniazid and rifampin were compared with a 6-mo placebo control. Analyzing only those patients who were assumed to be compliant yielded an estimate of efficacy in preventing TB of 63% for the 3-mo rifampin regimen, 48% for the 6-mo isoniazid regimen, and 41% for the 3-mo isoniazid-rifampin regimen. All of these differences were significantly different from the placebo regimen but were not statistically different from each other. The annual incidence rate was about 7% per year in the placebo group and about 4% per year in the three active-treatment regimens combined.

The largest programmatic experience using rifampin-based treatment of LTBI comes from Blackburn, England, where children at increased risk of TB have been treated with daily rifampir-isoniazid since 1981 (108). During 1981-1996, the treatment duration was shortened from 9 to 3 mo, and the proportion of pediatric TB case patients as a percentage of all reported cases decreased from 25 to 4%. Although not a controlled clinical trial, these data suggest that this intervention has been highly effective in reducing the rate of childhood TB in this city. Thus, this regimen is currently recommended for the treatment of both adults and children with LTBI in the United Kingdom (109).

Clinical trials in HIV-positive persons. Most clinical trials of rifampin-based treatment of LTBI have been conducted among HIV-infected persons (Table 6); two were placebo controlled. The Uganda study also evaluated regimens of isoniazid–rifampin and isoniazid-rifampin-pyrazinamide taken daily for 3 mo in tuberculin-positive persons (84). The isoniazid-rifampin regi-

men provided 59% protection, and the three-drug regimen with pyrazinamide provided 57% protection-levels similar to those provided by 6 mo of isoniazid alone. The Zambia study also evaluated a self-administered regimen of rifampin and pyrazinamide taken twice weekly for 3 mo (86). The level of protection was 42%, similar to that conferred by the 6-mo, twice-weekly isoniazid regimen. Among tuberculin-positive persons, the level of protection conferred by rifampin and pyrazinamide was 70%, comparable with that conferred by 6 mo of isoniazid taken twice weekly, but not statistically significant.

In two trials, rifampin and pyrazinamide regimens have been compared with regimens of isoniazid alone in tuberculin-positive persons. A second study conducted in Haiti during 1990-1994 compared twice-weekly regimens of 6 mo of isoniazid and 2 mo of rifampin and pyrazinamide, with half of the doses directly observed (110). Protection at 12 mo was similar in the two groups, and, compared with the rate of TB observed among patients who received placebo in the earlier Haiti trial, the twice-weekly regimens were estimated to have reduced the risk for TB by approximately 80%. A multinational study comparing a 12-mo regimen of isoniazid taken daily with a 2-mo regimen of rifampin and pyrazinamide taken daily was conducted in the United States, Haiti, Brazil, and Mexico (111). A total of 1583 patients were enrolled and followed for an average of 3 yr. The annual risk of culture-confirmed TB was 0.8% for patients assigned the 2-mo regimen and 1.1% for patients assigned the 12-mo isoniazid regimen, a difference that was not significant.

In conclusion, as evidenced by the large multinational study, a 2-mo regimen of rifampin and pyrazinamide taken daily provides protection against TB equivalent to a 12-mo regimen of isoniazid taken daily. The data supporting the use of a twice-weekly rifampin and pyrazinamide treatment regimen are less conclusive. The only study that has evaluated a rifampin-alone regimen, the Hong Kong study in persons with silicosis, suggests that daily rifampin for 3 mo provides similar protection to that conferred from 6 mo of isoniazid (36). In the Uganda study, 3-mo regimens of (I) isoniazid and rifampin and (2) isoniazid, rifampin, and pyrazinamide provided protection equivalent to that of 6 mo of isoniazid (84).

All of the studies of treatment of LTBI in HIV-infected persons included death and/or progression of HIV disease as endpoints. In the earlier Haiti study, isoniazid likely conferred protection against progression of HIV disease among tuberculin-positive subjects (83). In the multinational study, persons receiving the 2-mo regimen had lower mortality rates and less progression of HIV disease, although these differences were not statistically significant (111). In none of the other studies was active treatment protective against death or HIV progression.

Safety and tolerability. Before the conduct of the studies in HIV-infected persons, a pilot study to assess the safety and tolerability of short-course regimens was conducted in 402 HIV-seronegative adults in North America (112, 113). Participants were randomized to receive either 2 mo of rifampin and pyrazinamide, 4 mo of rifampin only, or 6 mo of isoniazid. The rifampin-pyrazinamide regimen was associated with a higher number of AST elevations of >100 IU (17 compared with only one in the rifampin group and five in the isoniazid group) and more frequent adverse reactions resulting in drug discontinuation (15 compared with none in the rifampin group and two in the isoniazid group). The rates of adverse reactions and abnormal AST elevations were higher than those reported in studies involving HIV-positive populations and those described in a clinical trial of isoniazid, rifampin, and pyrazinamide for the treatment of active TB in HIV-seronegative persons (114).

Two smaller pilot studies of rifampin and pyrazinamide treatment of LTBI using identical protocols were conducted in adults in Poland (115) and children in Germany (116). The results of the study in Poland were similar to those in the study in North America; the children in Germany tolerated the regimens well and did not experience changes in hepatic function.

In the Hong Kong study of patients with silicosis, no significant differences were noted in the occurrence of severe adverse reactions in the three drug regimens studied (36). However, patients receiving isoniazid had a higher incidence of abnormal liver function tests during treatment.

In the clinical trials involving HIV-infected persons, a trend of increased adverse reactions occurred among persons taking a daily regimen that included pyrazinamide. The Uganda study reported that persons taking the three-drug, pyrazinamide-containing regimen had higher rates of paresthesias, arthralgias, and significant increases in serum AST (84). The multinational study reported minimal increases in the number of persons receiving the 2-mo rifampin and pyrazinamide regimen who had the drugs permanently discontinued, most commonly because of nausea and vomiting and narcotic withdrawal (111). However, abnormal liver function tests were more common among patients taking isoniazid.

In the Haiti study conducted during 1990–1994 and the Zambia study, regimens of twice-weekly rifampin and pyrazinamide were well tolerated. In the Haiti study, no severe adverse reactions were observed; rates of abnormal liver function were low (1–3%) and did not differ by regimen (110). In the Zambia study, 3% of persons given isoniazid stopped treatment because of an adverse reaction compared with 4% of those given rifampin and pyrazinamide (86). Biochemical hepatitis was more frequent in the isoniazid group, whereas rash was more common in persons receiving rifampin and pyrazinamide.

Adherence

Testing for and treating LTBI requires several steps, including administering the test, reading the test, medically evaluating infected persons, initiating treatment, and completing therapy. Because persons with LTBI are not clinically ill and may not be motivated to undergo treatment, nonadherence occurs commonly in all steps of the treatment process.

The health care system can compromise patient adherence to testing and treatment of LTBI (117). A lengthy referral process may discourage patients from being evaluated for a positive tuberculin test or initiating treatment for LTBI. Long waiting times in the clinic may also discourage patients from attending follow-up visits. Other factors that may affect adherence with testing and treatment include the clinic's hours of operation, distance of the clinic from the patient's home, the cleanliness of the clinic, and the attitude of clinic staff.

Since the advent of effective chemotherapy for active TB, adherence to treatment regimens has been recognized as a substantial problem for TB control--especially for treatment of LTBI. Recent data reported to CDC indicate that only 60% of patients who start treatment for LTBI complete at least 6 mo of treatment (CDC, TB Program Management Reports); adherence is influenced by the length of therapy, complexity of the regimen, and side effects of the medications. Adherence to treatment decreases with time, whereas the efficacy of the regimen increases with the length of therapy (32). Patients may be more adherent to the 2-mo regimen of rifampin and pyrazinamide because of the shorter length of therapy; however, this regimen also involves taking multiple medications, and patients may not tolerate this regimen as well as isoniazid, thus potentially resulting in nonadherence.

The Haiti study of rifampin and pyrazinamide taken twice weekly and the multinational study both reported better adherence with the shorter, 2-mo regimens. In the Haiti study, 74% of

persons assigned to the 2-mo rifampin and pyrazinamide regimen were believed to have taken ≥ 80% of the prescribed medication compared with 55% of persons taking isoniazid for 6 mo (110). Nonadherence was similar during the first 2 mo of therapy for both groups. The multinational study reported an 80% completion rate for persons assigned to the 2-mo rifampin and pyrazinamide regimen compared with 69% for the 12-mo isoniazid regimen (111). In the pilot study of HIV-seronegative persons, during the first 2 mo of therapy about 60% of those assigned to the rifampin and pyrazinamide regimen were judged to be nonadherent, compared with about 20% of those assigned to the 6-mo isoniazid regimen (113). However, overall completion rates were lower for the isoniazid regimen because of continued nonadherence during the last 4 mo of therapy.

Determinants of adherence to treatment of TB and LTBI are not well understood (118). For example, demographic factors are not reliable predictors of adherence. However, culturally influenced beliefs and attitudes may result in misinformation about TB and may adversely affect adherence (119). The main strategies that have been employed to promote adherence with treatment of LTBI are patient education (120), the use of lay health workers from the patient's social and/or cultural group (118, 121), incentives (e.g., cash payments) (122), and directly observed therapy (DOT) (64).

The intervention most likely to improve adherence for treatment of LTBI has been DOT, which requires direct observation of the patient ingesting each dose of medication and usually includes the provision of comprehensive services that attempt to meet the patient's basic needs and the use of incentives and enablers (123-125). Although randomized trials have yet to be reported, available information suggests that DOT leads to higher rates of completion than self-supervised therapy, and, under certain circumstances, is more cost effective (67).

Recommendations

IMPLEMENTATION OF TARGETED TUBERCULIN TESTING

Decision to Tuberculin Test Is Decision to Treat

Targeted tuberculin testing programs should be designed for one purpose: to identify persons at high risk for TB who would benefit by treatment of LTBI. Following that principle, targeted tuberculin testing programs should be conducted among groups at risk for recent infection with ***M. tuberculosis*** and those who, regardless of duration of infection, are at increased risk for progression to active TB (Table 7). With the exception of initial testing of persons at low risk whose future activity will place them at increased risk of exposure (e.g., employment in a setting where TB transmission may occur), screening of low-risk persons is discouraged because it diverts resources from activities of higher priority. In addition, a substantial proportion of tuberculin-test-positive persons from low-risk populations may have false-positive skin tests (73).

Testing is also discouraged unless a plan has been developed to complete a course of treatment in persons found to have LTBI. Such planning should include arrangements for medical evaluation (e.g., chest radiographs) of persons with positive skin tests and for the medical supervision of the course of treatment.

Identification and Access to High-risk Groups

A flexible approach to identifying high-risk groups is recommended, and state and local public health agencies are encouraged to analyze their TB case reports and data obtained from tuberculin skin testing to identify high-risk groups based on local trends in the epidemiology of TB. Thus designing and conducting skin-test-screening surveys to determine whether population groups are at high risk for TB may be desirable. Populations at risk can be accessed at HIV treatment facilities, drug treatment centers, homeless shelters, community health centers and schools serving foreign-born persons, and selected community-based organizations. Mandated skin-testing programs (e.g., those that formerly were conducted among teachers and foodhandlers) should be discouraged unless the targeted groups contain substantial proportions of persons at high risk (126).

Role of the Health Department

In this community-based approach to targeted testing and treatment of LTBI, the health department TB program should be instrumental in planning and coordination, setting performance standards, and overseeing quality of service. The health department is responsible for assessing the community's TB problem, identifying high-risk groups based on the local epidemiology of TB, and ascertaining the sites of most convenient access to those groups. In addition, the health department should assume responsibility for organizing the community-based approach, recruiting health professionals, educating such professionals about TB, and motivating them to institute targeted testing and treatment programs. The health department should also serve as advisor, consultant, and facilitator to community providers and institutions that conduct testing and treatment programs. The health department should assist in identifying potential funding sources and ensure linkages with essential clinical and consultation sources. It should provide in-service training on tuberculin skin testing and treatment, written protocols for activities including patient tracking and skin testing, and patient and provider educational material translated into appropriate languages. The health department may also need to provide chest radiography and subsidize the supply of antituberculosis drugs. Finally, the health department should be responsible for providing or facilitating the ongoing evaluation of community-based targeted testing and treatment programs, including development and monitoring of program indicators (e.g., rates of skin tests administered that are read, proportion of tests read that are positive, and initiation and completion rates of treatment). The health department should also routinely collect and review these data to determine yield and relative effectiveness of targeted testing and treatment of LTBI in the community.

To achieve a high rate of acceptance of testing and completion of treatment in a community-based program, barriers to success should be anticipated, identified, and managed. The concept of taking drugs to treat a latent infection that is not causing current health problems is unfamiliar to most persons, and education of the patient is essential (120). Other known barriers include culturally derived health beliefs that differ from those of Western medicine, inability to communicate with medical providers in one's primary language, inability to afford the costs of medical evaluation and treatment, and lack of access to medical care (118). Patients should not be expected to pay directly for public health interventions (e.g., testing, evaluation, and treatment of LTBI). The more convenient this process of testing and treatment, the more likely patients will adhere to therapy-especially as targeted testing and treatment of LTBI are extended beyond the province of public health TB clinics to sites where primary health care is delivered.

DIAGNOSIS OF LATENT TUBERCULOSIS INFECTION

Tuberculin Skin Testing

Administering and reading tests. The tuberculin test, like all medical tests, is subject to variability, but many of the inherent variations in administering and reading tests can be avoided by careful attention to details. The preferred skin test for ***M. tuberculosis*** infection is the intradermal, or Mantoux, method. It is administered by injecting 0.1 ml of 5 tuberculin units (TU) PPD intradermally into the dorsal or volar surface of the forearm. Tests should be read 48-72 h after test administration, and the transverse diameter of induration should be recorded in millimeters. Multiple puncture tests (i.e., Tine and Heaf) and PPD strengths of 1 TU and 250 TU are not sufficiently accurate and should not be used.

Interpreting skin-test reactions. Based on the sensitivity and specificity of the tuberculin skin test and the prevalence of TB in different groups, three cut-off levels have been recommended for defining a positive tuberculin reaction: $\geq$ 5 mm, $\geq$ 10 mm, and $\geq$ 15 mm of induration (Table 7). For persons who are at highest risk for developing TB disease if they become infected with ***M. tuberculosis,*** a cut-off level of $\geq$ 5 mm is recommended. Persons who are immunosuppressed because of disease (e.g., HIV infection) or drugs (e.g., systemic corticosteroids) have a high likelihood of developing TB disease if they are infected with ***M. tuberculosis.*** Likewise, persons who have had recent close contact with an infectious TB case patient and those with abnormal chest radiographs consistent with prior TB are at high risk for TB. Thus, to ensure that persons at highest risk are evaluated and appropriately treated, the sensitivity provided by a $\geq$ 5 mm cut-off for a positive test is appropriate.

A reaction of $\geq$ 10 mm of induration should be considered positive for those persons with an increased probability of recent infection or with other clinical conditions that increase the risk for TB (e.g., recent immigrants from high-prevalence countries and injection drug users) (Table 7). In addition to those groups listed, high-prevalence populations identified by analysis of local epidemiologic data should be targeted for testing.

TABLE 7

CRITERIA FOR TUBERCULIN POSITIVITY, BY RISK GROUP

Reaction ≥ 5 mm of Induration	Reaction ≥ 10 mm of Induration	Reaction ≥ 15 mm of Induration
Human immunodeficiency virus (HIV)-positive persons	Recent immigrants (Le., within the last 5 yr) from high prevalence countries	Persons with no risk factors for TB
Recent contacts of tuberculosis (TB) case patients	Injection drug users	
Fibrotic changes on chest radiograph consistent with prior TB	Residents and employees+ of the following high-risk congregate settings: prisons and jails, nursing homes and other long-term facilities for the elderly, hospitals and other health care facilities, residential facilities for patients with acquired immunodeficiency syndrome (AIDS), and homeless shelters	
Patients with organ transplants and other immunosuppressed patients (receiving the equivalent of ≥ 15 mg/d of prednisone for 1 mo or more)	Mycobacteriology laboratory personnel	
	Persons with the following clinical conditions that place them at high risk: silicosis, diabetes mellitus, chronic renal failure, some hematologic disorders (e.g., leukemias and lymphomas), other specific malignancies (e.g., carcinoma of the head or neck and lung), weight loss of ≥ 10% of ideal body weight, gastrectomy, and jejunoileal bypass	
	Children younger than 4 yr of age or infants, children, and adolescents exposed to adults at high-risk	

. Risk of TB in patients treated with corticosteroids increases with higher dose and longer duration.
† For persons who are otherwise at low risk and are tested at the start of employment, a reaction of ≥ 15 mm induration is considered positive.
Source: Adapted from Centers for Disease Control and Prevention. Screening for tuberculosis and tuberculosis infection in high-risk populations: recommendations of the Advisory Council for the Elimination of Tuberculosis. M.M.W.R. 1995;44(No. RR-1 1):19–34.

Routine tuberculin testing is not recommended for populations at low risk for LTBI. However, if these persons are tested (e.g., at entry into a work site where risk for exposure to TB is anticipated and a longitudinal tuberculin testing program is in place), a higher cut-off of ≥ 15 mm is recommended.

Skin-test conversion. For persons with negative tuberculin skin-test reactions who undergo repeat skin testing (e.g., health care workers), an increase in reaction size of ≥ 10 mm within a period of 2 yr should be considered a skin-test conversion indicative of recent infection with ***M. tuberculosis.***

Previous vaccination with BCG. Tuberculin skin testing is not contraindicated for persons who have been vaccinated with BCG, and the skin-test results of such persons can be used as described to support or exclude the diagnosis of ***M. tuberculosis*** infection. However, no method can reliably distinguish tuberculin reactions caused by vaccination with BCG from those caused by natural mycobacterial infections. Therefore, a positive reaction to tuberculin in BCG-vaccinated persons indicates infection with ***M. tuberculosis*** when the person tested is at increased risk for recent infection or has medical conditions that increase the risk for disease (Table 7).

Anergy testing in persons infected with HIV. Anergy testing is not recommended for routine use in persons who are infected with HIV or otherwise immunocompromised (77). However, it may assist in guiding individual treatment decisions in selected situations.

Chest Radiographs

A chest radiograph is indicated for all persons being considered for treatment of LTBI to exclude active pulmonary TB. Children younger than 5 yr of age should have both posterior–anterior and lateral radiographs. All other persons should receive posterior-anterior radiographs; additional radiographs should be performed at the physician's discretion. Because of the risk for progressive and/or congenital TB, pregnant women who have a positive tuberculin skin test or who have negative skin-test results but who are recent contacts of persons with infectious TB disease should have chest radiographs (with appropriate shielding) as soon as feasible, even during the first trimester of pregnancy.

If chest radiographs are normal and no symptoms consistent with active TB are present, tuberculin-positive persons may be candidates for treatment of LTBI. If radiographic or clinical findings are consistent with pulmonary or extrapulmonary TB, further studies (e.g., medical evaluation, bacteriologic examinations, and a comparison of the current and old chest radiographs) should be done to determine if treatment for active TB is indicated.

Sputum Examinations

Sputum examination is not indicated for most persons being considered for treatment of LTBI. However, persons with chest radiographic findings suggestive of prior, healed TB infections should have three consecutive sputum samples, obtained on different days, submitted for AFB smear and culture. Most persons with radiographs that show only calcified pulmonary nodules do not require bacteriologic examination. HIV-infected persons with respiratory symptoms who are being considered for treatment of LTBI should also have sputum specimens submitted for mycobacterial examination, even if the chest radiograph is normal. If the results of sputum smears and cultures are negative and respiratory symptoms can be explained by another etiology, the person is a candidate for treatment of LTBI. If bacteriologic results are negative but the activity or etiology of a radiographic abnormality is questionable, further evaluation with bronchoscopy or needle aspiration biopsy should be undertaken. Single drug treatment of LTBI should not be started until active TB has been excluded. In such situations, multidrug therapy can be started and continued pending results of sputum cultures. A repeat chest film should be obtained to exclude active TB, as indicated by improvement in the abnormality even in the presence of negative cultures.

TREATMENT OF LATENT TUBERCULOSIS INFECTION

Individual Drugs

Zsoniazid. Isoniazid is the most widely used of the antituberculosis agents-it is bactericidal, relatively nontoxic, easily administered, and inexpensive. Isoniazid is highly active against *M. tuberculosis* (most strains being inhibited ***in vitro*** by concentrations of 0.05-0.20 μg/ml). Absorption from the gas-

trointestinal tract is nearly complete, with peak serum concentrations of 2-5 μg/ml occurring 0.5–2.0 h after administration of a 300-mg dose. The drug penetrates well into all body fluids and cavities, producing concentrations similar to those found in serum. Hepatitis is the most severe toxic effect of isoniazid, and alcohol consumption may increase toxicity (Table 8). Peripheral neuropathy, caused by interference with metabolism of pyridoxine, is associated with isoniazid administration but is uncommon at a dose of 5 mg/kg. In persons with conditions in which neuropathy is common (e.g., diabetes, uremia, alcoholism, malnutrition, and HIV infection), pyridoxine should be given with isoniazid. Pregnant women and persons with sei-

TABLE 8

MEDICATIONS TO TREAT LATENT TUBERCULOSIS INFECTION: DOSES, TOXICITIES, AND MONITORING REQUIREMENTS

	Oral Dose (*mg/kg*) (Maximum Dose)						
	Daily		Twice Weekly*				
Drug	Adults	Children	Adults	Children	Adverse Reactions	Monitoring	Comments
Isoniazid	5 (300 mg)	1 O-20 (300 mg)	15 (900 mg)	20-40 (900 mg)	Rash Hepatic enzyme elevation Hepatitis Peripheral neuropathy Mild central nervous system effects Drug interactions resulting in increased phenytoin (Dilantin) or Disulfiram (Antabuse) levels	Clinical monitoring monthly Liver function tests† at baseline in selected cases‡ and repeat measurements if Baseline results are abnormal Patient is pregnant, in the immediate postpartum period, or at high risk for adverse reactions Patient has symptoms of adverse reactions	Hepatitis risk increases with age and alcohol consumption Pyridoxine (vitamin B_6, 1 O-25 mg/d) might prevent peripheral neurophathy and central nervous system effects
Rifampin	10 (600 mg)	1 O-20 (600 mg)	10 (600 mg)	—	Rash Hepatitis Fever Thrombocytopenia Flu-like symptoms Orange-colored body fluids (secretions, urine, tears)	Clinical monitoring at Weeks 2, 4, and 8 when pyrazinamide given Complete blood count, platelets, and liver function tests† at baseline in selected cases‡ and repeat measurements if Baseline results are abnormal Patient has symptoms of adverse reactions	Rifampin is contraindicated or should be used with caution in human immunodeficiency virus (HIV)-infected patients taking protease inhibitors (PIs) or nonnucleoside reverse transcriptase inhibitors (NNRTIs) Decreases levels of many drugs (e.g., methadone, coumadin derivatives, glucocorticoids, hormonal contraceptives, estrogens, oral hypoglycemic agents, digitalis, anticonvulsants, dapsone, ketoconazole, and cyclosporin) Might permanently discolor soft contact lenses
Rifabutin	5 (300 mg)§		5 (300 mg)¶	—	Rash Hepatitis Fever Thrombocytopenia Orange-colored body fluids (secretions, urine, tears) With increased levels of rifabutin Severe arthralgias Uveitis Leukopenia	Clinical monitoring at Weeks 2, 4, and 8 when pyrazinamide given Complete blood count, platelets, and liver function tests† at baseline in selected cases‡ and repeat measurements if Baseline results are abnormal Patient has symptoms of adverse reactions Use adjusted daily dose of rifabutin and monitor for decreased antiretroviral activity and for rifabutin toxicity if rifabutin taken concurrently with PIs or NNRTIs§	Rifabutin is contraindicated for HIV-infected patients taking hard-gel saquinavir or delavirdine; caution is also advised if rifabutin is administered with soft-gel saquinavir Reduces levels of many drugs (e.g., PIs, NNTRIs, methadone, dapsone, ketoconazole, coumadin derivatives, hormonal contraceptive, digitalis, sulfonylureas, diazepam, p-blockers, anticonvulsants, and theophylline) Might permanently discolor contact lenses
Pyrazinamide	15-20 (2.0 g)	—	50 (4.0 g)	—	Gastrointestinal upset Hepatitis Rash Arthralgias Gout (rare)	Clinical monitoring at Weeks 2, 4, and 8 Liver function tests' at baseline in selected cases‡ and repeat measurements if Baseline results are abnormal Patient has symptoms of adverse reactions	Treat hyperuricemia only if patient has symptoms Might make glucose control more difficult in persons with diabetes Should be avoided in pregnancy but can be given after first trimester

* All intermittent dosing should be administered by directly observed therapy.

† AST or ALT and serum bilirubin.

‡ HIV infection, history of liver disease, alcoholism, and pregnancy.

§ If nelfinavir, indinavir, amprenavir, or ritonavir is administered with rifabutin, blood concentrations of these protease inhibitors decrease. Thus, the dose of rifabutin is reduced from 300 mg to 150 mg/d when used with nelfinavir, indinavir, or amprenavir; and to 150 mg (two or three times a week) when used with ritonavir. If efavirenz is adminiistered with rifabutin, blood concentrations of rifabutin decrease. Thus, when rifabutin is used concurrently with efavirenz, the daily dose of rifabutin should be increased from 300 mg to 450 mg or 600 mg. Pharmacokinetic studies suggest that rifabutin might be given at usual doses with nevirapine. It is not currently known whether dose adjustment of rifabutin is required when used concurrently with soft-gel saquinavir or nevirapine. For patients receiving multiple PIs or a PI in combination with an NNRTI, drug interactions with rifabutin are likely more complex; in such situations, the use of rifabutin is not recommended until additional data are available.

zure disorders should also take both pyridoxine and isoniazid. Mild central nervous system effects are common with isoniazid and may necessitate adjustments in the timing of administration of the drug to enhance compliance. The interaction of isoniazid and phenytoin increases the serum concentration of both drugs. When these drugs are given concomitantly, the serum level of phenytoin should be monitored. No known interactions exist between isoniazid and the antiretroviral medications used for the treatment of HIV infection.

Rifutnpin. Rifampin is a rifamycin derivative that is bactericidal for ***M. tuberculosis.*** Most strains of ***M. tuberculosis*** are inhibited ***in vitro*** by concentrations of 0.5 kg/ml. It is quickly absorbed from the gastrointestinal tract, with peak serum concentrations of 7-14 μg/ml occurring 1.5-3.0 h after ingestion. Although approximately 75% of the drug is protein bound, it penetrates well into tissues and cells. Penetration through noninflamed meninges is poor, but therapeutic concentrations are achieved in cerebrospinal fluid when the meninges are inflamed. The most common adverse reaction to rifampin is gastrointestinal upset. Other reactions include skin eruptions, hepatitis, and, rarely, thrombocytopenia (Table 8). The frequency of these reactions is low. Because rifampin induces hepatic microsomal enzymes, it may accelerate clearance of drugs metabolized by the liver (e.g., methadone, coumadin derivatives, glucocorticoids, hormonal contraceptives, oral hypoglycemic agents, digitalis, anticonvulsants, dapsone, ketoconazole, and cyclosporin). By accelerating the metabolism of estrogen, rifampin may interfere with the effectiveness of oral contraceptives. In persons with HIV infection who are taking HIV protease inhibitors, rifampin is usually contraindicated because drug interactions between rifampin and these agents can lead to increased rifampin levels and decreased protease-inhibitor levels, resulting in increased risk for rifampin toxicity and decreased protease-inhibitor efficacy. Rifampin is also contraindicated or should be used with caution in HIV-infected patients who are taking non-nucleoside reverse transcriptase inhibitors (NNRTIs). Intermittent administration of doses of rifampin > 10 mg/kg may be associated with thrombocytopenia, an influenza-like syndrome, hemolytic anemia, and acute renal failure. However, these reactions are uncommon at the recommended dose of 10 mg/kg/d. Rifampin is excreted in urine, tears, sweat, and other body fluids and colors them orange. Patients should be advised of discoloration of body fluids and of possible permanent discoloration of soft contact lenses.

Pyrazinamide. Pyrazinamide is bactericidal for ***M. tuberculosis*** in an acid environment. The drug is active against organisms in macrophages, presumably because of the acid environment within the cell. At a pH of 5.5, the minimal inhibitory concentration of pyrazinamide for ***M. tuberculosis*** is 20 μg/ml. Absorption from the gastrointestinal tract is nearly complete, with peak serum concentrations of 30-50 μg/ml occurring approximately 2 h after ingestion with doses of 20-25 mg/kg. The most common side effect of pyrazinamide is gastrointestinal upset (Table 8). The most severe adverse reaction is liver injury. No substantial increase in hepatotoxicity results from adding 15-30 mg/kg of pyrazinamide to a regimen of rifampin during 2 mo of therapy for active TB (114). Hyperuricemia also occurs, but acute gout is uncommon (127). No known interactions exist between pyrazinamide and antiretroviral medications.

Rifabutin. Rifabutin is another rifamycin that is highly active against ***M. tuberculosis.*** Its mechanism of action is the same as that of rifampin, so that most rifampin-resistant strains are also resistant to rifabutin. Most strains of ***M. tuberculosis*** are inhibited by concentrations of 0.1 μg/ml. A dose of 300 mg results in peak serum concentrations of 5 μg/ml after 2-3 h. The major advantage of rifabutin is the longer serum half-life and reduced hepatic induction of microsomal metabolism compared with that of rifampin. Rifabutin is extensively metabolized in the liver (and to a lesser extent in the intestinal wall); only 8% of a dose is excreted unchanged in the urine. Doses of up to 300 mg daily are usually well tolerated. Side effects attributed to rifabutin include rash, gastrointestinal intolerance, neutropenia, myalgias, and dysguesia. Hepatotoxicity is rare, but rifabutin can cause drug-induced hepatitis. Rates of side effects increase when rifabutin is administered with a CYP-3A4 inhibitor (e.g., clarithromycin); side effects that have been noted under these circumstances include uveitis (128) and abnormal skin pigmentation (129). Similar to rifampin, rifabutin can also decrease concentrations and clinical efficacy of methadone, coumadin derivatives, glucocorticoids, hormonal contraceptives, oral hypoglycemic agents, digitalis, anticonvulsants, dapsone, ketoconazole, and cyclosporin, as well as itraconazole, P-blockers, and theophylline. Doses of these medications may have to be increased when administered with rifabutin. When administered with rifabutin, protease inhibitors, used for the treatment of HIV infection, may lead to increased levels of rifabutin and decreased levels of the protease inhibitor; however, these effects are generally less than those that occur with rifampin and can be accommodated by dose adjustments (Table 8). NNRTIs, used for the treatment of HIV infection, may also necessitate rifabutin dose adjustment.

Treatment Regimens

Treatment of LTBI is an essential part of the strategy to eliminate TB in the United States. Persons with LTBI who are included among those at increased risk for TB should be offered treatment. The choice of the specific treatment regimen is based on many considerations as detailed in the following sections.

U.S. ***Public Health Service Rating System.*** To help clinicians make informed treatment decisions based on the most current research results, evidence-based ratings are assigned to the drug treatment recommendations (general recommendations have no rating) (Table 9). The ratings system is similar to that used in previous PHS documents (3) and includes a letter and a Roman numeral: the letter indicates the strength of the recommendation, and the Roman numeral indicates the quality of the evidence supporting the recommendation. Thus, clinicians can use the ratings to differentiate between recommendations based on data from clinical trials and those based on the opinions of experts familiar with the relevant clinical practice and scientific rationale for such practice (when clinical trial data are not available).

TABLE 9

ADAPTED PUBLIC HEALTH SERVICE RATING SYSTEM FOR THE STRENGTH OF TREATMENT RECOMMENDATIONS AND QUALITY OF EVIDENCE

Strength of the recommendation
A. Preferred; should generally be offered
B. Alternative; acceptable to offer
C. Offer when preferred or alternative regimens cannot be given
D. **Should generally not be offered**
E. Should never be offered
Quality of evidence supporting the recommendation
I. At least one randomized trial with clinical endpoints
II. Clinical trials that either are not randomized or were conducted in other populations
III. **Expert opinion**

Recommended regimens. Four regimens are recommended for the treatment of adults with LTBI (Table 10). The antituberculosis medications used in these regimens have varying doses, toxicities, and monitoring requirements (Table 8). All patients being given twice-weekly treatment should receive DOT, because nonadherence to intermittent dosing results in a larger proportion of the total doses missed than does daily dosing. DOT should be used whenever feasible, especially with 2-mo regimens and in certain settings (e.g., some institutional settings, community outreach programs, and for some persons living in households with patients who are receiving home-based DOT for active TB).

Isoniazid for 9 mo. The isoniazid daily regimen for 9 mo receives an A recommendation. Prospective, randomized trials of up to 12 mo of therapy in HIV-uninfected persons suggest that the maximal beneficial effect of isoniazid is achieved by 9 mo; minimal additional benefit is gained by extending treatment to 12 mo. Thus, this updated recommendation represents a shortening of the previous recommendation of isoniazid daily for 12 mo for HIV-infected persons and a lengthening of the previously recommended 6 mo for HIV-uninfected persons (1). Both 12-mo and 6-mo regimens of isoniazid have substantially reduced rates of TB in HIV-infected persons compared with placebo (88), but the 6-mo regimen has not been directly compared with the 12-mo regimen in HIV-infected persons. Thus, the recommendation for 9 mo of isoniazid in HIV-infected persons is based on extrapolation of available data. Intermittent dosing of 9 mo of isoniazid for treatment of LTBI has not been studied comparatively. However, analogous with the continuation phase of treatment for active TB (where twice-weekly dosing is equivalent to daily dosing), twice-weekly dosing of isoniazid is also acceptable for treatment of LTBI, but is recommended at the B level as an acceptable alternative regimen.

Isoniazid for 6 mo. Although a 9-mo regimen of isoniazid is the preferred treatment of LTBI for an individual patient, a 6-mo regimen also provides substantial protection and has been demonstrated to be superior to placebo in both HIV-infected and HIV-uninfected persons (32, 84). From a societal perspective, treatment for 6 mo rather than 9 mo may provide a more cost-effective outcome (81). Thus, based on individual situations, health departments or other providers may prefer to concentrate efforts in ensuring the implementation of a 6-mo rather than a 9-mo course of isoniazid. Isoniazid for 6 mo, taken either daily or twice weekly, is recommended at the B level for HIV-negative persons and at the C level for HIV-positive persons. The shorter regimen is not recommended for children or persons with radiographic evidence of prior tuberculosis.

Rifampin and pyrazinamide for 2 mo. The 2-mo daily regimen of rifampin and pyrazinamide is recommended on the basis of a prospective randomized trial of treatment of LTBI in HIV-infected persons that demonstrated the 2-mo regimen to be similar in safety and efficacy to a 12-mo regimen of isoniazid (111). Although this regimen has not been evaluated in HIV-uninfected persons with LTBI, the efficacy is not expected to differ significantly. However, the toxicities may be increased (113); therefore, the recommendation is made at the A level for HIV-infected persons and at the B level for HIV-uninfected persons until further data are available. Two randomized, prospective trials of intermittent dosing of rifampin and pyrazinamide for 2 and 3 mo, respectively, have been reported in HIV-infected persons (86, 110); in neither case was the sample size adequate to conclude with certainty that efficacy was equivalent to daily dosing. Moreover, both studies compared the twice-weekly rifampin and pyrazinamide regimen to the 6-mo isoniazid regimen. Therefore, rifampin and pyrazinamide given twice weekly for 2-3 mo may be considered when alternative regimens cannot be given. This recommendation is made at the C level.

Rifampin for 4 mo. Rifampin given daily for 3 mo has resulted in better protection than placebo in treatment of LTBI

TABLE 10

RECOMMENDED DRUG REGIMENS FOR TREATMENT OF LATENT TUBERCULOSIS (TB) INFECTION IN ADULTS

Drug	interval and Duration	Comments	Rating* (Evidence)? HIV-	HIV+
Isoniazid	Daily for 9 mo†,§	In human immunodeficiency virus (HIV)-infected patients, isoniazid may be administered concurrently with nucleoside reverse transcriptase inhibitors (NRTIs), protease inhibitors, or non-nucleoside reverse transcriptase inhibitors (NNRTIs)	A (II)	A (II)
	Twice weekly for 9 mo†,§	Directly observed therapy (DOT) must be used with twice-weekly dosing	B (II)	B (II)
Isoniazid	Daily for 6 mo§	Not indicated for HIV-infected persons, those with fibrotic lesions on chest radiographs, or children	B (I)	C (I)
	Twice weekly for 6 mo§	DOT must be used with twice-weekly dosing	B (II)	C (I)
Rifampin plus pyrazinamide	Daily for 2 mo	May also be offered to persons who are contacts of patients with isoniazid-resistant, rifampin-susceptible TB	B (II)	A (I)
		In HIV-infected patients, protease inhibitors or NNRTIs should generally not be administered concurrently with rifampin; rifabutin can be used as an alternative for patients treated with indinavir, nelfinavir, amprenivir, ritonavir, or efavirenz, and possibly with nevirapine or soft-gel saquinavir‖		
	Twice weekly for 2-3 mo	DOT must be used with twice-weekly dosing	C (II)	C (I)
Rifampin	Daily for 4 mo	For persons who cannot tolerate pyrazinamide	B (II)	B (III)
		For persons who are contacts of patients with isoniazid-resistant, rifampin-susceptible TB who cannot tolerate pyrazinamide		

* Strength of recommendation: A = preferred; B = acceptable alternative; C = offer when A and B cannot be given.

†Quality of evidence: I = randomized clinical trial data; II = data from clinical trials that are not randomized or were conducted in other populations; III = expert opinion.

‡ Recommended regimen for children younger than 18 yr of age.

§ Recommended regimens for pregnant women. Some experts would use rifampin and pyrazinamide for 2 mo as an alternative regimen in HIV-infected pregnant women, although pyrazinamide should be avoided during the first trimester.

‖ Rifabutin should not be used with ritonavir, hard-gel saquinavir, or delavirdine. When used with other protease inhibitors or NNRTIs, dose adjustment of rifabutin may be required (see Table 8).

in HIV-uninfected persons with silicosis in a randomized prospective trial (36). However, because the patients receiving rifampin had a high rate of active TB (4%), experts have concluded that a 4–mo regimen would be more prudent when using rifampin alone. This 4-mo rifampin regimen is recommended at the B level for both HIV-infected and HIV-uninfected persons. This option may be useful for patients who cannot tolerate isoniazid or pyrazinamide.

Choice of regimen. Because more than one regimen can be used to treat LTBI, health care providers should discuss options with the patient, and, when possible, help patients make the decision, unless medical indications dictate a specific regimen. Discussion should include the length and complexity of the regimens, possible adverse effects, and potential drug interactions.

Completion of treatment. Completion of therapy is based on total number of doses administered-not on duration of therapy alone. The 9-mo regimen of daily isoniazid should consist of 270 doses, at minimum, administered within 12 mo, allowing for minor interruptions in therapy. The 6-mo regimen of isoniazid should consist of at least 180 doses administered within 9 mo. Twice-weekly isoniazid regimens should consist of at least 76 doses administered within 12 mo for the 9-mo regimen and 52 doses within 9 mo for the 6-mo regimen. The daily regimen of rifampin (or rifabutin) and pyrazinamide should consist of at least 60 doses to be administered within 3 mo. The regimen of daily rifampin alone should consist of at least 120 doses administered within 6 mo.

Ideally, patients should receive medication on a regular dosing schedule until completion of the indicated course. However, in practice some doses may be missed, requiring the course to be lengthened. When reinstituting therapy for patients who have interrupted treatment, clinicians might need to continue the regimen originally prescribed (as long as needed to complete the recommended duration of the particular regimen) or renew the entire regimen if interruptions were frequent or prolonged enough to preclude completion of treatment as recommended. In either situation, when therapy is restored after an interruption of more than 2 mo, a medical examination to rule out active TB disease is indicated.

Special considerations.

Treatment of HIV-infected persons. Recommendations for HIV-infected adults largely parallel those for HIV-uninfected adults, although the quality of evidence and strengths of the recommendations vary (Table 10). However, when isoniazid is chosen for treatment of LTBI in persons with HIV infection, 9 mo is recommended rather that 6 mo. In addition, rifampin is generally contraindicated or should be used with caution in persons who are taking protease inhibitors (PIs) or NNRTIs (169). Experts have recommended that for HIV-infected persons who are candidates for treatment of LTBI and need PI or NNRTI therapy, rifabutin can be substituted for rifampin in some circumstances; rifabutin can safely be used with indinavir, nelfinavir, amprenavir, ritonavir, and efavirenz, but not with hard-gel saquinavir, or delavirdine. Caution is advised if rifabutin is administered with soft-gel saquinavir, because data regarding use of rifabutin with soft-gel saquinavir or nevirapine are limited.

No specific data have been generated for treatment of LTBI with rifabutin-containing regimens, but such a recommendation is supported by analogy with treatment for active TB (where rifabutin can be substituted for rifampin with no loss of efficacy) and by experimental studies in mice (107, 130). Rifabutin can be administered at one half the usual daily dose (i.e., reduced from 300 mg to 150 mg/d) with indinavir, nelfinavir, or amprenavir or at one-fourth the usual dose (i.e., 150 mg every other day or three times a week) with ritonavir. The daily rifabutin dose is 450 mg or 600 mg when used with efavirenz; pharmacokinetic studies suggest that rifabutin might be given at usual doses with nevirapine. For patients receiving multiple PIs or a PI in combination with an NNRTI, drug interactions with rifabutin are likely more complex; in such situations, the use of rifabutin is not recommended until additional data are available. The substitution of rifapentine for rifampin is not recommended because rifapentine's safety and effectiveness have not been established for patients infected with HIV (131). Furthermore, the drug interactions between rifapentine and HIV protease inhibitors have not been studied in detail, although one study has indicated that rifapentine causes substantial reduction in the serum level of indinavir when the drugs are given together (132).

In tuberculin-negative, HIV-infected persons, treatment of LTBI has not been effective (3). However, most tuberculin-negative HIV-infected contacts of patients with active TB should receive treatment for presumptive LTBI-even when repeat testing after contact has ended is not indicative of LTBI. Furthermore, some experts recommend treatment of possible LTBI for HIV-infected residents of institutions that pose an ongoing high risk for exposure to ***M. tuberculosis (e.g.,*** prisons, jails, and homeless shelters).

Persons with fibrotic lesions/suspected disease. For patients who have a chest radiograph demonstrating old fibrotic lesions thought to represent previous infection with TB and a positive tuberculin skin test ($\geq$ 5 mm) without evidence of active disease and no history of treatment for TB, three acceptable regimens can be used for treatment. These regimens include 9 mo of isoniazid, 2 mo of rifampin plus pyrazinamide, or 4 mo of rifampin (with or without isoniazid), providing that infection with drug-resistant organisms is judged to be unlikely. Patients who begin multidrug therapy for suspected pulmonary TB but are subsequently determined not to have active disease (i.e., AFB cultures are negative and chest radiographs are stable) should complete treatment with at least 2 mo of a regimen containing rifampin and pyrazinamide if the tuberculin skin test is positive and other causes of the radiographic abnormalities have been excluded.

Persons with evidence suggestive of healed, primary TB (i.e., calcified solitary pulmonary nodules, calcified hilar lymph nodes, and apical pleural capping) are not at increased risk for TB. Their risk for TB and need for treatment of LTBI should be determined by consideration of other risk factors and the size of the tuberculin reaction (Table 7).

Pregnancy and lactation. Pregnancy has minimal influence on the pathogenesis of TB or the likelihood of LTBI progressing to disease (133, 134). Although one study demonstrated a decrease in lymphocyte reactivity to tuberculin during pregnancy (135), other studies have not demonstrated an effect of pregnancy on cutaneous delayed hypersensitivity to tuberculin (136, 137). The current classification scheme for interpreting the Mantoux tuberculin skin test is likely valid in pregnancy, although it has not been verified in this group of women. There is no evidence that the tuberculin skin test has adverse effects on the pregnant mother or fetus (138).

Pregnant women should be targeted for tuberculin skin testing only if they have a specific risk factor for LTBI or for progression of LTBI to disease. Although the need for treatment of active TB during pregnancy is unquestioned, the treatment of LTBI in pregnant women is more controversial. Some experts prefer to delay treatment until after delivery because pregnancy itself does not increase the risk of progression to disease, and two studies suggest that women in pregnancy and the early postpartum period may be vulnerable to isoniazid hepatotoxicity (91, 92). However, because conditions that promote hematogenous spread of organisms to the placenta (e.g., recent

infection and HIV infection) or progression of LTBI to disease can endanger both the mother and baby (139), many experts agree that pregnant women with these conditions and LTBI should be treated during pregnancy and have careful clinical and laboratory monitoring for hepatitis. The possible risk for isoniazid hepatotoxicity must be weighed against the risk for developing active TB and the consequences to both the mother and her child should active disease develop.

Extensive use of isoniazid during pregnancy has indicated that although it readily crosses the placental barrier, the drug is not teratogenic even when given during the first 4 mo of gestation (140). Regarding rifampin, one study revealed that 3% of 446 fetuses exposed in *utero* to rifampin had abnormalities (i.e., limb reductions, central nervous system abnormalities, and hypoprothrombinemia) compared with 2% for ethambutol and 1% for both isoniazid and controls (138). Hemorrhagic disease of the newborn has been described following the use of rifampin in the mother (141). However, extensive experience with the use of rifampin to treat TB in pregnant women suggests it is safe in most circumstances. Although pyrazinamide has been used to treat TB in pregnant women, no published data exist concerning the effects of the drug on the fetus. Thus, although pyrazinamide may be considered after the first trimester in women with HIV infection (142), it should otherwise be avoided.

The preferred regimen for treatment of LTBI in pregnant women is isoniazid, administered either daily or twice weekly. Although rifampin is probably safe, no efficacy data support its use. For women at high risk for progression of LTBI to disease, especially those who are infected with HIV or who have been infected recently, initiation of therapy should not be delayed on the basis of pregnancy alone, even during the first trimester. For these women, careful clinical and/or laboratory monitoring for hepatitis should be undertaken. Pregnant women taking isoniazid should receive pyridoxine supplementation.

Toxic effects of antituberculosis drugs delivered in breast milk have not been reported. One study concluded that a breastfeeding infant would develop serum levels of no more than 20% of the usual therapeutic levels of isoniazid for infants and $< 11\%$ of other antituberculosis drugs (143). Breastfeeding is not contraindicated when the mother is being treated for LTBI. However, infants whose breastfeeding mothers are taking isoniazid should receive supplemental pyridoxine. The amount of isoniazid provided by breast milk is inadequate for treatment of the infant.

Children and adolescents. Several fundamental aspects of the natural history and treatment of LTBI in children must be considered when making recommendations about therapy. Infants and young children (i.e., those younger than 5 yr of age) with LTBI have been infected recently, and are at high risk for progression to disease. Data suggest that untreated infants with LTBI have up to a 40% likelihood of developing TB (144). The risk for progression decreases gradually through childhood. Infants and young children are more likely than older children and adults to develop life-threatening forms of TB, especially meningeal and disseminated disease. Children with LTBI have more years at risk to develop TB than adults. Isoniazid therapy for LTBI appears to be more effective for children than adults, with several large clinical trials demonstrating risk reduction of 70–90% (145, 146). The risk for isoniazid-related hepatitis is minimal in infants, children, and adolescents, who generally tolerate the drug better than adults (147, 148). Isoniazid therapy is widely accepted for use in children. Because of differences in pathogenesis of TB infection and disease in children compared with adults, information from clinical trials involving adults cannot be applied directly to children without confirmatory pediatric trials. The only published efficacy trials of treatment of LTBI in children have studied isoniazid alone.

The only recommended regimen for treatment of LTBI in HIV-uninfected children is a 9-mo course of isoniazid as self-administered daily therapy or by DOT twice weekly. Routine monitoring of serum liver enzyme concentrations is not necessary but should be considered in children at risk for hepatic disease. When children taking antituberculosis therapy develop hepatitis, a search for causes other than isoniazid or other drugs should be undertaken and the therapy discontinued. Routine administration of pyridoxine is not recommended for children taking isoniazid, but should be given to (I) breastfeeding infants, (2) children and adolescents with diets likely to be deficient in pyridoxine, and (3) children who experience paresthesias while taking isoniazid.

Isoniazid given twice weekly has been used extensively to treat LTBI in children, especially schoolchildren and close contacts of case patients (125). On the basis of clinical experience, this method of administration is safe, but its effectiveness has not been established definitively. DOT should be considered when it is unlikely that the child and family will be adherent to daily self-administration.

In the United States, rifampin alone has been used for the treatment of LTBI in infants, children, and adolescents when isoniazid could not be tolerated or the child has had contact with a case patient infected with an isoniazid-resistant but rifamycin-susceptible organism (149). However, no controlled clinical trials have been conducted. A 3-mo regimen of rifampin and isoniazid has been used in England, with programmatic data suggesting that the regimen is effective (108). No reports have been published concerning the efficacy of rifampin and pyrazinamide therapy in children with LTBI, although a randomized study involving a limited number of children indicated that this regimen was well tolerated (116).

No studies have been published regarding the efficacy of any form of treatment for LTBI in HIV-infected children. The American Academy of Pediatrics currently recommends a 9-mo course of isoniazid (150). Most experts recommend that routine monitoring of serum liver enzyme concentrations be performed and pyridoxine given when HIV-infected children are treated with isoniazid. The optimal length of rifampin therapy in children with LTBI is not known; however, the American Academy of Pediatrics recommends 6 mo of treatment (150).

Contacts of patients with tuberculosis.

CONTACTS OF PATIENTS WITH DRUG-SUSCEPTIBLE TUBERCULOSIS. Persons who are contacts of patients with drug-susceptible TB and who have positive tuberculin skin-test reactions (≥ 5 mm) should be treated with one of the recommended regimens-regardless of age (Table 10). In addition, some tuberculin-negative contacts should be considered for treatment. Because of susceptibility to severe disease, children younger than 5 yr of age with negative skin tests should be treated and another skin test performed 8-12 wk after contact has ended. If the repeat skin test is positive, treatment should continue for the recommended period of time; if the repeat skin test is negative, the treatment should be stopped. Immunosuppressed persons, including those with HIV infection, who are contacts of persons with active TB should also receive treatment, even if repeat skin testing does not indicate LTBI.

CONTACTS OF PATIENTS WITH ISONIAZID-RESISTANT TUBERCULOSIS. No definitive data exist concerning treatment of contacts who have been exposed to patients with probable or confirmed isoniazid-resistant TB. A decision analysis and Delphi methodology have been used to recommend either rifampin alone or in combination with isoniazid or ethambutol when the risk of isoniazid-re-

sistant infection is > 50% (151). An expert panel has recommended use of rifampin for vulnerable contacts (e.g., those with HIV infection) of patients with isoniazid-resistant TB (152).

In an outbreak of isoniazid- and streptomycin-resistant TB among homeless persons, six (9%) of 71 persons with skin tests that converted who received no preventive therapy developed TB, compared with three (8%) of 38 who received isoniazid, and zero of 98 persons who received rifampin or isoniazid and rifampin (153). Similarly, of 157 high school students who took rifampin after being exposed to a patient with isoniazid-resistant, active TB, none developed TB during the second year of the study (149). However, one episode of rifampin prophylaxis failure was reported among contacts of a case patient with isoniazid-resistant TB in a community outbreak (154).

For contacts of patients with isoniazid-resistant, rifampin-susceptible TB, a 2-mo regimen of rifampin and pyrazinamide is recommended. For patients with intolerance to pyrazinamide, a 4-mo regimen of rifampin alone is recommended. In situations in which rifampin cannot be used, rifabutin can be substituted.

CONTACTS OF PATIENTS WITH MULTIDRUG-RESISTANT TUBERCULOSIS. The occurrence of outbreaks of multidrug-resistant TB (MDR TB) (i.e., TB caused by strains of *M. tuberculosis* resistant to at least isoniazid and rifampin) and the rise in resistance rates worldwide have focused attention on options for treatment of persons exposed to and presumed to be infected by such organisms (155). As with exposure to isoniazid-resistant TB, this problem has not been evaluated in prospective studies. A Delphi technique among 31 experts failed to achieve consensus on the management of such persons (156).

Persons infected with isoniazid- and rifampin-resistant organisms are unlikely to benefit from treatment with regimens containing these agents. Therefore, use of a regimen containing other agents active against *M. tuberculosis* should be considered. When possible, selection of drugs for such a regimen should be guided by *in vitro* susceptibility test results from the isolate to which the patient was exposed and is presumed infected.

For persons who are likely to be infected with MDR TB and at high risk of developing TB, pyrazinamide and ethambutol or pyrazinamide and a fluoroquinolone (i.e., levofloxacin or ofloxacin) for 6-12 mo are recommended, if the organisms from the index case-patient are known to be susceptible to these agents (157). Immunocompetent contacts may be observed without treatment or treated for at least 6 mo; immunocompromised contacts (e.g., HIV-infected persons) should be treated for 12 mo. Side effects of pyrazinamide and fluoroquinolones include gastrointestinal symptoms and hepatic transaminase elevations (158). All persons with suspected MDR TB infection should be followed for at least 2 yr, irrespective of treatment. Expert consultation should be sought for the treatment of persons exposed to patients with MDR TB.

No studies have been published regarding treatment of LTBI in children following exposure to multidrug-resistant TB. Ethambutol at 15 mg/kg is safe in children (159). The combination of pyrazinamide and cthambutol for 9-12 mo is recommended if the isolate is susceptible to both drugs. Long-term use of fluoroquinolones in children should bc avoided. Deleterious effects on growing cartilage have been observed in animals treated with fluoroquinolones (160), although no defects in bone growth occurred among a limited number of children with cystic fibrosis treated with ciprofloxacin or ofloxacin (161). When pyrazinamide and ethambutol cannot be used, many experts recommend using a combination of two other drugs to which the infecting organism is likely susceptible (162,163).

Low-risk tuberculin test reactors. When treatment of LTBI is being considered for persons who are at low risk for developing TB, the decision should be based on factors such as likelihood of drug toxicity if treatment is given and likelihood of TB transmission to vulnerable contacts (e.g., infants and HIV-infected persons) if treatment were not given and the patient were to develop active TB. Included in this decision are the patient's preferences and values. When the assessed risk of drug toxicity exceeds the anticipated benefits of therapy, treatment for LTBI is not usually appropriate.

BCG-vaccinated persons. A history of BCG vaccination, with or without a BCG scar, should not influence the decision regarding whether to treat LTBI. The criteria previously described should be applied without modification (164).

Directly observed therapy and measures to increase adherence. Any regimen that is given intermittently (i.e., twice weekly) should be given only under direct observation. Some experts recommend that the 2-mo regimen of daily rifampin and pyrazinamide also be given by DOT, which, for ease of administration, may consist of five observed and two self-administered doses each week.

Patients with the highest priority for DOT are those at the highest risk of progression from latent to active TB, including persons with HIV infection and young children who are contacts of infectious patients with pulmonary TB. DOT may be conveniently and effectively used for the treatment of household contacts of patients receiving DOT for active TB and for treatment observed by staff members in certain facilities (e.g., schools and homeless shelters).

If it is not possible to provide DOT to enhance adherence with treatment of LTBI, the prescribed regimen should be incorporated into patients' daily routines. Medical providers can encourage adherence to treatment by establishing rapport with patients. Providers should explain in simple, clear language what LTBI is, the health threat it presents, and how it is eradicated. Patients should be encouraged to ask questions. Patient education should ideally be conducted in the patient's primary language, or through a medical interpreter, if necessary. Each visit between patient and medical provider during therapy is an opportunity to reinforce the patient's understanding of LTBI and its treatment.

In addition to education about potential drug toxicity, patients should be told about common side effects and counseled on drug management. (For example, medications should be taken with food when gastrointestinal symptoms have occurred after medication was taken on an empty stomach, and salicylic acid can be used for symptomatic treatment of arthralgia caused by pyrazinamide.)

Most interventions to improve adherence require substantial financial resources. Providing flexible clinic hours, reducing waiting times for patients, spending time with patients to counsel and educate, and directly observing patients ingesting medications increase operating expenses. Even the least intensive approaches to improve adherence increase program costs. The costs of these approaches to improving patient adherence underscore the need to target tuberculin testing and treatment of LTBI to those groups with an increased risk for recent infection or those persons at high risk for progression to active TB, if infected. In addition, programs should invest in approaches to increase adherence, especially for those persons who are at greatest risk for progressing to disease. Better success in motivating patients to accept and to complete treatment is necessary to achieve the full potential of this intervention to protect persons from TB and to reduce the incidence of the disease in the community.

Pretreatment Evaluation and Monitoring of Treatment

Pretreatment evaluation. The pretreatment evaluation of persons who are targeted for treatment of LTBI provides an op-

portunity for health care providers to (I) establish rapport with patients, (2) discuss the details of the patients' risk for TB, (3) emphasize the benefits of treatment and the importance of adherence to the drug regimen, (4) review possible adverse effects of the regimen, including interactions with other drugs, and (5) establish an optimal follow-up plan. The evaluation should include an interview conducted in the patients' primary language with assistance of qualified medical interpreters, if necessary.

The patient history should document risk factors for TB, prior treatment for TB or LTBI, and preexisting medical conditions that constitute a contraindication to treatment or are associated with an increased risk for adverse effects of treatment. A detailed history of current and previous drug therapy should be obtained, with particular attention to previous adverse reactions to drugs contemplated for treatment of LTBI, and to current use of drugs which may interact with the drugs used for treatment. Women receiving rifampin and oral contraceptives are at increased risk for becoming pregnant and should be advised to consider an additional form of contraception. Practitioners should consider using a standardized history form to ensure that all elements of the pretest evaluation are thoroughly covered for each patient.

Baseline laboratory testing is not routinely indicated for all patients at the start of treatment for LTBI (Table 8). Patients whose initial evaluation suggests a liver disorder should have baseline hepatic measurements of serum AST (SGOT) or ALT (SGPT) and bilirubin. Baseline testing is also indicated for patients infected with HIV, pregnant women and those in the immediate postpartum period (i.e., within 3 mo of delivery), persons with a history of liver disease (e.g., hepatitis B or C, alcoholic hepatitis or cirrhosis), persons who use alcohol regularly, and others who are at risk for chronic liver disease. Baseline testing is no longer routinely indicated in persons older than 35 yr of age. However, such testing may be considered on an individual basis, particularly for patients who are taking other medications for chronic medical conditions. Active hepatitis and end-stage liver disease are relative contraindications to the use of isoniazid or pyrazinamide for treatment of LTBI.

Monitoring of treatment. Clinical monitoring is indicated for all patients; this involves education of patients about the symptoms and signs that can result as adverse effects of the drug(s) being prescribed and the need for prompt cessation of treatment and clinical evaluation should symptoms occur. These include any of the following: unexplained anorexia, nausea, vomiting, dark urine, icterus, rash, persistent paresthesias of the hands and feet, persistent fatigue, weakness ***or*** fever lasting 3 or more days, abdominal tenderness (especially right upper quadrant discomfort), easy bruising or bleeding, and arthralgia (Table 8). Clinical monitoring begins at the first visit and should be repeated at each monthly visit. At monthly visits, patients should be instructed to interrupt therapy and contact their providers immediately upon the onset of such symptoms or any unexplained illness occurring during treatment.

Patients being treated for LTBI should receive a clinical evaluation, including a brief physical assessment checking for signs of hepatitis, at least monthly if receiving isoniazid alone or rifampin alone and at 2, 4, and 8 wk if receiving both rifampin and pyrazinamide (Table 8). These evaluations represent opportunities to review the indications for treatment, adherence with therapy since the last visit, symptoms of adverse drug effects and drug interactions, and plans to continue treatment. As with the baseline evaluation, a standardized questionnaire may facilitate those interviews.

Routine laboratory monitoring during treatment of LTBI is indicated for patients whose baseline liver function tests are abnormal and for other persons at risk for hepatic disease (Table 8). In addition, laboratory testing (e.g., liver function studies for patients with symptoms compatible with hepatotoxicity or a uric acid measurement to evaluate patients who develop acute arthritis) should be used to evaluate possible adverse effects that occur during the course of treatment. Some experts recommend that isoniazid be withheld if a patient's transaminase level exceeds 3 times the upper limit of normal if associated with symptoms and five times the upper limit of normal if the patient is asymptomatic.

Reporting of serious adverse events. Practitioners and other health professionals should report serious adverse events associated with the treatment of LTBI to the U.S. Food and Drug Administration's MedWatch program. Serious adverse events include those associated with hospitalization, permanent disability, or death. Reporting may be by mail, telephone (1-800-FDA-1088), fax (1-800-FDA-0178), or the Internet site (www.fda.gov/medwatch).

Priorities for Future Research

DIAGNOSIS

The only widely available method to detect LTBI is the tuberculin skin test. However, the specificity of the test is decreased by cross reactions from BCG vaccination and sensitization by nontuberculous mycobacteria. When used in populations in which the risk for TB is low, the test's positive predictive value is poor. In addition, the requirement that the person tested return for the test to be read 48-72 h after test administration creates operational problems. Thus, more specific and sensitive tests are needed to diagnose LTBI and to identify persons at greatest risk for progressing to active disease. Especially useful would be tests that distinguish skin-test reactions caused by TB infection from those caused by BCG vaccination or infection with nontuberculous mycobacteria, tests that correlate with the presence of living organisms, and tests that accurately identify LTBI in immunodeficient persons.

OPERATIONAL RESEARCH

Acceptability, Tolerability, and Effectiveness of Daily Rifampin and Pyrazinamide

More data are needed regarding the acceptability, tolerability, and effectiveness of the 2-mo regimen of daily rifampin and pyrazinamide in HIV-negative persons. Data are especially needed from older adults and children.

Intermittent Rifampin-containing Regimens

No studies of rifampin alone taken twice weekly for the treatment of LTBI have been conducted. Data from two studies in HIV-infected persons that included intermittent (i.e., twice weekly) rifampin and pyrazinamide administration suggested that these regimens were effective (86,110). Before additional trials of intermittent rifampin regimens are undertaken, animal model data are needed to compare these regimens with regimens using other longer-acting rifamycin derivatives (see EFFICACY STUDIES OF NEW DRUGS).

Isoniazid Taken Twice Weekly

It is unlikely that a formal efficacy study of intermittent isoniazid for the treatment of LTBI will be undertaken, unless it is included as a control arm for studies of newer regimens. However, several TB-control programs have had considerable experience using this regimen. Data from these programs should be examined, especially as they relate to acceptability and completion of treatment. The analysis of aggregate data available in TB programs may also be useful in estimating the effectiveness of this regimen.

Studies in Children and Pregnant Women

Studies are needed to provide information regarding the use of newer regimens for the treatment of LTBI in children and pregnant women. The safety of pyrazinamide for pregnant women and their fetuses should be determined. More information is needed regarding hepatotoxicity of isoniazid in pregnant and postpartum women. Studies are needed to establish the safety and effectiveness of rifampin alone and rifampin plus pyrazinamide for treatment of LTBI in infants, children, and adolescents. The best target populations for these studies would be HIV-infected children in places in which TB is prevalent and household contacts of TB case patients. In addition, the effectiveness of twice-weekly regimens for treatment of LTBI in children should be confirmed. Data concerning the safety and effectiveness of alternative therapies for MDR LTBI in children are needed. Finally, epidemiologic research to determine the best tools to identify children at high risk for LTBI should be undertaken.

Reporting and Monitoring in New Settings

These recommendations call for the establishment of LTBI treatment programs in new community settings (e.g., managed care organizations and neighborhood clinics). Consequently, operational research will be needed to evaluate the implementation of these programs in settings other than health departments. These studies should assess the knowledge base of treating clinicians and identify the obstacles to be overcome for the successful implementation of community-based LTBI treatment programs.

Combination Rifampin and Pyrazinamide Preparations

If field and programmatic data establish the effectiveness and acceptability of the rifampin and pyrazinamide regimen for the treatment of LTBI, the availability of a combination product would facilitate its administration. However, the argument concerning the usefulness of combination products in preventing the emergence of drug resistance in patients with active TB is not as compelling for persons being treated for LTBI. Nonetheless, methods to facilitate provision of this treatment and increase adherence (e.g., blister packs containing medication for 2 wk of treatment for several different body weights) would be useful.

EFFICACY STUDIES OF NEW DRUGS

No novel compounds currently can be considered candidates for the treatment of LTBI. However, several rifamycin derivatives with half-lives substantially greater than rifampin are of interest because of the possibility of widely spaced, intermittent administration. In experimental studies involving mice, the combination of rifapentine and isoniazid given once weekly for 3 mo was as active as rifampin and pyrazinamide given daily for 2 mo (165). Rifalazil, which has an even longer half-life, is more active than rifapentine and perhaps could be dosed less frequently without compromising efficacy (166). The class of nitroimidazole compounds is also of interest because of their potential activity against dormant tubercle bacilli (167). Unfortunately, no animal models of LTBI exist that optimize the preclinical evaluation of new drugs.

STUDIES OF IMMUNOMODULATORS AND VACCINES

Recent studies have indicated that immunotherapy with specific cytokines and immunomodulators may be beneficial to response to TB treatment. However, their application in the treatment of LTBI is uncertain. Some epidemiologic studies have suggested that high levels of certain cytokines (e.g., interferon gamma) may protect against the development of active TB. If further studies support this finding, interventions that stimulate production of protective cytokines may have a role in the treatment of LTBI. The development of a postinfection vaccine to be administered to persons with LTBI has been given high priority (168).

DECISION/COST-EFFECTIVENESS ANALYSES

Focus on Testing for and Treatment of Latent TB Infection in High-risk and Diverse Populations

Future decision and cost-effectiveness analyses should be expanded to include targeted testing. Instead of beginning at the "treat-don't-treat" point, new models might be most useful if they begin with the decision of whether to test. These studies should focus on groups at high risk and specific subgroups char-

acterized by varied risks and benefits of treatment. Using this conceptual framework will help place decision modeling more clearly into a "real world" context, incorporating the linked contingencies that exist.

Comparison of Strategies Using Both Shorter and Longer Treatment Regimens.

Future decision and cost-effectiveness analyses should compare the shorter course regimens to the longer, 9-mo regimen of daily isoniazid. These analyses will benefit from investigations of the toxicities and efficacies of shorter regimens. In addition, although adherence presumably will be better with shorter treatment regimens, the rifampin and pyrazinamide regimen may be less well-tolerated in some groups of patients, thus resulting in low adherence. Decision and cost-effectiveness analyses should explore a range of toxicities in the models until investigations better establish these risks. By investigating the effect of a range of toxicities and adherence on the decision outcome, studies can help identify priority areas for research. Updated analyses on the use of alternate regimens for the treatment of drug-resistant LTBI are also needed.

Use of Multiple Analytic Perspectives

When two different perspectives are relevant for a decision, both perspectives should be modeled and analyzed. For example, when the benefits to an individual person with LTBI are different from the benefits to the public, both perspectives must be made explicit in decision models. When decision analysis is inadequate to deal with public health issues (e.g., reduction in contagion), additional models are needed to augment views of the benefits and costs of following each viable course of action.

Policies designed to target and treat populations at high risk for TB are motivated by the need to benefit the individual patient as well as the health of the public by averting active disease in persons most likely to develop it. As policies are instituted that identify high-risk groups for testing and treatment, the social and ethical ramifications of these policies must be considered. The individual persons who comprise many of the high-risk groups targeted for testing and treatment often represent disenfranchised segments of urban populations (e.g., persons who are homeless, incarcerated, and medically underserved, and residents in long-term care facilities). Ideally, the outcomes and utilities that are used in these decision models will incorporate the values and preferences of these patients and the outcomes important to the general public.

Fatal and Severe Hepatitis Associated With Rifampin and Pyrazinamide for the Treatment of Latent Tuberculosis Infection -- New York and Georgia, 2000

One of the recommended treatments for latent tuberculosis infection (LTBI) is a 9-month regimen of isoniazid (INH); a 2-month regimen of rifampin (RIF) and pyrazinamide (PZA) is an alternative in some instances. In September 2000, a man in New York died of hepatitis after 5 weeks of RIF-PZA, and in December, a woman in Georgia was admitted to a hospital because of hepatitis after 7 weeks of this regimen. This report summarizes the findings of the investigations of these incidents, which underscore the need for clinical monitoring for adverse effects in all patients receiving treatment for LTBI.

Case 1

A 53-year-old incarcerated man received 600 mg (6.7 mg/Kg) RIF and 1750 mg (19 mg/Kg) PZA daily after screening revealed a tuberculin skin test (TST) with 20 mm induration and no radiologic or clinical findings of active tuberculosis (TB). His risk factors for TB included previous work as a medical orderly, homelessness, and multiple incarcerations. He had a history of hypertensive heart disease and alcoholism without evidence of chronic liver disease. He was not known to inject drugs.

RIF-PZA was standard treatment for LTBI at the jail. Baseline and 1-month serum aminotransferase and bilirubin levels were measured routinely. The patient's baseline aminotransferase levels were slightly higher than the upper-normal limits. He was instructed to stop taking RIF-PZA if he developed symptoms suggestive of hepatitis. He also received 325 mg enteric-coated aspirin daily, 90 mg extended-release nifedipine, and 50 mg hydrochlorothiazide. Nurses supervised the administration of all medication to assure compliance.

Blood specimens tested on day 33 of treatment revealed alanine aminotransferase (ALT) 1734 U/L (normal range: 0--41 U/L), aspartate aminotransferase (AST) 1449 U/L (normal range: 0--38 U/L), and total bilirubin 4.2 mg/dL (normal range: 0--1.0 mg/dL). Blood cell counts showed leukocytosis. On day 35, RIF-PZA was discontinued when the test results were received. On the same day, a correctional officer urged the patient to visit the infirmary because of poor appetite and lassitude that had developed over several days; he declined. Five days after the cessation of RIF-PZA, the patient was evaluated in the infirmary for jaundice and altered mental status and was admitted to a hospital. Serum total bilirubin peaked at 17.8 mg/dL and blood ammonia at 378 μmol/L (normal range: 17--47 μmol/L). He died 3 days after admission.

On postmortem histology, the liver had bridging necrosis, lymphocytic infiltration, focal cholestasis, increased fibrosis, and micronodular cirrhosis. Results were negative for serum anti-A IgM, antibody to hepatitis B core antigen (anti-HBc), antibody to hepatitis B surface antigen (anti-HBs), and antibody to hepatitis C virus (anti-HCV). Antinuclear antibody (ANA) was undetectable. Hepatitis B and C were undetectable by polymerase chain reaction assays. The reported cause of death was liver necrosis and failure as a result of hepatitis following LTBI treatment.

Case 2

A 59-year-old woman received 600 mg (7.2 mg/Kg) RIF and 2000 mg (24 mg/Kg) PZA daily after testing revealed a TST with 27 mm induration and no findings for active TB. She chose this regimen because of suspected exposure to drug-resistant TB and concern about liver injury from INH. In addition to RIF-PZA, she received beclomethasone dipropionate nasal spray, budesonide inhalation powder, and albuterol inhalation aerosol for nasal allergies and asthma. She had no history of liver disease, rarely drank alcohol, and did not inject drugs. She was vaccinated against hepatitis A but not B. She had a history of anaphylactic reactions to penicillin and an estrogen sulfates blend. Baseline ALT and AST, bilirubin levels, and blood cell counts were normal. She was instructed to contact her health-care provider about adverse effects during treatment. On day 2 of treatment, she reported queasiness. On day 17, her blood tests were repeated: serum aminotransferase and bilirubin levels were normal, and her eosinophil count, which had been 157 cells/μL, was 510 cells/μL (normal range: 50--550 cells/μL).

She subsequently experienced malaise, anorexia, and feverishness, and she occasionally took one bismuth subsalicylate chewable tablet. On the 49th and last day of treatment, she returned to her health-care provider and was admitted to a hospital because of jaundice and altered mental status. AST was 986 U/L (normal range: 7--40 U/L), ALT 1735 U/L (normal range: 17--63 U/L), and total bilirubin 11.4 mg/dL (normal range: 0.1--1.1 mg/dL). The bilirubin peaked at 27.5 mg/dL after 14 days. Peak eosinophil count was 2580 cells/μL. No ova or protozoa were detected by stool examinations. Serum ANA was 1:640 (speckled pattern). Antibody (not IgM) to hepatitis A virus was detected. Test results were negative for hepatitis B surface antigen (HBsAg), anti-HBs, and anti-HCV. After receiving 40 mg prednisone daily, the symptoms and laboratory abnormalities slowly abated, and she was released after 25 days in the hospital.

Editorial Note:

Case 1 is the first report to CDC of fatal hepatitis associated with the RIF-PZA regimen for LTBI, although sporadic cases of liver injury have been attributed to PZA used in treatment regimens for TB disease (*1*). Both cases illustrate that the usually well-tolerated regimens for LTBI occasionally can result in severe adverse effects and that clinical monitoring is crucial during treatment. In these cases, biochemical monitoring did not help to avoid severe liver injury and does not substitute for clinical monitoring (*2*). Idiosyncratic liver injury can be

caused by hypersensitivity, as suspected for case 2, or by toxic drug metabolites. Other cases have implicated various medicines and alcohol as potential co-factors for INH liver injury (*3*,*4*). A similar association has not been assessed for RIF and PZA because of small case numbers.

Patients with LTBI and risk factors for active TB should be offered treatment (*1*,*5*). Health-care providers should instruct and frequently remind patients about the initial symptoms of hepatitis (e.g., fatigue, nausea, abdominal pain, and anorexia) and the importance of stopping medication if symptoms develop (*2*). In this report, both patients continued taking their medicines while symptoms were developing, a phenomenon also reported for INH-associated hepatitis (*4*).

CDC's Division of Tuberculosis Elimination is interested in receiving reports of severe hepatitis in patients being treated for LTBI. To report possible cases, telephone (404) 639-8125.

Update: Fatal and Severe Liver Injuries Associated With Rifampin and Pyrazinamide for Latent Tuberculosis Infection, and Revisions in American Thoracic Society/CDC Recommendations --- United States, 2001

During February 12--August 24, 2001, a total of 21 cases of liver injury associated with a 2-month rifampin-pyrazinamide (RIF-PZA) regimen for the treatment of latent tuberculosis infection (LTBI) was reported to CDC. These 21 cases are in addition to two previously reported RIF-PZA--associated cases (*1*). Cases of liver injury have occurred each year since 1999. CDC also received reports of 10 cases associated with other LTBI treatment regimens; however, risk for liver injury cannot be compared among treatment regimens in part because the number of patients treated for LTBI with each treatment regimen is unknown. This report provides preliminary information about the 21 cases associated with RIF-PZA and the revised recommendations on selecting appropriate LTBI therapy for patients and monitoring the use of RIF-PZA to treat LTBI (*2*). In most instances, the 9-month isoniazid (INH) regimen is preferred for the treatment of patients with LTBI. RIF-PZA may be used in selected cases and requires more intensive clinical and laboratory monitoring than previously recommended.

A case was defined as liver injury (i.e., clinical and laboratory findings consistent with hepatitis) leading to hospital admission or death of a patient being treated for LTBI with RIF-PZA. The median age of the 21 patients was 44 years (range: 28--73 years) and 12 were men. For patients in which the information was known, jaundice was reported in 15 of 18, and human immunodeficiency virus (HIV) test results were negative for all 11 who were tested. One patient had been diagnosed with hepatitis C disease at the start of RIF-PZA treatment. Three of the 21 RIF-PZA--associated cases occurred when patients received this regimen after recovering from INH-associated liver injury. One case was associated with a patient who received RIF-PZA after taking INH without problems.

Of the 21 patients with RIF-PZA--associated liver injury, 16 recovered and five died of liver failure. No patient received a liver transplant. The five patients who died had LTBI diagnosed under the current recommendations, and each had indications for RIF-PZA treatment (*2*). Patient 1 was a 68-year-old man who had diabetes and a positive tuberculin skin test (TST) result, patient 2 was a 62-year-old woman who had a TST conversion detected by employee screening, and patient 3 was a 36-year-old man who had a TST conversion during incarceration. Patient 4 was a 32-year-old woman who had emigrated from a high-prevalence country to the United States in 2000 and had a positive TST result of 20 mm induration, and patient 5 was a

34-year-old man who had emigrated from a high-prevalence country to the United States in 1988 and had a positive TST result of 22 mm induration. Patient 3 had HIV risk factors but a negative serology result; the other four did not have HIV risk factors. Patients 2, 4, and 5 were tested and had negative serology results. Patients 2 and 3 received RIF-PZA after recovering from INH-associated liver injury.

PZA dosages for the five patients were 19, 18, 23, 20, and 16 mg/kg/d (recommended dose: 15--20 mg/kg/d). After liver injury was diagnosed, all patients were tested for hepatitis A (acute), B (acute and chronic), and C. Patients 2 and 5 had serologic evidence of previous hepatitis A. Patient 5 had serologic evidence of past hepatitis B. Patient 1 had idiopathic nonalcoholic steatotic hepatitis confirmed by biopsy in 1997, and patient 3 used injection drugs and alcohol, although reportedly not during RIF-PZA treatment. Patient 2 had no risks for chronic liver disease and had neither a liver biopsy nor an autopsy. Patients 4 and 5 had autopsies; microscopic examination of the liver of patient 5 revealed acute hepatic necrosis, and results are pending for patient 4. Patients 1 and 2 were taking other medicines* that have been associated with idiosyncratic liver injury. All five patients had onset of liver injury during the second month of the 2-month course of treatment. Patients 1 and 3 continued RIF-PZA an estimated 3 days and 14 days, respectively, after symptom onset; the exact duration of RIF-PZA treatment could not be determined for patients 2 and 4. Patient 5 developed symptoms at the completion of treatment. Patients 1, 2, 4, and 5 received 30-day supplies of RIF-PZA. Patient 3 received directly observed therapy daily, but a language barrier possibly hampered patient education and communication about symptoms. Patient 4 also may have faced a language barrier.

Reported by: State and territorial health depts. Div of Tuberculosis Elimination, National Center for HIV, STD, and TB Prevention, CDC.

Editorial Note:

During June, tuberculosis (TB) and liver disease specialists consulted by CDC analyzed case reports and assessed current guidelines on the use of RIF-PZA and noted that the 2-month RIF-PZA regimen was well tolerated in LTBI treatment trials among HIV-infected persons (*3*--*5*). Although clinical trials of RIF-PZA did not include HIV-uninfected persons, the number of reports of severe liver injury among persons presumed or known not to be infected with HIV was unexpected. CDC continues to investigate the rate and risk factors for liver injury. To reduce the risk for liver injury associated with RIF-PZA therapy, the American Thoracic Society and CDC, with the endorsement of the Infectious Diseases Society of America, have prepared recommendations that supercede previous guidelines (*2*).

1. The 2-month RIF-PZA treatment regimen for LTBI should be used with caution, especially in patients concurrently taking other medications associated with liver injury, and those with alcoholism, even if alcohol use is discontinued during treatment. RIF-PZA is not recommended for persons with underlying liver disease or for those who have had INH-associated liver injury. Persons being considered for treatment with RIF-PZA should be informed of potential hepatotoxicity and asked whether they have had liver disease or adverse effects from INH.
2. For persons not infected with HIV, 9 months of daily INH remains the preferred treatment for LTBI; 4 months of daily RIF is an acceptable alternative. Two months of daily RIF-PZA may be useful when completion of longer treatment courses is unlikely and when the patient can be monitored closely.
3. Available data do not suggest excessive risk for severe hepatitis associated with RIF-PZA treatment among HIV-infected persons. In a large multinational trial, HIV-infected patients treated with RIF-PZA had lower rates of serum aminotransferase (AT) elevations than those given INH alone (*3*). The RIF-PZA regimen also was well tolerated when

given twice weekly to HIV-infected persons in Zambia and Haiti (*4*,*5*). However, experience from trials may not translate to all clinical practice settings, and it may be prudent to use 9 months of daily INH for treatment of HIV-infected persons with LTBI when completion of treatment can be assured.

4. No more than a 2-weeks supply of RIF-PZA (with a PZA dose ≤20 mg/kg/d and a maximum of 2 gm/d) should be dispensed at a time to facilitate periodic clinical assessments. Patients should be reassessed in person by a health-care provider at 2, 4, and 6 weeks of treatment for adherence, tolerance, and adverse effects, and at 8 weeks to document treatment completion. At each visit, health-care providers conversant in the patients' language should instruct patients to stop taking RIF-PZA immediately and seek medical consultation if abdominal pain, emesis, jaundice, or other hepatitis symptoms develop. Provider continuity is recommended for monitoring.
5. A serum AT and bilirubin should be measured at baseline and at 2, 4, and 6 weeks of treatment in patients taking RIF-PZA. Because some side effects may occur in the second month of treatment, patients should be monitored throughout the entire course of treatment. Asymptomatic serum AT increases are expected and usually do not require that treatment be stopped (*2*,*3*). However, treatment should be stopped and not resumed for any of these findings: AT greater than five times the upper limit of normal range in an asymptomatic person, AT greater than normal range when accompanied by symptoms of hepatitis, or a serum bilirubin greater than normal range.

The following considerations are crucial in deciding whom to test and treat for LTBI:

1. The purpose of targeted testing is to find and treat persons who have both LTBI and high risk for TB disease (e.g., recent exposure to a contagious case) (*2*). Persons at low risk for developing TB and who have had a TST for other reasons, such as baseline TST of health-care workers, are not necessarily candidates for treatment if found to be infected (*2*).
2. Treatment is recommended for foreign-born persons from countries with a high prevalence of TB who have LTBI and who have been in the United States <5 years (*2*). After 5 years, treatment decisions should be made on the same basis as other patients.
3. Because sporadic severe INH-associated liver injury still occurs, patients taking INH should be monitored as recommended (*2*).

CDC is collecting reports of severe liver injury (i.e., leading to hospital admission or death) in persons receiving any regimen for LTBI. Reports are being analyzed to assess contributing factors. Report possible cases to the Division of Tuberculosis Elimination; telephone (404) 639-8125.

Update: Adverse Event Data and Revised American Thoracic Society/CDC Recommendations Against the Use of Rifampin and Pyrazinamide for Treatment of Latent Tuberculosis Infection---United States, 2003

CDC has reported previously surveillance data of severe liver injury in patients treated for latent tuberculosis infection (LTBI) with a daily and twice-weekly 2-month* regimen of rifampin with pyrazinamide (RZ). On the basis of these initial reports, CDC cautioned clinicians in the use of this therapy with advised additional monitoring (*1*--*4*). To estimate the incidence of RZ-associated severe liver injury and provide more precise data to guide treatment for LTBI, CDC collected data from cohorts of patients in the United States who received RZ for the treatment of LTBI during January 2000--June 2002 and for whom data were reported to CDC through June 6, 2003. This report summarizes the analysis, which found high rates of hospitalization and death from liver injury associated with the use of RZ. On the basis of these findings, the American Thoracic Society (ATS) and CDC now recommend that this regimen should generally not be offered to persons with LTBI. The revised ATS/CDC recommendations described in this report have been endorsed by the Infectious Diseases Society of America (IDSA). Clinicians are advised to use the recommended alternative regimens for the treatment of LTBI (Table). Rifampin and pyrazinamide (PZA) should continue to be administered in multidrug regimens for the treatment of persons with active tuberculosis (TB) disease (*5*).

For surveillance purposes, a case of severe liver injury was defined as one leading to the hospitalization or death of a patient being treated for LTBI with RZ (*2*). During October 2000--June 2003, CDC received reports of 48 patients who had confirmed cases; 33 (69%) cases occurred in the second month of treatment. A total of 11 (23%) patients died†, including two persons known to be infected with human immunodeficiency virus (HIV).

A two-phase retrospective survey was conducted to estimate the incidence of severe liver injury among persons receiving RZ for treatment of LTBI. In December 2001 (phase I), CDC sent a questionnaire by e-mail to TB-control programs in 12 large cities and all 50 states, asking them to identify programs and health-care providers prescribing RZ for treatment of LTBI. All controllers responded, and in February 2002, CDC staff called the programs and health-care providers identified as prescribing RZ for LTBI to confirm its use. In September 2002 (phase II), CDC mailed a second questionnaire to the 150 health-care providers identified during the first phase, requesting aggregate cohort data for January 2000--June 2002; 109 (78%) health-care providers responded by June 6, 2003.

Of 7,737 patients who were reported to have started RZ for treatment of LTBI during the survey period, 5,980 (77%) received daily doses, and 1,757 (23%) received twice-weekly doses. A total of 204 patients discontinued using RZ because of aspartate aminotransferase (AST) concentrations greater than five times the upper limit of normal (rate: 26.4 per 1,000 treatment initiations; 95% confidence interval (CI) = 22.8--30.0). An additional 146 patients discontinued using RZ because of symptoms of hepatitis (rate: 18.9 per 1,000 treatment initiations; 95% CI = 17.4--20.4).

Of the 48 cases of severe liver injury reported to CDC through passive surveillance, 30 also were detected in the second phase of the survey. Of the 18 patients whose cases were not detected, six patients had liver injuries outside the survey period, five patients' health-care providers did not respond to the questionnaire, and seven (six of whom were in private practice) were not identified in the first phase of the survey. Of the 30 patients whose cases were detected, 23 (77%) recovered, and seven (23%) died. On the basis of these 30 cases, the estimated rates of hospitalization and death during the survey period were 3.0 (95% CI = 1.8--4.2) and 0.9 (95% CI = 0.2--1.6) per 1,000 treatment initiations, respectively.

Reported by: *State and territorial health depts. Div of Tuberculosis Elimination, National Center for HIV, STD, and TB Prevention, CDC.*

Editorial Note:

The CDC cohort analysis found that the rates of severe liver injury and death related to the use of RZ are higher than the rates for isoniazid (INH)-associated liver injury in the treatment of LTBI. Although initial studies attributed hospitalization rates as high as 5.0 per 1,000 treatment initiations and mortality rates as high as 1.0 per 1,000 to INH (*6,7*), studies conducted since 1991 involving more than one million persons treated with INH have reported hospitalization rates of 0.1--0.2 (median: 0.15) and mortality rates of 0--0.3 per 1,000 (median: 0.04) (*4,8,9*). This decrease from earlier studies might reflect careful selection of patients and active monitoring for early signs of adverse events. In addition to the survey on the use of RZ described in this report, recent studies have reported episodes of liver injury and hospitalization associated with RZ for treatment of LTBI (*10,11*), including the need for transplantation in one patient (*12*). Among first-line agents in the treatment of active TB disease, pyrazinamide (PZA) might be the most hepatotoxic (*13*).

These data and other recent studies (*4,10,11,14--16*) were reviewed by TB experts[§] at a meeting held during the 99th International ATS Conference in Seattle, Washington, on May 12, 2003, to discuss proposed revisions to guidelines for the treatment of LTBI. ATS and CDC now recommend that this regimen should generally not be offered to persons with LTBI for either HIV-negative or HIV-infected persons. On the basis of the investigation of potential cofactors in the 48 patients with serious liver injury, this regimen should never be offered to patients who 1) are concurrently taking other medications associated with liver injury; 2) drink excessive amounts of alcohol, even if alcohol use is discontinued during treatment; 3) have underlying liver disease; or 4) have a history of INH-associated liver injury.

If the potential benefits of this regimen outweigh the risk for severe liver injury and death associated with it, use of RZ might be considered in carefully selected patients, but only if 1) the preferred or alternative regimens (i.e., 9 months of daily or biweekly INH, 6 months of daily or biweekly INH, or 4 months of daily rifampin) are judged not likely to be completed and 2) oversight by a clinician with expertise in the treatment of LTBI can be provided. A TB/LTBI expert should be consulted before RZ is offered. In addition, patients should be asked whether they have had liver disease or adverse effects from taking INH or other drugs, informed of potential hepatotoxicity of the RZ regimen, and advised against the concurrent use of potentially hepatotoxic drugs, including over-the-counter drugs such as acetaminophen.

To facilitate periodic clinical assessments of persons taking an RZ regimen (2), clinicians should dispense no more than a 2-week supply (with a daily PZA dose of <20.0 mg/kg/d [maximum daily PZA dose: 2.0 g], and a twice-weekly dose of <50.0 mg/kg/d [maximum twice-weekly PZA dose: 4.0 g]). Patients should be reassessed in person by a health-care provider at 2, 4, 6, and 8 weeks of treatment for adherence, tolerance, and adverse effects. The 8-week assessment also should be used to document treatment completion. At each visit, health-care providers who speak the patient's own language should instruct the patient to stop taking RZ immediately and seek medical consultation if abdominal pain, emesis, jaundice, or other symptoms of hepatitis develop. Provider continuity is recommended for optimal monitoring.

For persons taking this regimen, serum aminotransaminases (AT) and bilirubin should be measured at baseline and at 2, 4, 6, and 8[¶] weeks of treatment. Because the majority of these patients had onset of symptoms of liver injury after the fourth week of therapy (Figure), patients should be monitored throughout the entire course of treatment. Use of RZ should be discontinued immediately and not resumed for any of

the following findings: 1) AT greater than five times the upper limit of normal range in an asymptomatic person, 2) AT greater than normal range when accompanied by symptoms of hepatitis, or 3) a serum bilirubin concentration greater than the normal range, whether or not symptoms are present.

The risk for progression from LTBI to active TB is increased substantially in persons with HIV infection (*4*). Therefore, as recommended previously for the treatment of all persons in whom LTBI is diagnosed, voluntary HIV counseling and testing should be offered routinely.

For progression to TB disease to be prevented, persons with LTBI should be identified in contact investigations and targeted screening programs and should complete treatment with safe and effective regimens. The successful treatment of LTBI is an essential component of the TB elimination strategy in the United States (*4*). In addition to this report, CDC and its partners are sending a letter to TB-control programs in 12 large cities and all 50 states and organizations active in TB control (e.g., the National Coalition to Eliminate Tuberculosis). To reach clinicians who are treating patients with LTBI, primary care medical associations (e.g., the American Medical Association and the American College of Physicians) are distributing this report to their members. This report and the letter are available at http://www.cdc.gov/tb. The letter is being added to the April 2000 CDC Targeted Tuberculin Testing and Treatment of Latent TB Infection Guidelines, and existing provider educational materials are being revised.

The recommendations against the use of RZ for treatment of LTBI described in this report do not apply to the appropriate use of rifampin and PZA in multidrug regimens for the treatment of persons with active TB disease. In these circumstances, the risk for morbidity and mortality from TB disease is substantially greater than with LTBI. Rifampin and PZA are essential components of recommended ATS/CDC/IDSA regimens that render patients noninfectious rapidly and are effective in curing patients with drug-susceptible *M. tuberculosis* strains within 6 months (*5*).

CDC continues to collect reports of severe liver injury leading to hospital admission or death in persons receiving any treatment for LTBI. Health-care providers are encouraged to report such events to CDC's Division of Tuberculosis Elimination, telephone 404-639-8442. Details of the RZ survey analysis and the case series will be described in a separate publication.

* The twice-weekly rifampin and pyrazinamide regimen for treatment of LTBI was specified to be completed within 2--3 months.

† Of the 11 deaths, eight were reported previously (*1*--*3*).

§ Representatives from state and local TB-control programs and health departments and hospitals, National TB Centers, ATS, the National Coalition to Eliminate Tuberculosis, the National Tuberculosis Controllers Association, Infectious Diseases Society of America, the American College of Chest Physicians, and CDC. CDC met separately with the Food and Drug Administration.

¶ In the interim revised recommendations, biochemical monitoring at 2, 4, and 6 weeks was recommended (*2*); however, because of the occurrence of serious adverse events late in the course of RZ treatment, monitoring at 8 weeks has been added.

Table

TABLE. Revised drug regimens for treatment of latent tuberculosis infection (LTBI) in adults*

Drug	Interval and duration	Comments†	Rating§ (Evidence)¶ HIV-negative	HIV-infected
Isoniazid	Daily for 9 months**††	In HIV-infected persons, isoniazid may be administered concurrently with nucleoside reverse transcriptase inhibitors (NRTIs), protease inhibitors, or non-nucleoside reverse transcriptase inhibitors (NNRTIs).	A (II)	A (II)
	Twice weekly for 9 months**††	Directly observed therapy (DOT) must be used with twice-weekly dosing.	B (II)	B (II)
Isoniazid	Daily for 6 months††	Not indicated for HIV-infected persons, those with fibrotic lesions on chest radiographs, or children.	B (I)	C (I)
	Twice weekly for 6 months††	DOT must be used with twice-weekly dosing.	B (II)	C (I)
Rifampin§§	Daily for 4 months	Used for persons who are contacts of patients with isoniazid-resistant, rifampin-susceptible TB. In HIV-infected persons, most protease inhibitors or delavirdine should not be administered concurrently with rifampin. Rifabutin with appropriate dose adjustments can be used with protease inhibitors (saquinavir should be augmented with ritonavir) and NNRTIs (except delavirdine). Clinicians should consult web-based updates for the latest specific recommendations.	B (II)	B (III)
Rifampin plus pyrazinamide (RZ)	Daily for 2 months	RZ generally should not be offered for treatment of LTBI for HIV-infected or HIV-negative persons.	D (II)	D (II)
	Twice weekly for 2–3 months		D (III)	D (III)

* Adapted from CDC. Targeted tuberculin testing and treatment of latent tuberculosis infection. MMWR 2000;49(No. RR-6).
† Interactions with human immunodeficiency virus (HIV)–related drugs are updated frequently and are available at http://www.aidsinfo.nih.gov/guidelines.
§ Strength of the recommendation:
A. Both strong evidence of efficacy and substantial clinical benefit support recommendation for use. Should always be offered.
B. Moderate evidence for efficacy or strong evidence for efficacy but only limited clinical benefit supports recommendation for use. Should generally be offered.
C. Evidence for efficacy is insufficient to support a recommendation for or against use, or evidence for efficacy might not outweigh adverse consequences (e.g., drug toxicity, drug interactions) or cost of the treatment or alternative approaches. Optional.
D. Moderate evidence for lack of efficacy or for adverse outcome supports a recommendation against use. Should generally not be offered.
E. Good evidence for lack of efficacy or for adverse outcome support a recommendation against use. Should never be offered.
¶ Quality of evidence supporting the recommendation:
I. Evidence from at least one properly randomized controlled trial.
II. Evidence from at least one well-designed clinical trial without randomization from cohort or case-controlled analytic studies (preferably from more than one center), from multiple time-series studies, or from dramatic results from uncontrolled experiments.
III. Evidence from opinions of respected authorities based on clinical experience, descriptive studies, or reports of expert committees.
** Recommended regimen for persons aged <18 years.
†† Recommended regimens for pregnant women.
§§ The substitution of rifapentine for rifampin is not recommended because rifapentine's safety and effectiveness have not been established for patients with LTBI.

POLICY STATEMENT

The Teen Driver

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Injury, Violence, and Poison Prevention
Committee on Adolescence

ABSTRACT

Motor vehicle–related injuries to adolescents continue to be of paramount importance to society. Since the original policy statement on the teenaged driver was published in 1996, there have been substantial changes in many state laws and much new research on this topic. There is a need to provide pediatricians with up-to-date information and materials to facilitate appropriate counseling and anticipatory guidance. This statement describes why teenagers are at greater risk of motor vehicle–related injuries, suggests topics suitable for office-based counseling, describes innovative programs, and proposes preventive interventions for pediatricians, parents, legislators, educators, and other child advocates.

MAGNITUDE OF THE PROBLEM

Motor vehicle crashes continue to be the leading cause of death for 16- to 20-year-olds, accounting for approximately 5500 occupant fatalities annually (27 deaths per 100 000 population).[1] Each year, approximately 450 000 teenagers are injured, and 27 000 of them require hospitalization.[1,2] Of those killed, approximately 63% are drivers and 37% are passengers. Two thirds of the teenagers who die in automobile crashes are male.[1]

In 2004, 7700 teenaged drivers were involved in a crash in which someone died. Although the 12 million adolescent drivers represent only approximately 6% of total drivers, they account for approximately 14% of the fatal crashes.[3] In terms of total crashes per million miles driven, 16- to 19-year-olds have a crash rate almost twice that of 20- to 24-year-olds, almost 3 times that of 25- to 29-year-olds, and more than 4 times that of 30- to 69-year olds.[4] Within the 16- to 19-year age range, the youngest drivers have the highest risk. The crash rate for 16-year-olds (35 crashes per million miles) is much higher than that even for 17-year-olds (20 crashes per million miles) and is almost 9 times greater than that of the general population of drivers (4 crashes per million miles).

ADOLESCENT RISK FACTORS

Inexperience

The adolescent, as a novice driver, lacks the experience and ability to perform many of the complex tasks of ordinary driving. Compared with experienced drivers, the novice adolescent driver is less proficient in detecting and responding to hazards and controlling the vehicle, especially at higher speeds. The risk of having a crash during the learner-permit stage is low, because the teenager is supervised and is generally not driving in high-risk conditions.[4] In contrast, data from Nova Scotia show that the highest crash rate is seen during the first month after the teenager gets his or her license (120 crashes per 10 000 drivers).[5] After

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

the first month, the crash rate decreases rather quickly over the next 5 months (70 crashes per 10 000 drivers) and then shows a slower decline for the next 18 months (50 crashes per 10 000 drivers). Because rapid improvement is seen over such a short time period, inexperience appears to be a much more important factor in crash rates than young age. Although these data also show that driver experience improves driving skills, traditional driver education programs usually provide only 6 hours of on-the-road training.

Risk Taking

It is normal for adolescents to take chances, succumb to peer pressures, overestimate their abilities, and have emotional mood swings. These behaviors can all place the teenaged driver at greater risk of having automobile crashes. Males seem to be at especially high risk, possibly as a result of social norms and media images that equate fast driving and ability to perform difficult driving maneuvers as masculine.[6] In 2004, 38% of male and 25% of female drivers 15 to 20 years of age involved in fatal crashes were speeding at the time of the crash.[7] These rates were higher than for any other age group. It must be stressed, however, that the great majority of nonfatal crashes involving 16-year-old drivers result from inexperience rather than from speeding or patently risky behavior.[8]

There is evidence from MRI research that the prefrontal cortex (the area of the brain responsible for planning, impulse control, and executive decision-making) does not mature fully until the early to mid-20s.[9] Although some legislators are using such brain-development research to support limits on teenaged driving, no scientific data have yet been published that link driving behavior to neuroimaging findings.

Teenaged Passengers

With adolescent drivers, the chance of being involved in a car crash is directly proportional to the number of teenaged passengers being transported.[4,10] Compared with driving alone, 16- to 17-year-olds have a 40% increased risk of crashing when they have 1 friend in the car, double the risk with 2 passengers, and almost 4 times the risk with 3 or more teenaged passengers. This relationship was not seen with adult drivers and is much less marked with 18- to 19-year-old drivers.[4]

The most dangerous way a teenager can get to and from school is by driving in a car with a teenaged driver.[11] Open-campus school lunch policies, in which groups of teenagers drive away from school to eat, are also associated with high crash rates.[12] The underlying reasons that teenaged passengers increase driving risk are not clear. In addition to general distraction, intentional encouragement of risky driving behavior and other social interactions may play a role. For both male and female teenaged drivers, the presence of a male passenger results in faster speeds and more risky driving behaviors than does the presence of a female passenger.[13]

Nighttime Driving

Young teenaged drivers (16- and 17-year-olds) have a higher rate of nighttime crashes than do drivers of any other age group. Before nighttime driving curfews were instituted widely, only 14% of the miles driven by 16- to 17-year-old drivers occurred between 9 PM and 6 AM, yet this time period accounted for 32% of fatal crashes in this age group. Although nighttime restrictions for teenagers commonly limit driving after midnight, 58% of the fatal nighttime crashes occur in the 3-hour period before midnight.[14] For young teenaged drivers, fatal nighttime crashes are more likely to be associated with multiple teenaged passengers, speeding, and alcohol use.[15] Although it is inherently more difficult to drive in the dark for drivers of all ages, fatigue and lack of practice may play a greater role for teenagers.

Alcohol, Marijuana, and Medications

During the period 1982–2001, fatal alcohol-related crash rates decreased by 60% for 16- to 17-year-old drivers.[16] In 1982, 31% of teenagers fatally injured had an especially high blood alcohol concentration (BAC) of 0.10% or greater, but this statistic dropped to 12% by 1995–2001. Teenagers drink and drive less often than adults, but their crash risks are higher than adults when they do drink, especially at low and moderate BACs.[17] In the 2005 Youth Risk Behavior Surveillance Study, 9.9% of 9th- through 12th-graders said that in the last month they had driven after drinking, and 28.5% admitted to riding with a driver who had been drinking.[18]

The prevalence of acute marijuana use among drivers is estimated to be 1% to 6%.[19] Of those drivers involved in severe injury crashes, positive cannabis levels or self-reports of recent use have been found in higher numbers (6%–25%),[19–21] suggesting a relationship between marijuana and crashes. Much, but not all, of this relationship may be the result of other risky driving habits (positive BAC, no seat belt, speeding, sleepy while driving) that often are associated with marijuana use.[19,20]

In a study of 414 injured drivers (all ages) in Colorado, urine toxicology assays detected marijuana more frequently than alcohol (17% vs 14%).[22] Evidence from experimental studies has demonstrated impaired performance on various driving skills tests after the use of marijuana.[23] Furthermore, when just moderate doses of alcohol and marijuana were used together, a dramatic deterioration in driving performance (swerving, slowed reaction time) resulted.

A variety of prescription and over-the-counter medications, such as sedatives, analgesics, sedating antihistamines, stimulants, and antihypertensives, may have detrimental effects on driving abilities. Drug combinations and drugs mixed with alcohol can be especially

problematic. A single 50-mg dose of diphenhydramine has been shown to have a greater effect on driving performance than a BAC of 0.10%.[24] Failure to warn patients about the possibility of driving impairment from medications has resulted in successful lawsuits against physicians.

Safety Belts

As with adults, low safety belt use by teenagers results in preventable injuries and deaths. Approximately 82% of all motorists wear safety belts, but the rate reported by the National Center for Statistics and Analysis for 16- to 24-year-olds is 77%.[25] In a study of teenaged drivers who were observed arriving at high school, only 62% were wearing their seat belts.[26] The passengers of these teenaged drivers wore restraints only 47% of the time. Analysis of fatal crashes with teenaged drivers demonstrates that safety belt use is lower in high-risk situations (driving under the influence of alcohol, nighttime driving, having multiple teenaged passengers, when the car is older, and when the driver is male or unlicensed or has a suspended license). Safety belts were used by only 18% of drivers with a BAC of 0.10% or higher, compared with 40% of sober drivers.[27]

For teenaged occupants, approximately 58% of those who were killed in automobile crashes in 2004 were unbelted.[1] Because safety belts have been shown to be 45% effective in preventing front-seat fatalities, many of these deaths could have been prevented.[28] Air bags alone have been found to be only 10% effective in preventing deaths.[29] The reasons teenagers give for not wearing seat belts include not "cool," peer pressure, wrinkles clothes, traveling short distance, and feeling that "nothing will happen to me."[30] Almost half of teenagers (47%) say they feel that safety belts are "as likely to cause harm as to help," 27% said wearing a safety belt makes them "worry more about being in an accident," and 30% indicated they would feel "self-conscious if they were going against the group norm in wearing safety belts."[31] Only 27% of the actors playing motor vehicle occupants in 25 recent G-rated and PG-rated films were portrayed wearing safety belts.[32]

Vehicles Driven

There is evidence that adolescents are more likely than adults to drive smaller and older-model cars, especially if the teen is the owner of the car.[33,34] This is problematic, because smaller cars provide less crash protection than larger cars, and older-model cars often have fewer modern safety features.[35] When teenagers drive sport utility vehicles, they are significantly more likely to have a rollover than are drivers older than 24 years.[36] Sporty cars with high-performance features may encourage speeding.[37] One survey showed that parents choose cars for their teenagers more on the basis of price and style than on the basis of safety features.[33]

Distractions Including Cellular Phones

Distractions are contributing factors for motor vehicle crashes for both adolescents and adults. Eating, drinking, and adjusting the radio or the climate controls each cause more crashes than cellular phone use.[38] Cellular phone use has been estimated to increase crash rates by fourfold,[39] and hands-free models are not associated with significantly less risk.[40] There is some evidence that distractions may be a greater problem for the inexperienced driver. Distracted novice drivers tend to glance away from the road for longer periods of time, during which they have trouble responding to hazards and staying in their lane.[41]

Unlicensed Drivers

Drivers without valid licenses (unlicensed, revoked, suspended) tend to be younger and male, are more apt to have been involved in a fatal nighttime crash or to have a recent conviction for driving while intoxicated, and are more likely to have had multiple license suspensions. Approximately 5% of drivers younger than 20 years who have been involved in a fatal crash were driving with their license suspended or revoked, and 10% had never held a license.[42] Unlicensed teenaged drivers are 5 times more likely to have had a conviction for driving while intoxicated and 3 times more likely to have had a previous license suspension than are fatally injured teenagers with valid licenses.[3]

Attention-Deficit/Hyperactivity Disorder

Teenaged drivers with attention-deficit/hyperactivity disorder (ADHD) are 2 to 4 times more likely to be injured in a motor vehicle crash than are their peers without ADHD.[43] They are also more likely to have repeat traffic citations and to have their licenses suspended or revoked. Driving performance of teenagers with ADHD seems to improve with psychostimulant medication, primarily because of decreased errors of inattentiveness.[44] Compared with 3-times-a-day dosing of methylphenidate, longer-acting, controlled-release medication may result in better driving throughout the day and, particularly, during the evening hours.[45]

PROPOSED INTERVENTIONS

Graduated Licensing Systems

Since the American Academy of Pediatrics published the 1996 statement on the teenaged driver, almost all states have enacted some form of a graduated driver licensing (GDL) law. In the traditional 2-stage approach, after the novice passed vision and knowledge tests, he or she obtained a learner's permit. Because most states had no requirement for the permit to be held for a minimum time period, many teens moved quickly through this learning stage without much chance to develop adequate driving skills.[46] Once a specified age was reached,

the teenaged driver passed a road test and obtained an unrestricted license.

In contrast, in a GDL system, there are 3 stages: a learner's permit, an intermediate or provisional stage, and a regular driver's license. Each stage has specific components, restrictions, and minimum time requirements. To graduate to the next stage, the novice must spend the required time at the lower stage, acquire and demonstrate proficiency in driving skills, and not incur a driving violation for a defined period. The provisional stage, with its restrictions, is designed to give the novice a chance to gain extensive driving experience under low-risk conditions. Although currently there are inadequate research data to determine exactly when the permit and provisional stages should begin and for how long they should last, some consensus of expert opinion does exist.[47]

Initial evaluations of GDL programs have been encouraging. In Florida, the first state to pass a GDL law, the number of fatal crashes for 15- to 17-year-olds decreased by 9% in the year after the law was instituted.[48] A *Cochrane Database* review of 13 GDL programs found reductions in total crashes (26%–41%), crashes resulting in injuries (4%–43%), and crashes resulting in hospitalizations (35%) for 16-year-old drivers. Furthermore, these crash rates remained decreased for multiple years after the new GDL laws went into effect.[49] It is unlikely that safer driving by young teenagers is the main reason for decreased crash rates seen with GDL. Data show that after GDL laws are passed, there are fewer licensed young drivers and they are driving fewer unsupervised miles because of the imposed restrictions.[50] Between 1993 and 2003, the percentage of 16-year-olds who became licensed decreased by 26%, and there was a 13% decrease for 17-year-olds and a 5% decrease for 18-year-olds.[51] Over the same 10-year period, the likelihood that a 16-year-old license holder would be involved in a fatal crash remained unchanged (73–74 crashes per 100 000 license holders). Fatal crash rates per licensed driver were also unchanged for older teenaged drivers.

In addition to delay in licensure, it appears that the 3 provisions of GDL responsible for the most benefit are (1) limits on nighttime driving, (2) restrictions on the number of passengers during the intermediate stage, and (3) requirements that novice drivers remain crash and violation free for a certain period of time before advancing to the next level.[52] Unfortunately, many states have not incorporated these components into their laws. As of March 2006, the Insurance Institute for Highway Safety's evaluation of GDL laws rated 23 states and the District of Columbia as "good," 15 states as "fair," 11 states as "marginal," and 1 state as "poor."[53] For 15- to 17-year-old drivers, data from 1992–2002 show that good GDL programs decreased fatal crashes by 19%, fair programs reduced nighttime crashes by 13% (but had no effect on daytime crashes), and marginal laws had no measured benefit.[54]

Nighttime and Passenger Restrictions

Although GDL laws are effective, it is difficult to know how much each individual restriction contributes to improved crash and injury rates. Historically, when jurisdictions implemented general curfew ordinances for teenagers, crash and injury rates decreased substantially.[55] In the decade between 1993 and 2003, the percentage of fatal crashes that occurred between midnight and 5 AM remained unchanged (10%) for 16-year-old drivers.[51] Recently published evidence shows that in states with a driving restriction that starts before midnight, there has been a 13% decrease in evening crash fatalities for 15- to 17-year-old drivers.[54] Although there are no crash data to support the practice, many states exempt school, work, and religious activities from the nighttime driving restriction. The Insurance Institute for Highway Safety supports such an exemption, stating that "the intention is not to deny essential driving at night, but to limit high-risk recreational driving."[47]

Driving with fewer teenaged passengers has been proven safer. For 16-year-old drivers from 1993–2003, the proportion of fatal crashes involving teenaged passengers decreased from 53% to 44%.[51] Data from 1992–2002 for 15- to 17-year-old drivers show that the decrease in teenaged fatalities from passenger restrictions was more the result of fewer teenagers being put at risk rather than a substantial reduction in the "distraction factor" associated with teenaged passengers.[54] Unfortunately, many teenagers do not comply with a passenger restriction, many parents do not support it, and police frequently do not enforce it. As of March 2006, 44 states and the District of Columbia restrict nighttime driving to some degree, but only 21 states have driving curfews that start before midnight. Sixteen states still have not implemented any form of passenger restriction, and only 3 states and the District of Columbia maintain the passenger restriction until the driver is 18 years of age.[53]

Driver Education

Traditional driver education programs contain 30 hours of classroom and 6 hours of on-road instruction. Several reviews of the literature have shown that such courses are not effective in creating safe drivers and decreasing crash risk.[56] In fact, some studies show that high school driver education programs encourage early licensure of the youngest, most dangerous drivers, with resulting increased crashes, injuries, and deaths.[57,58] GDL laws provide an opportunity to redesign driver education for teenagers. Several states have recognized that traditional driver education courses do not have adequate behind-the-wheel training and have added GDL requirements for 20 to 50 hours of supervised driving (5–10 hours at night) during the initial permit stage. Furthermore, a

2-step approach has been suggested (but not yet widely implemented or evaluated) in which the basic course in vehicle handling and "rules of the road" are taught during the permit stage. In the second step, the intermediate stage, the student would be required to take a more advanced safety course in which skills such as hazard recognition, avoidance of risk, and adjusting to road and weather conditions are taught.[59] Courses that teach skid control and advanced maneuvering techniques should be avoided by novice drivers, because they can encourage overconfidence and a more aggressive driving style, resulting in increased crash rates.[60]

It has been suggested that driving experience, not training, is the key to becoming a safer driver.[61] When permit and provisional stages are shortened and training time is reduced for graduates of formal driver education programs, crash rates increase.[62] Some states have lowered the permit age to allow for more supervised practice, but this could potentially lead to early licensure of the youngest, most dangerous drivers.

The American Automobile Association and other organizations sell driver education materials including instruction manuals, log books, videotapes, and CD-ROMs that are designed to help parents supervise this on-road training.[63] Relatively inexpensive driving-simulation programs for use on a home computer may be beneficial in helping students learn to identify road hazards.[63,64] Whether practice on such simulators translates into safer driving or decreased crashes remains to be shown.

Alcohol-Related Measures

Two types of alcohol-related regulations exist: minimum drinking-age laws and drunk-driving laws. The latter include "zero-tolerance" alcohol laws and regulations for licensure suspension or revocation. All 50 states currently have minimum drinking-age laws that prohibit the sale of alcohol to anyone younger than 21 years. An analysis of 46 scientific studies on the efficacy of raising the minimum legal drinking age to 21 years showed a 17% median decrease in fatal automobile crashes in adolescents.[65] The National Highway Traffic Safety Administration estimates that minimum legal drinking-age laws have saved the lives of almost 24 000 18- to 20-year-olds since 1975.[3] Unfortunately, youth can still obtain alcohol relatively easily, and underaged drinkers are rarely caught or punished. For example, a study in a metropolitan area of northern California showed that minors were able to purchase alcohol in 39% of attempts.[66]

By 1998, all states had passed zero-tolerance laws that set a maximum BAC of 0.02% or less for young drivers. An offender is faced with administrative (not involving the courts) suspension or revocation of his or her driver's license. Meta-analysis of several studies revealed that fatal crash rates decreased 9% to 24% after zero-tolerance laws were enacted.[65] These laws work both by deterring youth through fear of losing their driver's license if they drive after drinking and by reinforcing the broad community disapproval of drinking and driving. Although underaged drinking is prevalent and often tolerated, drinking and driving has become less socially acceptable among youth.[67] There is evidence that drunk driving is influenced more by friends' approval or disapproval than by fear of arrest and sanction.[68]

Although youth and community educational programs such as Mothers Against Drunk Driving (MADD) and Students Against Destructive Decisions (SADD) have the potential to change knowledge and attitudes, there is little evidence to prove that they have a direct effect on youth drinking and alcohol-related driving.[67] Using a designated driver has become common, but in many instances the designated driver does not abstain from drinking alcoholic beverages.[69] On the other hand, there is significant evidence that sobriety checkpoints, an aggressive enforcement strategy, can decrease crash rates by approximately 20%.[65] Sobriety checkpoints are designed to be a deterrent to alcohol-related driving and are most effective when heavily publicized so that drivers perceive that there is a significant chance they will be caught and arrested.

Improved Safety Belt Laws

There are 2 types of safety belt laws: primary and secondary. With a primary law, a police officer can issue a citation when he or she simply observes an unbelted occupant. With secondary laws, a safety belt citation can be written only after the officer has stopped the car for another infraction. As of September 2005, 21 states and the District of Columbia have primary laws, but many of those laws are limited to the driver and front-seat passengers.[70] Safety belt use is approximately 85% in states with primary laws but only 75% in states with secondary laws.[71] Teenaged drivers killed during 1995–2000 were wearing safety belts 47% of the time in states with primary laws but only 30% of the time in states with secondary laws.[72]

Highly visible strict enforcement is the key to increasing use of restraints. People will buckle up if they perceive that they are likely to be fined. Selective traffic enforcement programs with intense media publicity and increased police patrols have been shown, at least in the short term, to increase safety belt use by 8% to 24% and decrease fatal and nonfatal injuries by 7% to 15%.[29]

GDL laws that include requirements that prohibit graduation to the next phase for a safety belt citation may be effective.[73] Although many states do require all passengers with an intermediate licensed driver to be restrained, many parents and teenagers may not be aware of this regulation.[74] Community programs that combine education, peer-to-peer persuasion, publicized enforcement (especially in schools), and parental monitoring may have some potential for increasing safety

belt use among teenagers.[73,75] Economic incentives may also increase safety belt use.[76] Technologic solutions, such as electronic safety belt reminders, safety belt use recorders, and interlock systems that do not allow the car stereo to function unless the safety belt is fastened, may be valuable but require further evaluation.[73]

Parental Interventions

With regard to teenaged driving, parents have several roles: (1) give permission for the teenager to obtain a license, (2) control access to the vehicle, (3) set family restrictions and punishments for infractions, (4) influence selection of the vehicle, (5) be a driving instructor and supervisor, and (6) serve as a role model for safe driving. Unfortunately, parents are often completely unaware of their teenager's risky driving habits.[77] They tend to place more restrictions on the details of the trip (permission, destination, time home) than on dangerous driving conditions (eg, night driving with teenaged passengers).[78]

Risky teenaged driving behaviors, traffic violations, and crashes are less common when parents impose strict limitations.[79] Although not yet studied in great detail, parent-teenager written driving contracts that clearly delineate rules and consequences may result in better communication, more restrictions, and safer parent and teenager attitudes.[78,80,81] To date, there is insufficient evidence that such contracts improve driver safety or decrease violations and crashes.

Emerging technologies, such as on-board cameras and computers, allow parents to determine whether their teenager is driving safely, but this approach has not yet been evaluated. Finally, parents must recognize their importance as positive role models in terms of safe driving and safety belt use. Parents with bad driving records are much more likely to have children who get traffic citations and are involved in motor vehicle crashes.[82]

RECOMMENDATIONS

Because motor vehicle crashes pose a major, continuing threat to the health of teenagers, the American Academy of Pediatrics makes the following recommendations.

Anticipatory Guidance by Pediatricians

Pediatricians should:

- Know their state laws regarding teenaged drivers, the teenaged driver-licensing process, and physician reporting requirements for medical conditions that could impair driving ability.
- Distribute educational materials about local GDL programs and teenaged driver safety to their adolescent patients (see Appendix 1).
- Alert parents and teenagers to high-risk situations for teenaged drivers (Table 1).

TABLE 1 Contributors to Teenaged Driver Crashes and Injury

Lack of driver experience
Young age at licensure
Failure to use safety belts
Inadequate hazard-perception skills
Distraction (cellular phone, food, drink, music)
Transporting teenaged passengers
Nighttime driving
Speeding and reckless driving
Fatigue
Unsafe vehicle choice
Alcohol use
Drug or medication use
Inadequate parental limit setting
Unlicensed or revoked license
ADHD

- Encourage seat belt use.
- Discourage distractions when driving (eating, drinking, music, cellular phones).
- Encourage teenager-parent written contracts (see Appendix 2 for sample) that place restrictions on the teenaged driver. At a minimum, parents should place restrictions on nighttime driving (preferably after 9:00 PM) and limits on the number of teenaged passengers. Initially, the rules should be fairly strict, but they can be relaxed as the teenager becomes older and gains more driving experience.
- Counsel teenagers about the dangers of driving while impaired (under the influence of alcohol, drugs, or medications or feeling ill, tired, depressed, or angry). Encourage a "safe-ride" agreement in which the teenager agrees to call the parent rather than drive while impaired and the parent promises to assist in arranging a ride home in a nonjudgmental manner.
- Encourage parents to require that the vehicle driven by the teenager is safe and in good condition.
- Advise parents that in many states, they have the authority to request that the driver's license of their minor child be revoked.
- Encourage parents to be positive role models.
- Advise parents about the various driving schools, Web sites, computer driving simulations, and parent-supervised driving lessons that are available (Appendix 1).

Community Advocacy by Pediatricians

Pediatricians should:

- Support community efforts that encourage safe teenaged driving.
- Work with schools to encourage safety belt use and discourage alcohol use.
- Discourage school systems from continuing traditional driver education programs that are ineffective and encourage licensure of young teenagers.

TABLE 2 **Essential Features That Should Be Mandated in GDL Systems**

1. A learner-permit phase that starts no earlier than 16 y of age and lasts at least 6 mo
2. A minimum of 30 h (preferably 50 h) of adult-supervised, on-road driving during the permit stage (at least 5–10 of these supervised practice hours should be at night)
3. A provisional (intermediate) stage, with restrictions, that lasts until 18 y of age
4. A nighttime driving restriction (9:00 PM to 5:00 AM until driving with provisional license for 6 mo, followed by a midnight to 5:00 AM restriction until 18 y of age)
5. Passenger limits (unless supervised by an adult)
   a. First 6 mo with provisional license: no teenaged passengers
   b. Until 18 y of age: no more than 1 teenaged passenger
6. Prompt imposition of fines, remedial driver classes, or license suspension for violation of passenger or curfew restrictions
7. Use of safety belts and appropriate child restraints by all occupants
8. No cellular phone use while in the provisional stage
9. Zero tolerance for alcohol and provisions for administrative license revocation for drunk driving, excessive speeding, or reckless driving
10. Documented safe driving record before full licensure is granted

It is suggested that states also consider a requirement for additional supervised driver experience/education (focused on hazard recognition and risk avoidance) during the provisional stage and a requirement for an additional on-road test to graduate from provisional to full licensure.

- Discourage school policies that allow students to drive off campus for lunch.
- Encourage police to enforce GDL and seat belt laws.
- Collaborate with police and media to promote sobriety checkpoints and safety belt education and enforcement programs.

Legislative Advocacy by Pediatricians

Pediatricians should:

- Support strong GDL legislation in their states (Table 2).
- Support improvement and enforcement of laws designed to limit the purchase, possession, and consumption of alcohol by underage adolescents.
- Support primary enforcement of safety belt laws for all occupants.

Involvement of the Alcoholic Beverage and Entertainment Industries in Encouraging Responsible Behavior

Pediatricians should:

- Encourage the alcoholic beverage industry to eliminate advertising aimed at youth.
- Encourage the media to avoid portrayal of speeding and reckless driving in contexts that invite imitation.
- Encourage the media to show universal use of safety belts.

APPENDIX 1: RESOURCES FOR PEDIATRICIANS

1. American Academy of Pediatrics (www.aap.org): pediatricians can purchase a parent-teen driver agreement and fact sheet for use in their practices.
2. National Highway Traffic Safety Administration (NHTSA) (www.nhtsa.gov): the NHTSA Web site contains a booklet and a downloadable brochure about GDL (go to Traffic Safety: New Drivers). The site also has information about impaired and distracted driving, occupant protection, and other driving issues. Detailed motor vehicle crash statistics are available in the annual traffic safety facts report.
3. Insurance Institute for Highway Safety (IIHS) (www.iihs.org): the IIHS Web site contains a huge amount of information about teenaged driving and GDL programs, including specific information about the laws in each state (go to Laws & Regulations, then State Law Facts). There is also a downloadable brochure about GDL, a list of commonly asked questions about GDL, and an excellent review of the topic (Graduated Licensing: A Blueprint for North America).
4. National Safety Council (NSC) (www.nsc.org): the NSC has a publication (available for $10) titled *Teen Driver: A Family Guide to Teen Driver Safety*. This 68-page publication describes the science behind GDL recommendations and contains easy-to-understand advice for parents about setting limits and developing a teenager-parent contract.
5. AAA Foundation for Traffic Safety (www.aaafoundation.org): the AAA Foundation sells a CD-ROM with an interactive driver-simulation program for use on a personal computer (DriverZed, $13). The teenaged driver gets a chance to practice identifying and reacting to a variety of dangerous on-road situations. Similar computer simulation programs may be available from automobile insurance companies.
6. Safe Young Drivers (www.safeyoungdrivers.com): this Web site is maintained by Phil Berardelli, who wrote the book *Safe Young Drivers: A Guide for Parents and Teens*. The book (approximately $12–$15) is organized into 10 driving lessons with suggested drills and driving maneuvers to practice. The Web site has a long list of frequently asked questions about driver education.
7. Centers for Disease Control and Prevention (www.cdc.gov/ncipc): this site contains fact sheets and references about teenaged drivers and GDL. The Web-based Injury Statistics Query and Reporting System (WISQARS) can be used to find motor vehicle–related mortality and injury data according to age, gender, state, and region.
8. Network of Employers for Traffic Safety (www.trafficsafety.org): the "Novice Driver Roadmap" (available for $15) is a series of 8 practice drives, each with specific skills to be mastered. The program also contains information for the adult driving coach.
9. Substance Abuse and Mental Health Services Administration (www.samhsa.gov): the Children and Families section of the Web site contains information for parents about talking to teenagers about underaged drinking and impaired driving.
10. Daimler-Chrysler's "Road Ready Teens" (www.roadreadyteens.org): the site contains a parent guide, teen quiz, and computerized teenaged driving contract that can be easily personalized and printed.
11. Ford's "Driving Skills for Life" (www.realworlddriver.com): this Web site contains tips for parents and teenagers as well as a short program of slides and videos that focuses on hazard recognition, vehicle handling, space management, and speed management.
12. Some individual states have Web sites that contain information about their GDL programs, license-application requirements, and driver training guides for parents.
13. Several automobile insurance companies have helpful information about discounts and reward programs for teenaged drivers with excellent driving records and good grades in school.

APPENDIX 2: SAMPLE TEEN DRIVER CONTRACT

I will drive carefully and cautiously and will be courteous to other drivers, bicyclists, and pedestrians at all times. I will obey all traffic lights, stop signs, other street signs, and road makings. I will never use the car to race or to try to impress others.

I promise that I will:

- stay within the speed limit and drive safely.
- drive only when I am alcohol and drug free.
- be a passenger only with drivers who are alcohol and drug free.
- always wear a seat belt and make all my passengers buckle up.
- drive with both hands on the wheel.
- never eat, drink, or use a cellular phone while I drive.
- drive only when I am alert and in emotional control.
- never give rides to hitchhikers.

If I am impaired in any way that interferes with my ability to drive safely, I will call my parents for a ride home.

I will drive only when I have permission to use the car and I will not let anyone else drive the car unless I have permission. I will respect laws about drugs and alcohol and never allow any alcohol or illegal drugs in the car. I will only drive someone else's car if I have parental permission. I will pay for all traffic citations or parking tickets.

I will complete my family responsibilities and will maintain good grades at school.

I will contribute to the costs of gasoline, maintenance, and insurance as listed below:

_____

I agree to the following restrictions, but understand that these restrictions will be modified by my parents as I get more driving experience and demonstrate that I am a responsible driver.

For the next _____ months, I will not drive after _____ o'clock at night.
For the next _____ months, I will not transport more than ____ teenaged passengers (unless I am supervised by a responsible adult).
For the next _____ months, I won't adjust the stereo or air conditioning/heater while the car is moving.
For the next _____ months, I will not drive in bad weather.

I understand that I am not permitted to drive to "off limit" locations or on roads and highways listed below:

_____

(continued on next page)

I AGREE TO FOLLOW ALL THE RULES AND RESTRICTIONS IN THIS CONTRACT. I UNDERSTAND THAT MY PARENTS WILL IMPOSE PENALTIES (SEE BELOW), INCLUDING REMOVAL OF MY DRIVING PRIVILEGES, IF I VIOLATE THE CONTRACT. I ALSO UNDERSTAND THAT MY PARENTS WILL ALLOW ME GREATER DRIVING PRIVILEGES AS I BECOME MORE EXPERIENCED AND AS I DEMONSTRATE THAT I AM ALWAYS A SAFE AND RESPONSIBLE DRIVER.

Penalties for contract violations:

Drove after drinking alcohol or using drugs.....No driving for ____ months
Got ticket for speeding or moving violation.....No driving for ____ months
Violated night restriction.....No driving for ____ weeks/months
Violated passenger restriction.....No driving for ____ weeks/months
Broke promise about seat belts (self and others).....No driving for ____ weeks/months
Drove on a road or to an area that is "off limits".....No driving for ____ weeks/months

Signatures:

Driver_____ Date_____

Parent (or guardian)_____ Date_____

Parent (or guardian)_____ Date_____

Suggested Restrictions: Initially the restrictions on teenaged driving should be strict (no teenaged passengers and no driving after 9:00 PM). After the teenager demonstrates 6 months of SAFE driving, the restrictions may be relaxed to some degree (1 teenaged passenger, no driving after 10:00 PM or 11:00 PM). After 12 months of demonstrated safe driving, parents may choose to relax the restrictions further, depending on the maturity level of their teenager. Once the teenager obtains a full license (usually after 18 years of age), nighttime and passenger restrictions can be removed. In states with nighttime and passenger restrictions, parents should strongly consider setting stricter limits than required by law, especially for the most novice teenaged driver.

Testing for Drugs of Abuse in Children and Adolescents (RE9628)

AMERICAN ACADEMY OF PEDIATRICS

Committee on Substance Abuse

*** ABSTRACT. The American Academy of Pediatrics (AAP) recognizes the abuse of psychoactive drugs as one of the greatest problems facing children and adolescents and condemns all such use. Diagnostic testing for drugs of abuse is frequently an integral part of the pediatrician's evaluation and management of those suspected of such use. "Voluntary screening" is the term applied to many mass non-suspicion-based screening programs, yet such programs may not be truly voluntary as there are often negative consequences for those who choose not to take part. Participation in such programs should not be a prerequisite to participation in school activities. Involuntary testing is not appropriate in adolescents with decisional capacity--even with parental consent--and should be performed only if there are strong medical or legal reasons to do so. The AAP reaffirms its position that the appropriate response to the suspicion of drug abuse in a young person is the referral to a qualified health care professional for comprehensive evaluation.**

The widespread abuse of psychoactive drugs has resulted in an increase in laboratory testing to identify abusers. The significant health and social consequences of drug abuse are intensified in the pediatric population because of the added possibilities of long-term effects in a developing person. Furthermore, immature minors are often unable to make informed, autonomous decisions about their health care, creating an impediment to diagnosis and treatment.[1,2] This statement defines the position of the American Academy of Pediatrics (AAP) on laboratory testing for drugs of abuse.

The abuse of psychoactive drugs among children, adolescents, and adults is an issue of national importance.[3] Concerns have focused not only on the physiologic and behavioral impact of drug abuse on the developing child and adolescent but also on the public health hazards that drug abusers pose to others.[4] This statement presents issues relevant to laboratory testing to identify drug users and does not discuss drug abuse in children and adolescents, which the academy strenuously opposes. Proposals for involuntary urine drug screening programs are also discussed. Testing for drugs of abuse in neonates, however, is discussed in another statement by the AAP.[5] Testing student athletes for performance-enhancing drugs not identified by routine urine toxicology tests, such as anabolic steroids and growth hormone, is not addressed.

SCREENING VERSUS DIAGNOSTIC TESTING

Screening refers to a test, examination, or procedure performed on a population to identify asymptomatic disease in apparently well persons for the purpose of early detection and treatment. Screening tests are rarely diagnostic, and confirmatory tests are usually required for a definitive diagnosis.[6,7] Diagnostic testing, however, involves specific procedures that are performed when the possibility of a disease is identified by screening, medical or social history, or physical examination. The following examples apply these principles to the identification of drug abuse. An example of screening would be the random testing of the urine of each adolescent who presents to the pediatrician's office, whereas an example of diagnostic testing would be the analysis of an individual patient's urine in whom specific signs and symptoms are indicative of substance abuse. Other examples of diagnostic testing include the laboratory confirmation of suspected drug abuse as a contributory cause of acute injuries in an adolescent patient in the emergency department and the monitoring of abstinence as part of an agreed-to substance abuse treatment program.[1,5]

The procedure used for both screening and diagnostic testing is commonly known as a urine drug screen. A drug screen ordered from a laboratory should not be confused with a drug screening program. A drug screen is a battery of tests performed on a specimen to identify the presence of one or more drugs. A laboratory report that indicates the presence of drugs should be based on a confirmatory test of high specificity. In addition, the laboratory must be certified, with the clinician being aware of its capabilities and limitations for drug testing, because these vary from facility to facility.[6,7]

INVOLUNTARY VERSUS VOLUNTARY TESTING

Voluntary testing is an imprecise concept when implemented in a population that is generally considered incompetent to consent. Therefore, testing can only be truly voluntary among young people considered competent, including many older adolescents.[2] (Decisional competency in this statement refers to the patient's ability to understand the relationship between the use of a drug, its consequences, and testing for the presence of the drug in the patient's body. The patient whose cognitive development has reached the stage of formal operational thinking approaches an ability for decisional competency. This developmental achievement reflects an ability to conceptualize cause-and-effect phenomena.)[8] However, it is not clear why such individuals would volunteer to be tested, because those who are using drugs will presumably decline. Those who have not used drugs for several days or longer may consent to testing to obtain a negative test result. Voluntary testing, therefore, is not likely to detect most drug users.

Although so-called voluntary programs may have some perceived benefits, such as providing a legitimized reason to reject peer pressure, they also can be used to coerce a person into being screened. If the majority of a group, such as an athletic team, agrees to be screened, those who refuse may be stigmatized to a degree that they feel forced into submitting. Such required voluntary group screening programs are not truly voluntary. For these reasons, the primary focus of this statement is on proposals to screen adolescents involuntarily.

REASONS FOR INVOLUNTARY SCREENING

Two reasons are generally advanced for involuntary drug screening to identify drug abuse: health promotion by identifying candidates for treatment and identifying abusers for purposes of punishment.

Health Promotion by Identifying Candidates for Treatment

The AAP does not object to diagnostic testing for the purpose of drug abuse treatment. Testing should be approached in a fashion similar to diagnostic testing for other diseases, which includes obtaining informed consent from individuals with decisional capacity. Involuntary testing would be justified only if the adolescent were at risk of serious harm that could be averted only if the specific drug were identified. If the treatment and therapy would not be changed by testing, involuntary testing would not be justified.[9-12]

Involuntary drug screening is often a condition of high school sports participation. In June 1995, a US Supreme Court ruling held that random drug testing of high school athletes is constitutional.[13] Screening would be an appropriate school requirement if the purpose were to identify conditions that, when combined with physical activity, may be hazardous to the student's health. Requiring the involuntary screening of athletes for illicit drug use, however, is often not motivated primarily by this consideration.[11,14] If the promotion of good health were the primary purpose of drug screening, the entire adolescent population--not only athletes--would be required to undergo screening because of the prevalence of illicit drug, alcohol, and tobacco use. The social, personal, and financial costs of such a program would be prohibitive, and the implication of a comprehensive non-suspicion-based screening program would be far reaching.

Because serious legal consequences may result from a positive drug screen, it is a minimal requirement that there be candid discussion regarding confidentiality and the need for informed consent from a competent individual.[2] If confidentiality issues are adequately addressed, a competent adolescent may consent to testing and counseling without the knowledge of parents, police, or school administrators.

Identification for Purposes of Punishment

Minors should not be immune from the criminal justice system, but physicians should not initiate or participate in a criminal investigation except when required by law, as in the case of court-ordered drug testing or child abuse reporting. Legal requirements for testing include an existing statute or a specific binding order. Physician involvement in police work creates the risk of establishing an adversarial rather than therapeutic relationship with a patient. There also may be constitutional objections to such activities based on privacy considerations, immunities against unwarranted search and seizure, and protection from self-incrimination. If an individual is suspected of criminal behavior, the police should obtain authorization to search for drugs and/or test for drug abuse unless specifically mandated by local statute.

Similarly, pediatricians should cautiously regard requests to initiate drug screening programs in schools where results might be used for punitive purposes or where confidentiality may be difficult to maintain. A positive therapeutic relationship with a child or adolescent should always be of paramount concern.[15] Therefore, physicians should avoid involvement with involuntary screening programs or participation in covert drug testing.

PRACTICAL CONSIDERATIONS

Screening or testing under any circumstances is improper if clinicians cannot be reasonably certain that the laboratory results are valid and that patient confidentiality is assured. This requires careful attention to the collection of specimens; the labeling, storage, and transfer of specimens to the laboratory; the avoidance of errors in recording or communicating results; the protection of the confidentiality of results; and the assurance that the techniques for identification of drugs are reliable, particularly with regard to minimizing false-positive results.[6,7] Because the consequences of inaccurate results can have profound implications, it is especially important that physicians be assured of the reliability, validity, and limitations of the testing system used.

CONCLUSIONS AND RECOMMENDATIONS

1. The AAP is opposed to the nontherapeutic use of psychoactive drugs by children and adolescents.
2. The appropriate response to suspicion of drug abuse is referral of the child or adolescent to a qualified health care professional for evaluation, counseling, and treatment as needed.
3. The role of pediatricians is one of prevention, diagnosis, counseling, and treatment or appropriate referral for care.
4. Voluntary screening may be a deceptive term, in that there often are negative consequences for those who decline to volunteer. Parental permission is not sufficient for involuntary screening of the older, competent adolescent, and the AAP opposes such involuntary screening. Consent from the older adolescent may be waived when there is reason to doubt competency or in those circumstances in which information gained by history or physical examination strongly suggests that the young person is at high risk of substance abuse.[16]
5. Diagnostic testing for the purpose of drug abuse treatment is within the ethical tradition of health care, and in the competent patient, it should be conducted noncovertly, confidentially, and with informed consent in the same context as for other medical conditions.
6. Involuntary testing in a minor who lacks the capacity to make informed judgments may be done with parental permission. Parental permission is not sufficient for involuntary testing of the adolescent with decisional capacity, and the AAP opposes such involuntary testing. Suspicion that an adolescent may be using a psychoactive drug does not justify involuntary testing, and it is not sufficient justification to rely solely on parental agreement to test the patient. Testing adolescents requires their consent unless: (1) a patient lacks decision-making capacity; or (2) there are strong medical indications or legal requirements to do so.
7. Notwithstanding the Supreme Court ruling,[13] students and student athletes should not be singled out for involuntary screening for drugs of abuse. Such testing should not be a condition for participation in sports or any school functions except for health-related purposes. Suspicion of drug use warrants a comprehensive evaluation by a qualified health care professional.

POLICY STATEMENT

Testing for Drugs of Abuse in Children and Adolescents: Addendum—Testing in Schools and at Home

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Substance Abuse and Council on School Health

ABSTRACT

The American Academy of Pediatrics continues to believe that adolescents should not be drug tested without their knowledge and consent. Recent US Supreme Court decisions and market forces have resulted in recommendations for drug testing of adolescents at school and products for parents to use to test adolescents at home. The American Academy of Pediatrics has strong reservations about testing adolescents at school or at home and believes that more research is needed on both safety and efficacy before school-based testing programs are implemented. The American Academy of Pediatrics also believes that more adolescent-specific substance abuse treatment resources are needed to ensure that testing leads to early rehabilitation rather than to punitive measures only.

BACKGROUND

In 1996, the American Academy of Pediatrics (AAP) published (and reaffirmed in 2006) a policy statement titled "Testing for Drugs of Abuse in Children and Adolescents," which opposed involuntary testing of adolescents for drugs of abuse.[1] The policy statement also stated that laboratory testing for drugs under any circumstances is improper unless the patient and clinician can be assured that the test procedure is valid and reliable and patient confidentiality is ensured. This policy statement was published shortly after a 1995 US Supreme Court ruling (*Vernonia v Acton* [515 US 646]) held that random drug testing of high school athletes is constitutional. Since that time, national interest in school-based drug testing has increased. In June 2002, the US Supreme Court, in a 5-to-4 decision, ruled that public schools have the authority to perform random drug tests on all middle and high school students participating in extracurricular activities (*Board of Education v Earls* [536 US 822, 122 S Ct 2559, 153 L Ed 2 days 735 {2002}]). Writing for the majority, Justice Clarence Thomas wrote, "Testing students who participate in extracurricular activities is a reasonably effective means of addressing the School District's legitimate concerns in preventing, deterring and detecting drug use." Shortly after this Supreme Court ruling, the President's Office of National Drug Control Policy published a guidebook designed to encourage schools to incorporate drug-testing policies for all students.[2]

Interest in drug testing of adolescents reaches beyond public schools. During recent years, a substantial number of companies have begun to market home

drug-testing products directly to parents.[3] Products that identify alcohol and drugs in urine, saliva, and hair are now available at retail outlets and via the Internet. Pediatricians may be asked about home drug testing by parents of their adolescent patients. Pediatricians involved in school health may be asked to assist in implementing school-based drug-testing programs. For these reasons, the Committee on Substance Abuse has conducted a review of the available science on drug testing of adolescents and is issuing this addendum to the 1996 policy statement. Although much has been written on the pros and cons of testing adolescents for drugs, relatively little has been published in peer-review scientific journals.

BENEFITS AND RISKS OF DRUG TESTING IN SCHOOLS AND AT HOME

School- and home-based drug testing poses a number of potential benefits and risks. On the positive side, both procedures would likely increase the number of adolescents who are screened for use of illicit drugs. Population-based screening also offers the potential for providing early intervention and treatment services to more adolescents. The Office of National Drug Control Policy guidebook states: "Results of a positive drug test should not be used merely to punish a student. Drug and alcohol use can lead to addiction, and punishment alone may not necessarily halt this progression. However, the road to addiction can be blocked by timely intervention and appropriate treatment."[2] Proponents of drug testing also claim that the existence of a school- or home-based drug-testing program will help adolescents refuse drugs and provide legitimate reasons to resist peer pressure to use drugs, although these claims are not yet proven. On the negative side, drug testing poses substantial risks—in particular, the risk of harming the parent-child and school-child relationships by creating an environment of resentment, distrust, and suspicion.[4] In addition to the effects on the individual adolescent, the safety and efficacy of random drug testing requires additional scientific evaluation. Broad implementation of random drug testing as a component of a comprehensive drug-use prevention program should await the results of these studies.

Currently, there is little evidence of the effectiveness of school-based drug testing in the scientific literature. Goldberg et al[5] compared 2 schools, one of which implemented a mandatory drug-testing program for student athletes and the other of which did not. They found at follow-up that the use of illicit drugs, but not alcohol, was significantly lower among athletes who were drug tested. However, they also found that athletes who were drug tested experienced an increase in known risk factors for drug use, including an increase in normative views of use, belief in lower risk of use, and poorer attitudes toward the school.

A larger observational study by Yamaguchi et al,[6] which analyzed data from the national Monitoring the Future study, found no association between school-based drug testing and students' reports of drug use. Among the nationally representative group of more than 300 schools, drug testing was most commonly conducted "for cause" (ie, suspicion; 14% of schools) and was far less commonly required for student athletes (4.9% of schools) or students participating in other extracurricular activities (2.3% of schools). Regardless of the reason it was performed, drug testing was not significantly associated with reduction in the use of marijuana or any other illicit drug among students in any grade studied (ie, 8th, 10th, or 12th grade). However, 1 observational study is not sufficient to establish causation or lack of causation. In addition, no detail was provided regarding the extent of drug testing in the study schools, and at some schools, it may have been minimal. Further scientific investigation is warranted.

Laboratory testing for drugs of abuse is a technically complex procedure. To ensure the validity of the specimen, urination must be directly observed, which is a potentially embarrassing procedure for all involved, or the collector must use a fairly complex and expensive federally approved protocol, which involves documentation of a continuous chain of custody in handling and includes temperature testing and controls for adulteration and dilution.[7] Few schools will have sufficient staff with proper training to implement these costly procedures, and a recent survey of pediatricians, adolescent medicine specialists, and family physicians found that few physicians will be able to help, because less than 25% are familiar with proper procedures for collection, validation, and interpretation of urine drug tests.[8] Similarly, most parents cannot implement the federal collection protocol and, for ethical and developmental reasons, should not directly observe their teenaged children urinating. Although drug testing of hair and saliva is available, validity has not been firmly established. Questions remain regarding how passive exposure to drugs as well as differences among races and sexes can affect hair testing.[9–12] In addition, hair testing is more likely to be useful in detecting historical drug use rather than current use.[9,13] Oral fluid testing (ie, saliva or oral swab), by contrast, gives a more accurate picture of current use.[14] However, accuracy of oral fluid testing varies across drugs of abuse. Oral fluid testing performs well in detecting the use of opiates and methamphetamine, but it performs poorly in detecting the use of benzodiazepines and cannabinoids.[15–17]

Interpretation of drug tests can also be complex. School staff members and/or parents need to be able to assess possible false-positive results, especially when screening test results are positive for amphetamines or opioids. Over-the-counter cold medications containing pseudoephedrine can cause false-positive screening re-

sults for amphetamine, although follow-up testing with gas chromatography and mass spectrometry is highly specific and can reliably confirm the presence of amphetamine.[17] Ingestion of foods that contain poppy seeds makes interpretation of drug testing more difficult, because it can cause screening and gas chromatography and mass spectrometry results to be falsely positive for morphine and/or codeine.[18]

It is fairly easy to defeat drug tests, and most drug-involved youth are all too familiar with ways to do so. Even properly collected specimens must have checks for validity (eg, urine specific gravity and creatinine), because the easiest way to defeat a drug testing is by simple dilution.[19] Even when properly collected and validated, urine drug tests yield very limited information. With the exception of marijuana, the window of detection for most drugs of abuse is 72 hours or less.[19] Therefore, negative test results indicate only that the adolescent did not use a specific drug during the past several days. Even adolescents with serious drug problems may have negative test results on most occasions.[20] Standard drug-testing panels also do not detect many of the drugs most frequently abused by adolescents, such as alcohol, ecstasy (3,4-methylenedioxymethamphetamine [MDMA]), and inhalants, and information on the limitations of screening tests and ways to defeat them is widely available to adolescents via the Internet.[3] Widespread implementation of drug testing may, therefore, inadvertently encourage more students to abuse alcohol, which is associated with more adolescent deaths than any illicit drug but is not included in many standard testing panels. Mandatory drug testing may also motivate some drug-involved adolescents to change from using drugs with relatively less associated morbidity and mortality, such as marijuana, to those that pose greater danger (eg, inhalants) but are not detected by screening tests. No studies have yet been conducted on this important issue. Safety of randomly testing adolescents for the use of drugs should be scientifically established before it is widely implemented.

Drug testing may also be perceived by adolescents as an unwarranted invasion of privacy. A policy statement is being developed by the Council on School Health on the role of schools in combating substance abuse. It will discuss the potential risks of school-based drug testing and alternative approaches to school-based prevention of drug abuse. Few physicians support school-based testing of adolescents for drugs; a national survey of physicians (pediatrics, family medicine, and adolescent medicine) found that 83% disagreed with drug testing in public schools.[20]

A key issue at the heart of the drug-testing dilemma is the lack of developmentally appropriate adolescent substance abuse and mental health treatment.[21] Adequate resources for assessment and treatment must be available to students who have positive test results. However, many communities lack substance abuse treatment services dedicated to adolescents, and adult substance abuse treatment programs may be inappropriate and ineffective for adolescents.[21] Federal support for school-based drug testing should include an allocation of resources that will facilitate greater access to adolescent substance abuse treatment.

ADDITIONAL CONCLUSIONS AND RECOMMENDATIONS

1. The AAP supports rigorous scientific study of both the safety and efficacy of school- and home-based drug testing of adolescents.
2. The AAP recommends that school- and home-based drug testing not be implemented before its safety and efficacy are established and adequate substance abuse assessment and treatment services are available.
3. The AAP encourages parents who are concerned that their child may be using drugs or alcohol to consult their child's primary care physician or other health professional rather than rely on school-based drug screening or use home drug-testing products.
4. The AAP recommends that health care professionals who obtain drug tests or assist others in interpreting the results of drug tests be knowledgeable about the relevant technical aspects and limitations of the procedures.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT
Guidance for the Clinician in Rendering Pediatric Care

John W. Kulig, MD, MPH; and the Committee on Substance Abuse

Tobacco, Alcohol, and Other Drugs: The Role of the Pediatrician in Prevention, Identification, and Management of Substance Abuse

ABSTRACT. Substance abuse remains a major public health concern, and pediatricians are uniquely positioned to assist their patients and families with its prevention, detection, and treatment. The American Academy of Pediatrics has highlighted the importance of such issues in a variety of ways, including its guidelines for preventive services. The harmful consequences of tobacco, alcohol, and other drug use are a concern of medical professionals who care for infants, children, adolescents, and young adults. Thus, pediatricians should include discussion of substance abuse as a part of routine health care, starting with the prenatal visit, and as part of ongoing anticipatory guidance. Knowledge of the nature and extent of the consequences of tobacco, alcohol, and other drug use as well as the physical, psychological, and social consequences is essential for pediatricians. Pediatricians should incorporate substance-abuse prevention into daily practice, acquire the skills necessary to identify young people at risk of substance abuse, and provide or facilitate assessment, intervention, and treatment as necessary. *Pediatrics* 2005;115:816–821; *tobacco, alcohol, drugs, substance abuse.*

ABBREVIATION. AAP, American Academy of Pediatrics.

PERVASIVENESS OF DRUG USE

In a recent public opinion poll of Americans' views of the top 2 or 3 problems facing adolescents today, 67% identified drugs or drug abuse, 13% identified alcohol abuse, and 6% identified smoking. In the same poll, a question assessing Americans' views of the seriousness of 36 health problems revealed that drug abuse (82%) was rated higher than cancer (78%), followed by drunk driving (75%), smoking (68%), and alcohol abuse (65%).[1]

The pattern of substance abuse among adolescents has changed significantly during the past 35 years. Before the late 1960s, it was predominantly adults who were abusing alcohol and other psychoactive drugs, including tobacco. Beginning in the late 1960s and early 1970s, substance abuse became widespread among adolescents and, more recently, among preadolescents. Alcohol and tobacco as well as opiates, cocaine, amphetamines, barbiturates, marijuana, hallucinogens, anabolic steroids, and prescription and nonprescription medications and inhalants (volatile substances) are used and abused by many adolescents and a growing number of preadolescents.[2] Tobacco use in these groups represents a significant health threat and is associated with an increased likelihood of future use of marijuana and other illicit drugs.[3,4] In *Healthy People 2010*,[5] multiple national goals have been established to decrease child and adolescent substance use (Table 1).

Three periodic surveys track national trends in use of alcohol, tobacco, and other drugs by adolescents: (1) the annual Monitoring the Future Study[6] of students in grades 8, 10, and 12; (2) the biannual Youth Risk Behavior Survey[7] of students in grades 9 through 12; and (3) the annual National Household Survey on Drug Abuse (renamed in 2003 to the National Survey on Drug Use and Health),[8] in which computer-assisted interviewing is conducted in the home for residents 12 years and older. In reviewing survey data and published reports, pediatricians should be aware that adolescent substance use may be reported as lifetime, annual, 30-day, 2-week, or daily.

Alcohol and tobacco use often begins in adolescence or earlier. Data analysis from the National Survey on Drug Use and Health[9] demonstrates that adolescents who smoke or drink experience immediate negative health consequences and report poorer health during adolescence than those who do not. Alcohol is involved in more than one third of the deaths attributable to unintentional injury, homicide, and suicide, which together account for 76% of mortality in the 15- to 19-year age group. By the end of high school, 77% of students have tried alcohol, and 46% have done so by eighth grade. More than half (58%) of 12th-grade students and one fifth (20%) of 8th-grade students report having been drunk at least once in their life.[6] Tobacco is associated with the 5 leading causes of death in adult Americans, accounting for 435 000 deaths annually.[10] By the 12th grade, 54% of American youth have tried cigarettes and 24% are current smokers.[6] Alcohol and tobacco are often referred to as licit (or lawful) drugs, but in the United States the legal age for use of alcohol remains 21 years or older, and the legal minimum age for purchase of tobacco remains 18 years.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

TABLE 1. *Healthy People 2010*: Child- and Adolescent-Specific Goals for Substance Use[5]

7-2	Increase the proportion of middle, junior high, and senior high schools that provide school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol and other drug use; unintended pregnancy, HIV/AIDS, and sexually transmitted diseases; unhealthy dietary patterns; inadequate physical activity; and environmental health.
16-18	Reduce the occurrence of fetal alcohol syndrome.
26-1	Reduce deaths and injuries caused by alcohol- and drug-related motor vehicle crashes.
26-6	Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol.
26-9	Increase the age and proportion of adolescents who remain alcohol- and drug-free.
26-10	Reduce past-month use of illicit substances.
26-11	Reduce the proportion of persons engaging in binge drinking of alcoholic beverages.
26-14	Reduce steroid use among adolescents.
26-15	Reduce the proportion of adolescents who use inhalants.
26-16	Increase the proportion of adolescents who disapprove of substance abuse.
26-17	Increase the proportion of adolescents who perceive great risk associated with substance abuse.
27-2	Reduce tobacco use by adolescents.
27-3	Reduce the initiation of tobacco use among children and adolescents.
27-4	Increase the average age of first use of tobacco products by adolescents and young adults.
27-7	Increase tobacco-use cessation attempts by adolescent smokers.
27-9	Reduce the proportion of children who are regularly exposed to tobacco smoke at home.
27-14	Reduce the illegal buy rate among minors through enforcement of laws prohibiting the sale of tobacco products to minors.
27-16	Eliminate tobacco advertising and promotions that influence adolescents and young adults.
27-17	Increase adolescents' disapproval of smoking.

Overall, more than half (51%) of American youth have tried an illicit (unlawful) drug by the time they complete high school. Data obtained in 2003 from the Monitoring the Future survey document a second year of decline in the use of ecstasy (3,4-methylenedioxymethamphetamine [MDMA]) by adolescents and young adults, with lifetime prevalence of 8.3% by the 12th grade, reversing a sharp increase that began in 1998 and peaked at 11.7% in 2001. Lifetime use of marijuana (46%), amphetamines (14%), tranquilizers (10%), barbiturates (9%), lysergic acid diethylamide (LSD [6%]), and inhalants (11%) showed gradual decreases among high-school seniors. Lifetime use held steady for cocaine (8%), anabolic steroids (4%), heroin (2%), and 3 of the "club drugs": Rohypnol, gammahydroxybutyrate (GHB), and ketamine (each less than 2%). Among 12th-graders, no drug showed increased use in 2003. Divergence in trends for substance use is attributable in part to perceived benefits and perceived risks of each drug. Perception of risks often lags behind perception of benefits; thus, newly introduced drugs experience a "grace period," as was seen with ecstasy. Older drugs may be rediscovered by youth, in a process termed "generational forgetting," as knowledge of adverse consequences fades.[6]

Possible factors implicated in changing patterns of substance use include a decrease in perceived risk, fewer school-based substance-abuse prevention programs, pervasive messages in the electronic and print media as well as advertisements that glamorize tobacco and alcohol, and changing patterns of parenting in the 1990s.[2,11] The perception that casual use of recreational drugs is not a significant concern is held by many adults as well, including a sizable number of pediatricians surveyed by the American Academy of Pediatrics (AAP) in 1995. Although the prevalence of drug use may vary from community to community, there is general agreement that use of tobacco and alcohol at an early age is a predictive factor for use of other drugs, use of a greater variety of drugs, and use of more potent agents.[3,4] Furthermore, the onset of tobacco addiction occurs primarily among children. Most adults who smoke began to do so before 19 years of age, at an average age of 12 years; most were regular smokers by 14 years of age. Thus, it is critical for pediatricians to be knowledgeable about smoking prevention and treatment measures. Youth-oriented prevention and cessation interventions can be successful, as demonstrated by a recent decrease in tobacco use.[12] Cigarette smoking among adolescents continued to decrease significantly in 2003, extending a trend that began in 1997. Daily smoking by eighth-graders decreased by half (10.4% to 4.5%) since the recent peak in 1996.[6]

BARRIERS TO PHYSICIAN INVOLVEMENT

Data from a periodic survey of AAP members[13] in 1995 indicate that fewer than 50% of pediatricians screen adolescent patients for substance abuse. Primary barriers to physician involvement in prevention, screening, and management of substance abuse include: (1) time constraints associated with high patient volume; (2) inadequate reimbursement relative to the time and effort required to address sub-

stance-abuse disorders with patients and their families; (3) physician fear of alienating or labeling patients and their families; (4) inadequate education and training in substance abuse and addiction; (5) lack of dissemination to physicians of research supporting positive treatment outcomes and negative effects of failure to intervene early in substance abuse; and (6) lack of information about how to access referral and treatment resources. A White House conference[14] recently defined 3 levels of core competencies for clinicians to address substance-abuse issues, ranging from screening and referral to assuming responsibility for long-term treatment.

MAXIMIZING THE PEDIATRIC EVALUATION

Given their longstanding relationship with patients and their families, primary care pediatricians may be the only health care professionals in a position to recognize problems with substance abuse as they develop. This relationship may also facilitate referral and provide support through the process of substance-abuse evaluation and treatment and during recovery and aftercare.

Adolescent substance abuse may be the most commonly missed pediatric diagnosis. Primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists need to maintain a high index of suspicion and be aware of both the medical and behavioral presentations of substance use as well as its association with psychiatric comorbidity. Newly published resources provide guidelines for pediatric office assessment of substance abuse.[2,15]

Appropriate interviewing techniques are critical in obtaining a comprehensive substance-abuse history. Confidentiality is central in this issue, and the most useful information will be obtained in an atmosphere of mutual trust and comfort. Adolescents should be interviewed privately during each office visit with assurance of limited confidentiality.[16] This approach is appropriate for many preadolescents as well.

Although substance abuse commonly has behavioral manifestations, pediatricians should recognize medical manifestations as well. Even an apparently straightforward complaint such as headache or sore throat may be associated with underlying substance use. Trauma, chronic cough, chest pain, worsening asthma unresponsive to therapy, or abdominal complaints associated with gastritis, hepatitis, and even pancreatitis may be signs of substance abuse. Open-ended questions are usually the most nonthreatening to the patient, and an empathic, nonjudgmental style of interviewing facilitates the development of an honest doctor-patient relationship. It may be helpful to begin with questions about the patient's attitudes toward use of tobacco, alcohol, and other drugs within his or her environment (home, school, and friends) rather than probing personal beliefs or habits. This questioning may lead logically to inquiry about the patient's experiences with tobacco, alcohol, and other drugs. Many clinicians use structured interviews and questionnaires to elicit a substance-abuse history.[2] The CRAFFT questionnaire was validated recently as 1 of the few brief screening tools specific to identifying adolescent alcohol and substance abuse (Table 2).[17]

TABLE 2. CRAFFT: Questions to Identify Adolescents With Substance Abuse Problems[17]

C	Have you ever ridden in a *c*ar driven by someone (including yourself) who was "high" or had been using alcohol or drugs?
R	Do you ever use alcohol or drugs to *r*elax, feel better about yourself, or fit in?
A	Do you ever use alcohol or drugs while you are by yourself, or *a*lone?
F	Do you ever *f*orget things you did while using alcohol or drugs?
F	Do your family or *f*riends ever tell you that you should cut down on your drinking or drug use?
T	Have you ever gotten into *t*rouble while you were using alcohol or drugs?

Two or more "yes" answers suggest that the adolescent may have a serious problem with substance abuse, and additional assessment is warranted.

Research has identified multiple risk and protective factors that influence adolescent substance use (Table 3).[2,18–21] Obtaining an age-appropriate psychosocial history such as family and peer relationships, academic progress, nonacademic activities, acceptance of authority, degree of self-esteem, and ongoing episodes of intrafamilial or extrafamilial conflict may reveal risk and/or protective factors for current or future substance abuse. These issues should be part of a routine history when a patient 8 years or older is seen for health care.

Family history is especially important, because substance abuse among family members is associated with childhood behavior problems, school problems, and multiple somatic complaints. It is estimated that 1 in 5 children grows up in a home in which there is someone who abuses alcohol or other drugs.[22] Inquiry regarding the extent of tobacco, alcohol, or other drug use by family members and peers should be a part of the routine history of every child who is seen in the pediatrician's office. After questioning, an age-appropriate discussion of the possible consequences of such use should be held with the child and his or her parent or guardian. If this discussion reveals a family history of chemical dependency, the pediatrician should address the issue and make appropriate referrals for care.

Inquiry regarding other risk behaviors is also important in dealing with the issue of substance abuse. Research suggests behaviors such as early sexual activity, membership in gangs, illegal use of firearms, use of drugs while riding in or driving a motor vehicle, and engaging in other illegal activities are clustered: those who engage in 1 risk behavior are more likely to engage in others.[4]

Information should be obtained on the adolescent's use of specific drugs, including tobacco and alcohol; the extent of such use; settings in which the use occurs; and the degree of social, educational, and vocational disruption attributable to drug use. Continually updated Web sites (Table 4) may be useful in obtaining general information about substance abuse, following national trends, and identifying

TABLE 3. Risk and Protective Factors Associated With Adolescent Use of Tobacco, Alcohol, and Other Drugs[2,18–21]

	Risk Factors	Protective Factors
Individual	Early initiation of substance use	Late initiation of substance use
	Attitude favorable to substance use	Perceived risk of substance use
	Low self-esteem or poor coping skills	Positive sense of self, assertiveness, social competence
	Early antisocial or delinquent behavior	
	Psychopathologic problems, particularly depression	
	Attention-deficit/hyperactivity disorder	Pharmacotherapy for attention-deficit/hyperactivity disorder
	Conduct disorder or aggressive behavior	
	Sensation seeking, impulsivity, distractibility	Resilient temperament
	Perinatal complications or brain injury	
	Low intensity of religious beliefs and observance	High intensity of religious beliefs and observance
	Rebelliousness and alienation from the dominant values of society and conventional norms	Positive social orientation, adoption of conventional norms about substance use
Family	Permissive or authoritarian parenting	Authoritative parenting, parental monitoring of activities
	Parental and older sibling use of alcohol, tobacco, or other drugs	Clearly communicated parental expectation of nonuse and clear rules of conduct consistently enforced
	Family history of alcoholism	Parent in recovery
	High levels of family conflict	Positive, supportive relationships with family
	Parental divorce during adolescence	Open communication with parents
	Child abuse and neglect or sexual abuse	Supportive relationships with prosocial adults
Peers	Friends who drink, smoke, or use other drugs	Friends not engaged in substance use
	Perceived peer drug use	Peer disapproval of substance use
School	Poor academic achievement and school failure	Good academic achievement and school success
	Low interest in school and achievement	High academic aspirations
Community	Disorganization in the community or neighborhood	Less acculturation and higher ethnic identification
	Availability of tobacco and alcohol	Increased legal smoking and drinking ages
	Marketing of tobacco and alcohol	Increased excise taxes on tobacco and alcohol
	Availability of licit and illicit drugs	Strict law enforcement
Sociocultural	Media portrayal of substance use	Media literacy
	Advertising licit substances	Comprehensive, theory-based antidrug education programs

drugs of abuse by their "street names," which often vary by geographic region. Adolescents may display varying degrees of honesty when discussing their use of tobacco, alcohol, and other drugs. Use may be exaggerated or minimized, and the pediatrician may need to rely on other contextual clues such as mood, appearance, and physical and behavioral symptoms (such as illegal activity or problems at home or school) to fully assess usage patterns.

DRUG TESTING

Laboratory investigation (drug testing) may be used when it is necessary to determine the cause of dysfunctional behavior and other changes in mental status or suspicious physical findings. It is important to differentiate between screening and testing for drugs of abuse. "Screening" is a technique used to evaluate broad populations, such as screening all athletes trying out for a school team. "Testing," on the other hand, implies evaluation on the basis of a clinical suspicion of use. Guidelines published by the AAP[23] as well as issues of consent and confidentiality[16] should be considered when deciding whether to use drug testing in the diagnosis and management of substance abuse. When obtaining urine for testing, it is critical that accidental or purposeful contamination, dilution, or substitution be avoided. Office policies should be developed to preserve the chain of custody in processing urine specimens for testing. Knowledge about the capability of the laboratory to identify specific substances and the sensitivity and specificity of the procedures used is necessary when such testing is ordered.[24]

Initially, a clinical history of substance abuse may obviate the need for testing. In general, testing should be performed only with the patient's consent. Exceptions include situations in which the patient's mental status or judgment is impaired. Testing is often used as a routine component of treatment and maintenance of abstinence.

OFFICE MANAGEMENT

The preadolescent or adolescent who admits repeated use of alcohol, tobacco, or other drugs re-

quires careful evaluation to determine appropriate intervention and treatment. Any substance use by preadolescents carries extraordinary risk because of the likelihood of progression to the use of additional and more dangerous substances and the effect of such use on physical, physiologic, neurologic, and emotional development.

Intervention is required for any patient when substance use is having an effect on academic, social, or vocational functioning. Use of substances in association with other risk behaviors also warrants immediate intervention. Substance abuse in adolescence is often associated with psychiatric comorbidity, such as depression, bipolar disorder, posttraumatic stress disorder, oppositional-defiant disorder, attention-deficit/hyperactivity disorder, schizophrenia, bulimia nervosa, and social phobia.[25] Referral of adolescents with suspected "dual diagnosis" to a mental health professional for additional evaluation and management is indicated.[25] Clinicians may wish to refer to the *Diagnostic and Statistical Manual for Primary Care (DSM-PC) Child and Adolescent Version* for assistance in classification of substance use behaviors.[26]

Adolescents may be more able to accept that they need help if they are shown how their use has progressed from occasional use in safe situations to more regular use in more risky situations. Discussing reasons and motivations to quit using tobacco, alcohol, and other drugs may encourage the adolescent to consider changing such behaviors and to recognize the importance of seeking treatment. Pediatricians with an interest in substance-abuse treatment may also consider implementing brief, office-based interventions incorporating motivational interviewing and cognitive-behavioral therapy for their substance-abusing patients.[27,28] Help may consist of 1 or more of the following approaches: counseling (family or individual); behavioral therapy; inpatient or outpatient drug treatment; psychologic evaluation and/or testing; psychiatric assessment; and drug detoxification. Environmental changes such as living in a different community with a relative may be integrated with any of these options. Pediatricians can be most helpful if they are familiar with the referral resources within their communities, including private and public facilities, those offering inpatient and outpatient treatment, and the capability to treat adolescents from diverse backgrounds. Availability of the pediatrician for follow-up after successful treatment is essential for relapse prevention.[28]

A far more common scenario is the use of drugs, particularly alcohol and marijuana, as an occasional activity without disruption of behavior or academic performance. Because many adolescents and their families do not regard such use as a health issue, the pediatrician will need to offer advice regarding the associated risks although no such advice has been solicited. At other times, the pediatrician may be asked to help resolve a conflict between parent and child over the use of these drugs. Thus, pediatricians need to be knowledgeable, objective, and able to give adolescents and their families accurate information on the health and safety hazards of using tobacco, alcohol, and other drugs. Recently published AAP statements have addressed alcohol,[29] tobacco,[30] and marijuana[31] use as well as indications for management and referral of patients.[32]

Even infrequent casual use poses increased risk of serious problems, including abuse, date rape, and intentional or unintentional injury. Of 1023 consecutive admissions at 1 trauma unit (two thirds from automobile crashes), approximately half of the patients tested positive for alcohol, marijuana, or both. Positive tests for both were found in one third of those affected, and marijuana and alcohol alone each accounted for one third.[33] Death and serious injury often result from risk-taking behavior while impaired.

Pediatricians hold valued, respected positions with their patients and their patients' families and within the community. Armed with the knowledge of normal adolescent development, the pediatrician has the unique ability to provide appropriate anticipatory guidance and counseling in substance-abuse prevention and to place tobacco, alcohol, and other drug use in the context of risk behavior in general, which may lead to the identification of other risk behaviors and provide the opportunity to intervene by encouraging protective behaviors.

ADVICE FOR PEDIATRICIANS

The AAP advises the following actions to promote the pediatrician's role in the prevention and management of tobacco, alcohol, and other drug abuse.

1. Pediatricians are encouraged to:
   - Be knowledgeable about the prevalence, patterns, cultural differences, and health consequences of substance abuse in their community; incorporate substance-abuse prevention into anticipatory guidance at routine and episodic office visits; be aware of the manifesting signs and symptoms of substance abuse, the association with other risk behaviors, and the possibility of dual diagnoses with other mental health disorders; be able to screen for and evaluate the nature and extent of substance use among patients and their families; be aware of confidentiality issues related to substance abuse, including obtaining patient consent before drug testing; be aware of community services for evaluation, referral, and treatment of substance-abuse disorders; and be available to provide aftercare for adolescent patients completing substance-abuse treatment programs and to assist in their reintegration into the community.
   - Serve as a community resource for smoking prevention and cessation and as a community resource for evidence-based substance-abuse prevention initiatives.
   - Advocate for community-based prevention and treatment services.
2. Patients and their families should be advised that even casual use of alcohol, tobacco, and other

drugs by children and adolescents, regardless of amount or frequency, is illegal and has potential adverse health consequences.

abstract

Tobacco use is the leading preventable cause of morbidity and death in the United States. Because 80% to 90% of adult smokers began during adolescence, and two thirds became regular, daily smokers before they reached 19 years of age, tobacco use may be viewed as a pediatric disease. Every year in the United States, approximately 1.4 million children younger than 18 years start smoking, and many of them will die prematurely from a smoking-related disease. Moreover, there is recent evidence that adolescents report symptoms of tobacco dependence early in the smoking process, even before becoming daily smokers. The prevalence of tobacco use is higher among teenagers and young adults than among older adult populations. The critical role of pediatricians in helping to reduce tobacco use and addiction and secondhand tobacco-smoke exposure in the pediatric population includes education and prevention, screening and detection, and treatment and referral. *Pediatrics* 2009;124:e1045–e1053

TOBACCO AS A SUBSTANCE OF ABUSE

Tobacco products contain the addictive drug nicotine as well as many other toxic chemicals. The use of tobacco, in any form, can lead to addiction, significant morbidity, and premature death. There are several different ways in which tobacco is used, including smokeless chewing tobacco and snuff, as well as tobacco that is smoked through a hookah or water pipe or as a cigar (large cigar, cigarillo, or little cigar), bidi, kretek, or cigarette. Because cigarette smoking is the most prevalent method of tobacco use, it will be the predominant focus of this report. Tobacco smoke contains thousands of toxic chemicals, including many known carcinogens. There is no safe method, level, frequency, or duration of tobacco use or exposure.[1] Moreover, smokeless tobacco is not a safe alternative to cigarette smoking. A policy statement[2] and additional technical report[3] from the American Academy of Pediatrics (AAP) accompany this technical report.

Nicotine in tobacco is a powerfully addictive substance with multiple physiologic and psychological effects. Like many other drugs of addiction, it activates the same brain reward system involved in pleasurable activities such as eating and sexual activity.[4,5] Tobacco withdrawal symptoms make it difficult for individuals to quit, are variable among individuals, and usually include unpleasant effects such as anxiety, irritability, difficulty concentrating, restlessness, impatience, hunger, tremor, racing heart, sweating, dizziness, nicotine craving, insomnia, drowsiness, headaches, digestive disturbances, and depression.[6] The addictive nature of nicotine combined with the unpleasant withdrawal

symptoms experienced when individuals try to quit are what make nicotine dependence such a chronic, relapsing disease.

EPIDEMIOLOGY OF TOBACCO USE

Tobacco addiction usually begins in childhood or adolescence.[7,8] Children younger than 10 years have reported experimenting with tobacco. Every year in the United States, approximately 1.4 million children younger than 18 years start smoking, and many of them will die prematurely from a smoking-related disease.[9] The prevalence of tobacco use among teenagers and young adults is comparable to and slightly higher than prevalence rates among other adult populations. According to data from the 2007 National Health Interview Survey, an estimated 19.7% of all adults in the United States are current cigarette smokers. In comparison, 20% of high school students are current smokers.[10] The prevalence of current cigarette use is highest among 12th-grade students (26.5%), followed by 11th-grade (21.6%), 10th-grade (19.6%), and 9th-grade (14.3%) students.[10] Unfortunately, the prevalence of quitting (ie, the percentage of those who have ever smoked and who are now former smokers) is lower among younger age groups than among older adults. Approximately 21.3% of male and 18.7% of female high school students in the United States are current cigarette smokers, defined as use in the previous 30 days. Rates of current smokers are highest among non-Hispanic white high school students (23.2%), followed by Hispanic (16.7%) and non-Hispanic black (11.6%) students.[10] Among US middle school students, approximately 6.3% are current cigarette smokers, and estimated rates are slightly higher for girls (6.4%) than for boys (6.3%). Approximately 6.5% of white students, 6.8% of Hispanic students, 5.5% of black students, and 2.6% of Asian American students in middle school are current cigarette smokers.[11] Cigarette-smoking estimates in the US adult population according to age are as follows: 18 to 24 years: 23.9%; 25 to 44 years: 23.5%; 45 to 64 years: 21.8%; and 65 years or older: 10.2%.[12]

In the United States, approximately 7.9% of high school students are current smokeless-tobacco users, defined as use of smokeless tobacco on at least 1 day during the 30 days before the survey. The prevalence of current smokeless-tobacco use is higher among male (13.4%) than among female (2.3%) students and higher among white (10.3%) than among Hispanic (4.7%) or black (1.2%) students. Regarding current cigar use, 13.6% of high school students had smoked cigars, cigarillos, or little cigars on at least 1 day during the 30 days before the survey. Overall, the prevalence of current cigar use was higher among male (19.4%) than among female (7.6%) students and higher among white (14.8%) than among Hispanic (12.7%) and black (10%) students.[10]

Education and Socioeconomic Status

There is an inverse relationship between rates of cigarette smoking and both socioeconomic status and education in young people and adults. For example, in 2006, smoking a half-pack or more per day was approximately 3 times as prevalent among 12th-graders who were not going to college as among those who were college bound (13.0% vs 3.9%, respectively). Among survey respondents of college age (1–4 years past high school), those not enrolled in college had a dramatically higher rate of half-pack-a-day smoking than those who were in college (17.0% vs 4.9%, respectively).[13] Cigarette-smoking prevalence is highest for adults with a general education development (GED) diploma (46.0%) or 9 to 11 years of education (35.4%) and lowest for adults with an undergraduate college degree (9.6%) or a graduate college degree (6.6%).[12]

Tobacco Use and Mental Illness

Nicotine dependence is more common among adults with mental health disorders such as schizophrenia and depression. Likewise, in youth, tobacco use may be a marker for mental health problems such as depression and anxiety disorders.[14–19] Tobacco use may represent a means of self-treating symptoms often associated with these disorders.[20] Depending on the population studied, 55% to 90% of individuals with other mental disorders smoke, compared with approximately 20% in the general population. Mood disorders, anxiety, and other substance use–related disorders may be more common in individuals who smoke than in those who are former smokers and those who have never smoked.[14–19]

Facilities that offer mental health services often do not treat tobacco addiction[21,22]; however, inpatient mental health and substance abuse treatment facilities with no-smoking policies have been successful in promoting smoking cessation, even among adolescents.[23,24] Monihan et al[25] reported that after implementing a smoking ban, some inpatient psychiatric facilities noted an increase in staff satisfaction and a significant decrease in violence and behavioral problems related to smoking habits. These results lend support to the recommendation that inpatient facilities should offer tobacco-addiction treatment.

Tobacco Use Among Lesbian, Gay, Bisexual, and Transgender Youth

Studies show that lesbian, gay, bisexual, and transgender youth are significantly more likely than heterosexual youth to engage in high-risk behaviors (such as fighting, substance use, and

alcohol use).[26,27] Adolescents who report same-sex attraction or activity were 2.5 times as likely to smoke at least weekly compared with heterosexuals; bisexual/lesbian girls were 9.7 times more likely.[28] Ryan et al[29] found that 59% of teenagers who classified themselves as lesbian, gay, or bisexual reported using tobacco (compared with 35% of heterosexual teenagers), and almost half tried their first cigarette before 13 years of age. Lesbian and gay teenagers are also 4 times more likely than their heterosexual counterparts to use smokeless-tobacco products. Given that these youth are at considerable risk of tobacco use, population-specific tobacco-prevention and -cessation strategies are warranted.

INITIATION OF TOBACCO USE AND ONSET OF ADDICTION

Initiation of tobacco use is considered multifactorial. Several factors are involved in influencing youth to experiment with tobacco, including socioenvironmental (eg, advertising/media influences, peer influences, parental influences, ethnic and gender factors), psychological (eg, psychiatric illness or history, child development, weight concerns), and biological (eg, genetics) factors.[8,30–38] Teenagers with at least 1 smoking parent are twice as likely to become smokers compared with teenagers whose parents do not smoke.[39] This is attributed to the availability of tobacco products in the home, modeling of the behavior, and the hypothesized role of nicotine receptor priming as a result of being exposed to nicotine in utero and secondhand smoke after birth.

Studies of twins and cigarette smoking have indicated that genetic influences play a crucial role in smoking initiation, persistence, and ability to quit smoking, with the heritability of smoking initiation considered to be 50% and that for smoking persistence to be 70%.[40–43] It is hypothesized that multiple polymorphic genes are involved, with each modestly increasing the risk of developing nicotine dependence.[40,41,44,45] These genes affect nicotine metabolism as well as the dopamine receptors and transporters that mediate reward in the brain nucleus accumbens.[46]

Peer influences are also important in the uptake of tobacco use; teenagers with more friends who smoke are more likely to start smoking. Teenagers who have an inaccurately high perception of smoking prevalence among their peers and who believe that smoking is popular among the elite/successful elements of society are more likely to smoke.[47] Studies have also shown among adolescent girls a relatively consistent association between having higher body weight or concerns about weight and a greater likelihood of smoking.[48]

Nicotine is the primary addictive component in tobacco. Like other drug addictions, nicotine addiction is a chronic condition with the potential for periods of relapse and remission throughout life. The time interval from experimentation or initiation of tobacco use to regular use varies considerably among individuals but typically averages 2 to 3 years.[8] Experts traditionally believed that nicotine addiction developed after 2 or 3 years of regular tobacco use, but recent evidence has shown that symptoms of nicotine addiction may be apparent in some youth after short-term use of tobacco.[49–51] DiFranza et al[51] demonstrated that 10% of youth who become hooked on cigarettes exhibit "loss of autonomy" within 2 days of first inhaling from a cigarette, and 25% demonstrate evidence within 1 month. The study also revealed that even adolescents who smoke only a few cigarettes per month and those who have smoked as few as 100 cigarettes can suffer physical and psychological withdrawal symptoms when they attempt to quit using tobacco and are deprived of nicotine. Despite not yet being daily smokers, these youth may benefit from help to overcome withdrawal symptoms. Adolescent tobacco users often underestimate the addictive nature of nicotine. Of adolescent smokers who reported believing that they would not be smoking in 5 years, approximately 75% were still smoking 5 to 6 years later.[8] The younger a person is when starting tobacco use, the more likely he or she is to become heavily addicted to nicotine and experience more difficulty with trying to quit.[52] This is likely related to the vulnerability of the developing brain, because animal research has shown that the adolescent brain is more susceptible than the adult brain to the reinforcing effects of nicotine.[53]

SOURCES OF TOBACCO USED BY YOUTH

Youth obtain tobacco from a variety of sources. Noncommercial sources of tobacco include friends, siblings, parents, relatives, and even baby-sitters.[54] Youth most commonly obtain their first cigarettes from friends or siblings, although stealing their first cigarettes from parents is not uncommon.[54] After the first cigarette, those who continue to smoke typically will rely on same-aged friends as their first steady source.[55] Sharing cigarettes among friends is very common. In 1 study, 99% of young smokers reported having, at some time, obtained tobacco from friends.[54]

The 2007 Monitoring the Future survey revealed that 56% of 8th-graders and 78% of 10th-graders said cigarettes were easy for them to get.[56] Although all states have laws that prohibit the sale of tobacco products to people younger than 18 years, the level of enforcement of these prohibitions varies.

The 2003 National Survey on Drug Use and Health revealed that among 12- to 17-year-olds who had smoked in the previous month, more than three quarters of them (77%) had purchased their own cigarettes. More than half (53.3%) had directly purchased their own cigarettes; 63.3% had given money to others to buy cigarettes for them; nearly one third (30.5%) had purchased cigarettes from a friend, family member, or someone at school; and a small portion had purchased cigarettes over the Internet or through the mail (2.6% and 2.9%, respectively). In addition, 62% had "bummed" cigarettes from others, and 13.1% had taken cigarettes from others without asking, with 0.8% having stolen cigarettes from a store. Older underaged smokers were more likely to buy directly in stores than were younger smokers.

TOBACCO AS A GATEWAY DRUG

Tobacco is often described as a gateway drug that can lead to the use and abuse of other substances. Teenagers who smoke are 3 times more likely than nonsmokers to use alcohol, 8 times more likely to use marijuana, and 22 times more likely to use cocaine.[1,57] Smoking has been associated with other high-risk behaviors including high-risk sexual practices, such as having multiple sexual partners or unprotected sex, and perpetration of youth violence.[8,58] In fact, tobacco use is an individual risk factor for youth violence.[58]

EFFECTS OF TOBACCO USE

Smoking harms nearly every organ of the body, causing many diseases and reducing the health of smokers as well as those exposed to secondhand smoke[1] (see Table 1 and the accompanying AAP policy statement[2] and technical report[3]). The adverse health effects from cigarette smoking account for an estimated 438 000 deaths each year in the United States. Although most people are aware of the negative health consequences of tobacco use in adults, youth also experience negative health consequences attributable to tobacco use. Smoking impairs lung growth and results in decreased lung function. A smoker's resting heart rate is, on average, 2 to 3 beats per minute faster than that of a nonsmoker. Also, smokers experience more coughing as well as more frequent and severe respiratory illnesses. Smokers have less physical endurance and tend to experience shortness of breath even with minimal exertion.[1] Nicotine staining of teeth can be identified early by pediatric dentists. Smokeless-tobacco use is associated with periodontal disease, gum recession, leukoplakia, and cancers of the oral cavity.[8,59]

TABLE 1 Major Conclusions of the 2004 Surgeon General Report[1]

Smoking harms nearly every organ of the body, causing many diseases and reducing the health of smokers in general.
Quitting smoking has immediate and long-term benefits, reducing risks of diseases caused by smoking and improving health in general.
Smoking cigarettes with lower machine-measured yields of tar and nicotine provides no clear benefit to health.
The list of diseases caused by smoking has been expanded to include abdominal aortic aneurysm, acute myeloid leukemia, cataract, cervical cancer, kidney cancer, pancreatic cancer, pneumonia, periodontitis, and stomach cancer. These are in addition to diseases previously known to be caused by smoking, including bladder, esophageal, laryngeal, lung, oral, and throat cancers; chronic lung diseases; coronary heart and cardiovascular diseases; and reproductive effects and sudden infant death syndrome.

Smoking poses some additional risks for women and girls. As a direct consequence of smoking, lung cancer now exceeds breast cancer as the leading cause of cancer-related deaths in women. Women who smoke also have an increased risk of other cancers, including cancers of the oral cavity, pharynx, larynx, esophagus, pancreas, kidney, bladder, and uterine cervix.[1] Women who smoke double their risk of developing coronary heart disease and increase by more than 10-fold their likelihood of dying from chronic obstructive pulmonary disease.[1] Moreover, cigarette smoking increases the risk of infertility, preterm delivery, stillbirth, low birth weight, and sudden infant death syndrome.[1]

PREVENTION

Effective strategies for preventing adolescent tobacco use include public health approaches as well as individual strategies. Some public health approaches that may be effective include restricting the promotion of tobacco products in general and specifically prohibiting promotions aimed at children, including laws prohibiting the sale of tobacco to minors and raising the price of tobacco through aggressive taxation.[60] Also, changing the social norm about the normality and acceptability of tobacco use is an effective prevention strategy that can be accomplished through the use of school smoking bans, health education, household smoking bans, and restrictions on smoking in public places.[22,61,62] As part of the 1998 Master Settlement Agreement between 46 states' attorneys general and the 4 largest tobacco companies in the United States, the tobacco manufacturers agreed to stop using cartoon characters in their advertisements, advertising on billboards, and putting their brand names on articles such as clothing and also agreed to avoid targeting children and adolescents with marketing and advertising.[63] However, the tobacco industry has continued to devise new ways to target product marketing to children through using print ads, sponsoring motor sports, and depicting smoking in movies.

Pediatricians and parents have important roles in preventing tobacco use by children and adolescents. Pediatri-

cians should use anticipatory guidance to implement and encourage individual patient-level strategies to educate patients and families and prevent tobacco use and exposure. Children should be screened for smoking risks beginning by 5 years of age. All clinical encounters should include inquiries about tobacco use and secondhand smoke exposure and clear documentation of the information in the medical record. Children and adolescents should be warned about the harmful effects of tobacco and the ease with which experimentation progresses to addiction and regular use.[50,51] Because children with smoking parents are more likely to smoke and to start at an earlier age, screening for parental tobacco use is an important preventive measure.[64] Parents should be advised to maintain smoke-free households and vehicles and to articulate clear messages that they expect their children to remain smoke free. Parental attitudes, opinions, and feelings about their children's smoking status greatly influence whether children will smoke, even when parents smoke.[65–67]

PUBLIC POLICIES FOR TOBACCO-USE REDUCTION

Comprehensive tobacco-control programs should include interventions that have been proven effective in preventing tobacco-use initiation among youth and young adults, promote cessation among adults and youth, and eliminate secondhand smoke exposure and tobacco-related disparities. The ideal comprehensive approach to tobacco control includes population-based and individual-level interventions.[61,68] Population-based interventions include clean indoor-air legislation, tobacco tax increases, restricted youth access to tobacco, and mass-media anti-tobacco campaigns.[61,68] Individual-level interventions include treatment services that have been proven to increase tobacco-cessation rates, such as behavioral counseling and pharmacotherapy.

The progress that has been made thus far in reducing youth smoking rates has been accomplished through a combination of such strategies, including raising tobacco taxes, passing legislation that limits minors' access to tobacco products and prohibits smoking in public places, and running aggressive media countermarketing campaigns.[69] Studies have demonstrated that youth are particularly susceptible to tobacco advertising and promotions. One important source of tobacco promotions is movies. Tobacco is depicted in 56% of films with Motion Picture Association of America ratings of G, PG, or PG-13—the films children are most likely to see—and in 87.5% of films with an R rating.[70] Research has indicated that exposure to movie smoking is a primary independent risk factor for youth smoking initiation.[36,71] Given the prevalence of protobacco images in movies viewed by children and the impact it has on smoking initiation among youth, there is a critical need to support the Smoke Free Movies effort. The Motion Picture Association of America recently agreed to consider whether a film depicts smoking when determining its ratings of movies.

Youth tobacco users are also very price sensitive, so raising tobacco taxes causes a dramatic decrease in youth tobacco-use rates. Raising taxes also leads to more adults seeking smoking-cessation services.[60,61] Clean indoor-air legislation also correlates with more tobacco-use cessation. The American Legacy Foundation's social marking campaign, Truth (www.thetruth.com), has been independently associated with significant declines in youth smoking.[72]

Cigarette warning labels are an important component of comprehensive tobacco-control and smoking-cessation efforts. In 1984, Congress enacted the Comprehensive Smoking Education Act (Pub L No. 98–474), which required rotation of the following 4 black-and-white text messages on the side of cigarette packages:

1. Surgeon General's Warning: Smoking causes lung cancer, heart disease, emphysema, and may complicate pregnancy.
2. Surgeon General's Warning: Quitting smoking now greatly reduces serious risks to your health.
3. Surgeon General's Warning: Smoking by pregnant women may result in fetal injury, premature birth, and low birth weight.
4. Surgeon General's Warning: Cigarette smoke contains carbon monoxide.

For the past 20 years, there have been no changes to US cigarette package warning labels; however, several other countries, including Canada, Australia, Thailand, South Africa, Singapore, and Poland, have mandated stronger health warnings on cigarette packages by requiring the addition of graphic images, detailed statistical information about tobacco-use health risks, and information about how to quit smoking. In a study that compared US and Canadian warning labels, young adult (18–24 years of age) focus-group participants perceived the larger, more graphic Canadian warning labels to be more informative and more likely to attract a smoker's attention.[73] Hammond et al[74] found that large, comprehensive warnings on cigarette packages are more likely to get noticed and have been rated as more effective by smokers in deterring them from smoking. Active discussion and advocacy efforts in the United States currently focus on legislation that passed in 2009, giving the US Food and Drug Administration (FDA) the authority to regulate tobacco products and

TABLE 2 Brief Interventions to Treat Tobacco Dependence[7,81]: The 6 A's for Brief Intervention to Treat Tobacco Dependence

Anticipate risk of tobacco use	Routinely ask parents about smoking. Make parents aware of age of smoking onset. Discuss health effects of tobacco use. Be aware of populations at increased risk of tobacco initiation.
Ask about tobacco use	Identify and document tobacco-use status and secondhand smoke exposure for every patient at every visit.
Advise to quit	In a clear, strong, and personalized manner, urge every tobacco user to quit and nonusers to remain tobacco free. (Focus on short-term effects with youth; remind parents of their responsibility as role models.)
Assess willingness to make a cessation attempt	Is the tobacco user willing to make a cessation attempt at this time? (Assess risk of future tobacco use; praise and reinforce healthy decisions; help youth practice refusal skills.)
Assist in cessation attempt	For the patient willing to make a cessation attempt, use counseling to help him or her quit. (Set a quit date; provide brief counseling and self-help materials; refer to quit line.)
Arrange follow-up	Schedule follow-up contact, preferably within the first week after the cessation date. (Monitor progress and problems; reinforce antismoking messages; discuss possibility of relapse and ways to prevent relapse.)

marketing and strengthen warning labels.

CLINICAL PRACTICES FOR TOBACCO-USE REDUCTION

Studies have indicated that most adolescent and young adult smokers want to quit and even try to quit smoking, but few are successful. In 2007, the percentage of high school smokers who made a quit attempt ranged from 43.4% to 62.5%, with a median of 55.7%.[75] Although youth report a desire to quit and quit attempts, few seek medical help with quitting.[76,77] A number of possible reasons have been cited for this, including the lack of smoking-cessation modalities proven effective for youth, youth not believing that quitting tobacco use warrants professional help, youth preferring privacy, and available cessation programs not addressing the unique concerns and issues most relevant to youth tobacco users.[76] When pediatricians do provide medical care related to tobacco use, they must uphold confidentiality standards established through pediatric and adolescent medicine professional organizations and supported by state laws.[78–80]

Although extensive scientific evidence supports best-practice recommendations and strategies for tobacco dependence treatment in adults, the scientific evidence for treating tobacco use and dependence effectively in adolescents is still evolving.[7] The recently released Public Health Service clinical practice guideline, "Treating Tobacco Use and Dependence: 2008 Update," states that counseling has been shown to be effective in the treatment of adolescent smokers.[7] The cognitive-behavioral counseling approach involves establishing awareness of tobacco use, identifying motivations to quit, preparing to quit, and providing strategies for maintaining abstinence after cessation. The 5 A's model, as out-

TABLE 3 Smoking-Cessation Medications[7]

Medication[a]	Dose	Adverse Effects, Precautions, Warnings, and Contraindications
Bupropion	Begin treatment 1–2 wk before quit date; 150 mg/day for 3 d, 150 mg twice daily for 7–12 wk after quit date	Adverse effects: insomnia, dry mouth; contraindications: monoamine oxidase (MAO) inhibitor use in past 14 d, history of seizure or eating disorder
Nicotine gum: 2 mg if <25 cigarettes per day, 4 mg if ≥25 cigarettes per day	At least 1 piece every 1–2 h for the first 6 wk (≤24 pieces per day)	Adverse effects: mouth soreness, hiccups, dyspepsia; acidic drinks interfere with absorption of nicotine
Nicotine inhaler: 4 mg of nicotine per cartridge (80 inhalations)	6–16 cartridges per day	Acidic drinks interfere with absorption of nicotine
Nicotine lozenge: 2 mg if first cigarette >30 min after waking, 4 mg if first cigarette <30 min after waking	1 lozenge every 1–2 h for first 6 wk (at least 9 lozenges per day), 1 every 2–4 h during weeks 7–9, then 1 every 4–8 h (≤20 lozenges per day)	Adverse effects: nausea, hiccups, heartburn; acidic drinks interfere with absorption of nicotine
Nicotine nasal spray: a dose is 0.5 mg per nostril (1 mg total)	1–2 doses per hour (minimum: 8 doses per day; maximum 40 doses per day)	Adverse effects: nasal irritation, nasal congestion; precaution: do not use in people with severe reactive airways disease
Nicotine patch	21 mg/24 h for 4 wk, 14 mg/24 h for 2 wk, and 7 mg/24 h for 2 wk (step-down dosage) or 15 mg/16 h for 8 wk (single dosage)	Adverse effects: local skin reaction, insomnia, and/or vivid dreams
Varenicline (Chantix [Pfizer, Mission, KS])	Start treatment 1 wk before quit date; 0.5 mg/d for 3 d, 0.5 mg twice daily for 4 d, 1 mg twice daily for 3 mo	Precaution: decrease dose if kidney disease ; warning: depressed mood, agitation, behavior changes, suicidal ideation, and suicide have been reported; adverse effects: nausea, trouble sleeping, abnormal/vivid dreams

[a] See FDA package insert for more complete information.

lined in the Public Health Service guideline, has been modified for children and adolescents.[7] The AAP has advocated a sixth A—anticipate—that takes into account child development and the importance of anticipatory guidance in pediatric practice[81] (see Table 2). Counseling for children and adolescents should be developmentally appropriate and relevant across various age groups. Behavioral counseling from a health care professional can range in intensity from brief advice and encouragement to quit, to more intense multisession group-therapy programs, to proactive telephone quit lines, to interactive computer-based programs. The Public Health Service guideline recommends that all clinicians strongly advise patients who use tobacco in any form to quit.[7]

Pediatricians should be familiar with the pharmacotherapies for smoking cessation that have been approved by the FDA, including various forms of nicotine-replacement therapy, the antidepressant bupropion, and a nicotine receptor partial agonist, varenicline, although none of these have been approved by the FDA for tobacco cessation in people younger than 18 years (see Table 3). A few studies have examined the use of pharmacotherapy agents in helping youth quit smoking; however, most of the studies have suffered from small sample sizes, limited power, and high attrition rates. Although nicotine-replacement medications have been shown to be safe in adolescents, there is little evidence that these medications or bupropion are effective in promoting long-term abstinence among adolescent smokers. They are, therefore, not recommended as components of pediatric tobacco intervention by the Public Health Service guideline.[7]

ADDITIONAL RESEARCH NEEDED

There are major gaps in the scientific literature used to support decisions regarding youth tobacco control. Although there are challenges to conducting this research, including recruitment and retention, researchers have been making steady progress. Some areas that require further study in youth populations include the factors that motivate tobacco-cessation attempts, safety and effectiveness of tobacco-cessation pharmacotherapy in adolescents, use and efficacy of telephone quit lines, and Web-based strategies for engaging youth in tobacco cessation.

CONCLUSIONS

Smoking remains the most common preventable cause of illness and death in the United States. Smokeless-tobacco and secondhand smoke exposure cause additional morbidity and mortality. Clinicians caring for pediatric patients should provide tobacco-use and exposure prevention and cessation education and advice, screening and counseling, and intervention and referral for patients and their families.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Tobacco Use: A Pediatric Disease

abstract

Tobacco use and secondhand tobacco-smoke (SHS) exposure are major national and international health concerns. Pediatricians and other clinicians who care for children are uniquely positioned to assist patients and families with tobacco-use prevention and treatment. Understanding the nature and extent of tobacco use and SHS exposure is an essential first step toward the goal of eliminating tobacco use and its consequences in the pediatric population. The next steps include counseling patients and family members to avoid SHS exposures or cease tobacco use; advocacy for policies that protect children from SHS exposure; and elimination of tobacco use in the media, public places, and homes. Three overarching principles of this policy can be identified: (1) there is no safe way to use tobacco; (2) there is no safe level or duration of exposure to SHS; and (3) the financial and political power of individuals, organizations, and government should be used to support tobacco control. Pediatricians are advised not to smoke or use tobacco; to make their homes, cars, and workplaces tobacco free; to consider tobacco control when making personal and professional decisions; to support and advocate for comprehensive tobacco control; and to advise parents and patients not to start using tobacco or to quit if they are already using tobacco. Prohibiting both tobacco advertising and the use of tobacco products in the media is recommended. Recommendations for eliminating SHS exposure and reducing tobacco use include attaining universal (1) smoke-free home, car, school, work, and play environments, both inside and outside, (2) treatment of tobacco use and dependence through employer, insurance, state, and federal supports, (3) implementation and enforcement of evidence-based tobacco-control measures in local, state, national, and international jurisdictions, and (4) financial and systems support for training in and research of effective ways to prevent and treat tobacco use and SHS exposure. Pediatricians, their staff and colleagues, and the American Academy of Pediatrics have key responsibilities in tobacco control to promote the health of children, adolescents, and young adults. *Pediatrics* 2009;124:1474–1487

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

BACKGROUND

Tobacco use is the leading preventable cause of death and illness in the United States, causing more than 443 000 deaths each year.[1] The consequences of tobacco use include harms to the health of the fetus, such as low birth weight and sudden infant death; harms to children from tobacco use and secondhand tobacco-smoke (SHS) exposure, including respiratory illness, infection, and decreased lung function; the uptake and establishment of tobacco use and nicotine addiction by the

next generation; fires attributable to smoking; the economic costs of purchasing tobacco and tobacco-use materials; litter and debris from tobacco products; additional cleaning and maintenance of facilities in which tobacco is used; the health care and emotional costs of diseases associated with tobacco use and SHS exposure; and the costs to families and society because of poor health and lost productivity.[2]

Most tobacco users (~80%) started using tobacco products before 18 years of age.[3] Initiation of tobacco use is often instigated by exposure to tobacco use by parents or peers, depiction in movies and other media, advertising targeting children and adolescents, and other environmental and cultural factors.[3–12] The connection between children and tobacco use is so strong that the commissioner of the US Food and Drug Administration declared tobacco use a "pediatric disease" in 1995.[13]

Tobacco use is a pediatric disease because of the extent of harms to children caused by tobacco use and SHS exposure, the relationship of pediatric tobacco use and exposure to adult tobacco use, the existence of effective interventions to reduce tobacco use,[14] and the documented underuse of those interventions.[15] This statement provides guidance for providers of pediatric services, including the American Academy of Pediatrics (AAP) and its members, and summarizes other AAP policies that have addressed tobacco use and control.

Because tobacco use has significant effects on children and families, its management has been reviewed in many AAP policies and official documents.[16–18] The information and recommendations described in this statement are consistent with recommendations in the other AAP publications cited as well as with tobacco policies from other clinical professional membership organizations, including the Academic Pediatric Association,[19] the American Academy of Allergy Asthma & Immunology,[20] the American Academy of Family Practice,[21] the American Academy of Pediatric Dentistry,[22] and the American Medical Association.[23,24] The policy is accompanied by 2 technical reports: "Secondhand and Prenatal Tobacco Smoke Exposure"[25] and "Tobacco as a Substance of Abuse."[26]

The AAP recognizes the dangers of tobacco use and SHS exposure to children's health. Tobacco control was named a strategic priority by the AAP in 2005, and the Julius B. Richmond Center of Excellence (www.aap.org/richmondcenter), dedicated to the elimination of children's exposure to tobacco and SHS, was established in 2007 to foster tobacco-control initiatives at the AAP.

TERMS USED AND THEIR DEFINITIONS

The term "tobacco" includes all smoked and smokeless forms. The term "tobacco control" refers to any and all aspects of efforts to reduce or eliminate tobacco use in any form, except ceremonial uses, where legal. The term "parent" is meant to include anyone acting in the role of parent, including legal guardians and foster parents. "Community" is used broadly and includes local-, city-, county-, state-, national-, and international-level groups and organizations.

THE ROLE OF PEDIATRICIANS IN TOBACCO CONTROL

Pediatricians have important roles in efforts to reduce family tobacco use and SHS exposure. In their practices, they can (1) provide counseling to expectant parents to quit using tobacco products and avoid SHS exposure during and after pregnancy, (2) assist new parents in their efforts to continue their tobacco use-abstinence or -cessation efforts after delivery, (3) counsel parents to prevent and eliminate children's exposure to SHS, (4) counsel preadolescents and adolescents to prevent initiation of tobacco use, and (5) counsel adolescents and parents to quit using tobacco. Important adjuncts to these efforts include quitlines and pharmacotherapies for tobacco-use cessation.[14,27,28] Quitlines (toll-free telephone-based tobacco use-cessation services that offer evidence-based information and counseling support, including referral of the tobacco user to his or her primary care provider for pharmacotherapies) are an effective way to deliver tobacco use-cessation services.[28] Quitlines are available throughout the United States, Canada, and many other countries. Pharmacotherapies approved for adult use, including nicotine-replacement products and medications such as varenicline and bupropion, are extremely effective in promoting tobacco-use cessation when used in conjunction with cessation counseling.[14]

AAP members are uniquely positioned to disseminate information about the effects of tobacco use and effective tobacco-control methods through their practices and other efforts. In addition to practice-based efforts in tobacco control, other roles for pediatricians include participating in community, advocacy, and media campaigns that inform the public of the harms of tobacco use, SHS exposure, and the risks of tobacco-use initiation; promoting treatment; and helping to enact and enforce laws and regulations that limit access to tobacco and promote tobacco control.

TOBACCO CONTROL AND PUBLIC POLICY

Legislative and regulatory efforts that have been effective in controlling and eliminating tobacco use include clean indoor-air legislation, taxes on tobacco products, restricting youth access to

tobacco products, mass-media campaigns, tobacco-advertising restrictions, and comprehensive community interventions.[29] Interventions in single arenas have not been sufficient to achieve tobacco control. The most effective strategies use multiple interventions that target different aspects of tobacco control, including school-based programs, anti–tobacco-use advertisements, and enforcement of existing tobacco-control policies.[30] Many successful public-policy changes have begun with the efforts of individuals—including pediatricians—who initiated, supported, and led tobacco-control efforts in their practices, communities, professional organizations, and legislatures. A promising effort, supported by the AAP, is the recent federal law that grants the US Food and Drug Administration regulatory control over tobacco.

ECONOMICS OF TOBACCO USE AND SHS EXPOSURE

Tobacco use is costly, and the resulting harms are completely preventable. Health care costs attributable to tobacco use and SHS exposure are estimated to be in the billions of US dollars annually.[31–34] Other costs attributable to tobacco use and SHS exposure include loss of life and productivity,[35,36] income diverted to purchase tobacco-use materials,[37,38] and fires.[39–43] Treatments for tobacco use and dependence are among the most efficacious and cost-effective preventive services in both the short-term and long-term[2,14,44] and are second only to childhood immunization in terms of cost-effectiveness.[2,45–48]

THE TOBACCO INDUSTRY

The goal of the tobacco industry is profit, not health. Tobacco industry–sponsored research programs have been designed to gain an air of legitimacy and produce results favorable (or less unfavorable) to tobacco use.[49] The tobacco industry has attempted to present the evidence of harms from tobacco use and SHS exposure as "controversial."[50] Youth exposure to tobacco industry–sponsored prevention advertising does not prevent tobacco use, and industry-sponsored prevention programs that target parents may actually promote youth tobacco use.[51]

SOCIOECONOMICALLY DISADVANTAGED CHILDREN AND ADOLESCENTS

The prevalence of cigarette smoking is greatest among adults who live below the poverty line and those who have not completed high school[52]; accordingly, SHS exposure disproportionately affects children who live in low-income households.[52] Use of other forms of tobacco is similarly distributed according to income and education levels.[53] The costs associated with tobacco use exacerbate the health harms to children by decreasing available family funds while increasing the likelihood of poor health in their parents, which can lead to decreased family income[54] and stratification of tobacco use in the population that is least able to afford the consequences.[55]

TOBACCO USE AND PSYCHIATRIC AND SUBSTANCE USE DISORDERS

People with psychiatric and substance use disorders, including youth and young adults, are far more likely to use tobacco than those in the general population,[56–61] yet they are less likely to have a diagnosis of and receive treatment for nicotine addiction.[62–64] These people deserve treatment of their nicotine addiction and can successfully quit using tobacco.[14] Although people with psychiatric and substance use disorders are more likely to relapse in their tobacco-cessation efforts than the population at large, there is little evidence that nicotine withdrawal will escalate psychiatric symptoms.[14] One study of patients in a maximum-security forensic hospital showed a decrease in sick calls, total disruptive behavior, and verbal aggression after a smoking ban was implemented.[65] Several psychiatric facilities, including facilities for adolescents, have successfully eliminated tobacco use.[66,67] Because nicotine withdrawal may unmask psychiatric symptoms or disorders, this potential should be anticipated, and treatment of these symptoms or disorders should be considered an adjunct to treatment of tobacco use and dependence.[68]

TOBACCO AND ALASKA NATIVE AND AMERICAN INDIAN PEOPLE

Tobacco-use and smoking rates are highest among Alaska Native and American Indian people.[69–73] In addition to the high prevalence of smoking in these groups, the use of smokeless tobacco is common, even among adolescents and children.[74,75] Smokeless tobacco has been used by Alaska Native parents to calm their children while they are teething.[76] It is important to note that traditional ceremonial use of tobacco does not include smoking cigarettes, the use of smokeless tobacco, or the use of other commercial tobacco products.[70,77] Although traditional ceremonial uses of tobacco still play a role within many American Indian tribes, every effort should be made to prevent nontraditional uses.

TOBACCO USE AND MILITARY SERVICE

Historically, tobacco use and smoking have been accepted, even encouraged, by the military services. More recently, the US Department of Defense (DoD) took an active approach to reducing tobacco use by members of the military services. Subsidized sales of tobacco products were eliminated in 1996,[78] most DoD-operated facilities are smoke free (see DoD instruction No. 1010.15, January 2, 2001, for exceptions), and resources for tobacco-use

prevention and cessation are widely available.[79] These and other efforts have contributed to a decline in cigarette use by military personnel from 51% (1980) to 32% (2005).[80] Despite these efforts, the prevalence of tobacco use remains higher in military personnel than in comparable civilian populations.

ORGANIZATION OF THE POLICY STATEMENT

Because of the effects of tobacco use on children and their families and the extent to which tobacco permeates our society, the recommendations in this policy statement are numerous and detailed. The recommendations to pediatricians address personal and professional behavior as well as clinical practices. The recommendations to government and policy makers include public actions needed to eliminate SHS exposure, support prevention and treatment of tobacco use and dependence, support control of tobacco product-distribution, and expand research. Three overarching principles can be identified: (1) there is no safe way to use tobacco; (2) there is no safe level or duration of exposure to SHS[81]; and (3) the financial and political power of individuals and organizations should be used to support tobacco control and eliminate tobacco use. Many AAP statements have tobacco-related content and provide additional detail on specific topics (Table 1), and additional resources are available (Table 2).

RECOMMENDATIONS TO PEDIATRICIANS

1. Personal Behavior
   A. Maintain a tobacco-free environment at home, at work, at play, and in vehicles. Do not smoke or use tobacco in any way. Encourage family members and friends to do the same. Do not wear or display tobacco products, advertisements, or promotional items on your person or property.
   B. Consider tobacco control when making financial decisions. Support smoke-free restaurants, hotels, and other venues as well as print and electronic media companies that decline tobacco advertising. Review your personal financial holdings and divest or avoid tobacco stocks (Table 2).
2. Professional Behavior
   A. Patronize tobacco- and smoke-free venues. Hold conferences and meetings at smoke-free locations in smoke-free jurisdictions (Table 2).
   B. Support comprehensive tobacco control and prevention, education, and cessation programs and policies in schools and your community. Participate in education of community leaders and elected officials about tobacco control. Promote linkages among community resources and organizations related to tobacco control. Serve as a conduit for information about the harms of tobacco use and common challenges to prevention and cessation and as an advocate for tobacco control in your community. Be available to provide profes-

sional consultation for these programs. Advocate for community-based tobacco-use prevention and treatment services, including services in residential facilities (see Table 1 for related AAP policy statements with more extensive discussions of these facilities).

C. Support clean-air and smoke-free–environment ordinances and legislation in your community and state, particularly for environments in which children learn, live, and play, such as schools, multiunit housing, public parks, child care settings, public beaches, sidewalks, restaurants, and sporting arenas. These environments should be smoke free even when children are not present.

3. Clinical Practice

A. For the office, clinic, or hospital facility

i. Provide tobacco-free environments in all work settings, indoors and outdoors, and in all vehicles, including employees' vehicles used professionally or on work property. Enforce this policy. Some employers insist on no tobacco use by their employees during work hours and while performing official duties; some employers do not hire tobacco users.[82] Consider implementation of these or similar policies.

ii. Encourage and provide support for your employees' efforts to quit tobacco use, including fostering their use of prescription and nonprescription medications, counseling, and other evidence-based methods. When selecting a health insurer for employees, contract with one that provides tobacco-use and -dependence treatment benefits, including coverage for tobacco-use–cessation counseling.

iii. Use office systems that promote cessation and prevention of tobacco use. The most effective way to change clinical practice is to change the "system" of care delivery to one that promotes best practices in cessation and prevention of tobacco use. Resources that facilitate such office-systems changes are available (Table 2). One of the most important changes is to use paper or electronic health records that require documentation of tobacco use and SHS exposure status. This information should be readily available, easy to use, and easy to find. The use of cues to promote counseling in tobacco-use prevention and cessation in the clinical encounter is very effective.[14]

iv. Eliminate tobacco advertising from all materials associated with your clinical practice, including magazines and other media in patient care and waiting areas (Table 2).

v. Do not accept funding from the tobacco industry. The tobacco industry is defined as companies that support or engage in manufacturing, advertising, promotion, exportation, or importation of tobacco or tobacco products.

B. For patients and their family members

i. Ask about and document tobacco use and SHS exposure at all clinical encounters, including prenatal visits, nursery visits, and well- and sick-child visits, whether inpatient or outpatient. Include prenatal exposure as well as SHS exposure from in-home child care providers and family and other household members in these inquiries. Responses should be prominently recorded in the patient's record. This is more likely to be successful if all members of the staff are included in this effort.[14]

ii. Know the harms of tobacco use and SHS exposure and educate patients and their families about those harms.

a. Counsel children and parents about the harms of tobacco use and SHS exposure.

b. Include tobacco in all discussions of substances of abuse and risky behaviors. Discussion and anticipatory guidance about tobacco use should ideally begin by 5 years of age and emphasize resisting the influence of advertising and rehearsal of peer-refusal skills. Be aware of confidentiality issues related to tobacco use and other substance abuse, including testing for nicotine and its metabolites.

c. Encourage parents to start discussions of tobacco use with their children early in their life and continue to do so throughout childhood and adolescence; these discussions should include delivery of clear messages disapproving of tobacco use. Both parents and children should be counseled that

it is not safe to "experiment" with tobacco, because nicotine is so highly addictive and there is no safe way to use tobacco. Tobacco dependence can begin almost as soon as use begins, with some users exhibiting signs of dependence with only occasional or monthly use.[83,84] As a result, prevention of tobacco use is one of the most important messages you can deliver.

d. When discussing safety, instruct parents and caregivers that cigarettes and other lighted tobacco products are the cause of a significant proportion of residential fires that result in fatalities. All smoking materials are dangerous and should be kept out of the reach of children.

iii. Advocate for tobacco-free homes, cars, schools, child care programs, playgrounds, and other venues.

a. Advise avoidance of SHS exposure and suggest ways to eliminate SHS exposure. Counsel all families to make their homes and cars completely "smoke free." The dangers of SHS and the risk of modeling tobacco use should be discussed with parents and caregivers, particularly those who smoke, and reinforced with culturally and ethnically appropriate resources and cessation referrals.[25]

b. Advise parents to inquire about policies on tobacco use when selecting schools, child care programs, and other venues for their children. There should be no tobacco use in or around the premises, regardless of whether children are present.

C. For patients or family members who use tobacco or who are exposed to SHS

i. Advise all families to make their homes and cars smoke free, and urge all tobacco users to quit. Provide appropriate advice and counseling to foster tobacco users to quit. Routinely offer help and referral to those who use tobacco—even if the person is not your patient. Be familiar with evidence-based guidelines for treatment of tobacco use and dependence and apply them to patients and their families.[14] There is a growing body of literature on the effectiveness of pediatric clinician-provided treatment for parental nicotine addiction that demonstrates a role for pediatricians in this effort.[14,85,86]

a. Pharmacotherapy is an effective component of tobacco use-cessation treatment in adults.[14] Encourage tobacco users to include these medications in their quit plan, whenever appropriate. Be familiar with and offer information and instruction on correct use. Many nicotine-replacement products are available without a prescription, although prescriptions are required for any nicotine-containing product if the patient is younger than 18 years.

Most (85%) parents who smoke consider it acceptable for their child's pediatrician to prescribe a smoking-cessation medication for them,[87] but few pediatricians do so.[88] Liability concerns, record-keeping challenges, and lack of insurance reimbursement are cited as barriers to prescribing these products to parents.[89] In response to these concerns, the American Medical Association adopted a policy statement in 2005 supporting the practice of pediatricians addressing parental smoking.[90]

Pediatricians who choose not to prescribe pharmacotherapies should make referrals to cessation services and recommend that parents discuss pharmacotherapies with their health care providers or purchase over-the-counter products.

b. Be familiar with tobacco-use–cessation services in your community and provide referrals to these programs for your patients and their families. Memorize the national quitline telephone number (1-800-QUIT NOW), prominently post it, and provide it to all tobacco users. Whenever possible, proactively enroll tobacco users in cessation programs, using "fax-back" or similar programs. Such referrals are more effective in connecting the tobacco user to the resource than referrals that

require the tobacco user to initiate the contact.

ii. Counsel all parents, including those who smoke, on how to deliver antitobacco messages and ways to discuss the addictive nature of nicotine.

a. When parents or caregivers use tobacco, their children are more likely to experiment with tobacco and to begin to use tobacco regularly. Maintain a high index of suspicion for early onset of tobacco use by these children. It can be a particularly powerful message when the parent or caregiver who uses tobacco advises the child never to start using tobacco[91] (Table 2).

b. Help patients and families understand that even casual use of tobacco by children and adolescents, regardless of amount or frequency, is illegal and associated with adverse health consequences.

iii. Code for tobacco use and SHS exposure and bill for treatment. Consider SHS exposure a risk factor when justifying immunizations, respiratory syncytial virus prophylaxis, and other care. The additional time needed to counsel families about tobacco use should be documented and billed as the counseling that it is (Table 2). Whenever appropriate, list on death certificates that tobacco use or SHS exposure was the cause of or a contributor to death.

iv. Tobacco use by mothers is not a contraindication to breastfeeding, but tobacco use immediately before and during breastfeeding is strongly discouraged. Nicotine and its metabolites are present in human milk, and all tobacco users, including breastfeeding mothers, should make their home smoke free immediately and quit using tobacco products as soon as possible. Infants of mothers who smoke and breastfeed are more likely to be weaned at a younger age and to experience other adverse effects. For a more complete discussion of tobacco use by breastfeeding mothers, see specific AAP policy statements (Table 1).

v. SHS exposure may arise as a concern when children are involved in custody disputes. The AAP supports a healthy environment for children, meaning that the physical, emotional, and educational environment should provide support, nourishment, and education. Custody arrangements are complex agreements that should be decided on the basis of the best interests of the child, and all aspects of the child's well-being should be considered. All parents should be encouraged to eliminate their child's exposure to SHS; however, custody arrangements based solely on tobacco use or SHS exposure may not be in the overall best interests of the child.

D. Special considerations for populations at high risk of harm from tobacco or of tobacco use

i. Emphasize the significant health harms of tobacco use and SHS exposure when treating children with chronic diseases or health risks such as preterm birth, low birth weight, asthma, diabetes, cystic fibrosis, and sickle cell disease. Several AAP policy statements have addressed tobacco use and SHS exposure in children with chronic diseases (Table 1), including sickle cell disease and Turner syndrome. When preparing future AAP policies, guidelines, and other products, authors should consider and mention the effects of tobacco use and SHS exposure on the subject addressed. Whenever relevant, AAP products should provide information on or access to information about treatment of tobacco use and dependence and SHS exposure.

ii. When assessing mental health and substance abuse, include assessment of tobacco use and SHS exposure. Urge adolescent substance abuse treatment programs to treat tobacco dependence in their patients and their families. Treatment for nicotine addiction, if indicated, should be part of any inpatient or outpatient treatment plan. Closely monitor such individuals for changes in their symptom and adverse-effect profile during early nicotine withdrawal.

iii. The following groups of people are more likely to use tobacco than those in the general population and should be counseled accordingly:

a. Lesbian, gay, bisexual, and transgender children and youth[92,93] (Table 1).

b. Alaska Native and American Indian people. Respect for

ceremonial tobacco use should be demonstrated.

c. Current or former military personnel.

RECOMMENDATIONS FOR GOVERNMENT AND ADVOCACY

Whenever new public policy is developed or existing policy is revised, the wide range of consequences of tobacco use on children and their families should be considered. Local, county, state, and federal policies should support and enforce tobacco control. The AAP, through its chapters, committees, councils, sections, and staff, can provide information and support for public-policy advocacy efforts. See www.aap.org/advocacy.html for further information or contact chapter leadership.

1. Tobacco-Free Environments

   A. The use of tobacco products in all indoor and outdoor public places should be prohibited. Federal, state, and local governments should enact and enforce laws that mandate the provision of smoke-free environments in all public places and require employers to provide smoke-free work environments for their employees.

   B. Health care and educational facilities should be completely tobacco free, inside and outside, at all times. This includes all buildings, grounds, parking lots, satellite facilities, vehicles, and temporary venues. Tobacco-dispensing machines and sale of tobacco products should be banned from schools, hospitals, affiliated clinics, and pharmacies. The only exception to this ban would be legitimate research centers that study tobacco use or cessation.

2. Treatment of Tobacco Use and Dependence

   A. Clinicians should be trained and skilled in counseling to prevent tobacco use and SHS exposure and the treatment of tobacco use and dependence. Medical schools, nursing schools, residency training programs, fellowship programs, and continuing medical education programs should include training in tobacco-use treatment and the prevention of tobacco use and SHS exposure.

   B. Treatment of tobacco use and dependence should be available to patients and their families in both inpatient and outpatient settings. Children's hospitals and pediatric inpatient and outpatient facilities should specifically address the tobacco use of parents and other family members.

   C. Proactive enrollment in cessation programs such as "fax-back" quitlines should be implemented in every jurisdiction and be available through all clinical settings, including pediatric settings.[28] The additional staff and resources needed to implement a proactive program should be supported.

   D. Public and private employers should develop or provide access to tobacco-use–cessation programs for their employees and provide employee incentives for participation in these programs. Incentives, such as tax exemptions, should be offered to public and private employers who offer tobacco-use–cessation programs for their employees.

   E. All public and private health insurance should provide coverage for comprehensive tobacco-cessation treatment, including counseling (individual and group) and medications (both prescription and over-the-counter) that have been shown to be effective. Health insurance should provide adequate reimbursement for services related to the treatment of tobacco use and SHS exposure of children and families, including behavioral modification treatments and US Food and Drug Administration–approved pharmacotherapies.

3. Tobacco-Use Prevention. Local, state, and federal authorities should promote programs that contribute to the prevention and decrease of tobacco use by youth, including programs that discourage tobacco use, support antitobacco advertising, and teach skills to resist peer and advertising influences. Evidence-based antitobacco education, as recommended by the Centers for Disease Control and Prevention,[30] the US Surgeon General,[94] and the Institute of Medicine,[95] should be provided to students at all levels of education, including early childhood, elementary, secondary, and higher. It is important to differentiate between genuine effective tobacco-prevention curricula and those developed and supported by the tobacco industry, which have been shown to encourage tobacco use.[96,97]

4. Tobacco Product Control

   A. Control access to tobacco products.

      i. Sales and distribution of tobacco to youth should be strictly prohibited. Venues for unsupervised purchase of tobacco products, such as vending machines and online merchants, should be eliminated. All tobacco products should be placed behind sales counters to reduce

shoplifting. Provision of tobacco products to youth by adults should be made illegal, with significant consequences for noncompliance. Sales of tobacco products should be eliminated from schools, including secondary schools; health care facilities; military bases; and other sites that serve youth and young adults. The promotional distribution of tobacco products should be prohibited.

ii. The sale of tobacco products on the same premises as pharmacies should be eliminated, including pharmacies located in supermarkets.

B. Control marketing of tobacco products.

i. All tobacco products should be labeled to warn users of the health hazards of tobacco use. Warnings should use clear wording, in the strongest possible terminology, and be in the primary language of the country in which the product is sold. Warnings should be prominently displayed on packaging (occupying >50% of the front), on advertisements, and on displays at tobacco sales facilities. These warnings should be rotated to present a new warning on a regular basis.[98]

ii. Advertising of tobacco products should be banned from all media, events, and venues, including the Internet. Products such as t-shirts, sports equipment, and other items should not bear messages or images that depict tobacco products or promote tobacco use. All forms of advertising and media, especially advertising and media aimed at children, adolescents, and young adults, should not contain messages that promote tobacco use or images of tobacco or tobacco use. The single exception is historically accurate depictions of real people who used tobacco.

iii. Sales of candy cigarettes, cigars, and other products that imitate tobacco products or smoking should be banned. These products have been shown to promote tobacco use by children and youth.[99,100] The sale or dispensing of electronic or e-cigarettes, which imitate smoking while delivering nicotine to the user, should also be banned.

iv. Exposure to and depiction of tobacco use should be reduced in films, videos, DVDs, and television programs. The evidence is very strong that depiction of tobacco use in films, videos, DVDs, and television programs is a significant factor in the uptake of tobacco use by children and youth.[9] The following 4 steps should be taken:

a. Any new film that shows or implies tobacco use should be given a Motion Picture Association of America† rating of R. The only exceptions should be when the presentation of tobacco clearly and unambiguously reflects the risks and consequences of tobacco use or the depicted tobacco use is necessary to represent that of a real historical figure who actually used tobacco.

b. It should be certified that no one working on or associated with the production received anything of value (money, gifts, publicity, loans, or anything else) in exchange for using or displaying tobacco products. The closing credits of every film depicting tobacco use or displaying images of tobacco products should contain such a declaration.

c. Definitive and unambiguous antismoking ads (not produced or funded by a tobacco company) should be required to preview before any film with any tobacco presence. This should occur in any distribution channel and regardless of the rating for the film.

d. Tobacco brand identification and tobacco brand imagery (such as billboards) should be eliminated from movies.

C. Use tax policies, funding, and evidence to control tobacco.

i. Local, state, and federal tax policies should support tobacco control. Higher taxes have been shown to deter the purchase and use of tobacco and prompt cessation attempts; accordingly, local, state, and federal taxes on tobacco products should be implemented and/or increased. The revenue from these taxes can be used to support evidence-based tobacco-control programs. Tax deductions for advertising tobacco

†The Motion Picture Association of America (MPAA) is the organization that provides the G, PG, PG-13, R, and NC-17 ratings for movies.

products and tobacco-farming price supports and subsidies should be eliminated. Alternative revenue sources should be developed for and promoted to tobacco farmers.

ii. The evidence-based recommendations of *Best Practices for Comprehensive Tobacco Control Programs*[30] should be funded and implemented. Proceeds of the Tobacco Master Settlement Agreement[101] should be used for tobacco-control activities, as intended. More information about state expenditures of funds from the Tobacco Master Settlement Agreement is available from the AAP Division of State Government Affairs.

D. Other aspects of tobacco-control recommendations

i. Foster families should provide smoke-free environments to children whenever possible but specifically in the home and in vehicles used to transport children. These spaces should remain smoke free even when children are not present to reduce the exposure via off-gassing or "thirdhand smoke."‡ Although the smoking status of foster parents need not be a barrier to program participation, smoking-cessation treatments should be made available to foster parents. Evidence of smoking in the home or in vehicles should be assessed during required inspections. Evidence of smoking in the home or in vehicles should be considered a possible reason for removal of foster families from the program and for selecting alternative, smoke-free environments for children.

ii. Traditional sacred tobacco use by American Indian and Alaska Native people should be preserved while preventing nicotine addiction. Images, names, and icons from American Indian culture, such as "Noble," "Geronimo," "Red Man," and "American Spirit," should not be used to "brand" and market tobacco products to US and international markets.

iii. All cigarettes should be required to use "fire-safe" technology, which makes them less likely to cause fires (Table 1).

5. Research

B. Funding should not be accepted from the tobacco industry.

C. Pediatric tobacco-control research should be considered a high priority and funded accordingly. Priorities include development of evidence-based curricula to educate pediatric clinicians on the health effects of SHS exposure, nicotine addiction, and tobacco use as well as effective treatments for tobacco use and nicotine addiction. The spectrum of pediatric tobacco control includes prevention of youth tobacco use and dependence, treatment of youth tobacco dependence, prevention and treatment of SHS exposure of children, and prevention and treatment of tobacco use and SHS exposure of pregnant women.

i. Research in basic science, clinical outcomes, behavior, family structure and tobacco use, health services, underserved populations, health education, and policy analysis must be included in this comprehensive research effort.

ii. Funding for training the next generation of investigators in pediatric tobacco control should be supported.

iii. Translation of research on effective interventions to promote smoking cessation and reduction of SHS exposure from adult to pediatric settings is needed. Transdisciplinary efforts to maximize the positive effects on children of these research endeavors should be encouraged and supported.

6. International Tobacco Control

A. The World Health Organization Framework Convention on Tobacco Control should be ratified by the United States (Table 2). However, any resulting federal legislation to implement the Framework Convention should expressly not preempt stronger state or local restrictions.

B. As an exporter of tobacco, the United States should conform to all domestic policies when making treaties, agreements, and other arrangements with other governments. Tobacco products sold on American Indian reservations and tobacco products manufactured for export markets should be required to conform to the same requirements as tobacco products intended for the US market, except when the destination country has stronger requirements.

‡Thirdhand smoke is the smoke residue that is left in an environment after smoking has ceased. Some components of thirdhand smoke persist for weeks and provide a lasting source of exposure.

CONCLUSIONS

Tobacco use is the leading preventable cause of death and illness in the United States. Pediatricians and other clinicians who care for children are uniquely positioned to assist patients and families with prevention and treatment. Pediatricians and the AAP have key responsibilities in tobacco control and place a high priority on these goals for the health of children.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Toward Transparent Clinical Policies

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Steering Committee on Quality Improvement and Management

ABSTRACT

Clinical policies of professional societies such as the American Academy of Pediatrics are valued highly, not only by clinicians who provide direct health care to children but also by many others who rely on the professional expertise of these organizations, including parents, employers, insurers, and legislators. The utility of a policy depends, in large part, on the degree to which its purpose and basis are clear to policy users, an attribute known as the policy's transparency. This statement describes the critical importance and special value of transparency in clinical policies, guidelines, and recommendations; helps identify obstacles to achieving transparency; and suggests several approaches to overcome these obstacles.

INTRODUCTION

The mission of the American Academy of Pediatrics (AAP) is to promote the attainment of optimal physical, mental, and social health and well-being for all children. To aid in the accomplishment of this mission, the AAP develops clinical policies that are valued highly by members who provide direct health care to children, members of other organizations that share similar goals, and by parents, payers, and legislators. The utility of a policy depends, in large part, on the degree to which its purpose and basis are clear to policy users. This attribute is referred to as the policy's transparency. The purpose of this policy statement is to describe the critical importance and special value of transparency in clinical policies, guidelines, and recommendations; to identify obstacles to achieving transparency; and to suggest several approaches to overcome these obstacles. The term "policy" is used to refer generally to policies, guidelines, recommendations, and other similar statements.

The purpose of creating most clinical policies is to improve processes and outcomes of care by decreasing inappropriate variation in practice and increasing the implementation of effective strategies of health promotion and disease management. Such policies serve to guide clinical practice by summarizing the accumulated scientific evidence and combining it with the opinions of expert clinicians to define courses of action that are appropriate for patient care. Policies may provide guidance about:

- educating or counseling patients about their health and health care;
- implementing effective strategies of health promotion and disease management;
- using tests appropriately;
- monitoring patient status;
- defining criteria for diagnosis;
- performing procedures;
- prescribing medications and devices;
- referring for specialized care;
- documenting in the medical record;
- outlining ethical behaviors;
- defining an appropriate setting for care;
- promoting patient well-being;
- preparing clinicians and facilities to provide safe and effective care; and/or
- advocating on behalf of patients[1] and pediatricians.

Policies that are intended to influence the clinical actions of health care professionals should be based on the best available evidence and should include guidance regarding the application of such evidence to the individual patient.

Application of policy recommendations, like all clinical decision-making, is attended by some degree of uncertainty. Will this treatment be effective for this patient at this time? Will the patient suffer from an adverse effect that will interfere with successful treatment? Will the cost of the regimen make it impossible for the family to adhere to the prescribed intervention? Astute clinicians weigh the anticipated benefits of a policy recommendation against potential risks, harms, and costs viewed in the context of the patient's individual situation and preferences. Users' confidence that a given policy will result in particular benefits, risks, harms, and costs is enhanced when the policy is based on the best available clinical research and is free from bias and when the evidence and reasoning that support the policy are explicitly stated.

TRANSPARENCY

Transparency requires explicit statements regarding the reasons for developing a policy and explaining how published scientific evidence, pathophysiologic reasoning, clinicians' experiences, and perceptions of society's and patients' values are weighed. It also requires disclosure of potential biases of policy authors. Transparency allows potential users to judge the credibility of a policy by observing how the policy authors arrived at a result; thus, it has the potential to promote acceptance of the judgments and choices that have been made.

OPPORTUNITIES TO IMPROVE POLICY

Policies will decrease inappropriate variability in practice only when they are accepted and adhered to by clinicians. Obstacles to the successful acceptance and implementation of a policy include concern about lack of credibility and bias on the part of policy writers; poor understanding of the process of policy formulation; apparent or actual lack of scientific evidence to support policies; and poorly articulated or vague policy statements. Each of these obstacles has the potential to diminish the user's confidence in the policy and, thereby, the authority and utility of a statement.

Confidence in Policy Makers

Ultimately, the authority accorded to a policy depends on the policy authors' credibility as child health experts. It is valuable for policies to include a concise summary of the breadth of skills and experience represented on the writing team. In general, national specialty societies, such as the AAP, and their policy-writing committees are accorded a high level of credibility by members and other users, because policy authors are considered to have considerable scientific knowledge and clinical expertise and to share and represent the values of stakeholders in the policy.[2]

Concerns may also be raised about policy authors' potential biases. Despite the best intentions, policy authors may be influenced—consciously or unconsciously—by financial, personal, and intellectual conflicts in the development of policy. Potential conflicts of interest of all members of the formulating body must be declared. Disclosure of conflicts allows the reader to interpret the policy in light of those potential conflicts and permits other members of the policy-writing team to decide how to interpret contributions from a potentially conflicted team member. Public recognition of potential conflicts may also make policy authors more cognizant of otherwise-unrecognized biases.

Understanding of the Process of Policy Formulation

An explicit statement of the purpose of the policy can help users to understand the values applied by the policy authors. For example, if the goal of a policy is to decrease inappropriate practice variation when scientific evidence supports a particular clinical practice, it may be interpreted differently from a policy with a goal of diminishing cost or influencing funding decisions.

The process of policy formulation should include a complete review of the available scientific evidence and formulation of guidance based on a combination of evidence and expert consensus. Because the validity of the guidance depends on these processes, an explicit statement of how evidence, expertise, and values were weighed by policy authors can help policy users to understand how best to apply the policy recommendations. The approved process of the AAP for creation of recommendations in evidence-based practice guidelines, for example, calls on policy authors to appraise evidence quality and make an explicit judgment regarding anticipated benefits, harms, risks, and costs.[3] These declarations are summarized in a statement of evidence quality and strength of recommendation for each recommendation in a guideline.

Availability of Evidence

For many situations in pediatric health care, high-quality evidence is not yet available.[4] Because evidence is often absent or conflicting, many statements will inevitably be based largely on expert opinion. This is entirely appropriate, provided the basis is readily apparent to the critical reader. Indeed, it is when evidence is lacking, scant, or conflicting that expert guidance is most often sought. In these situations, policy authors must rely on lower-quality evidence, such as reasoning based on basic principles or expert consensus, to formulate coherent recommendations.

It is particularly important that users of a policy be aware if the policy relies on lower-quality evidence so they may be alert to the publication of new information and so those to whom the policy is applied are aware of the relatively tenuous state of the supporting evidence. Moreover, an understanding of the quality

of supporting evidence should influence the expectations of payers and those who define legal standards of care. When policies are written in a spirit of full disclosure, policy users will be aware of the potential for change when new evidence becomes available and will be more likely to understand, and accept, changes in policy. Moreover, expectations of adherence should be lower when evidence quality is limited or there is a balance between anticipated benefits versus harms, risks, and costs.

Vague Policy Statements

Thoughtfully crafted statements that reflect hours of travail by policy authors may be difficult to put into practice consistently because of lack of clarity.[5,6] Ambiguous policy statements are those that are capable of being interpreted in more than one way. It seems obvious that policy statements that are intended to improve the consistency of clinical care should not be ambiguous. Yet, policy implementers regularly complain about the lack of clarity of published policies. A related problem is that authors often deliberately introduce vagueness into policy by using terms with meanings that lack precise boundaries.[7]

Reasons for intentionally creating vague recommendations include:

- insufficient evidence (commonly, the scientific literature in pediatrics has not addressed critical topics, or the conclusions of published studies are suspect because of methodologic flaws);
- inability to achieve consensus among the authors regarding evidence quality, anticipated benefits and harms, or interpretation of the published literature;
- legal considerations (ie, unwillingness to create a potential legal "standard of care");
- economic reasons (one approach is clearly best but may not be affordable or cost-effective); and
- ethical/religious issues (such as attitudes about the "burden" or "futility" of care, premarital sex, or the use of blood products).

An explicit statement of the reasons for writing deliberately vague recommendations can help users interpret and apply them.

RECOMMENDATIONS

The Steering Committee on Quality Improvement and Management makes these recommendations to improve transparency and credibility of policy documents while recognizing the challenges involved in their full implementation.

1. Enhance the credibility of policy-making groups. Policy-writing panels should seek input from major stakeholders who are likely to apply the policy themselves or be influenced by it and from experts in the area of interest. Policy authors should disclose potential and actual conflicts of interest that might affect their policy writing and describe how they are addressed.
2. Make the process of policy formulation clear to users. A statement should include an explicit statement of the reason it was decided to make policy in this area and the intended goals of the statement. Authors should describe how the evidence was selected and assessed and what evidence exists to support the policy. Authors should clearly note when consensus and expert opinion have been required to formulate policy.
3. Improve the clarity of recommendations to facilitate implementation. Policy authors should be explicit about the exact circumstances under which a recommended action should be performed (decidability) and should describe precisely how that action should be performed when those circumstances exist (executability). By improving the decidability and executability of policies, such precision would improve consistent application of recommendations. If vagueness is introduced intentionally, the rationale should be documented.
4. Train skilled policy authors. Effectively implementing these recommendations will require training of policy authors in critical appraisal of evidence; differentiating questions of evidence and expertise from questions of value; consensus building; and understanding the policy-formation process. Opportunities for such training should be developed and sustained.

CONCLUSIONS

Professional societies, government agencies, and other organizations have created a vast array of policies that are widely used and highly valued. When such policies advise actions that have significant clinical and resource implications, it is particularly important that the policy-writing process explicitly recognize uncertainty and include careful literature review; systematic appraisal of evidence quality; weighing of anticipated benefits, harms, and costs; and documentation of the process. Every policy should be subject to a scheduled periodic review with reaffirmation, revision, or retirement as possible outcomes.

The solutions proposed in this statement may be applied as new policies are created or when policies are revised. Such gradual implementation will also help to ensure both continuity and accurate transformation to more transparent formats. Ensuring a high degree of transparency by standardizing the process for assessing the quality of evidence and strength of recommendations and defining reasons for deliberate vagueness will facilitate the work of policy developers, achieve better methodologic consistency across the broad range of clinical and policy statements, and thereby sustain and enhance the credibility of an organization's policies.

Committee on Injury and Poison Prevention

Transporting Children With Special Health Care Needs

ABSTRACT. Children with special health care needs should have access to proper resources for safe transportation. This statement reviews important considerations for transporting children with special health care needs and provides current guidelines for the protection of children with specific health care needs, including those with a tracheostomy, a spica cast, challenging behaviors, or muscle tone abnormalities as well as those transported in wheelchairs.

ABBREVIATION. FMVSS, Federal Motor Vehicle Safety Standard.

All children, including those with special health care needs, should have access to proper resources for safe transportation. Families and health care professionals should be informed of basic guidelines for selecting restraints, positioning children into them, and securing these restraints in all types of vehicles, primarily the family vehicle and school bus.[1] Parents should be informed of the resources available for proper restraint of children with special health care needs during travel[2] and thereby avoid use of substandard products, makeshift restraint systems, or unsafe methods of securement in motor vehicles.

Federal Motor Vehicle Safety Standard (FMVSS) 213, which regulates design and performance of child restraint systems, does not recognize that children with special needs may require the use of special occupant restraint systems.[3] The standard also does not regulate specific design and performance criteria for occupant protection devices that can provide safe seating for children with disabilities. Crash testing of car safety seats that meet FMVSS 213 has been done with test dummies representing children without special medical problems that would affect restraint use in motor vehicles. The biomechanical effects of a crash on test dummies representative of children with special medical needs in any restraint system have not been studied. Further research is needed, including development of such test dummies by the National Highway Traffic Safety Administration to address these concerns.

Children with special needs should not be exempt from the requirements of each state's laws regarding child restraint and seat belt use. Pediatricians can serve as resources for information to legislators, policy makers, and law enforcement professionals, as well as school officials who may be unaware of the importance and availability of occupant protection systems for children with special needs.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

IMPORTANT CONSIDERATIONS

1. The rear seat is the safest place for all children, and rear-facing car safety seats must never be placed in the front seat of a vehicle that has a front passenger air bag. The impact of a deploying air bag can severely injure or kill an infant or small child. Children may also be at risk of injury if they are out of position or lie against the door of a vehicle with a side air bag.
2. For a child with special health care needs who requires frequent observation during travel and for whom no adult is available to accompany the child in the back seat, an air bag on/off switch should be considered for the vehicle.
3. Instructions provided by the manufacturer of the vehicle and the manufacturer of the car safety seat must be followed.
4. Plans for procurement of the most appropriate restraint and training for the proper use of the device and its installation in the vehicle should be incorporated into hospital discharge planning for all children with special needs.[4] Any child with a medical problem should have a special care plan that includes what to do during transport if a medical emergency occurs.
5. Parents, health care professionals, and educators should be encouraged to incorporate a child's special transportation needs into the individual education plan developed with the school.
6. There have been rapid changes in development and availability of resources for safer transportation of children with special needs. The current version of the American Academy of Pediatrics' "*Car Seat Shopping Guide for Children With Special Needs*" should be a helpful reference for health care professionals, parents, and school transportation providers.[5]
7. For additional information on transporting newborns or premature infants and children with special needs on school buses, refer to the appropriate policy statements by the American Academy of Pediatrics.[6,7]

GUIDELINES FOR PROTECTION

Although research has been limited, current information suggests the following guidelines be adhered to when selecting an appropriate occupant protection system and positioning a child with special needs properly.

General: Infants and Young Children

1. The child restraint system should meet FMVSS 213.[3] Standard child restraint devices may be used for many children with special health care needs, and, whenever possible, a standard child restraint is the preferable choice. Use of a "special" child restraint system for a child with health care needs often may be postponed until a child exceeds the physical limitations of a car safety seat.
2. Car restraint systems should not be modified or used in a manner other than that specified by the manufacturer unless the modified restraint system has been crash tested and has met all applicable Federal Motor Vehicle Safety Standards approved by the National Highway Traffic Safety Administration.
3. Infant-only car safety seats with capacity to recline are useful for infants with many medical problems, especially respiratory conditions. Some convertible car safety seats also can be used in the rear-facing position for children up to a weight of 13.5 kg (30 lb). These restraints may be especially useful for children with poor head and neck control.
4. If the child's head drops forward while in a rear-facing car safety seat because the position of the seat is too upright, a roll of cloth can be wedged in the vehicle seat crease and under the car safety seat base at the child's feet, so that the child reclines at no more than a 45° angle or as specified in the manufacturer's instructions (Fig 1).
5. Premature and small infants should not be placed in car safety seats with a harness-tray/shield combination or an armrest that could directly contact the infant's neck or face during an impact.[4,7,8]
6. Car safety seats with five-point harnesses anchored at both shoulders, both hips, and between the legs, can be adjusted to provide good upper torso support for many children with special needs.

General: Older Children and Adolescents

1. When a child has outgrown a car safety seat, other choices are available for proper and secure occupant restraint. Some systems provide for full support for the child's head, neck, and back and accommodate children up to 47.2 kg (105 lb). Others, such as the conventional E-Z-On Vest (E-Z-On Products, Jupiter, FL), can be used to provide additional trunk support for a child who already has stable neck control. Tethers, additional lap seat belts, or appropriate tie-down systems are required for some of these devices and should be a consideration for selection and proper use (Fig 2).
2. Some older children with disabilities can be transported in a special needs belt-positioning booster or a conventional belt-positioning booster for trunk support. The booster seats help to position the shoulder and lap belt across the child's chest and pelvis.
3. Conventional lap-shoulder belt systems may also be useful in providing for chest restraint of some children with special needs. Lap-shoulder belts should be used properly. Lap belts should be low and flat across the child's hips, and the shoulder belt should be snug across the chest. If a lap belt lies on the child's abdomen or if a shoulder belt rests on a child's neck, use of a belt-positioning booster seat will help assure proper placement of the belts. The shoulder belt should never be placed underneath the child's arm(s) or behind the child's back.

TRACHEOSTOMIES

Infants and children with a tracheostomy should not use child restraint systems with a harness-tray/shield combination or an armrest. On sudden impact, the child could fall forward causing the tracheostomy to contact the shield or armrest, possibly resulting in injury and a blocked airway.[9] A rear-facing car safety seat with a three-point harness or a

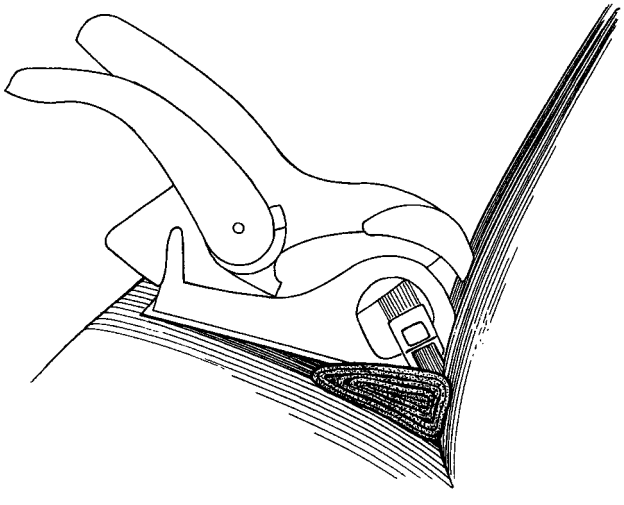

Fig 1. Rear-facing seat with wedge to recline seat at a 45° tilt.

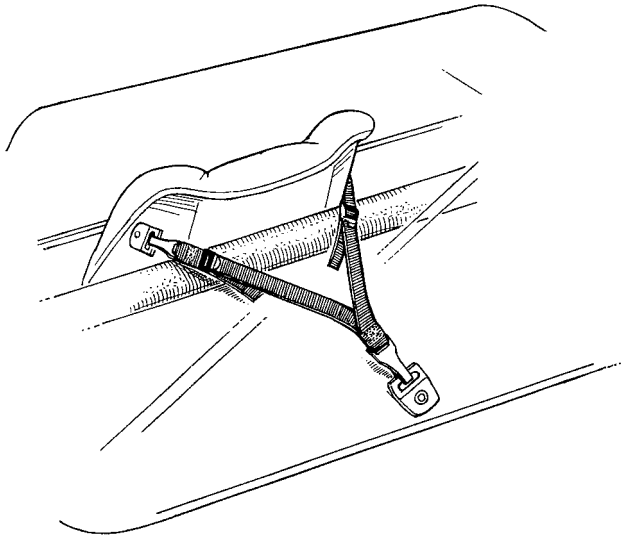

Fig 2. Large child forward-facing safety seat with tether anchored to vehicle.

car safety seat with a five-point harness should be selected for children with a tracheostomy.

MUSCLE TONE ABNORMALITIES

1. For toddlers with poor head control, a convertible car safety seat approved by the manufacturer for use in a semireclining position when facing forward may be beneficial.
2. Crotch rolls, made with a rolled towel or a diaper, may be added between the child's legs and the crotch strap to keep the hips against the back of the seat and prevent the child from slumping forward in the seat. This modification should be used for any child who cannot maintain appropriate posture.
3. Lateral support may be provided with rolled blankets, towels, or foam rolls (Fig 3).
4. Soft padding that does not alter the function of the harness may be positioned behind the neck and on either side of the head to promote anatomic alignment. However, padding should never be placed behind or under the child in the seat.[10] Soft padding (such as blankets, pillows, or soft foam) compresses on impact and can prevent harness straps from maintaining a secure, tight fit on a child's body (Fig 3).
5. A foam roll or rolled blanket may be placed under a child's knees to inhibit hypertonicity or opisthotonic posturing (Fig 3).

PRONE AND SUPINE POSITIONING OF INFANTS

Infants who must lie prone after surgical repair of myelomeningocele or infants who must lie prone to maintain an open airway, such as those with Pierre Robin sequence, may require a restraint that allows prone positioning.[5,11,12]

SPICA CASTS

1. For children with spica casts, a specially modified convertible car safety seat, the Spelcast (Snug Seat, Inc, Matthews, NC), has cut-away sides and seat bottom that provide room for a comfortable and snug fit into the restraint system (Fig 4). This seat fits infants up to a weight of 9.0 kg (20 lb) (rear-facing position) and toddlers who weigh up to 18.0 kg (40 lb) (front-facing position).
2. Many older toddlers and preschool and school-aged children in body or hip spica casts have limited resources available for safe transport in motor vehicles. One resource, the modified E-Z-On Vest, has performed satisfactorily during dynamic crash testing with a test dummy weighted to 47.2 kg (105 lb) and is available commercially. Two sets of seat belts routed through the vest are used to secure the child at the child's side against the vehicle seat. An ancillary belt loops around the casted leg or legs at the knees and is routed through the other seat belt (Fig 5). When it is not possible to fit a child onto a vehicle seat, use of an ambulance for transport is recommended. For lateral positioning on the vehicle seat (eg, as required by a car bed restraint or the modified E-Z-On Vest), position the child's head as far as possible from the side of the vehicle (Fig 6).

Fig 3. Child in convertible car seat with soft padding behind the neck, on either side of the head and along the sides to promote anatomic alignment. Foam roll or rolled blanket may be placed under knees to inhibit hypertonicity.

Fig 4. Child with spica cast seated in modified seat with cut-away sides and seat bottom.

CHALLENGING BEHAVIOR

1. Older children with hyperactivity, autism, or emotional problems may require a safety restraint

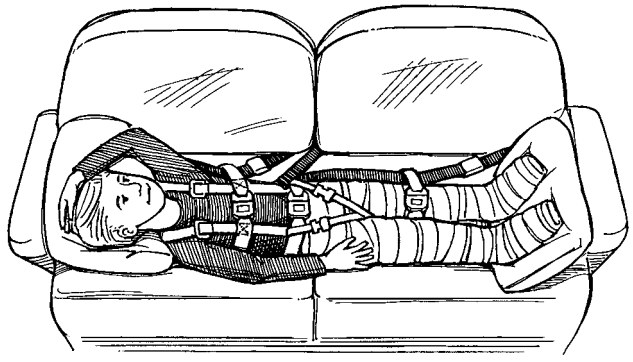

Fig 5. Child with modified E-Z-On Vest (E-Z-On Products, Inc, Jupiter, FL).

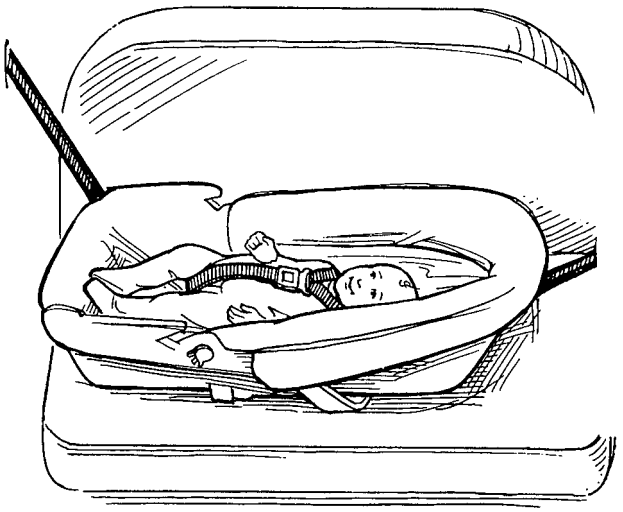

Fig 6. Infant positioned supine in the Ultra Dream Ride car bed (Cosco, Columbus, IN).

that is less likely to be unbuckled by the child. High back booster seats with internal harnesses that have seat belts routed underneath the seat base may be helpful in reducing the child's likelihood of unbuckling the restraint during travel. Large child car safety seats with a 5-point harness may be required for children weighing over 40 lb who cannot be restrained in a belt positioning booster seat with only a lap/shoulder harness.

2. Vests with rear back closure also may be helpful for use with children who have behavioral problems that may interfere with safe travel.[5]

WHEELCHAIR TRANSPORTATION

Any child who can assist with transfer or be "reasonably" moved from a wheelchair, stroller, or special seating device to the original manufacturer's forward-facing vehicle seat equipped with dynamically-tested occupant restraints or be "reasonably" moved to a child restraint system complying with FMVSS 213 requirement should be so transferred for transportation. The unoccupied wheelchair also should be secured adequately in the vehicle to prevent it from becoming a dangerous projectile in the event of a sudden stop or crash.[13]

Occupied wheelchair(s) should be secured in a forward-facing position. Any occupied wheelchair should be secured with four-point tie-down devices. Lap boards or metal or plastic trays attached to the wheelchair or to adaptive equipment should be removed and secured separately for transport. An occupant restraint system that has been tested at 30 mph and 20G force conditions and that includes upper torso restraint (ie, shoulder harness) and lower torso restraint (ie, a lap belt over the pelvis) should be provided for each wheelchair-seated occupant.[14] Head bands should not be used to restrain the child's head separately from the torso.

EQUIPMENT TRANSPORTATION

1. When a child with special needs is in transit, ancillary pieces of medical equipment (eg, walkers, crutches, oxygen tanks, monitors) should be secured on the vehicle floor; underneath a vehicle seat or wheelchair; or to the bus seat, bus floor, or bus wall below the window line so that they do not become a projectile during a crash and strike an occupant.
2. Electrical equipment for use during transit should have portable self-contained power for twice the expected duration of the trip. For improved safety, lead acid batteries or electrically powered wheelchairs or other mobile seating devices and respiratory systems should be converted, when possible, to gel-cell or dry-cell batteries. To house and protect batteries during everyday use, transportation, and collision, the use of external battery boxes is recommended.

RESOURCE AVAILABILITY

The National Easter Seal Society (800–221-6827) can assist identifying local community resources for procurement of specific restraint systems.[5]

Guideline Update Development and Use

The 2008 update to *Treating Tobacco Use and Dependence*, a Public Health Service-sponsored Clinical Practice Guideline, is the result of an extraordinary partnership among Federal Government and nonprofit organizations comprised of the Agency for Healthcare Research and Quality; Centers for Disease Control and Prevention; National Cancer Institute; National Heart, Lung, and Blood Institute; National Institute on Drug Abuse; Robert Wood Johnson Foundation; American Legacy Foundation; and University of Wisconsin School of Medicine and Public Health's Center for Tobacco Research and Intervention. Each member of this consortium is dedicated to improving the Nation's public health, and their participation in this collaboration clearly demonstrates a strong commitment to tobacco cessation.

This Guideline is an updated version of the 2000 *Treating Tobacco Use and Dependence* Guideline. It is the product of a private-sector panel of experts ("the Panel"), consortium representatives, and staff. The update was written to include new, effective clinical treatments for tobacco dependence that have become available since the 2000 Guideline was published. *Treating Tobacco Use and Dependence: 2008 Update* will make an important contribution to the quality of care in the United States and the health of the American people.

The Panel employed an explicit, science-based methodology and expert clinical judgment to develop recommendations on the treatment of tobacco use and dependence. Extensive literature searches were conducted, and critical reviews and syntheses were used to evaluate empirical evidence and significant outcomes. Peer reviews were undertaken and public comment invited to evaluate the validity, reliability, and utility of the Guideline for clinical practice. The Panel's recommendations primarily are based on published, evidence-based research. When the evidence was incomplete or inconsistent in a particular area, the recommendations reflect the professional judgment of Panel members.

The recommendations herein may not be appropriate for use in all circumstances and are designed particularly for clinical settings. Decisions to adopt any particular recommendation must be made by clinicians in light of available resources and circumstances presented by individual patients and in light of new clinical information such as that provided by the U.S. Food and Drug Administration (FDA).

This Public Health Service-sponsored Clinical Practice Guideline update gives hope to the 7 out of 10 smokers who visit a clinician each year. This Guideline urges every clinician, health plan, and health care institution to make treating tobacco dependence a top priority during these visits. Please ask your patients two key questions: "Do you smoke?" and "Do you want to quit?" followed by use of the recommendations in this Guideline.

Abstract

Treating Tobacco Use and Dependence: 2008 Update, a Public Health Service-sponsored Clinical Practice Guideline, is a product of the Tobacco Use and Dependence Guideline Panel ("the Panel"), consortium representatives, consultants, and staff. These 37 individuals were charged with the responsibility of identifying effective, experimentally validated tobacco dependence treatments and practices. The updated Guideline was sponsored by a consortium of eight Federal Government and nonprofit organizations: the Agency for Healthcare Research and Quality (AHRQ); Centers for Disease Control and Prevention (CDC); National Cancer Institute (NCI); National Heart, Lung, and Blood Institute (NHLBI); National Institute on Drug Abuse (NIDA); American Legacy Foundation; Robert Wood Johnson Foundation (RWJF); and University of Wisconsin School of Medicine and Public Health's Center for Tobacco Research and Intervention (UW-CTRI). This Guideline is an updated version of the 2000 *Treating Tobacco Use and Dependence: Clinical Practice Guideline* that was sponsored by the U.S. Public Health Service, U. S. Department of Health and Human Services.

An impetus for this Guideline update was the expanding literature on tobacco dependence and its treatment. The original 1996 Guideline was based on some 3,000 articles on tobacco treatment published between 1975 and 1994. The 2000 Guideline entailed the collection and screening of an additional 3,000 articles published between 1995 and 1999. The 2008 Guideline update screened an additional 2,700 articles; thus, the present Guideline update reflects the distillation of a literature base of more than 8,700 research articles. Of course, this body of research was further reviewed to identify a much smaller group of articles that served as the basis for focused Guideline data analyses and review.

This Guideline contains strategies and recommendations designed to assist clinicians; tobacco dependence treatment specialists; and health care administrators, insurers, and purchasers in delivering and supporting effective treatments for tobacco use and dependence. The recommendations were made as a result of a systematic review and meta-analysis of 11 specific topics identified by the Panel (proactive quitlines; combining counseling and medication relative to either counseling or medication alone; varenicline; various medication combinations; long-term medications; cessation interventions for individuals with low socioeconomic status/limited

formal education; cessation interventions for adolescent smokers; cessation interventions for pregnant smokers; cessation interventions for individuals with psychiatric disorders, including substance use disorders; providing cessation interventions as a health benefit; and systems interventions, including provider training and the combination of training and systems interventions). The strength of evidence that served as the basis for each recommendation is indicated clearly in the Guideline update. A draft of the Guideline update was peer reviewed prior to publication, and the input of 81 external reviewers was considered by the Panel prior to preparing the final document. In addition, the public had an opportunity to comment through a *Federal Register* review process. The key recommendations of the updated Guideline, *Treating Tobacco Use and Dependence: 2008 Update,* based on the literature review and expert Panel opinion, are as follows:

Ten Key Guideline Recommendations

The overarching goal of these recommendations is that clinicians strongly recommend the use of effective tobacco dependence counseling and medication treatments to their patients who use tobacco, and that health systems, insurers, and purchasers assist clinicians in making such effective treatments available.

1. Tobacco dependence is a chronic disease that often requires repeated intervention and multiple attempts to quit. Effective treatments exist, however, that can significantly increase rates of long-term abstinence.

2. It is essential that clinicians and health care delivery systems consistently identify and document tobacco use status and treat every tobacco user seen in a health care setting.

3. Tobacco dependence treatments are effective across a broad range of populations. Clinicians should encourage every patient willing to make a quit attempt to use the counseling treatments and medications recommended in this Guideline.

4. Brief tobacco dependence treatment is effective. Clinicians should offer every patient who uses tobacco at least the brief treatments shown to be effective in this Guideline.

5. Individual, group, and telephone counseling are effective, and their effectiveness increases with treatment intensity. Two components of counseling are especially effective, and clinicians should use these when counseling patients making a quit attempt:

   - Practical counseling (problemsolving/skills training)

   - Social support delivered as part of treatment

6. Numerous effective medications are available for tobacco dependence, and clinicians should encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).

   - Seven first-line medications (5 nicotine and 2 non-nicotine) reliably increase long-term smoking abstinence rates:
     - Bupropion SR
     - Nicotine gum
     - Nicotine inhaler
     - Nicotine lozenge
     - Nicotine nasal spray
     - Nicotine patch
     - Varenicline

   - Clinicians also should consider the use of certain combinations of medications identified as effective in this Guideline.

7. Counseling and medication are effective when used by themselves for treating tobacco dependence. The combination of counseling and medication, however, is more effective than either alone. Thus, clinicians should encourage all individuals making a quit attempt to use both counseling and medication.

8. Telephone quitline counseling is effective with diverse populations and has broad reach. Therefore, both clinicians and health care delivery systems should ensure patient access to quitlines and promote quitline use.

9. If a tobacco user currently is unwilling to make a quit attempt, clinicians should use the motivational treatments shown in this Guideline to be effective in increasing future quit attempts.

10. Tobacco dependence treatments are both clinically effective and highly cost-effective relative to interventions for other clinical disorders. Providing coverage for these treatments increases quit rates. Insurers and purchasers should ensure that all insurance plans include the counseling and medication identified as effective in this Guideline as covered benefits.

The updated Guideline is divided into seven chapters that provide an overview, including methods (Chapter 1); information on the assessment of tobacco use (Chapter 2); clinical interventions, both for patients willing and unwilling to make a quit attempt at this time (Chapter 3); intensive interventions (Chapter 4); systems interventions for health care administrators, insurers, and purchasers (Chapter 5); the scientific evidence supporting the Guideline recommendations (Chapter 6); and information relevant to specific populations and other topics (Chapter 7).

A comparison of the findings of the updated Guideline with the 2000 Guideline reveals the considerable progress made in tobacco research over the brief period separating these two publications. Tobacco dependence increasingly is recognized as a chronic disease, one that typically requires ongoing assessment and repeated intervention. In addition, the updated Guideline offers the clinician many more effective treatment strategies than were identified in the original Guideline. There now are seven different first-line effective agents in the smoking cessation pharmacopoeia, allowing the clinician and patient many different medication options. In addition, recent evidence provides even stronger support for counseling (both when used alone and with other treatments) as an effective tobacco cessation strategy; counseling adds to the effectiveness of tobacco cessation medications, quitline counseling is an effective intervention with a broad reach, and counseling increases tobacco cessation among adolescent smokers.

Finally, there is increasing evidence that the success of any tobacco dependence treatment strategy cannot be divorced from the health care system in which it is embedded. The updated Guideline contains new evidence that health care policies significantly affect the likelihood that smokers

will receive effective tobacco dependence treatment and successfully stop tobacco use. For instance, making tobacco dependence treatment a covered benefit of insurance plans increases the likelihood that a tobacco user will receive treatment and quit successfully. Data strongly indicate that effective tobacco interventions require *coordinated interventions*. Just as the clinician must intervene with his or her patient, so must the health care administrator, insurer, and purchaser foster and support tobacco intervention as an integral element of health care delivery. Health care administrators and insurers should ensure that clinicians have the training and support to deliver consistent, effective intervention to tobacco users.

One important conclusion of this Guideline update is that the most effective way to move clinicians to intervene is to provide them with information regarding multiple effective treatment options and to ensure that they have ample institutional support to use these options. Joint actions by clinicians, administrators, insurers, and purchasers can encourage a culture of health care in which failure to intervene with a tobacco user is inconsistent with standards of care.

Acknowledgments

This Guideline would not have been possible without the collaborative efforts of many individuals and organizations. Each made significant contributions throughout the process of updating this document. Although too numerous to list here, the Contributors section of this publication provides a listing of support staff, individual peer reviewers, and others. Some individuals and organizations, however, deserve special mention.

The Panel wishes to acknowledge the support and guidance provided by the consortium partners in general and their dedicated, hard-working representatives in particular. In addition to the Guideline Liaisons, the Panel gratefully acknowledges the extraordinarily supportive efforts and substantial contributions of Jean Slutsky, Director, Center for Outcomes and Evidence, AHRQ, and the staff at the Office of Communications and Knowledge Transfer, AHRQ; Sandra Cummings, Deputy Director of Operations, Publishing Team; Harriett Bennett, Public Affairs and Marketing Specialist; and Julius Patterson, Guideline Managing Editor.

The Panel also wishes to thank Victor Hasselblad, PhD, who served the project as statistical consultant.

Executive Summary

Context

The 1996 *Smoking Cessation Clinical Practice Guideline*[1] emphasized the dire health consequences of tobacco use and dependence, the existence of effective treatments, and the importance of inducing more smokers to use such treatments. It also called for newer, even more effective tobacco dependence treatments. All of these points still are germane. Nevertheless, heartening progress has been made in tobacco control since that time, and this progress is part of a larger pattern of change that stretches back over the past 40 years. This progress reflects the achievements of clinicians, the public health community, scientists, government agencies, health care organizations, insurers, purchasers, and smokers who have successfully quit. As a result, the current prevalence of tobacco use among adults in the United States (about 20.8%) is less than half the rate observed in the 1960s (about 44%).[2,3]

This Guideline concludes that tobacco use presents a rare confluence of circumstances: (1) a highly significant health threat;[4] (2) a disinclination among clinicians to intervene consistently;[5] and (3) the presence of effective interventions. This last point is buttressed by evidence that tobacco dependence interventions, if delivered in a timely and effective manner, significantly reduce the smoker's risk of suffering from smoking-related disease.[6-13] Indeed, it is difficult to identify any other condition that presents such a mix of lethality, prevalence, and neglect, despite effective and readily available interventions.

Although tobacco use still is an enormous threat, the story of tobacco control efforts during the last half century is one of remarkable progress and promise. In 1965, current smokers outnumbered former smokers three to one.[14] During the past 40 years, the rate of quitting has so outstripped the rate of initiation that, today, there are more former smokers than current smokers.[15] Moreover, 40 years ago smoking was viewed as a habit rather than a chronic disease. No scientifically validated treatments were available for the treatment of tobacco use and dependence, and it had little place in health care delivery. Today, numerous effective treatments exist, and tobacco use assessment and intervention are considered to be requisite duties

of clinicians and health care delivery entities. Finally, every state now has a telephone quitline, increasing access to effective treatment.

The scant dozen years following the publication of the first Guideline have ushered in similarly impressive changes. In 1997, only 25 percent of managed health care plans covered any tobacco dependence treatment; this figure approached 90 percent by 2003,[16] although this increased coverage often includes barriers to use. Numerous states added Medicaid coverage for tobacco dependence treatment since the publication of the first Guideline so that, by 2005, 72 percent offered coverage for at least one Guideline-recommended treatment.[16-18] In 2002, The Joint Commission (formerly JCAHO), which accredits some 15,000 hospitals and health care programs, instituted an accreditation requirement for the delivery of evidence-based tobacco dependence interventions for patients with diagnoses of acute myocardial infarction, congestive heart failure, or pneumonia (*www.coreoptions.com/new_site/jcahocore.html*; hospital-specific results: *www.hospitalcompare.hhs.gov*). Finally, Medicare, the Veterans Health Administration, and the United States Military now provide coverage for tobacco dependence treatment. Such policies and systems changes are paying off in terms of increased rates of assessment and treatment of tobacco use.

Data show that the rate at which smokers report being advised to quit smoking has approximately doubled since the early 1990s.[19-22] Recent data also suggest a substantial increase in the proportion of smokers receiving more intensive cessation interventions.[23,24] The National Committee for Quality Assurance (NCQA) reports steady increases for both commercial insurers and Medicaid in the discussion of both medications and strategies for smoking cessation.[25] Finally, since the first Guideline was published in 1996, smoking prevalence among adults in the United States has declined from about 25 percent to about 21 percent.[26]

An inspection of the 2008 Guideline update shows that substantial progress also has been made in treatment development and delivery. Telephone quitlines have been shown to be effective in providing wide access to evidence-based cessation counseling.[27,28] Seven U.S. Food and Drug Administration (FDA)-approved medications for treating tobacco dependence are now available, and new evidence has revealed that particular medications or combinations of medications are especially effective.

This Guideline update also casts into stark relief those areas in which more progress is needed. There is a need for innovative and more effective counseling strategies. In addition, although adolescents appear to benefit from counseling, more consistent and effective interventions and options for use with children, adolescents, and young adults clearly are needed. Smoking prevalence remains discouragingly high in certain populations, such as in those with low socioeconomic status (SES)/low educational attainment, some American Indian populations, and individuals with psychiatric disorders, including substance use disorders.[3] New techniques and treatment delivery strategies may be required before the needs of these groups are adequately addressed. Moreover, although much of the available data come from randomized clinical trials occurring in research settings, it is imperative that new research examine implementation of effective treatments in real-world clinical settings. Finally, new strategies are needed to create consumer demand for effective treatments among tobacco users; there has been little increase in the proportion of smokers who make quit attempts, and too few smokers who do try to quit take advantage of evidence-based treatment that can double or triple their odds of success.[29] New research and communication efforts must impart greater hope, confidence, and increased access to treatments so that tobacco users in ever greater numbers attempt tobacco cessation and achieve abstinence. To succeed, all of these areas require adequate funding.

Thus, this 2008 Guideline update serves as a benchmark of the progress made. It should reassure clinicians, policymakers, funding agencies, and the public that tobacco use is amenable to both scientific analysis and clinical interventions. This history of remarkable progress should encourage renewed efforts by clinicians, policymakers, and researchers to help those who remain dependent on tobacco.

Guideline Origins

This Guideline, *Treating Tobacco Use and Dependence: 2008 Update,* a Public Health Service-sponsored Clinical Practice Guideline, is the product of the Treating Tobacco Use and Dependence Guideline Panel ("the Panel"), government liaisons, consultants, and staff. These individuals were charged with the responsibility of identifying effective, experimentally validated tobacco dependence clinical treatments and practices. This Guideline update is the third Public Health Service Clinical Practice Guideline published on

tobacco use. The first Guideline, the 1996 *Smoking Cessation Clinical Practice Guideline No. 18,* was sponsored by the Agency for Healthcare Policy and Research (AHCPR, now the Agency for Healthcare Research and Quality [AHRQ]), U.S. Department of Health and Human Services (HHS). That Guideline reflected scientific literature published between 1975 and 1994. The second Guideline, published in 2000, *Treating Tobacco Use and Dependence*, was sponsored by a consortium of U. S. Public Health Service (PHS) agencies (AHRQ; Centers for Disease Control and Prevention [CDC]; National Cancer Institute [NCI]; National Heart, Lung, and Blood Institute [NHLBI]; National Institute on Drug Abuse [NIDA]) as well as the Robert Wood Johnson Foundation (RWJF) and the University of Wisconsin Center for Tobacco Research and Intervention (UW-CTRI). That Guideline reflected the scientific literature published from 1975 to 1999. The current 2008 update addresses literature published from 1975 to 2007.

The updated Guideline was written in response to new, effective clinical treatments for tobacco dependence that have been identified since 1999. These treatments promise to enhance the rates of successful tobacco cessation. The original 1996 Guideline was based on some 3,000 articles on tobacco treatment published between 1975 and 1994. The 2000 Guideline required the collection and screening of an additional 3,000 articles published between 1995 and 1999. The 2008 Guideline update screened an additional 2,700 articles; thus, the present Guideline update reflects the distillation of a literature base of more than 8,700 research articles. This body of research of course was further reviewed to identify a much smaller group of articles, based on rigorous inclusion criteria, which served as the basis for focused Guideline data analyses and review.

The 2008 updated Guideline was sponsored by a consortium of eight Federal Government and private nonprofit organizations: AHRQ, CDC, NCI, NHLBI, NIDA, American Legacy Foundation, RWJF, and UW-CTRI. All of these organizations have as their mission reducing the human costs of tobacco use. Given the importance of this issue to the health of all Americans, the updated Guideline is published by the PHS, HHS.

Guideline Style and Structure

This Guideline update was written to be applicable to all tobacco users—those using cigarettes as well as other forms of tobacco. Therefore, the terms "tobacco user" and "tobacco dependence" will be used in prefer-

ence to "smoker" and "cigarette dependence." In some cases, however, the evidence for a particular recommendation consists entirely of studies using cigarette smokers as participants. In these instances, the recommendation and evidence refers to "smoking" to communicate the parochial nature of the evidence. In most cases, though, Guideline recommendations are relevant to all types of tobacco users. Finally, most data reviewed in this Guideline update are based on adult smokers, although data relevant to adolescent smokers are presented in Chapter 7.

The updated Guideline is divided into seven chapters that integrate prior and updated findings:

Chapter 1, Overview and Methods, provides the clinical practice and scientific context of the Guideline update project and describes the methodology used to generate the Guideline findings.

Chapter 2, Assessment of Tobacco Use, describes how each patient presenting at a health care setting should have his or her tobacco use status determined and how tobacco users should be assessed for willingness to make a quit attempt.

Chapter 3, Clinical Interventions for Tobacco Use and Dependence, summarizes effective brief interventions that can easily be delivered in a primary care setting. In this chapter, separate interventions are described for the patient who is *willing* to try to quit at this time, for the patient who is *not yet willing* to try to quit, and for the patient who has recently quit.

Chapter 4, Intensive Interventions for Tobacco Use and Dependence, outlines a prototype of an intensive tobacco cessation treatment that comprises strategies shown to be effective in this Guideline. Because intensive treatments produce the highest success rates, they are an important element in tobacco intervention strategies.

Chapter 5, Systems Interventions, targets health care administrators, insurers, and purchasers, and offers a blueprint to changes in health care delivery and coverage such that tobacco assessment and intervention become a standard of care in health care delivery.

Chapter 6, Evidence and Recommendations, presents the results of Guideline literature reviews and statistical analyses and the recommendations

that emanate from them. Guideline analyses address topics such as the effectiveness of different counseling strategies and medications; the relation between treatment intensities and treatment success; whether screening for tobacco use in the clinic setting enhances tobacco user identification; and whether systems changes can increase provision of effective interventions, quit attempts, and actual cessation rates. The Guideline Panel also made specific recommendations regarding future research needs.

Chapter 7, Specific Populations and Other Topics, evaluates evidence on tobacco intervention strategies and effectiveness with specific populations (e.g., HIV-positive smokers; hospitalized smokers; lesbian/gay/bisexual/transgender smokers; smokers with low SES/limited educational attainment; smokers with medical comorbidities; older smokers; smokers with psychiatric disorders, including substance use disorders; racial and ethnic minorities; women smokers; children and adolescents; light smokers; pregnant smokers; and noncigarette tobacco users). The Guideline Panel made specific recommendations for future research on topics relevant to these populations. This chapter also presents information and recommendations relevant to weight gain after smoking cessation, with specific recommendations regarding future research on this topic.

Findings and Recommendations

The key recommendations of the updated Guideline, *Treating Tobacco Use and Dependence: 2008 Update*, based on the literature review and expert Panel opinion, are as follows:

Ten Key Guideline Recommendations

The overarching goal of these recommendations is that clinicians strongly recommend the use of effective tobacco dependence counseling and medication treatments to their patients who use tobacco, and that health care systems, insurers, and purchasers assist clinicians in making such effective treatments available.

1. Tobacco dependence is a chronic disease that often requires repeated intervention and multiple attempts to quit. Effective treatments exist, however, that can significantly increase rates of long-term abstinence.

2. It is essential that clinicians and health care delivery systems consistently identify and document tobacco use status and treat every tobacco user seen in a health care setting.

3. Tobacco dependence treatments are effective across a broad range of populations. Clinicians should encourage every patient willing to make a quit attempt to use the counseling treatments and medications recommended in this Guideline.

4. Brief tobacco dependence treatment is effective. Clinicians should offer every patient who uses tobacco at least the brief treatments shown to be effective in this Guideline.

5. Individual, group, and telephone counseling are effective, and their effectiveness increases with treatment intensity. Two components of counseling are especially effective, and clinicians should use these when counseling patients making a quit attempt:

   - Practical counseling (problemsolving/skills training)

   - Social support delivered as part of treatment

6. Numerous effective medications are available for tobacco dependence, and clinicians should encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).

   - Seven first-line medications (5 nicotine and 2 non-nicotine) reliably increase long-term smoking abstinence rates:

     – Bupropion SR
     – Nicotine gum
     – Nicotine inhaler
     – Nicotine lozenge
     – Nicotine nasal spray
     – Nicotine patch
     – Varenicline

- Clinicians also should consider the use of certain combinations of medications identified as effective in this Guideline.

7. Counseling and medication are effective when used by themselves for treating tobacco dependence. The combination of counseling and medication, however, is more effective than either alone. Thus, clinicians should encourage all individuals making a quit attempt to use both counseling and medication.

8. Telephone quitline counseling is effective with diverse populations and has broad reach. Therefore, clinicians and health care delivery systems should both ensure patient access to quitlines and promote quitline use.

9. If a tobacco user currently is unwilling to make a quit attempt, clinicians should use the motivational treatments shown in this Guideline to be effective in increasing future quit attempts.

10. Tobacco dependence treatments are both clinically effective and highly cost-effective relative to interventions for other clinical disorders. Providing coverage for these treatments increases quit rates. Insurers and purchasers should ensure that all insurance plans include the counseling and medication identified as effective in this Guideline as covered benefits.

Guideline Update: Advances

A comparison of the findings of the 2008 Guideline update with the 2000 Guideline reveals the considerable progress made in tobacco research over the brief period separating these two works. Among many important differences between the two documents, the following deserve special note:

- The updated Guideline has produced even stronger evidence that counseling is an effective tobacco use treatment strategy. Of particular note are findings that counseling adds significantly to the effectiveness of tobacco cessation medications, quitline counseling is an effective intervention with a broad reach, and counseling increases abstinence among adolescent smokers.

- The updated Guideline offers the clinician a greater number of effective medications than were identified in the previous Guideline. Seven

different effective first-line smoking cessation medications are now approved by the FDA for treating tobacco use and dependence. In addition, multiple combinations of medications have been shown to be effective. Thus, the clinician and patient have many more medication options than in the past. The Guideline also now provides evidence regarding the effectiveness of medications relative to one another.

- The updated Guideline contains new evidence that health care policies significantly affect the likelihood that smokers will receive effective tobacco dependence treatment and successfully stop tobacco use. For instance, making tobacco dependence a benefit covered by insurance plans increases the likelihood that a tobacco user will receive treatment and quit successfully.

Future Promise

The research reviewed for this 2008 Guideline update suggests a bright future for treating tobacco use and dependence. Since the first AHCPR Clinical Practice Guideline was published in 1996, encouraging progress has been made in tobacco dependence treatment. An expanding body of research has produced a marked increase in the number and types of effective treatments and has led to multiple new treatment delivery strategies. These new strategies are enhancing the delivery of tobacco interventions both inside and outside health care delivery systems. This means that an unprecedented number of smokers have access to an unprecedented number of effective treatments.

Although the data reviewed in this Guideline update are encouraging and portend even greater advances through future research, for many smokers, the progress has been an undelivered promissory note. Most smokers attempting to quit today still make unaided quit attempts,[29-32] although the proportion using evidence-based treatments has increased since the publication of the 1996 AHCPR Guideline.[33-35] Because of the prevalence of such unaided attempts (those that occur without evidence-based counseling or medication), many smokers have successfully quit through this approach.[6,36] It is clear from the data presented in this Guideline, however, that smokers are significantly more likely to quit successfully if they use an evidence-based counseling or medication treatment than if they try to quit without such aids. Thus, a future challenge for the field is to ensure that smokers, clinicians, and health systems have accurate

information on the effectiveness of clinical interventions for tobacco use, and that the 70 percent of smokers who visit a primary care setting each year have greater access to effective treatments. This is of vital public health importance because the costs of failure are so high. Relapse results in continuing lifetime exposure to tobacco, which leads to increased risk of death and disease. Additional progress must be made in educating clinicians and the public about the effectiveness of clinical treatments for tobacco dependence and in making such treatments available and attractive to smokers.

Continued progress is needed in the treatment of tobacco use and dependence. Treatments should be even more effective and available, new counseling strategies should be developed, and research should focus on the development of effective interventions and delivery strategies for populations that carry a disproportionate burden from tobacco (e.g., adolescents; pregnant smokers; American Indians and Alaska Natives; individuals with low SES/limited educational attainment; individuals with psychiatric disorders, including substance use disorders). The decrease in the prevalence of tobacco use in the United States during the past 40 years, however, has been a seminal public health achievement. Treatment of tobacco use and dependence has played an important role in realizing that outcome.

Chapter 1 Overview and Methods

Introduction

Tobacco use has been cited as the chief avoidable cause of illness and death in our society and accounts for more than 435,000 deaths each year in the United States.[37,38] Smoking is a known cause of multiple cancers, heart disease, stroke, complications of pregnancy, chronic obstructive pulmonary disease (COPD), and many other diseases.[4] In addition, recent research has documented the substantial health dangers of involuntary exposure to tobacco smoke.[4] Despite these health dangers and the public's awareness of those dangers, tobacco use remains surprisingly prevalent. Recent estimates are that about 21 percent of adult Americans smoke,[3] representing approximately 45 million current adult smokers.[3,39] Moreover, tobacco use remains a pediatric disease.[40-42] Each day, about 4,000 youth ages 12 to 17 years smoke their first cigarette, and about 1,200 children and adolescents become daily cigarette smokers.[43-44] As a result, new generations of Americans are at risk for the extraordinarily harmful consequences of tobacco use.

Tobacco use exacts a heavy cost to society as well as to individuals. Smoking-attributable health care expenditures are estimated at $96 billion per year in direct medical expenses and $97 billion in lost productivity.[28] It has been estimated that the per pack additional cost of smoking to society is approximately $7.18 per pack,[45] and the combined cost of each pack to society and the individual smoker and family is nearly $40.[46] If all smokers covered by state Medicaid programs quit, the annual savings to Medicaid would be $9.7 billion after 5 years.[47]

Despite the tragic consequences of tobacco use, clinicians and health care systems often fail to treat it consistently and effectively. For instance, in 1995, about the time of the release of the first clinical practice guideline, smoking status was identified in only about 65 percent of clinic visits, and smoking cessation counseling was provided in only 22 percent of smokers' clinic visits.[48,49] Moreover, treatment typically was offered only to patients already suffering from tobacco-related diseases.[48] This pattern gradually began to improve as of 2005, with up to 90 percent of smokers reporting they had been asked about smoking status and more than 70 percent reporting having received some counseling to quit.[23,50,51] However, the failure to assess and intervene consistently with all tobacco users continues despite sub-

stantial evidence that even brief interventions can be effective among many different populations of smokers.[52-58] Also, the use of effective medications is low. Among current smokers who attempted to stop for at least 1 day in the past year, only 21.7 percent used cessation medication.[33]

This Guideline concludes that tobacco use presents a rare confluence of circumstances: (1) a highly significant health threat;[4] (2) a lack of consistent intervention by clinicians; and (3) the presence of effective interventions. This last point is buttressed by evidence that tobacco use interventions, if delivered in a timely and effective manner, can rapidly reduce the risk of suffering from smoking-related disease.[6-13] Indeed, it is difficult to identify any other condition that presents such a mix of lethality, prevalence, and neglect, despite effective and readily available interventions.

Significant barriers interfere with clinicians' assessment and treatment of smokers. Many clinicians lack knowledge about how to identify smokers quickly and easily, which treatments are effective, how such treatments can be delivered, and the relative effectiveness of different treatments.[59-62] Additionally, clinicians may fail to intervene because of inadequate clinic or institutional support for routine assessment and treatment of tobacco use[48,60,63] and for other reasons such as time constraints, limited training in tobacco cessation interventions, a lack of insurance coverage for tobacco use treatment, or inadequate payment for treatment.[64-67]

Rationale for Guideline Development and Periodic Updates

In the early 1990s, the Agency for Healthcare Policy and Research ([AHCPR] now the Agency for Healthcare Research and Quality [AHRQ]) convened an expert panel to develop the *Smoking Cessation Clinical Practice Guideline* (the "Guideline"), Number 18 in the AHCPR series of Clinical Practice Guidelines. The need for this Guideline was based on several factors, including tobacco use prevalence, related morbidity and mortality, the economic burden imposed by tobacco use, variation in clinical practice, availability of methods for improvement of care, and availability of data on which to base recommendations for care. More than 1 million copies of the 1996 Guideline and its affiliated products were disseminated. The original Guideline recommendations inspired changes in diverse health care settings such as managed care organizations and the Veterans Health Administration. The original Guideline also provided a framework for edu-

cating clinicians, administrators, and policymakers about the importance of tobacco dependence and its treatment. It stimulated discussions that addressed the development of tobacco dependence treatment programs at the Federal and State levels and by professional medical organizations.

Significant new research findings regarding tobacco use and its treatment led to the 2000 Guideline update, which was authored by the expert panel that developed the 1996 Guideline. The 2000 Guideline update was a product of the U. S. Public Health Service (PHS), sponsored by a consortium of private and public partners, including AHRQ; National Cancer Institute (NCI); National Heart, Lung, and Blood Institute (NHLBI); National Institute on Drug Abuse (NIDA); Centers for Disease Control and Prevention (CDC); Robert Wood Johnson Foundation (RWJF); and University of Wisconsin School of Medicine and Public Health Center for Tobacco Research and Intervention (UW-CTRI).

The 2000 Guideline, titled *Treating Tobacco Use and Dependence,* comprised specific evidence-based recommendations to guide clinicians, tobacco treatment specialists, insurers, purchasers, and health care administrators in their efforts to develop and implement clinical and institutional changes that support the reliable identification, assessment, and treatment of patients who use tobacco. This title underscores three truths about tobacco use.[68] First, all tobacco products—not just cigarettes—exact devastating costs on the Nation's health and welfare. Second, for most users, tobacco use results in true drug dependence, comparable to the dependence caused by opiates, amphetamines, and cocaine.[69-72] Third, both chronic tobacco use and dependence warrant clinical intervention and, as with other chronic disorders, these interventions may need to be repeated over time.[73,74]

The 2000 *Treating Tobacco Use and Dependence* document was the most widely disseminated Guideline ever released by AHRQ, with more than 5 million copies of the Guideline and related products distributed. Moreover, it has had an enormous influence on tobacco use treatment and policy worldwide, serving as the basis for Guidelines in Australia, Canada, Chile, Japan, Portugal, and Switzerland, among other countries.

The continued expansion of new scientific findings on the effective treatment of tobacco use led to calls for the current update, *Treating Tobacco Use and Dependence: 2008 Update*. The 2008 update reviewed scientific

evidence from 1975 to 2007 on selected topics and in total reviewed more than 8,700 scientific publications. The result of this methodologically rigorous review is an updated set of recommendations on effective counseling and medication treatments and institutional policies that can guide clinicians, specialists, and health systems in intervening with tobacco users. Appendix D summarizes new recommendations and changes to the 2000 Guideline.

The clinician audience for this Guideline update is all professionals who provide health care to tobacco users. This includes: physicians, nurses, physician assistants, medical assistants, dentists, hygienists, respiratory therapists, psychologists, mental health counselors, pharmacists, and others. The ultimate beneficiaries of the Guideline are tobacco users and their families.

Most tobacco users in the United States are cigarette smokers. As a result, the majority of clinician attention and research in the field has focused on the treatment and assessment of smoking. Clinicians, however, should intervene with all tobacco users, not just with those who smoke cigarettes. To foster a broad implementation of this Guideline update, every effort has been made to describe interventions so that they are relevant to all forms of tobacco use. In some sections of this Guideline, the term "smoker" is used instead of "tobacco user." The use of the term "smoker" means that all relevant evidence for a recommendation arises from studies of cigarette smokers. Additional discussion of noncigarette forms of tobacco use is found in Chapter 7.

The 2008 Guideline update generally is consistent with the findings of the 2000 Guideline (see Appendix D). It also is important to note that other Guidelines and analyses on the treatment of tobacco dependence have been published with essentially consistent findings, including those from the American Psychiatric Association,[75,76] the American Medical Association,[77] the American Dental Association,[78] the American Nurses Association,[79] the American College of Obstetricians and Gynecologists, the Institute of Medicine,[80] the United Kingdom Guideline,[81] and the Cochrane Collaboration (*www.cochrane.org/index.htm*). Finally, throughout the Guideline update, the terms "tobacco use treatment" and "tobacco dependence treatment" will be used interchangeably to emphasize the fact that both chronic use and dependence merit clinical intervention.

Tobacco Dependence as a Chronic Disease

Tobacco dependence displays many features of a chronic disease. Only a minority of tobacco users achieve permanent abstinence in an initial quit attempt. The majority of users persist in tobacco use for many years and typically cycle through multiple periods of remission and relapse. A failure to appreciate the chronic nature of tobacco dependence may impede clinicians' consistent assessment and treatment of the tobacco user over time.

Epidemiologic data suggest that more than 70 percent of the 45 million smokers in the United States today report that they want to quit, and approximately 44 percent report that they try to quit each year.[3] Unfortunately, most of these efforts are both unaided and unsuccessful. For example, among the 19 million adults who attempted to quit in 2005,[39] only 4 to 7 percent were likely successful.[82,83] These statistics may discourage both smokers and clinicians.

Modern approaches to treating tobacco use and dependence should reflect the chronicity of tobacco dependence. A chronic disease model recognizes the long-term nature of the disorder with an expectation that patients may have periods of relapse and remission. If tobacco dependence is recognized as a chronic disease, clinicians will better understand the relapsing nature of the condition and the requirement for ongoing, rather than just acute, care. The existence of numerous effective treatments gives the clinician and patient many options should repeated quit attempts be needed.

A chronic disease model emphasizes for clinicians the importance of continued patient education, counseling, and advice over time. Although most clinicians are comfortable in counseling their patients about other chronic diseases such as diabetes, hypertension, or hyperlipidemia, many believe that they are less effective in providing counseling to patients who use tobacco.[84,85] As with these other chronic disorders, clinicians should be encouraged to provide tobacco-dependent patients with brief advice, counseling, and appropriate medication. It is important for clinicians to know that assessing and treating tobacco use generally leads to greater patient satisfaction with health care.[23,50,86-88] Moreover, policy changes (e.g., tax increases, smoke-free ordinances) often lead smokers to seek treatment for this chronic disease.

In updating the Guideline, the Panel has presented evidence-based analytic findings in a format accessible and familiar to practicing clinicians. Although this should aid clinicians in the assessment and treatment of tobacco users, clinicians should remain cognizant that relapse is likely and that it reflects the chronic nature of dependence. Most smokers who ultimately quit smoking experience episodes of relapse on the way to success. Relapse should not discourage the clinician or the tobacco user from renewed quit attempts.

Coordination of Care: Institutionalizing the Treatment of Tobacco Dependence

Increasing evidence shows that the success of any tobacco dependence treatment strategy cannot be divorced from the health care system in which it is embedded. Data strongly indicate that the consistent and effective delivery of tobacco interventions requires *coordinated interventions*. Just as a clinician must intervene with his or her patient, so must the health care administrator, insurer, and purchaser ensure the provision of tobacco dependence treatment as an integral element of health care delivery. Health care purchasers and insurers should ensure that evidence-based tobacco dependence counseling and medications are a covered and available health insurance benefit for all enrollees and that enrollees are aware of such benefits. Health care administrators also should provide clinicians with the training and institutional support and systems to ensure consistent identification of and intervention with patients who use tobacco. Therefore, insurers, purchasers, and health care organizations should promote the utilization of covered treatments and assess usage and outcomes in performance measurement systems.[89] Finally, increasing evidence shows that, for maximum public health benefit, access to effective treatments should be increased during and following the implementation of population-level tobacco control policies (i.e., tobacco tax increases and clean indoor air laws), which boost motivation and support for quitting efforts.[90]

Guideline Development Methodology

Introduction

Panel recommendations are intended to provide clinicians with effective strategies for treating patients who use tobacco. Fundamentally, this document is a clinical practice guideline. Recommendations were influ-

enced by two goals. The first was to identify effective treatment strategies. The second was to formulate and present recommendations that can be implemented easily across diverse clinical settings (e.g., primary care and specialty clinics; pharmacies; hospitals, including emergency departments; worksites; and school-based clinics) and patient populations.

The Guideline update is based on three systematic reviews of the available scientific literature. The first review occurred during the creation of the original Guideline published in 1996 and included literature published from 1975 through 1994. The second review was conducted for the 2000 Guideline and included literature from 1995 through January 1999. The third review was conducted on literature published from 1999 to June 2007. The three data sets were combined into a single database that was used for the 2008 analyses.

The Panel identified randomized placebo/comparison controlled trials as the strongest level of evidence for the evaluation of treatment effectiveness. Thus, evidence derived from randomized controlled trials serves as the basis for meta-analyses and for almost all of the recommendations contained in this Guideline. Questions have been raised about medication placebo controls because individuals sometimes guess their actual medication condition at greater than chance levels.[91] It is possible, therefore, that the typical randomized control trial does not control completely for placebo effects. This should be borne in mind when appraising the results of the medication meta-analyses. Further, in studies of counseling, it often is not possible to control for a nonspecific placebo effect.

The Panel occasionally made recommendations in the absence of randomized controlled trials when faced with an important clinical practice issue for which other types of evidence existed. This Guideline clearly identifies the level or strength of evidence that serves as the basis for each of its recommendations.

Topics Included in the Guideline

The Panel identified tobacco use as the targeted behavior and tobacco users as the clinical population of interest. Tobacco dependence treatments were evaluated for effectiveness, as were interventions aimed at modifying both clinician and health care delivery system behavior. At the start of the 2008 update process, Guideline Panel members, outside experts, and

consortium representatives were consulted to determine those aspects of the 2000 Guideline that required updating. These consultations resulted in the following chief recommendations that guided the update efforts: (1) to conduct new literature reviews and meta-analyses on topics distinguished by their public health importance and for which significant new evidence is available; (2) to review previous recommendations and to identify a subset of recommendations for which to review new data; special attention was paid to clinical situations for which the Panel had previously achieved consensus in the absence of relevant controlled trials ("C"-level recommendations) to ensure that these still warranted Guideline Panel support; (3) to consider anew the strategies that might be used in clinical settings to deliver brief tobacco dependence interventions (see Chapter 3); and (4) to identify important topics for future research. Eleven topics out of 64 considered were chosen by the Panel for updated meta-analysis (see Table 1.1).

Table 1.1. Topics chosen by the 2008 Guideline Panel for updated meta-analysis

Effectiveness of proactive quitlines
Effectiveness of combining counseling and medication relative to either counseling or medication alone
Effectiveness of varenicline
Effectiveness of various medication combinations
Effectiveness of long-term medication use
Effectiveness of tobacco use interventions for individuals with low SES/limited formal education
Effectiveness of tobacco use interventions for adolescent smokers
Effectiveness of tobacco use interventions for pregnant smokers
Effectiveness of tobacco use interventions for individuals with psychiatric disorders, including substance use disorders
Effectiveness of providing tobacco use interventions as a health benefit
Effectiveness of systems interventions, including provider training and the combination of training and systems interventions

This Guideline update was specifically intended to review the evidence regarding clinical treatment of tobacco dependence. Interventions for the primary prevention of tobacco use were not examined in detail, with the exception of interventions directly relevant to clinical practice. Readers also may refer to the 1994 Surgeon General's Report, *Preventing Tobacco Use Among Young People*[41] and the 2000 Surgeon General's Report, *Reducing Tobacco Use,*[6] for information on the primary prevention of tobacco

use. Community-level interventions (e.g., mass media campaigns) that are not usually implemented in primary care practice settings were not addressed. For more information on community-based tobacco use prevention, refer to the Centers for Disease Control and Prevention *Guide to Community Preventive Services*.[92] The Guideline update did not examine evidence regarding unaided quit attempts as this Guideline focused on clinical interventions. Finally, the use of exposure reduction strategies[93] (strategies in which tobacco users alter, rather than eliminate, their use of nicotine or tobacco in an attempt to reduce or avoid its harmful consequences) were not considered due to a lack of data and the fact that they are beyond the scope of a clinical practice guideline focused on treating tobacco use and dependence. Current research does not offer answers to key questions regarding exposure reduction strategies: their population-wide impact on cessation and initiation of smoking, their long-term benefits as compared with those of a strategy focused on tobacco abstinence, and their success in reducing long-term exposure to tobacco toxins.

This Guideline update is designed for two main audiences: first, clinicians; and second, health care administrators, insurers, and purchasers. It is designed to be used in a wide variety of clinical practice settings, including private medical practices; dental offices; pharmacies; academic health centers; mental health and substance abuse treatment clinics; telephone quitlines; managed care organizations; public health department clinics; hospitals, including emergency departments; and school or worksite clinics. The ultimate beneficiaries of the Guideline are tobacco users and their families.

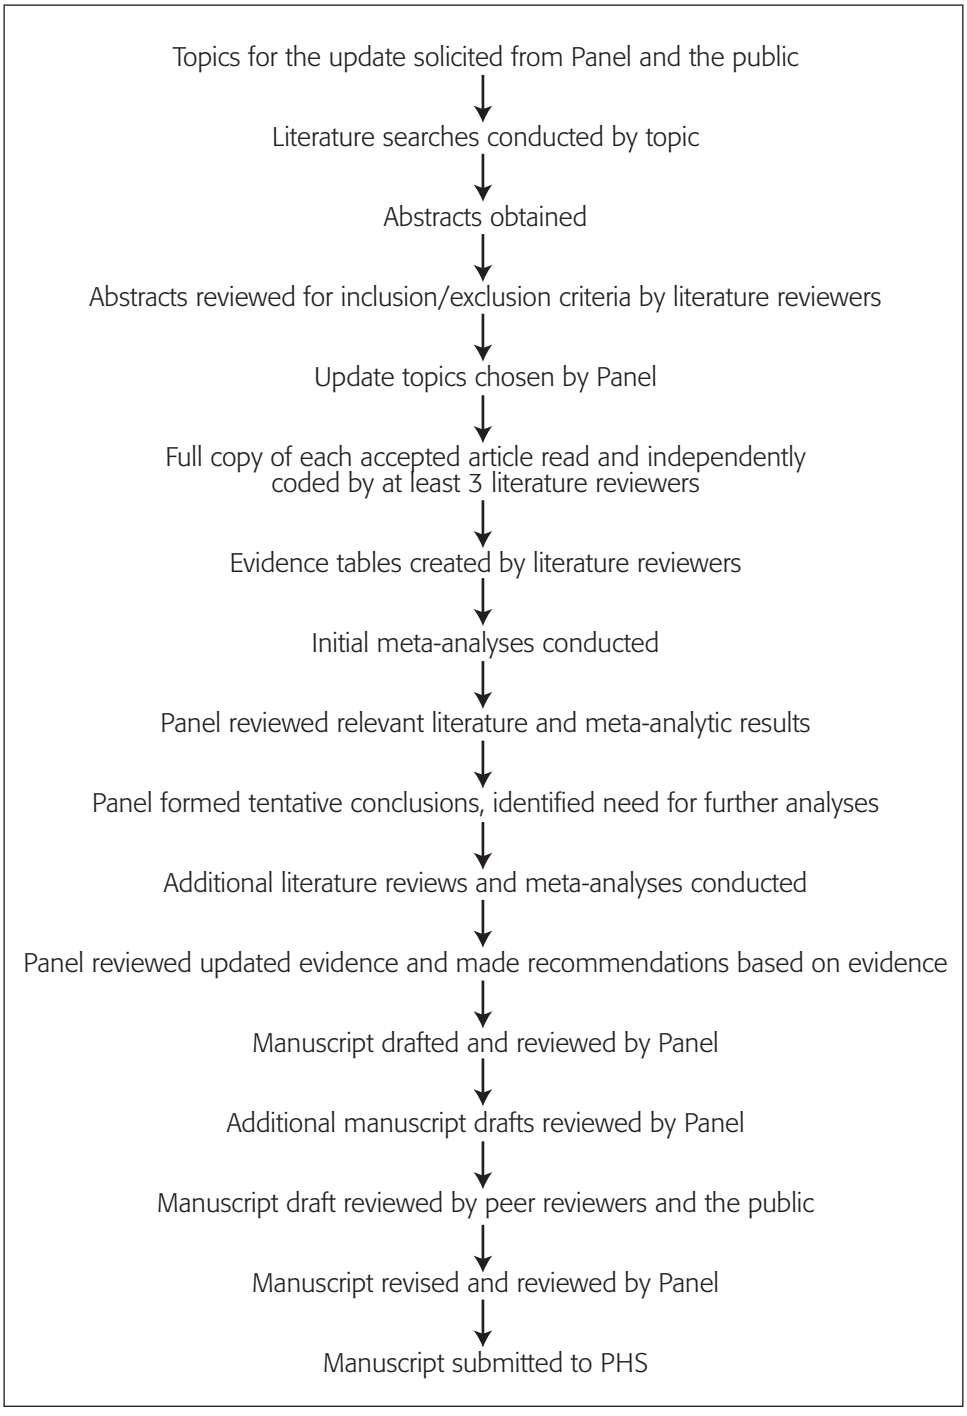
Guideline Development Process

The 2008 Guideline update development process (see Figure 1.1) was initiated in mid-2006. The methodology was consistent with that followed by the 2000 Guideline except where specifically identified below.

Selection of Evidence

Published, peer-reviewed, randomized controlled studies were considered to constitute the strongest level of evidence in support of Guideline recommendations. This decision was based on the judgment that randomized controlled trials provide the clearest scientifically sound basis for judging

Figure 1.1. 2008 Guideline development process



comparative effectiveness. Most of these randomized trials, however, were conducted with individuals who proactively sought treatment and who volunteered to fulfill various research requirements. It is possible that these individuals were more highly motivated to quit smoking than the typical smoker encountered in a clinical practice setting. Thus, the percentage abstinent estimates supplied with the meta-analyses may overestimate the actual level of abstinence produced by some of the treatments in real-world settings. Analyses conducted for the previous Guideline editions, though, suggest that the treatment effect sizes (odds ratios or ORs) are relatively stable across individuals seeking treatment ("treatment seekers") and those recruited via inclusive recruitment strategies ("all-comers"). Randomized controlled trials were exclusively used in meta-analyses. However, the Panel recognized that variations in study inclusion criteria sometimes were warranted. For instance, research on tobacco interventions in adolescents frequently assigns interventions on the basis of larger units, such as schools. These units, rather than individuals, were allowed to serve as units of analysis when analyzing interventions for adolescents. In such cases, studies were combined for inclusion in meta-analyses if the study satisfied other review criteria. A similar strategy was followed in the review of health systems research.

In certain areas, research other than randomized clinical trials was evaluated and considered to inform Panel opinion and judgment, though not submitted to meta-analysis. This occurred with topics such as tobacco dependence treatment in specific populations, tailoring interventions, and cost-effectiveness of tobacco dependence treatment.

Literature Review and Inclusion Criteria

Approximately 8,700 articles were screened to identify evaluable literature. This figure includes approximately 2,700 articles added to the literature since publication of the 2000 Guideline. These articles were obtained through searches of 11 electronic databases and reviews of published abstracts and bibliographies. An article was deemed appropriate for meta-analysis if it met the criteria for inclusion established *a priori* by the Panel. These criteria were that the article: (a) reported the results of a randomized, placebo/comparison controlled trial of a tobacco use treatment intervention randomized on the patient level (except as noted above); (b) provided followup results at least 5 months after the quit date (except in the case of studies evaluating tobacco dependence treatments

for pregnant smokers); (c) was published in a peer-reviewed journal; (d) was published between January 1975 and June 2007; (e) was published in English; and (f) was one of the 11 topics chosen to be included in the 2008 update (see Table 1.1). It is important to note that the article-screening criteria were updated for the 2008 Guideline update. Additionally, articles were screened for relevance to safety, economic, or health systems issues. As a result of the original and update literature reviews, more than 300 articles were identified for possible inclusion in a meta-analysis, and more than 600 additional articles were examined in detail by the Panel. These latter articles were used in the formulation of Panel recommendations that were not supported by meta-analyses. The literature search for the update project was validated by comparing the results against a search conducted by the CDC and through review by the expert Panel.

When individual authors published multiple articles meeting the meta-analytic inclusion criteria, the articles were screened to determine whether they contained unique data. When two articles reported data from the same group of subjects, both articles were reviewed to ensure that complete data were obtained. The data were treated as arising from a single study in meta-analyses.

Preparation of Evidence Tables

Two Guideline staff reviewers independently read and coded each article that met inclusion criteria. The reviewers coded the treatment characteristics that were used in data analyses (see Tables 6.1 and 6.2 in Chapter 6). The same general coding procedure employed during the 2000 Guideline process was employed during the update. When adjustments to the coding process were made, articles coded with the original process were re-coded to reflect the changed coding (e.g., more refined coding criteria were used for the coding of treatment intensity).

A third reviewer then examined the coding of both reviewers and adjudicated any differences. Discrepancies that could not be resolved through this process were adjudicated by the project manager, Panel chair, and/or the Panel's senior scientist. Finally, each article accepted for a meta-analysis had key fields reviewed by the project manager as a final quality check. The data then were compiled and used in relevant analyses and/or Panel deliberations. Analyses done for the 2000 Guideline revealed that intervention coding categories could be used reliably by independent raters.[94]

Outcome Data

Six-month followup after the quit date is a standard followup duration for reporting data from clinical trials. Therefore, focusing on a 6-month timepoint in meta-analyses allowed the investigators to capture the greatest number of studies for analysis. Also, research indicates that a high percentage of those who ultimately return to smoking will do so by 6 months.[95-98] Because a strict adherence to a 6-month timepoint would have eliminated a significant number of studies, a 1-month window was permitted such that studies with 5 months of followup data were included, but 6-month data were used if both 5- and 6-month data were available. When quit rates were provided for longer endpoints, outcome data from the endpoint closest to 6 months were used, so long as they did not exceed 3 years. Outcome data beyond 3 years rarely were available and were not included in the Guideline analyses. In the area of medication treatment, the inclusive meta-analysis reported in Table 6.26 was repeated with longer term outcome data (10–14 month postquit). This additional meta-analysis largely replicated the results of the meta-analysis based on a 6-month followup time frame. This suggested that the shorter, more inclusive, followup timepoint captured effect sizes that were similar to those yielded by the use of longer followup timepoints. There was one exception to the selection of followup data described above. In the case of pregnancy studies, both predelivery and postdelivery (5 months) outcomes were analyzed.

Panel staff also coded biochemical confirmation of self-reported tobacco use abstinence. Previous Guideline analyses show that studies with and without biochemical confirmation yield similar meta-analysis results. Therefore, meta-analyses presented in the Guideline reflect a pooling of these studies. If both biochemically confirmed and nonconfirmed data were available from the same study, however, the confirmed data were used in analyses. As in the 2000 Guideline, only studies that used biochemical verification were used in the meta-analyses of pregnant smokers because of the under-reporting of smoking status by pregnant women.

All of the new meta-analyses conducted for the 2008 Guideline were based exclusively on intent-to-treat data, in which the denominator was the number of participants randomized to treatment and the numerator was the number of abstinent participants contacted at followup. Some meta-analyses conducted for the 1996 and 2000 Guideline comprised a small number of studies in which the denominator consisted only of participants

who completed treatment. The vast majority of studies across all analyses reported intent-to-treat data and these data were used if both types of data were available.

Studies were coded for how the outcome measures were reported—"point prevalence," "continuous," or "unknown/other." If abstinence data were based on tobacco use occurrence within a set time period (usually 7 days) prior to a followup assessment, the outcome measure was coded as "point prevalence." "Continuous" was used when a study reported abstinence based on whether study subjects were continuously abstinent from tobacco use since their quit day. "Unknown/other" was used when it was not possible to discern from the study report whether the authors used a point prevalence or continuous measure for abstinence or if abstinence was measured from some point other than the quit day.

As in the 1996 and 2000 Guidelines, a point prevalence outcome measure (7-day point prevalence, when available), rather than continuous abstinence, was used as the chief outcome variable. Point prevalence was preferred for several reasons. First, this was the modal reporting method among the analyzable studies. Second, continuous abstinence data may underestimate the percentage of individuals who are abstinent at particular followup timepoints, although some data suggest that these rates are similar.[99] Finally, most relapse begins early in a quit attempt and persists.[95-97,100-102] A point prevalence measure taken at 6 months certainly would capture the great majority of those relapse events. Therefore, whenever possible, 7-day point prevalence abstinence data were used. If point prevalence data were not available, the preferred alternative was continuous abstinence data.

Meta-Analytic Techniques

The principal analytic technique used in this Guideline update was meta-analysis. This statistical technique estimates the impact of a treatment or variable across a set of related investigations. The primary meta-analytic model used in this and the previous two Guidelines was logistic regression using random effects modeling. The modeling was performed at the level of the treatment arm, and study effects were treated as fixed. The panel methodologist chose to employ random effects modeling, assuming that both the subject populations and the treatment elements analyzed would

vary from study to study (e.g., counseling might be done somewhat differently at two different sites). Random effects modeling is well suited to accommodate such variation among studies.[103] The statistician used the EGRET Logistic Normal Model.[104] A complete and detailed review of the meta-analytic methods used in the Guideline can be found in the *Smoking Cessation Guideline Technical Report No. 18,* available from AHRQ as AHCPR Publication No. 97-N004. The specific articles used in each meta-analysis included in the 2008 Guideline can be found at *www.surgeongeneral.gov/tobacco/gdlnrefs.htm*.

In general, meta-analysis was used only with studies with randomization at the level of subject. In some areas (health systems changes, adolescents), however, studies often involved randomization at another level (e.g., clinician, clinic, etc.). Such studies were used in meta-analyses of a small number of topics when such studies occurred in sufficient numbers to permit inferences. Screening of such articles considered factors such as data nonindependence, the evaluation of pre-intervention or baseline status, and the number and types of higher level units.

The initial step in meta-analysis was the selection of studies that were relevant to the treatment characteristic being evaluated. After relevant studies were identified (i.e., those that contained a self-help intervention if self-help treatments were being evaluated), Panel staff reviewed the studies to ensure that they passed screening criteria. Some screening criteria were general (e.g., study presents greater than 5 months of followup data), whereas other criteria were specific to the type of treatment characteristic evaluated (i.e., in the analysis of quit lines, screening ensured that treatment arms were not confounded with differing intensities of in-person counseling).

The separate arms (treatment or control groups) in each study then were inspected to identify confounders that could compromise interpretation. Seriously confounded arms were excluded from analysis. Relevant characteristics of each arm were then coded to produce meaningful analytic comparisons. Criteria for performing a meta-analysis included: (1) the Guideline Panel judged the topic to be addressed in the meta-analysis as having substantial clinical significance; (2) at least two studies meeting selection criteria existed on the topic and the studies contained suitable within-study control or comparison conditions (e.g., each study had to contribute at least two arms that would permit the estimation of within-study effects); and (3) there was an acceptable level of interstudy homogeneity in the

analyzed variable or treatment so as to permit meaningful inference (e.g., an analyzed treatment was sufficiently similar across various studies so that combining studies was meaningful).

Limitations of Meta-Analytic Techniques. Several factors can compromise the internal validity of meta-analyses. For example, publication biases (particularly the tendency to publish only those studies with positive findings) may result in biased summary statistics. The complement to publication bias is the "file-drawer effect," in which negative or neutral findings are not submitted for publication. In addition, either the magnitude or the significance of the effects of meta-analyses may be influenced by factors such as the frequency with which treatments occurred in the data set and by the extent to which treatments co-occurred with other treatments. All else being equal, a treatment that occurs infrequently in the data set is less likely to be found significant than a more frequently occurring treatment. Also, when two treatments co-occur frequently in the same groups of subjects, it is difficult to apportion statistically the impact of each. In addition, comparability biases can exist when substantially different groups or treatments are coded as being the same (e.g., when treatments are similar only on a superficial attribute).

The generalizability of meta-analytic findings was evaluated for previous Guideline editions with respect to whether patients sought cessation treatment ("self-selected") or whether treatment was delivered without the patient seeking it ("all-comers," as when cessation treatment occurred as an integral part of health care). Conducting separate meta-analyses in these different subject populations yielded very similar findings across a variety of treatment dimensions (e.g., treatment format, treatment intensity). No other population characteristic (e.g., years smoked, severity of dependence) was explored in meta-analyses.

Interpretation of Meta-Analysis Results. The meta-analyses yielded logistic regression coefficients that were converted to odds ratios. The meaning or interpretation of an odds ratio can be seen most easily by means of an example depicted in a 2 x 2 table. Table 1.2 contains data showing the relation between maternal smoking and low birth-weight in infants. Data are extracted from Hosmer and Lemeshow, 2000.[105] The odds of a low birth-weight infant if the mother smokes are 30:44, or 0.68 to 1. The odds of a low birth-weight infant if the mother does not smoke are 29:86, or 0.34 to 1. The odds ratio may be estimated as (30/44)/(29/86) = 2.02 to 1. There-

fore, the odds ratio can be seen roughly as the odds of an outcome on one variable, given a certain status on another variable(s). In the case above, the odds of a low birth-weight infant are about double for women who smoke compared with those who do not.

Table 1.2. Relation between maternal smoking and low birth-weight in infants

		Maternal smoking		
		Yes	No	
Low birth-weight	Yes	30	29	59
	No	44	86	130
		74	115	189

Once odds ratios were obtained from the meta-analyses, 95 percent confidence intervals (C.I.) were estimated around the odds ratios. An odds ratio is only an estimate of a relation between variables. The 95 percent confidence interval presents an estimate of the precision of the particular odds ratio obtained. If the 95 percent confidence interval for a given odds ratio does not include "1," then the odds ratio represents a statistically significant difference between the evaluated treatment and the reference or control condition at the 0.05 level. The confidence intervals generally will not be perfectly symmetrical around an odds ratio because of the distributional properties of the odds ratio. The confidence intervals do not reveal whether active treatments differ significantly from one another, only whether they differ from the comparison condition (e.g., placebo medication, no contact). In the inclusive meta-analysis on medications, comparisons of an active medication versus the nicotine patch were accomplished via *a posteriori* contrasts, not on the basis of nonoverlapping confidence intervals.

After computing the odds ratios and their confidence intervals, the odds ratios were converted to abstinence percentages and their 95 percent confidence intervals (based on reference category abstinence rates). Abstinence percentages indicate the estimated long-term abstinence rate achieved under the tested treatment or treatment characteristic. The abstinence percentage results are approximate estimates derived from the odds ratio data. Therefore, they essentially duplicate the odds ratio results but are presented because their meaning may be clearer for some readers. Because the placebo/control abstinence percentage for a particular analysis is calculated exclusively from the studies included within that meta-analysis, these abstinence percentages vary across the different analyses. Therefore, the

odds ratios and abstinence rates presented across the different tables are estimated relative to different placebo or control conditions.

How To Read the Data Tables

Table 1.3 depicts results from one of the meta-analyses reported in this Guideline update. This table presents results from the analysis of the effects of proactive telephone counseling (see Formats of Psychosocial Treatments in Chapter 6). In this table, the comparison condition, or "reference group," for determining the impact of different treatment options was smokers who received minimal or no counseling or self-help. The "Estimated odds ratio" column reveals that treatment conditions receiving proactive telephone counseling had an odds ratio of 1.6. The odds ratio indicates a statistically significant effect because the lower boundary of the confidence interval did not include "1." This odds ratio means that when smokers receive proactive telephone counseling, they are more than one and one-half times more likely to remain abstinent than if they had received minimal or no counseling or self-help.

Table 1.3. Meta-analysis (2008): Effectiveness of and estimated abstinence rates for proactive telephone counseling compared to minimal interventions, self-help, or no counseling (n = 9 studies)

Intervention	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
Minimal or no counseling or self-help	11	1.0	10.5
Quitline counseling	11	1.6 (1.4–1.8)	15.5 (13.8–17.3)

The column labeled "Estimated abstinence rate" shows the abstinence percentages for the two treatment conditions. For instance, the reference condition (minimal or no counseling) in the analyzed data set was associated with an abstinence rate of 10.5 percent. Consistent with the odds ratio data reviewed above, proactive telephone counseling produced modest increases in abstinence rates (15.5%).

The total number of studies included in each meta-analysis is provided within the title of the corresponding table. A list of published articles used in each meta-analysis can be found at: *www.surgeongeneral.gov/tobacco/gdlnrefs.htm*. Finally, the 2008 Guideline update includes meta-analyses

completed for the 1996, 2000, and 2008 Guidelines. In the title of each meta-analysis, the year in which it was first published is provided.

The column labeled "Number of arms" specifies the number of treatment groups across all analyzed studies that contributed data to the various treatment conditions (e.g., Quitline counseling was provided in 11 treatment arms). Therefore, this column depicts the number of treatment groups relevant to each analyzed category. Because a study may have multiple treatment groups, the number of treatment arms may exceed the number of studies included in a meta-analysis.

The outcome data in the tables may include findings from both studies with "all-comers" (individuals who did not seek a treatment intervention) and "self-selected" populations, studies using point-prevalence and continuous abstinence endpoints, and studies with and without biochemical confirmation, except where otherwise described. Some meta-analyses (such as those evaluating medications) included predominantly studies with "self-selected" populations who volunteered for intensive treatment. In addition, in medication studies, both experimental and control subjects typically received substantial counseling. Both of these factors might have produced higher abstinence rates in reference or placebo subjects than typically are observed among self-quitters. Finally, although there is an important scientific distinction between "efficacy" and "effectiveness,"[106] this 2008 clinical update uses the term "effectiveness" exclusively, recognizing that the majority of the studies summarized here reflect efficacy research, which requires random assignment and a high degree of experimental control. This was done for purposes of clarity for the intended clinical audience.

Strength of Evidence

Every recommendation made by the Panel bears a strength-of-evidence rating that indicates the quality and quantity of empirical support for the recommendation. Each recommendation and its strength of evidence reflects consensus of the Guideline Panel.

The three strength-of-evidence ratings are described below:

A. Multiple well-designed randomized clinical trials, directly relevant to the recommendation, yielded a consistent pattern of findings.

B. Some evidence from randomized clinical trials supported the recommendation, but the scientific support was not optimal. For instance, few randomized trials existed, the trials that did exist were somewhat inconsistent, or the trials were not directly relevant to the recommendation.

C. Reserved for important clinical situations in which the Panel achieved consensus on the recommendation in the absence of relevant randomized controlled trials.

As noted previously, the Panel evaluated evidence from nonrandomized trials to inform members' understanding of certain topics (e.g., policy issues). If treatment recommendations were based primarily on such evidence, they were of the "C" level and depended on the consistency of findings across different studies. In some areas, the highest quality evidence does not depend on randomized trials (e.g., cost-effectiveness). In these areas, the strength-of-evidence rating depended on the number, quality, and consistency of the studies and evidence. Finally, the Panel declined to make recommendations when there was no relevant evidence or the evidence was too weak or inconsistent to support a recommendation.

Caveats Regarding Recommendations

The reader should note some caveats regarding Guideline recommendations. First, an absence of studies should not be confused with a proven lack of effectiveness. In certain situations, there was little direct evidence regarding the effectiveness of some treatments, and in these cases the Panel usually rendered no opinion. Second, even when there were enough studies to perform a meta-analysis, a nonsignificant result does not prove ineffectiveness. Rather, nonsignificance merely indicates that effectiveness was not demonstrated given the data available.

The primary emphasis of this Guideline update is to identify effective interventions, not to rank-order interventions in terms of effectiveness. The most important goal of the analytic process is to identify effective interventions. Selection or use of particular intervention techniques or strategies usually is a function of practical factors: patient preference, time available, training of the clinician, cost, and so on. The Panel believes clinicians should choose the most appropriate intervention from among

the effective interventions identified in this Guideline update, given clinical circumstances. An excessive emphasis on relative effectiveness might discourage clinicians from using interventions that have a small but reliable impact on quit rates. One meta-analysis that is new to this update does provide focused tests of the relative effectiveness of different interventions. Specifically, the inclusive meta-analysis of the tobacco use medications involved *a posteriori* tests of medication effectiveness versus the nicotine patch (Table 6.28). These tests of relative effectiveness were conducted on this topic because: (1) numerous treatments were available for comparison; (2) selection from among the various tobacco use medications has been noted as an important clinical concern;[107-109] and (3) the various interventions are somewhat interchangeable and widely available so that the clinician or patient might be able to select a medication based on effectiveness. Finally, the panel occasionally identified an intervention as superior to another in the absence of formal statistical contrasts; some interventions were so superior to control or no-treatment conditions that the Panel clearly identified them as superior to another intervention. For instance, although minimal person-to-person contact can increase smoking abstinence rates over no-treatment conditions, there is little doubt that longer person-to-person interventions have greater impact (see Chapter 6).

External Review of the Guideline

For the present update, the Panel and consortium members invited 106 reviewers to make comments. In addition, a draft of the Guideline was published in the *Federal Register* in September 2007 for public comment. A total of 81 invited reviewers and 15 members of the public supplied written comments. Peer reviewers included clinicians, health care administrators, social workers, counselors, health educators, researchers, consumers, key personnel at selected Federal agencies and State tobacco control programs, and others. All peer reviewers made financial disclosure statements, which were provided to the Panel. Reviewers were asked to evaluate the Guideline based on five criteria: validity, reliability, clarity, clinical applicability, and utility. Comments from the peer reviewers and public were incorporated into the Guideline when appropriate. Two individuals made oral presentations to the Guideline Panel during an advertised open presentation period.

Organization of the Guideline Update

This updated Guideline is divided into seven chapters that reflect the major components of tobacco dependence treatment (see Figure 1.2 for the treatment model):

Chapter 1, Overview and Methods, provides an overview and rationale for the updated Guideline, as well as a detailed description of the methodology used to review the scientific literature and develop the original and updated Guidelines.

Chapter 2, Assessment of Tobacco Use, establishes the importance of determining the tobacco use status of every patient at every visit.

Chapter 3, Clinical Interventions for Tobacco Use and Dependence, is intended to provide clinicians with guidance as they use brief interventions to treat tobacco users willing to quit, tobacco users unwilling to make a quit attempt at this time, and tobacco users who have recently quit.

A. For the Patient Willing To Quit, provides brief clinical approaches to assist patients in quit attempts.

B. For the Patient Unwilling To Quit, provides brief clinical approaches designed to motivate the patient to make a quit attempt.

C. For the Patient Who Has Recently Quit, provides clinicians with strategies designed to reinforce a former tobacco user's commitment to stay tobacco-free and assist patients who have relapsed.

Chapter 4, Intensive Interventions for Tobacco Use and Dependence, provides clinicians with more intensive strategies to treat tobacco users.

Chapter 5, Systems Interventions, targets health care administrators, insurers, purchasers, and other decisionmakers who can affect health care systems. This chapter provides these decisionmakers with strategies to modify health care systems to improve the delivery of tobacco treatment services.

Chapter 6, Evidence and Recommendations, presents the evidentiary basis for the updated Guideline recommendations.

A. Counseling and Psychosocial Evidence: Provides recommendations and analysis results regarding screening for tobacco use and specialized assessment, advice, intensity of clinical interventions, type of clinician, format, followup procedures, types of counseling and behavioral therapies, and the combination of counseling and medication.

B. Medication Evidence: Provides recommendations and analysis results regarding the seven first-line medications, combination medications, second-line medications, and other medication issues.

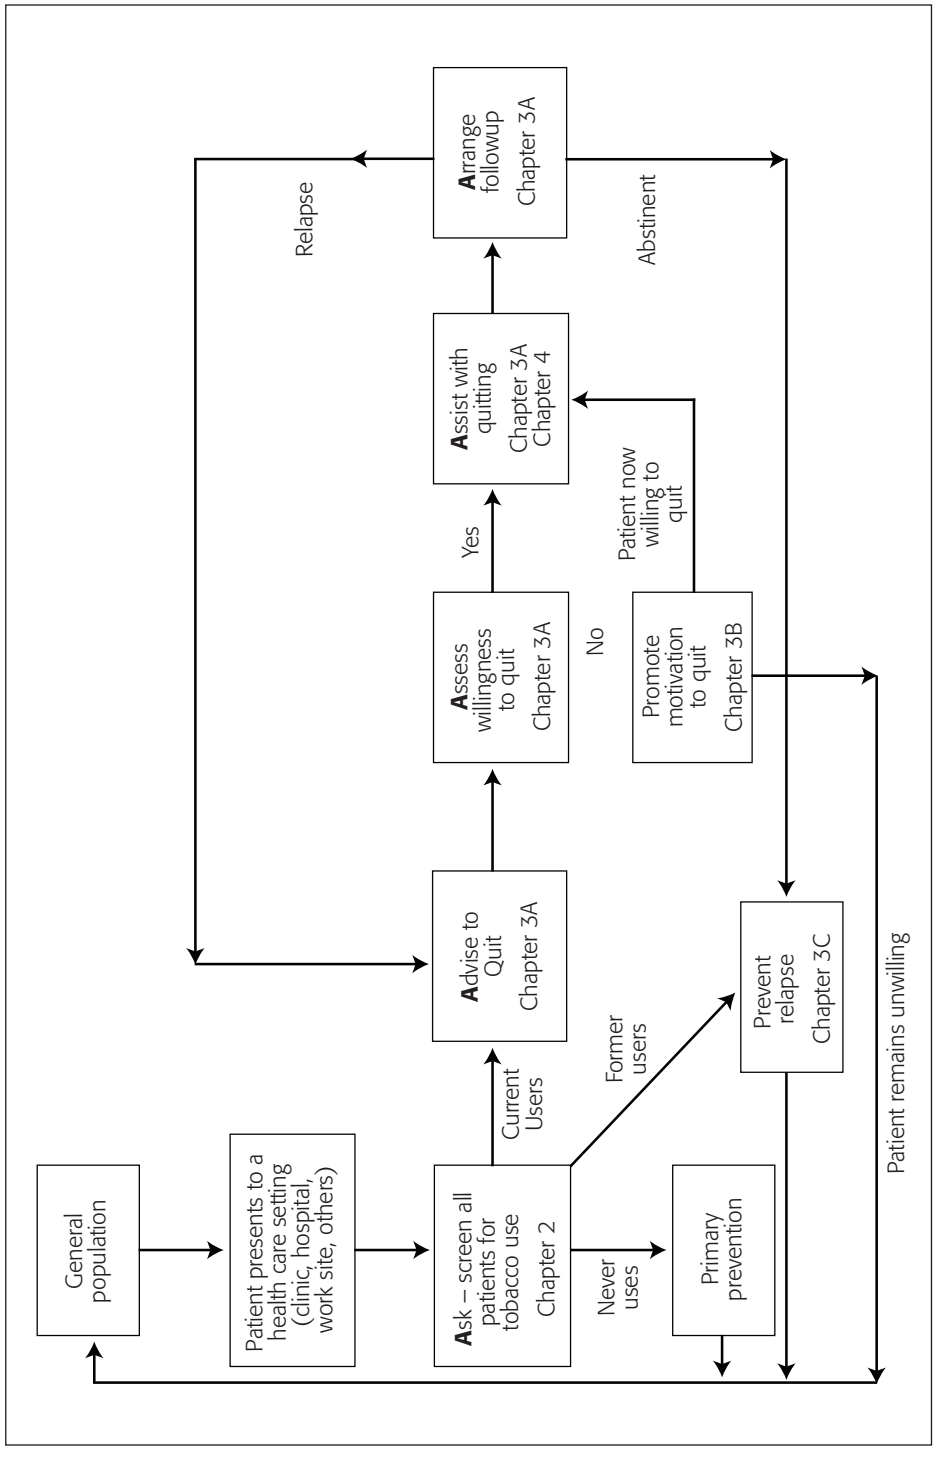
C. Systems Evidence: Provides recommendations and analysis results regarding systems changes, including provider training, cost-effectiveness, and health insurance coverage for tobacco use treatments.

Chapter 7, Specific Populations and Other Topics, provides information on specific populations, including HIV-positive smokers; hospitalized smokers; lesbian/gay/bisexual/transgender smokers; smokers with low SES/limited formal education; smokers with medical comorbidities; older smokers; smokers with psychiatric disorders, including substance use disorders; racial and ethnic minorities; women smokers; children and adolescents; light smokers; and noncigarette tobacco users. This chapter also presents information and recommendations relevant to weight gain after quitting smoking, with specific recommendations regarding future research on this topic.

References

Given the volume of literature referenced in this Guideline, references are listed at *www.surgeongeneral.gov/tobacco/gdlnrefs.htm*, rather than in this document. This was done to manage the length of this Clinical Guideline update and to facilitate electronic searches and manipulation of the references. Within this Web site, text references are numbered to match the numbers in this Guideline update. References to randomized control trials used in all of the meta-analyses (1996, 2000, 2008) are listed separately and by table number and title. The entire Guideline update, with and without references, can be downloaded from the site.

Figure 1.2. Model for treatment of tobacco use and dependence



Chapter 2 Assessment of Tobacco Use

At least 70 percent of smokers see a physician each year, and almost one-third see a dentist.[19,110] Other smokers see physician assistants, nurse practitioners, nurses, physical and occupational therapists, pharmacists, counselors, and other clinicians. Therefore, virtually all clinicians are in a position to intervene with patients who use tobacco. Moreover, 70 percent of smokers report wanting to quit,[111] and almost two-thirds of smokers who relapse want to try quitting again within 30 days.[112] Finally, smokers cite a physician's advice to quit as an important motivator for attempting to stop smoking.[113-118] These data suggest that most smokers are interested in quitting, clinicians and health systems are in frequent contact with smokers, and clinicians have high credibility with smokers.

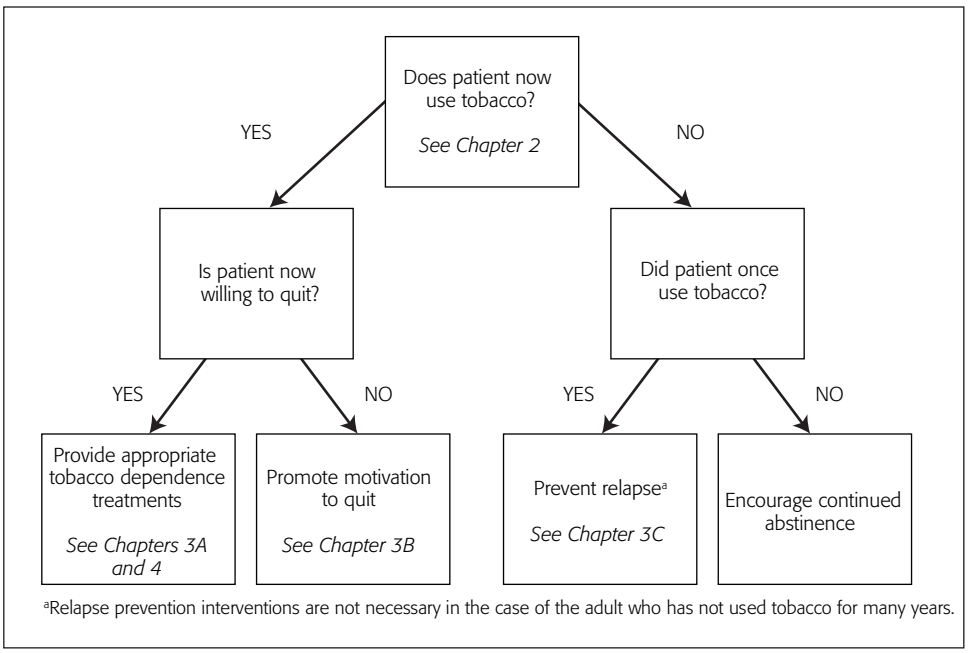
Unfortunately, clinicians and health systems do not capitalize on this opportunity consistently. According to the National Committee for Quality Assurance's (NCQA) *State of Health Care Quality Report*,[119] there has been some improvement in tobacco dependence clinical intervention for the insured population. In 2005, 71.2 percent of commercially insured smokers received cessation advice (up slightly from 69.6% in 2004); and 75.5 percent of Medicare smokers received advice to quit, up 11 percentage points from 2004 for this group. Despite this progress, there is a clear need for additional improvement. Only 25 percent of Medicaid patients reported any practical assistance with quitting or any ensuing followup of their progress.[22] Only one-third of adolescents who visited a physician or dentist report receiving counseling about the dangers of tobacco use, according to the 2000 National Youth Tobacco Survey.[120] Pregnant women who smoke were identified at 81 percent of physician visits but received counseling at only 23 percent of these visits.[121] In addition, few smokers get specific help with quitting. Recent Healthcare Effectiveness Data and Information Set (HEDIS) data showed that only 39 percent of smokers reported that their clinician discussed either medications or counseling strategies to quit (*www.web.ncqa.org/tabid/59/Default.aspx*). To capitalize on this opportunity, the 2008 Guideline update provides empirically validated tobacco treatment strategies designed to spur clinicians, tobacco treatment specialists, and health systems to intervene effectively with patients who use tobacco.

The first step in treating tobacco use and dependence is to identify tobacco users. As the data analysis in Chapter 6 shows, the identification of smok-

ers itself increases rates of clinician intervention. Effective identification of tobacco use status not only opens the door for successful interventions (e.g., clinician advice and treatment), but also guides clinicians to identify appropriate interventions based on patients' tobacco use status and willingness to quit. Based on these findings, the Guideline update recommends that clinicians and health care systems seize the office visit for universal assessment and intervention. Specifically, ask every patient who presents to a health care facility if s/he uses tobacco (Ask), advise all tobacco users to quit (Advise), and assess the willingness of all tobacco users to make a quit attempt at this time (Assess) (the first 3 of the 5 A's; see Chapter 3).

Screening for current or past tobacco use will result in four possible responses: (1) the patient uses tobacco and is willing to make a quit attempt at this time; (2) the patient uses tobacco but is not willing to make a quit attempt at this time; (3) the patient once used tobacco but has since quit; and (4) the patient never regularly used tobacco. This Clinical Practice Guideline is organized to provide the clinician with simple but effective interventions for all of these patient groups (see Figure 2.1).

Figure 2.1. Algorithm for treating tobacco use



[a]Relapse prevention interventions are not necessary in the case of the adult who has not used tobacco for many years.

Chapter 3 Clinical Interventions for Tobacco Use and Dependence

Background

This section of the Guideline presents specific strategies to guide clinicians providing brief interventions (less than 10 minutes). These brief interventions can be provided by all clinicians but are most relevant to clinicians who see a wide variety of patients and are bound by time constraints (e.g., physicians, nurses, physician assistants, nurse practitioners, medical assistants, dentists, hygienists, respiratory therapists, mental health counselors, pharmacists, etc.). The strategies in this chapter are based on the evidence described in Chapters 6 and 7, as well as on Panel opinion. Guideline analysis suggests that a wide variety of clinicians can implement these strategies effectively.

Why should members of a busy clinical team consider making the treatment of tobacco use a priority? The evidence is compelling: (1) clinicians can make a difference with even a minimal (less than 3 minutes) intervention (see Chapter 6); (2) a relation exists between the intensity of intervention and tobacco cessation outcome (see Chapter 6); (3) even when patients are not willing to make a quit attempt at this time, clinician-delivered brief interventions enhance motivation and increase the likelihood of future quit attempts[122] (see Chapter 6); (4) tobacco users are being primed to consider quitting by a wide range of societal and environmental factors (e.g., public health messages, policy changes, cessation marketing messages, family members); (5) there is growing evidence that smokers who receive clinician advice and assistance with quitting report greater satisfaction with their health care than those who do not;[23,87,88] (6) tobacco use interventions are highly cost effective (see Chapter 6); and (7) tobacco use has a high case fatality rate (up to 50% of long-term smokers will die of a smoking-caused disease[123]).

The goal of these strategies is clear: to change clinical culture and practice patterns to ensure that every patient who uses tobacco is identified,

advised to quit, and offered scientifically sound treatments. The strategies underscore a central theme: it is essential to provide at least a brief intervention to every tobacco user at each health care visit. Responsibility lies with both the clinician and the health care system to ensure that this occurs. Several observations are relevant to this theme. First, although many smokers are reluctant to seek intensive treatments,[124,125] they nevertheless can receive a brief intervention every time they visit a clinician.[66,126] Second, institutional support is necessary to ensure that all patients who use tobacco are identified and offered appropriate treatment (see Chapter 5, Systems Interventions: Importance to Health Care Administrators, Insurers, and Purchasers). Third, the time limits on primary care physicians in the United States today (median visit = 12–16 minutes),[127,128] as well as reimbursement restrictions, often limit providers to brief interventions, although more intensive interventions would produce greater success. Finally, given the growing use of electronic patient databases, smoker registries, and real-time clinical care prompts, brief interventions may be easier to fit into a busy practice and may be implemented in a variety of ways.

This chapter is divided into three sections to guide brief clinician interventions with three types of patients: (A) current tobacco users willing to make a quit attempt at this time; (B) current tobacco users unwilling to make a quit attempt at this time; and (C) former tobacco users who have recently quit. Patients who have never used tobacco or who have been abstinent for an extended period should be congratulated on their status and encouraged to maintain their tobacco-free lifestyle.

Given that more than 70 percent of tobacco users visit a physician and more than 50 percent visit a dentist each year,[129] it is essential that these clinicians be prepared to intervene with all tobacco users. The five major components (the "5 A's") of a brief intervention in the primary care setting are listed in Table 3.1. It is important for a clinician to *ask* the patient if he or she uses tobacco (Strategy A1), *advise* him or her to quit (Strategy A2), and *assess* willingness to make a quit attempt (Strategy A3). Strategies A1 to A3 need to be delivered to each tobacco user, regardless of his or her willingness to quit.

If the patient is willing to quit, the clinician should *assist* him or her in making a quit attempt by offering medication and providing or referring for counseling or additional treatment (Strategy A4), and *arrange* for fol-

Table 3.1. The "5 A's" model for treating tobacco use and dependence

Ask about tobacco use.	Identify and document tobacco use status for every patient at every visit. (Strategy A1)
Advise to quit.	In a clear, strong, and personalized manner, urge every tobacco user to quit. (Strategy A2)
Assess willingness to make a quit attempt.	Is the tobacco user willing to make a quit attempt at this time? (Strategy A3)
Assist in quit attempt.	For the patient willing to make a quit attempt, offer medication and provide or refer for counseling or additional treatment to help the patient quit. (Strategy A4) For patients unwilling to quit at the time, provide interventions designed to increase future quit attempts. (Strategies B1 and B2)
Arrange followup.	For the patient willing to make a quit attempt, arrange for followup contacts, beginning within the first week after the quit date. (Strategy A5) For patients unwilling to make a quit attempt at the time, address tobacco dependence and willingness to quit at next clinic visit.

lowup contacts to prevent relapse (Strategy A5). If the patient is unwilling to make a quit attempt, the clinician should provide a motivational intervention (Strategies B1 and B2) and *arrange* to address tobacco dependence at the next clinic visit. The Strategy tables below (A1–A5) comprise suggestions for the content and delivery of the 5 A's. The strategies are designed to be brief and require 3 minutes or less of direct clinician time. These intervention components constitute the core elements of a tobacco intervention, but they need not be applied in a rigid, invariant manner. For instance, the clinician need not deliver all elements personally. One clinician (e.g., a medical assistant) may ask about tobacco use status; and a prescribing clinician (e.g., physician, dentist, physician assistant, nurse practitioner) may deliver personal advice to quit, assess willingness to quit, and assist with medications, but then refer the patient to a tobacco intervention resource (e.g., a tobacco cessation quitline, health educator) that would deliver additional treatment to the patient. The clinician would remain responsible for the patient receiving appropriate care and subsequent followup, but, as with other sorts of health care, an individual clinician would not need to

deliver all care personally.[130] Evidence indicates that full implementation of the 5 A's in clinical settings may yield results that are superior to partial implementation.[131]

The effectiveness of tobacco intervention may reflect not only the contributions of the individual clinician, but also the systems and other clinical resources available to him or her. For instance, office systems that institutionalize tobacco use assessment and intervention will greatly foster the likelihood that the 5 A's will be delivered (see Chapter 5). The 5 A's, as described in Table 3.1, are consistent with those recommended by the NCI[132,133] and the American Medical Association,[77] as well as others.[75,134-137] The clinical situation may suggest delivering these intervention components in an order or format different from that presented, however. For example, clinical interventions such as: Ask/Assess, Advise, Agree on a goal, Assist, Arrange followup; Ask and Act; and Ask, Advise, and Refer have been proposed.[116,130,138-140]

When "Assisting" smokers, in addition to counseling, all smokers making a quit attempt should be offered medication, except when contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents). See Tables 3.2 to 3.11 for guidelines for prescribing medication for treating tobacco use and dependence.

A. For the Patient Willing To Quit

Strategy A1. *Ask*—Systematically identify all tobacco users at every visit

Action	Strategies for implementation
Implement an officewide system that ensures that, for *every* patient at *every* clinic visit, tobacco use status is queried and documented.[a]	Expand the vital signs to include tobacco use, or use an alternative universal identification system.[b] **VITAL SIGNS** Blood Pressure: _____ Pulse: _____ Weight: _____ Temperature: _____ Respiratory Rate: _____ Tobacco Use (circle one): Current Former Never

[a] Repeated assessment is *not* necessary in the case of the adult who has never used tobacco or has not used tobacco for many years and for whom this information is clearly documented in the medical record.

[b] Alternatives to expanding the vital signs include using tobacco use status stickers on all patient charts or indicating tobacco use status via electronic medical records or computerized reminder systems.

Strategy A2. *Advise*—Strongly urge all tobacco users to quit

Action	Strategies for implementation
In a *clear, strong, and personalized* manner, urge every tobacco user to quit.	Advice should be: • *Clear*—"It is important that you quit smoking (or using chewing tobacco) now, and I can help you." "Cutting down while you are ill is not enough." "Occasional or light smoking is still dangerous." • *Strong*—"As your clinician, I need you to know that quitting smoking is the most important thing you can do to protect your health now and in the future. The clinic staff and I will help you." • *Personalized*—Tie tobacco use to current symptoms and health concerns, and/or its social and economic costs, and/or the impact of tobacco use on children and others in the household. "Continuing to smoke makes your asthma worse, and quitting may dramatically improve your health." "Quitting smoking may reduce the number of ear infections your child has."

Strategy A3. *Assess*—Determine willingness to make a quit attempt

Action	Strategies for implementation
Assess every tobacco user's willingness to make a quit attempt at the time.	Assess patient's willingness to quit: "Are you willing to give quitting a try?" • If the patient is willing to make a quit attempt at the time, provide assistance (see Chapter 3A, Strategy A4). – If the patient will participate in an intensive treatment, deliver such a treatment or link/refer to an intensive intervention (see Chapter 4). – If the patient is a member of a special population (e.g., adolescent, pregnant smoker, racial/ethnic minority), consider providing additional information (see Chapter 7). • If the patient clearly states that he or she is unwilling to make a quit attempt at the time, provide an intervention shown to increase future quit attempts (see Chapter 3B).

Strategy A4. *Assist*—Aid the patient in quitting (provide counseling and medication)

Action	Strategies for implementation
Help the patient with a quit plan.	*A patient's preparations for quitting:* • ***S****et a quit date.* Ideally, the quit date should be within 2 weeks. • ***T****ell* family, friends, and coworkers about quitting, and request understanding and support. • ***A****nticipate* challenges to the upcoming quit attempt, particularly during the critical first few weeks. These include nicotine withdrawal symptoms. • ***R****emove* tobacco products from your environment. Prior to quitting, avoid smoking in places where you spend a lot of time (e.g., work, home, car). Make your home smoke-free.
Recommend the use of approved medication, except when contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).	Recommend the use of medications found to be effective in this Guideline (see Table 3.2 for clinical guidelines and Tables 3.3–3.11 for specific instructions and precautions). Explain how these medications increase quitting success and reduce withdrawal symptoms. The first-line medications include: bupropion SR, nicotine gum, nicotine inhaler, nicotine lozenge, nicotine nasal spray, nicotine patch, and varenicline; second-line medications include: clonidine and nortriptyline. There is insufficient evidence to recommend medications for certain populations (e.g., pregnant women, smokeless tobacco users, light smokers, adolescents).
Provide practical counseling (problemsolving/skills training).	*Abstinence.* Striving for total abstinence is essential. Not even a single puff after the quit date.[141] *Past quit experience.* Identify what helped and what hurt in previous quit attempts. Build on past success. *Anticipate triggers or challenges in the upcoming attempt.* Discuss challenges/triggers and how the patient will successfully overcome them (e.g., avoid triggers, alter routines). *Alcohol.* Because alcohol is associated with relapse, the patient should consider limiting/abstaining from alcohol while quitting. (Note that reducing alcohol intake could precipitate withdrawal in alcohol-dependent persons.) *Other smokers in the household.* Quitting is more difficult when there is another smoker in the household. Patients should encourage housemates to quit with them or to not smoke in their presence. For further description of practical counseling, see Table 6.19.

Strategy A4. *Assist*—Aid the patient in quitting (provide counseling and medication) (continued)

Action	Strategies for implementation
Provide intratreatment social support.	Provide a supportive clinical environment while encouraging the patient in his or her quit attempt. *"My office staff and I are available to assist you." "I'm recommending treatment that can provide ongoing support."* For further description of intratreatment social support, see Table 6.20.
Provide supplementary materials, including information on quitlines.	*Sources:* Federal agencies, nonprofit agencies, national quitline network (1-800-QUIT-NOW), or local/state/tribal health departments/quitlines (see Appendix B for Web site addresses). *Type:* Culturally/racially/educationally/age-appropriate for the patient. *Location:* Readily available at every clinician's workstation.
For the smoker unwilling to quit at the time	See Section 3B.

Strategy A5. *Arrange*—Ensure followup contact

Action	Strategies for implementation
Arrange for followup contacts, either in person or via telephone.	*Timing*: Followup contact should begin soon after the quit date, preferably during the first week. A second followup contact is recommended within the first month. Schedule further followup contacts as indicated. *Actions during followup contact*: For all patients, identify problems already encountered and anticipate challenges in the immediate future. Assess medication use and problems. Remind patients of quitline support (1-800-QUIT-NOW). Address tobacco use at next clinical visit (treat tobacco use as a chronic disease). For patients who are abstinent, congratulate them on their success. If tobacco use has occurred, review circumstances and elicit recommitment to total abstinence. Consider use of or link to more intensive treatment (see Chapter 4).
For smokers unwilling to quit at the time	See Section 3B.

Table 3.2. Clinical guidelines for prescribing medication for treating tobacco use and dependence

Who should receive medication for tobacco use? Are there groups of smokers for whom medication has not been shown to be effective?	All smokers trying to quit should be offered medication, except when contraindicated or for specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents; see Chapter 7).
What are the first-line medications recommended in this Guideline update?	All seven of the FDA-approved medications for treating tobacco use are recommended: bupropion SR, nicotine gum, nicotine inhaler, nicotine lozenge, nicotine nasal spray, nicotine patch, and varenicline. The clinician should consider the first-line medications shown to be more effective than the nicotine patch alone: 2 mg/day varenicline or the combination of long-term nicotine patch use + *ad libitum* nicotine replacement therapy (NRT). Unfortunately, there are no well-accepted algorithms to guide optimal selection among the first-line medications.
Are there contraindications, warnings, precautions, other concerns, and side effects regarding the first-line medications recommended in this Guideline update?	All seven FDA-approved medications have specific contraindications, warnings, precautions, other concerns, and side effects. Refer to FDA package inserts for this complete information and FDA updates to the individual drug tables in this document (Tables 3.3–3.9). (See information below regarding second-line medications.)
What other factors may influence medication selection?	Pragmatic factors also may influence selection, such as insurance coverage, out-of-pocket patient costs, likelihood of adherence, dentures when considering the gum, or dermatitis when considering the patch.
Is a patient's prior experience with a medication relevant?	Prior successful experience (sustained abstinence with the medication) suggests that the medication may be helpful to the patient in a subsequent quit attempt, especially if the patient found the medication to be tolerable and/or easy to use. However, it is difficult to draw firm conclusions from prior failure with a medication. Some evidence suggests that re-treating relapsed smokers with the same medication produces small or no benefit,[142,143] whereas other evidence suggests that it may be of substantial benefit.[144]

Table 3.2. Clinical guidelines for prescribing medication for treating tobacco use and dependence (continued)

What medications should a clinician use with a patient who is highly nicotine dependent?	The higher-dose preparations of nicotine gum, patch, and lozenge have been shown to be effective in highly dependent smokers.[145-147] Also, there is evidence that combination NRT therapy may be particularly effective in suppressing tobacco withdrawal symptoms.[148,149] Thus, it may be that NRT combinations are especially helpful for highly dependent smokers or those with a history of severe withdrawal.
Is gender a consideration in selecting a medication?	There is evidence that NRT can be effective with both sexes;[150-152] however, evidence is mixed as to whether NRT is less effective in women than men.[153-157] This may encourage the clinician to consider use of another type of medication with women, such as bupropion SR or varenicline.
Are cessation medications appropriate for light smokers (i.e., < 10 cigarettes/day)?	As noted above, cessation medications have not been shown to be beneficial to light smokers. However, if NRT is used with light smokers, clinicians may consider reducing the dose of the medication. No adjustments are necessary when using bupropion SR or varenicline.
When should second-line agents be used for treating tobacco dependence?	Consider prescribing second-line agents (clonidine and nortriptyline) for patients unable to use first-line medications because of contraindications or for patients for whom the group of first-line medications has not been helpful. Assess patients for the specific contraindications, precautions, other concerns, and side effects of the second-line agents. Refer to FDA package inserts for this information and to the individual drug tables in this document (Tables 3.10 and 3.11).
Which medications should be considered with patients particularly concerned about weight gain?	Data show that bupropion SR and nicotine replacement therapies, in particular 4-mg nicotine gum and 4-mg nicotine lozenge, delay—but do not prevent—weight gain.
Are there medications that should especially be considered for patients with a past history of depression?	Bupropion SR and nortriptyline appear to be effective with this population[158-162] (see Chapter 7), but nicotine replacement medications also appear to help individuals with a past history of depression.

Table 3.2. Clinical guidelines for prescribing medication for treating tobacco use and dependence (continued)

Should nicotine replacement therapies be avoided in patients with a history of cardiovascular disease?	No. The nicotine patch in particular has been demonstrated as safe for cardiovascular patients. See Tables 3.3–3.9 and FDA package inserts for more complete information.
May tobacco dependence medications be used long-term (e.g., up to 6 months)?	Yes. This approach may be helpful with smokers who report persistent withdrawal symptoms during the course of medications, who have relapsed in the past after stopping medication, or who desire long-term therapy. A minority of individuals who successfully quit smoking use *ad libitum* NRT medications (gum, nasal spray, inhaler) long-term. The use of these medications for up to 6 months does not present a known health risk, and developing dependence on medications is uncommon. Additionally, the FDA has approved the use of bupropion SR, varenicline, and some NRT medications for 6-month use.
Is medication adherence important?	Yes. Patients frequently do not use cessation medications as recommended (e.g., they do not use them at recommended doses or for recommended durations); this may reduce their effectiveness.
May medications ever be combined?	Yes. Among first-line medications, evidence exists that combining the nicotine patch long-term (> 14 weeks) with either nicotine gum or nicotine nasal spray, the nicotine patch with the nicotine inhaler, or the nicotine patch with bupropion SR, increases long-term abstinence rates relative to placebo treatments. Combining varenicline with NRT agents has been associated with higher rates of side effects (e.g., nausea, headaches).

Table 3.3. Clinical use of bupropion SR (See FDA package insert for more complete information.)

	Clinical use of bupropion SR 150 (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Bupropion has not been shown to be effective for tobacco dependence treatment in pregnant smokers. (Bupropion is an FDA pregnancy Class C agent.) Bupropion has not been evaluated in breastfeeding patients. *Cardiovascular diseases* – Generally well-tolerated; occasional reports of hypertension.

Table 3.3. Clinical use of bupropion SR (See FDA package insert for more complete information.) (continued)

	Clinical use of bupropion SR 150 (FDA approved)
Precautions, contraindications, and side effects *(continued)*	*Side effects* – The most common reported side effects were insomnia (35–40%) and dry mouth (10%). *Contraindications* – Bupropion SR is contraindicated in individuals who have a history of seizures or eating disorders, who are taking another form of bupropion, or who have used an MAO inhibitor in the past 14 days.
Dosage	Patients should begin bupropion SR treatment 1–2 weeks before they quit smoking. Patients should begin with a dose of 150 mg every morning for 3 days, then increase to 150 mg twice daily. Dosage should not exceed 300 mg per day. Dosing at 150 mg twice daily should continue for 7–12 weeks. For long-term therapy, consider use of bupropion SR 150 mg for up to 6 months postquit.
Availability	Prescription only
Prescribing instructions	*Stopping smoking prior to quit date* – Recognize that some patients may lose their desire to smoke prior to their quit date or will spontaneously reduce the amount they smoke. *Dosing information* – If insomnia is marked, taking the PM dose earlier (in the afternoon, at least 8 hours after the first dose) may provide some relief. *Alcohol* – Use alcohol only in moderation.
Cost[a]	1 box of 60 tablets, 150 mg = $97 per month (generic); $197 to $210 (Brand name)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.4. Clinical use of nicotine gum (See FDA package insert for more complete information.)

	Clinical use of nicotine gum (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Nicotine gum has not been shown to be effective for treating tobacco dependence in pregnant smokers. (Nicotine gum is an FDA pregnancy Class D agent.) Nicotine gum has not been evaluated in breastfeeding patients.

Table 3.4. Clinical use of nicotine gum (See FDA package insert for more complete information.) (continued)

	Clinical use of nicotine gum (FDA approved)
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list) (continued)	*Cardiovascular diseases* – NRT is not an independent risk factor for acute myocardial events. NRT should be used with caution among particular cardiovascular patient groups: those in the immediate (within 2 weeks) postmyocardial infarction period, those with serious arrhythmias, and those with unstable angina pectoris. *Side effects* – Common side effects of nicotine gum include mouth soreness, hiccups, dyspepsia, and jaw ache. These effects are generally mild and transient and often can be alleviated by correcting the patient's chewing technique (see *prescribing instructions,* below).
Dosage	Nicotine gum (both regular and flavored) is available in 2-mg and 4-mg (per piece) doses. The 2-mg gum is recommended for patients smoking less than 25 cigarettes per day; the 4-mg gum is recommended for patients smoking 25 or more cigarettes per day. Smokers should use at least one piece every 1 to 2 hours for the first 6 weeks; the gum should be used for up to 12 weeks with no more than 24 pieces to be used per day.
Availability	OTC only
Prescribing instructions	*Chewing technique* – Gum should be chewed slowly until a "peppery" or "flavored" taste emerges, then "parked" between cheek and gum to facilitate nicotine absorption through the oral mucosa. Gum should be slowly and intermittently "chewed and parked" for about 30 minutes or until the taste dissipates. *Absorption* – Acidic beverages (e.g., coffee, juices, soft drinks) interfere with the buccal absorption of nicotine, so eating and drinking anything except water should be avoided for 15 minutes before or during chewing. *Dosing information* – Patients often do not use enough *prn* NRT medicines to obtain optimal clinical effects. Instructions to chew the gum on a fixed schedule (at least one piece every 1–2 hours) for at least 1–3 months may be more beneficial than *ad libitum* use.
Cost[a]	2 mg (packaged in different amounts), boxes of 100–170 pieces = $48 (quantity used determines how long supply lasts) 4 mg (packaged in different amounts), boxes of 100–110 pieces = $63 (quantity used determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.5. Clinical use of the nicotine inhaler (See FDA package insert for more complete information.)

	Clinical use of nicotine inhaler (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. The nicotine inhaler has not been shown to be effective for treating tobacco dependence in pregnant smokers. (The nicotine inhaler is an FDA pregnancy Class D agent.) The nicotine inhaler has not been evaluated in breastfeeding patients. *Cardiovascular diseases* – NRT is not an independent risk factor for acute myocardial events. NRT should be used with caution among particular cardiovascular patient groups: those in the immediate (within 2 weeks) postmyocardial infarction period, those with serious arrhythmias, and those with unstable angina pectoris. *Local irritation reactions* – Local irritation in the mouth and throat was observed in 40% of patients using the nicotine inhaler. Coughing (32%) and rhinitis (23%) also were common. Severity was generally rated as mild, and the frequency of such symptoms declined with continued use.
Dosage	A dose from the nicotine inhaler consists of a puff or inhalation. Each cartridge delivers a total of 4 mg of nicotine over 80 inhalations. Recommended dosage is 6–16 cartridges/day. Recommended duration of therapy is up to 6 months. Instruct patient to taper dosage during the final 3 months of treatment.
Availability	Prescription only
Prescribing instructions	*Ambient temperature* – Delivery of nicotine from the inhaler declines significantly at temperatures below 40°F. In cold weather, the inhaler and cartridges should be kept in an inside pocket or other warm area. *Absorption* – Acidic beverages (e.g., coffee, juices, soft drinks) interfere with the buccal absorption of nicotine, so eating and drinking anything except water should be avoided for 15 minutes before or during use of the inhaler. *Dosing information* – Patients often do not use enough *prn* NRT medicines to obtain optimal clinical effects. Use is recommended for up to 6 months, with gradual reduction in frequency of use over the last 6–12 weeks of treatment. Best effects are achieved by frequent puffing of the inhaler and using at least six cartridges/day.
Cost[a]	1 box of 168 10-mg cartridges = $196 (quantity used determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.6. Clinical use of the nicotine lozenge (See FDA package insert for more complete information.)

	Clinical use of nicotine lozenge (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. The nicotine lozenge has not been shown to be effective for treating tobacco dependence for pregnant smokers. The nicotine lozenge has not been evaluated in breastfeeding patients. Because the lozenge was approved as an OTC agent, it was not evaluated by the FDA for teratogenicity. *Cardiovascular diseases* – NRT is not an independent risk factor for acute myocardial events. NRT should be used with caution among particular cardiovascular patient groups: those in the immediate (within 2 weeks) postmyocardial infarction period, those with serious arrhythmias, and those with unstable angina pectoris. *Side effects* – The most common side effects of the nicotine lozenge are nausea, hiccups, and heartburn. Individuals on the 4-mg lozenge also had increased rates of headache and coughing (less than 10% of participants).
Dosage	Nicotine lozenges are available in 2-mg and 4-mg (per piece) doses. The 2-mg lozenge is recommended for patients who smoke their first cigarette more than 30 minutes after waking, and the 4-mg lozenge is recommended for patients who smoke their first cigarette within 30 minutes of waking. Generally, smokers should use at least nine lozenges per day in the first 6 weeks; the lozenge should be used for up to 12 weeks, with no more than 20 lozenges to be used per day.
Availability	OTC only
Prescribing instructions	*Lozenge use* – The lozenge should be allowed to dissolve in the mouth rather than chewing or swallowing it. *Absorption* – Acidic beverages (e.g., coffee, juices, soft drinks) interfere with the buccal absorption of nicotine, so eating and drinking anything except water should be avoided for 15 minutes before or during use of the nicotine lozenge. *Dosing information* – Patients often do not use enough *prn* NRT medicines to obtain optimal clinical effects. Generally, patients should use 1 lozenge every 1–2 hours during the first 6 weeks of treatment, using a minimum of 9 lozenges/day, then decrease lozenge use to 1 lozenge every 2–4 hours during weeks 7–9, and then decrease to 1 lozenge every 4–8 hours during weeks 10–12.
Cost[a]	2 mg, 72 lozenges per box = $34 (quantity used determines how long supply lasts) 4 mg, 72 lozenges per box = $39 (quantity used determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.7. Clinical use of the nicotine nasal spray (See FDA package insert for more complete information.)

	Clinical use of nicotine nasal spray (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Nicotine nasal spray has not been shown to be effective for treating tobacco dependence in pregnant smokers. (Nicotine nasal spray is an FDA pregnancy Class D agent.) Nicotine nasal spray has not been evaluated in breastfeeding patients. *Cardiovascular diseases* – NRT is not an independent risk factor for acute myocardial events. NRT should be used with caution among particular cardiovascular patient groups: those in the immediate (within 2 weeks) postmyocardial infarction period, those with serious arrhythmias, and those with unstable angina pectoris. *Nasal/airway reactions* – Some 94% of users report moderate to severe nasal irritation in the first 2 days of use; 81% still reported nasal irritation after 3 weeks, although rated severity typically was mild to moderate. Nasal congestion and transient changes in sense of smell and taste also were reported. Nicotine nasal spray should not be used in persons with severe reactive airway disease. *Dependency* – Nicotine nasal spray produces higher peak nicotine levels than other NRTs and has the highest dependence potential. Approximately 15–20% of patients report using the active spray for longer periods than recommended (6–12 months); 5% used the spray at a higher dose than recommended.
Dosage	A dose of nicotine nasal spray consists of one 0.5-mg dose delivered to each nostril (1 mg total). Initial dosing should be 1–2 doses per hour, increasing as needed for symptom relief. Minimum recommended treatment is 8 doses/day, with a maximum limit of 40 doses/day (5 doses/hour). Each bottle contains approximately 100 doses. Recommended duration of therapy is 3–6 months.
Availability	Prescription only
Prescribing instructions	*Dosing information* – Patients should not sniff, swallow, or inhale through the nose while administering doses, as this increases irritating effects. The spray is best delivered with the head tilted slightly back.
Cost[a]	$49 per bottle (quantity used determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.8. Clinical use of the nicotine patch (See FDA package insert for more complete information.)

	Clinical use of the nicotine patch (FDA approved)	
Patient selection	Appropriate as a first-line medication for treating tobacco use	
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. The nicotine patch has not been shown to be effective for treating tobacco dependence treatment in pregnant smokers. (The nicotine patch is an FDA pregnancy Class D agent.) The nicotine patch has not been evaluated in breastfeeding patients. *Cardiovascular diseases* – NRT is not an independent risk factor for acute myocardial events. NRT should be used with caution among particular cardiovascular patient groups: those in the immediate (within 2 weeks) postmyocardial infarction period, those with serious arrhythmias, and those with unstable angina pectoris. *Skin reactions* – Up to 50% of patients using the nicotine patch will experience a local skin reaction. Skin reactions usually are mild and self-limiting, but occasionally worsen over the course of therapy. Local treatment with hydrocortisone cream (1%) or triamcinolone cream (0.5%) and rotating patch sites may ameliorate such local reactions. In fewer than 5% of patients, such reactions require the discontinuation of nicotine patch treatment. *Other side effects* – insomnia and/or vivid dreams	
Dosage	Treatment of 8 weeks or less has been shown to be as efficacious as longer treatment periods. Patches of different doses sometimes are available as well as different recommended dosing regimens. The dose and duration recommendations in this table are examples. Clinicians should consider individualizing treatment based on specific patient characteristics, such as previous experience with the patch, amount smoked, degree of dependence, etc.	
Availability	OTC or prescription	
Type	Duration	Dosage
Step-Down Dosage	4 weeks then 2 weeks then 2 weeks	21 mg/24 hours 14 mg/24 hours 7 mg/24 hours
Single Dosage	Both a 22 mg/24 hours and an 11 mg/24 hours (for lighter smokers) dose are available in a one-step patch regimen.	

Table 3.8. Clinical use of the nicotine patch (See FDA package insert for more complete information.) (continued)

	Clinical use of the nicotine patch (FDA approved)
Prescribing instructions	*Location* – At the start of each day, the patient should place a new patch on a relatively hairless location, typically between the neck and waist, rotating the site to reduce local skin irritation. *Activities* – No restrictions while using the patch *Dosing information* – Patches should be applied as soon as the patient wakes on the quit day. With patients who experience sleep disruption, have the patient remove the 24-hour patch prior to bedtime, or use the 16-hour patch (designed for use while the patient is awake).
Cost[a]	7 mg, box = $37 (quantity used determines how long supply lasts) 14 mg, box = $47 (quantity used determines how long supply lasts) 21 mg, box = $48 (quantity used determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.9. Clinical use of varenicline (See FDA package insert for more complete information.)

	Clinical use of varenicline (FDA approved)
Patient selection	Appropriate as a first-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Varenicline has not been shown to be effective for treating tobacco dependence in pregnant smokers. (Varenicline is an FDA pregnancy Class C agent.) Varenicline has not been evaluated in breastfeeding patients. *Cardiovascular diseases* – Not contraindicated *Precautions* – Use with caution in patients with significant kidney disease (creatinine clearance < 30mL/min) or who are on dialysis. Dose should be reduced with these patients. Patients taking varenicline may experience impairment of the ability to drive or operate heavy machinery.

Table 3.9. Clinical use of varenicline (See FDA package insert for more complete information.) (continued)

	Clinical use of varenicline (FDA approved)
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list) (continued)	*Warning* – In February 2008, the FDA added a warning regarding the use of varenicline. Specifically, it noted that depressed mood, agitation, changes in behavior, suicidal ideation, and suicide have been reported in patients attempting to quit smoking while using varenicline. The FDA recommends that patients should tell their health care provider about any history of psychiatric illness prior to starting this medication, and clinicians should monitor patients for changes in mood and behavior when prescribing this medication. In light of these FDA recommendations, clinicians should consider eliciting information on their patients' psychiatric history. *Side effects* – Nausea, trouble sleeping, abnormal/vivid/strange dreams
Dosage	Start varenicline 1 week before the quit date at 0.5 mg once daily for 3 days, followed by 0.5 mg twice daily for 4 days, followed by 1 mg twice daily for 3 months. Varenicline is approved for a maintenance indication for up to 6 months. Note: Patient should be instructed to quit smoking on day 8, when dosage is increased to 1 mg twice daily.
Availability	Prescription only
Prescribing instructions	*Stopping smoking prior to quit date* – Recognize that some patients may lose their desire to smoke prior to their quit date or will spontaneously reduce the amount they smoke. *Dosing information* –To reduce nausea, take on a full stomach. To reduce insomnia, take second pill at supper rather than bedtime.
Cost[a]	1 mg, box of 56 = $131 (about 30-day supply)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.10. Clinical use of clonidine (See FDA package insert for more complete information.)

	Clinical use of clonidine (not FDA approved for smoking cessation)
Patient selection	Appropriate as a second-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Clonidine has not been shown to be effective for tobacco cessation in pregnant smokers. (Clonidine is an FDA pregnancy Class C agent.) Clonidine has not been evaluated in breastfeeding patients. *Activities* – Patients who engage in potentially hazardous activities, such as operating machinery or driving, should be advised of a possible sedative effect of clonidine. *Side effects* – Most commonly reported side effects include dry mouth (40%), drowsiness (33%), dizziness (16%), sedation (10%), and constipation (10%). As an antihypertensive medication, clonidine can be expected to lower blood pressure in most patients. Therefore, clinicians should monitor blood pressure when using this medication. *Rebound hypertension* – When stopping clonidine therapy, failure to reduce the dose gradually over a period of 2–4 days may result in a rapid increase in blood pressure, agitation, confusion, and/or tremor.
Dosage	Doses used in various clinical trials have varied significantly, from 0.15–0.75 mg/day by mouth and from 0.10–0.20 mg/day transdermal (TTS), without a clear dose-response relation to treatment outcomes. Initial dosing is typically 0.10 mg b.i.d. PO or 0.10 mg/day TTS, increasing by 0.10 mg/day per week if needed. The dose duration also varied across the clinical trials, ranging from 3–10 weeks.
Availability	Oral – Prescription only Transdermal – Prescription only
Prescribing instructions	*Initiate* – Initiate clonidine shortly before (up to 3 days), or on the quit date. *Dosing information* – If the patient is using transdermal clonidine, at the start of each week, he or she should place a new patch on a relatively hairless location between the neck and waist. Users should not discontinue clonidine therapy abruptly.
Cost[a]	Oral – .1 mg, box of 60 = $13 (daily dosage determines how long supply lasts) Transdermal – 4-pack TTS = $106

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

Table 3.11. Clinical use of nortriptyline (See FDA package insert for more complete information.)

	Clinical use of nortriptyline (not FDA approved for smoking cessation)
Patient selection	Appropriate as a second-line medication for treating tobacco use
Precautions, warnings, contraindications, and side effects (see FDA package insert for complete list)	*Pregnancy* – Pregnant smokers should be encouraged to quit without medication. Nortriptyline has not been shown to be effective for tobacco cessation in pregnant smokers. (Nortriptyline is an FDA pregnancy Class D agent.) Nortriptyline has not been evaluated in breastfeeding patients. *Side effects* – Most commonly reported side effects include sedation, dry mouth (64–78%), blurred vision (16%), urinary retention, lightheadedness (49%), and shaky hands (23%). *Activities* – Nortriptyline may impair the mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a car; therefore, the patient should be warned accordingly. *Cardiovascular and other effects* – Because of the risk of arrhythmias and impairment of myocardial contractility, use with caution in patients with cardiovascular disease. Do not co-administer with MAO inhibitors.
Dosage	Doses used in smoking cessation trials have initiated treatment at a dose of 25 mg/day, increasing gradually to a target dose of 75–100 mg/day. Duration of treatment used in smoking cessation trials has been approximately 12 weeks, although clinicians may consider extending treatment for up to 6 months.
Availability	Nortriptyline HCl – prescription only
Prescribing instructions	*Initiate* – Therapy is initiated 10–28 days before the quit date to allow nortriptyline to reach steady state at the target dose. *Therapeutic monitoring* – Although therapeutic blood levels for smoking cessation have not been determined, therapeutic monitoring of plasma nortriptyline levels should be considered under American Psychiatric Association Guidelines for treating patients with depression. Clinicians may choose to assess plasma nortriptyline levels as needed.[163] *Dosing information* – Users should not discontinue nortriptyline abruptly because of withdrawal effects. Overdose may produce severe and life-threatening cardiovascular toxicity, as well as seizures and coma. Risk of overdose should be considered carefully before using nortriptyline.
Cost[a]	25 mg, box of 60 = $24 (daily dosage determines how long supply lasts)

[a] Cost data were established by averaging the retail price of the medication at national chain pharmacies in Atlanta, GA, Los Angeles, CA, Milwaukee, WI , Sunnyside, NY, and listed online during January 2008 and may not reflect discounts available to health plans and others.

B. For the Patient Unwilling To Quit

Promoting the Motivation To Quit

All patients entering a health care setting should have their tobacco use status assessed routinely. Clinicians should advise all tobacco users to quit and then assess a patient's willingness to make a quit attempt. For patients not ready to make a quit attempt at the time, clinicians should use a brief intervention designed to promote the motivation to quit.

Patients unwilling to make a quit attempt during a visit may lack information about the harmful effects of tobacco use and the benefits of quitting, may lack the required financial resources, may have fears or concerns about quitting, or may be demoralized because of previous relapse.[164-167] Such patients may respond to brief motivational interventions that are based on principles of Motivational Interviewing (MI),[168] a directive, patient-centered counseling intervention.[169] There is evidence that MI is effective in increasing future quit attempts;[170-174] however, it is unclear that MI is successful in boosting abstinence among individuals motivated to quit smoking.[173,175,176]

Clinicians employing MI techniques focus on exploring a tobacco user's feelings, beliefs, ideas, and values regarding tobacco use in an effort to uncover any ambivalence about using tobacco.[169,177,178] Once ambivalence is uncovered, the clinician selectively elicits, supports, and strengthens the patient's "change talk" (e.g., reasons, ideas, needs for eliminating tobacco use) and "commitment language" (e.g., intentions to take action to change smoking behavior, such as not smoking in the home). MI researchers have found that having patients use their own words to commit to change is more effective than clinician exhortations, lectures, or arguments for quitting, which tend to increase rather than lessen patient resistance to change.[177]

The four general principles that underlie MI are: (*1) express empathy, (2) develop discrepancy, (3) roll with resistance,* and *(4) support self-efficacy.*[168,179] Specific MI counseling strategies that are based on these principles are listed in Strategy B1. Because this is a specialized technique, it may be beneficial to have a member of the clinical staff receive training in motivational interviewing. The content areas that should be addressed in a motivational counseling intervention can be captured by the "5 R's": relevance, risks, rewards, roadblocks, and repetition (Strategy B2). Research suggests that the "5 R's" enhance future quit attempts.[169,180]

Strategy B1. Motivational interviewing strategies

Express empathy.	• Use open-ended questions to explore: – The importance of addressing smoking or other tobacco use (e.g., "How important do you think it is for you to quit smoking?") – Concerns and benefits of quitting (e.g., "What might happen if you quit?") • Use reflective listening to seek shared understanding: – Reflect words or meaning (e.g., "So you think smoking helps you to maintain your weight."). – Summarize (e.g., "What I have heard so far is that smoking is something you enjoy. On the other hand, your boyfriend hates your smoking, and you are worried you might develop a serious disease."). • Normalize feelings and concerns (e.g., "Many people worry about managing without cigarettes."). • Support the patient's autonomy and right to choose or reject change (e.g., "I hear you saying you are not ready to quit smoking right now. I'm here to help you when you are ready.").
Develop discrepancy.	• Highlight the discrepancy between the patient's present behavior and expressed priorities, values, and goals (e.g., "It sounds like you are very devoted to your family. How do you think your smoking is affecting your children?"). • Reinforce and support "change talk" and "commitment" language: – "So, you realize how smoking is affecting your breathing and making it hard to keep up with your kids." – "It's great that you are going to quit when you get through this busy time at work." • Build and deepen commitment to change: – "There are effective treatments that will ease the pain of quitting, including counseling and many medication options." – "We would like to help you avoid a stroke like the one your father had."
Roll with resistance.	• Back off and use reflection when the patient expresses resistance: – "Sounds like you are feeling pressured about your smoking." • Express empathy: – "You are worried about how you would manage withdrawal symptoms." • Ask permission to provide information: – "Would you like to hear about some strategies that can help you address that concern when you quit?"
Support self-efficacy.	• Help the patient to identify and build on past successes: – "So you were fairly successful the last time you tried to quit." • Offer options for achievable small steps toward change: – Call the quitline (1-800-QUIT-NOW) for advice and information. – Read about quitting benefits and strategies. – Change smoking patterns (e.g., no smoking in the home). – Ask the patient to share his or her ideas about quitting strategies.

Strategy B2. Enhancing motivation to quit tobacco—the "5 R's"

Relevance	Encourage the patient to indicate why quitting is personally relevant, being as specific as possible. Motivational information has the greatest impact if it is relevant to a patient's disease status or risk, family or social situation (e.g., having children in the home), health concerns, age, gender, and other important patient characteristics (e.g., prior quitting experience, personal barriers to cessation).
Risks	The clinician should ask the patient to identify potential negative consequences of tobacco use. The clinician may suggest and highlight those that seem most relevant to the patient. The clinician should emphasize that smoking low-tar/low-nicotine cigarettes or use of other forms of tobacco (e.g., smokeless tobacco, cigars, and pipes) will not eliminate these risks. Examples of risks are: • *Acute risks:* Shortness of breath, exacerbation of asthma, increased risk of respiratory infections, harm to pregnancy, impotence, infertility. • *Long-term risks:* Heart attacks and strokes, lung and other cancers (e.g., larynx, oral cavity, pharynx, esophagus, pancreas, stomach, kidney, bladder, cervix, and acute myelocytic leukemia), chronic obstructive pulmonary diseases (chronic bronchitis and emphysema), osteoporosis, long-term disability, and need for extended care. • *Environmental risks:* Increased risk of lung cancer and heart disease in spouses; increased risk for low birth-weight, sudden infant death syndrome (SIDS), asthma, middle ear disease, and respiratory infections in children of smokers.
Rewards	The clinician should ask the patient to identify potential benefits of stopping tobacco use. The clinician may suggest and highlight those that seem most relevant to the patient. Examples of rewards follow: • Improved health • Food will taste better • Improved sense of smell • Saving money • Feeling better about oneself • Home, car, clothing, breath will smell better • Setting a good example for children and decreasing the likelihood that they will smoke • Having healthier babies and children • Feeling better physically • Performing better in physical activities • Improved appearance, including reduced wrinkling/aging of skin and whiter teeth

Strategy B2. Enhancing motivation to quit tobacco—the "5 R's" (continued)

Roadblocks	The clinician should ask the patient to identify barriers or impediments to quitting and provide treatment (problemsolving counseling, medication) that could address barriers. Typical barriers might include: • Withdrawal symptoms • Fear of failure • Weight gain • Lack of support • Depression • Enjoyment of tobacco • Being around other tobacco users • Limited knowledge of effective treatment options
Repetition	The motivational intervention should be repeated every time an unmotivated patient visits the clinic setting. Tobacco users who have failed in previous quit attempts should be told that most people make repeated quit attempts before they are successful.

C. For the Patient Who Has Recently Quit

Treatments for the Recent Quitter

Smokers who have recently quit face a high risk of relapse. Although most relapse occurs early in the quitting process,[96,101,181] some relapse occurs months or even years after the quit date.[181-184] Numerous studies have been conducted to identify treatments that can reduce the likelihood of future relapse. These studies attempt to reduce relapse either by including special counseling or therapy in the cessation treatment, or by providing additional treatment to smokers who have previously quit. In general, such studies have failed to identify either counseling or medication treatments that are effective in lessening the likelihood of relapse,[185] although there is some evidence that special mailings can reduce the likelihood of relapse.[186,187] Thus, at present, the best strategy for producing high long-term abstinence rates appears to be use of the most effective cessation treatments available; that is, the use of evidence-based cessation medication during the quit attempt and relatively intense cessation counseling (e.g., four or more sessions that are 10 minutes or more in length).

Ex-smokers often report problems that have been worsened by smoking withdrawal or that coexisted with their smoking. If a clinician encounters a tobacco user who recently quit, the clinician might reinforce the patient's

success at quitting, review the benefits of quitting, and assist the patient in resolving any residual problems arising from quitting (Strategy C1). Such expressions of interest and involvement on the part of the clinician might encourage the patient to seek additional help with cessation should she or he ultimately relapse. When the clinician encounters a patient who is abstinent from tobacco and is no longer engaged in cessation treatment, the clinician may wish to acknowledge a patient's success in quitting. The abstinent former smoker also may experience problems related to cessation that deserve treatment in their own right (see Strategy C2).

Strategy C1. Intervening with the patient who has recently quit

The former tobacco user should receive congratulations on any success and strong encouragement to remain abstinent.

When encountering a recent quitter, use open-ended questions relevant to the topics below to discover if the patient wishes to discuss issues related to quitting:

- The benefits, including potential health benefits, the patient may derive from cessation
- Any success the patient has had in quitting (duration of abstinence, reduction in withdrawal, etc.)
- The problems encountered or anticipated threats to maintaining abstinence (e.g., depression, weight gain, alcohol, other tobacco users in the household, significant stressors)
- A medication check-in, including effectiveness and side effects if the patient is still taking medication

Strategy C2. Addressing problems encountered by former smokers

A patient who previously smoked might identify a problem that negatively affects health or quality of life. Specific problems likely to be reported by former smokers and potential responses follow:

Problems	Responses
Lack of support for cessation	• Schedule followup visits or telephone calls with the patient. • Urge the patient to call the national quitline network (1-800-QUIT-NOW) or other local quitline. • Help the patient identify sources of support within his or her environment. • Refer the patient to an appropriate organization that offers counseling or support.
Negative mood or depression	• If significant, provide counseling, prescribe appropriate medication, or refer the patient to a specialist.

Strategy C2. Addressing problems encountered by former smokers (continued)

Problems	Responses
Strong or prolonged withdrawal symptoms	• If the patient reports prolonged craving or other withdrawal symptoms, consider extending the use of an approved medication or adding/combining medications to reduce strong withdrawal symptoms.
Weight gain	• Recommend starting or increasing physical activity. • Reassure the patient that some weight gain after quitting is common and usually is self-limiting. • Emphasize the health benefits of quitting relative to the health risks of modest weight gain. • Emphasize the importance of a healthy diet and active lifestyle. • Suggest low-calorie substitutes such as sugarless chewing gum, vegetables, or mints. • Maintain the patient on medication known to delay weight gain (e.g., bupropion SR, NRTs—particularly 4-mg nicotine gum[147]—and lozenge. • Refer the patient to a nutritional counselor or program.
Smoking lapses	• Suggest continued use of medications, which can reduce the likelihood that a lapse will lead to a full relapse. • Encourage another quit attempt or a recommitment to total abstinence. • Reassure that quitting may take multiple attempts, and use the lapse as a learning experience. • Provide or refer for intensive counseling.

Chapter 4 Intensive Interventions for Tobacco Use and Dependence

Background

Intensive tobacco dependence treatment can be provided by any suitably trained clinician. The evidence in Chapter 6 shows that intensive tobacco dependence treatment is more effective than brief treatment. Intensive interventions (i.e., more comprehensive treatments that may occur over multiple visits for longer periods of time and that may be provided by more than one clinician) are appropriate for any tobacco user willing to participate in them; neither their effectiveness nor cost-effectiveness is limited to a subpopulation of tobacco users (e.g., heavily dependent smokers).[188-194] In addition, patients, even those not ready to quit, have reported increased satisfaction with their overall health care as tobacco counseling intensity increases.[50,88]

In many cases, intensive tobacco dependence interventions are provided by clinicians who specialize in the treatment of tobacco dependence. Such specialists are not defined by their certification, professional affiliation, or by the field in which they trained. Rather, specialists view tobacco dependence treatment as a primary professional role. Specialists possess the skills, knowledge, and training to provide effective interventions across a range of intensities. They often are affiliated with programs offering intensive treatment interventions or services (e.g., programs with staff dedicated to tobacco interventions in which treatment involves multiple counseling sessions, including quitlines). In addition to offering intensive treatments, specialists sometimes conduct research on tobacco dependence and its treatment.

As noted above, substantial evidence shows that intensive interventions produce higher success rates than do less intensive interventions. In addition, the tobacco dependence interventions offered by specialists represent an important treatment resource for patients even if they received tobacco dependence treatment from their own clinician.

The advent of state tobacco quitlines available through a national network at 1-800-QUIT-NOW (1-800-784-8669) means that intensive, specialist-delivered interventions are now available to smokers on an unprecedented basis. In addition to providing their own clinical tobacco dependence interventions, clinicians and health systems can take advantage of this availability by implementing systems that regularly refer patients to quitlines either directly or using fax referrals (e.g., via "fax-to-quit" referral procedures).[195-199]

Specialists also may contribute to tobacco control efforts through activities such as the following:

- Serving as a resource to nonspecialists who offer tobacco dependence services as part of general health care delivery. This might include training nonspecialists in counseling strategies, providing consultation on difficult cases or for inpatients, and providing specialized assessment services for high-risk populations.

- Developing, evaluating, and implementing changes in office/clinic procedures that increase the rates at which tobacco users are identified and treated.[200]

- Conducting evaluation research to determine the effectiveness of ongoing tobacco dependence treatment activities in relevant institutional settings.

- Developing and evaluating innovative treatment strategies that may increase the effectiveness and utilization of tobacco dependence treatments.

Strategies for Intensive Tobacco Dependence Intervention

Table 4.1 highlights Guideline findings based on meta-analyses and Panel opinion (see Chapters 6 and 7) that are particularly relevant to the implementation of intensive treatment programs. The findings in Table 4.1 support recommendations for components of an intensive intervention (Table 4.2). Of course, implementation of this strategy depends on factors such as resource availability and time constraints.

Table 4.1. Findings relevant to intensive interventions

Intensive counseling is especially effective. There is a strong dose-response relation between counseling intensity and quitting success. In general, the more intense the treatment intervention, the greater the rate of abstinence. Treatments may be made more intense by increasing (a) the length of individual treatment sessions and (b) the number of treatment sessions.
Many different types of providers (e.g., physicians, nurses, dentists, psychologists, social workers, cessation counselors, pharmacists) are effective at increasing quit rates; involving multiple types of providers can enhance abstinence rates.
Individual, group, and telephone counseling are effective tobacco use treatment formats.
Particular types of counseling strategies are especially effective. Practical counseling (problemsolving/skills-training approaches) and the provision of intratreatment social support are associated with significant increases in abstinence rates.
Medications such as bupropion SR, nicotine replacement therapies, and varenicline consistently increase abstinence rates. Therefore, their use should be encouraged for all smokers except in the presence of contraindications or for specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents). In some instances, combinations of medications may be appropriate. In addition, combining counseling and medication increases abstinence rates.
Tobacco dependence treatments are effective across diverse populations (e.g., populations varying in gender, age, and race/ethnicity).

Table 4.2. Components of an intensive tobacco dependence intervention

Assessment	Assessments should determine whether tobacco users are willing to make a quit attempt using an intensive treatment program. Other assessments can provide information useful in counseling (e.g., stress level, dependence; see Chapter 6A, Specialized Assessment).
Program clinicians	Multiple types of clinicians are effective and should be used. One counseling strategy would be to have a medical/health care clinician deliver a strong message to quit and information about health risks and benefits, and recommend and prescribe medications recommended in this Guideline update. Nonmedical clinicians could then deliver additional counseling interventions.
Program intensity	There is evidence of a strong dose-response relation; therefore, when possible, the intensity of the program should be: *Session length* – longer than 10 minutes *Number of sessions* – 4 or more

Table 4.2. Components of an intensive tobacco dependence intervention (continued)

Program format	Either individual or group counseling may be used. Telephone counseling also is effective and can supplement treatments provided in the clinical setting. Use of self-help materials and cessation Web sites is optional. Followup interventions should be scheduled (see Chapter 6B).
Type of counseling and behavioral therapies	Counseling should include practical counseling (problemsolving/skills training) (see Table 6.19) and intratreatment social support (see Table 6.20).
Medication	Every smoker should be offered medications endorsed in this Guideline, except when contraindicated or for specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents; see Table 3.2 for clinical guidelines and Tables 3.3–3.11 for specific instructions and precautions). The clinician should explain how medications increase smoking cessation success and reduce withdrawal symptoms. The first-line medications include: bupropion SR, nicotine gum, nicotine inhaler, nicotine lozenge, nicotine nasal spray, nicotine patch, and varenicline. Certain combinations of cessation medications also are effective. Combining counseling and medication increases abstinence rates.
Population	Intensive intervention programs may be used with all tobacco users willing to participate in such efforts.

Chapter 5 Systems Interventions—Importance to Health Care Administrators, Insurers, and Purchasers

Background

Efforts to integrate tobacco intervention into the delivery of health care require the active involvement of clinicians, health care systems, insurers, and purchasers of health insurance. Such integration represents an opportunity to increase rates of delivering tobacco dependence treatments, quit attempts, and successful smoking cessation.[201]

In contrast to strategies that target only the clinician or the tobacco user, systems strategies are intended to ensure that tobacco use is systematically assessed and treated at every clinical encounter. Importantly, these strategies are designed to work synergistically with clinician- and patient-focused interventions, ultimately resulting in informed clinicians and patients interacting in a seamless way that facilitates the treatment of tobacco dependence.[202-204]

Several considerations argue for the adoption of systems-level tobacco intervention efforts. First, such strategies have the potential to substantially improve population abstinence rates. Levy et al. estimated that, over time, widespread implementation of such strategies could produce a 2 percent to 3.5 percent reduction in smoking prevalence rates.[205] Second, despite recent progress in this area, many clinicians have yet to use evidence-based interventions consistently with their patients who use tobacco.[23,48,51] Some evidence indicates that institutional or systems support (e.g., adequate clinician training or automated smoker identification systems) improves the rates of clinical interventions.[206-208] Finally, agents such as administrators, insurers, employers, purchasers, and health care delivery organizations have the potential to craft and implement supportive systems, policies, and environmental prompts that can facilitate the delivery of tobacco dependence treatment for millions of Americans. For example, managed care organizations and other insurers influence

medical care through formularies, performance feedback to clinicians, specific coverage criteria, and marketing approaches that prompt patient demand for particular services.[139,209] Purchasers also have begun to use tobacco measures in pay-for-performance initiatives in which managed care organizations, clinics, and individual physicians receive additional reimbursement by achieving specific tobacco treatment-related goals. Indeed, research clearly shows that systems-level changes can reduce smoking prevalence among enrollees of managed health care plans.[210-212]

Unfortunately, the potential benefits of a collaborative partnership among health care organizations, insurers, employers, and purchasers have not been fully realized. For example, treatments for tobacco use (both medication and counseling) are not provided consistently as paid services for subscribers of health insurance packages.[213-215] Although substantial progress has been made since the publication of the first Guideline in 1996,[1,216-218] neither private insurers nor state Medicaid programs consistently provide comprehensive coverage of evidence-based tobacco interventions.[206,214,219] Findings such as these resulted in the *Healthy People 2010* objective:

> *Increase insurance coverage of evidence-based treatment for nicotine dependency to 100 percent.*[220]

In sum, without supportive systems, policies, insurance coverage, and environmental prompts, the individual clinician likely will not assess and treat tobacco use consistently. Therefore, just as clinicians must assume responsibility to treat their patients for tobacco use, so must health care administrators, insurers, and purchasers assume responsibility to craft policies, provide resources, and display leadership that results in a health care system that delivers consistent and effective tobacco use treatment.

Cost-Effectiveness of Tobacco Use Treatments

Tobacco use treatments are not only clinically effective, but are cost-effective as well. Tobacco use treatments, ranging from clinician advice to medication to specialist-delivered intensive programs, are cost-effective in relation to other medical interventions such as treatment of hypertension and hyperlipidemia and to other preventive interventions such as periodic mammography.[194,221-224] In fact, tobacco use treatment has been referred to as the "gold standard" of health care cost-effectiveness.[225] Tobacco use treatment remains highly cost-effective, even though a single application

of any effective treatment for tobacco dependence may produce sustained abstinence in only a minority of smokers. Finally, evidence-based tobacco dependence interventions produce a favorable return on investment from the perspective of both the employer and health plan due to reduced health care consumption and costs.[226-228] The cost-effectiveness of Guideline recommendations for tobacco use treatment is addressed in detail in Chapter 6.

Recommendations for Health Care Administrators, Insurers, and Purchasers

Health care delivery administrators, insurers, and purchasers can promote the treatment of tobacco dependence through a systems approach. Purchasers (often business entities or other employers, State or Federal units of government, or other consortia that purchase health care benefits for a group of individuals) should make tobacco assessment and coverage of treatment a contractual obligation of the health care insurers and/or clinicians who provide services to them. In addition to improving the health of their employees or subscribers, providing coverage for tobacco dependence treatment will result in lower rates of absenteeism[229,230] and lower utilization of health care resources.[229,231] Health care administrators and insurers should provide clinicians with assistance to ensure that institutional changes promoting tobacco dependence treatment are implemented universally and systematically. Various institutional policies would facilitate these interventions, including:

- Implementing a tobacco user identification system in every clinic (Systems Strategy 1).
- Providing adequate training, resources, and feedback to ensure that providers consistently deliver effective treatments (Systems Strategy 2).
- Dedicating staff to provide tobacco dependence treatment and assessing the delivery of this treatment in staff performance evaluations (Systems Strategy 3).
- Promoting hospital policies that support and provide tobacco dependence services (Systems Strategy 4).

- Including tobacco dependence treatments (both counseling and medication) identified as effective in this Guideline as paid or covered services for all subscribers or members of health insurance packages (Systems Strategy 5).

These strategies are based on the evidence described in Chapter 6, as well as on Panel opinion.

Strategies for Health Care Administrators, Insurers, and Purchasers

Systems Strategy 1. Implement a tobacco user identification system in every clinic

Action	Strategies for implementation
Implement an office-wide system that ensures that for *every* patient at every clinic visit, tobacco use status is queried and documented.	Office system change: Expand the vital signs to include tobacco use, or implement an alternative universal identification system. Responsible staff: Nurse, medical assistant, receptionist, or other individual already responsible for recording the vital signs. These staff must be instructed regarding the importance of this activity and serve as nonsmoking role models. Frequency of utilization: Every visit for every patient, regardless of the reason for the visit.[a] System implementation steps: Routine smoker identification can be achieved by modifying electronic medical record data collection fields or progress notes in paper charts to include tobacco use status as one of the vital signs. VITAL SIGNS Blood Pressure: _____ Pulse: _____ Weight: _____ Temperature: _____ Respiratory Rate: _____ Tobacco Use (circle one): Current Former Never

[a] Repeated assessment is not necessary in the case of the adult who has never used tobacco or who has not used tobacco for many years, and for whom this information is clearly documented in the medical record.

Systems Strategy 2. Provide education, resources, and feedback to promote provider intervention

Action	Strategies for implementation
Health care systems should ensure that clinicians have sufficient training to treat tobacco dependence, clinicians and patients have resources, and clinicians are given feedback about their tobacco dependence treatment practices.	*Educate* all staff. On a regular basis, offer training (e.g., lectures, workshops, inservices) on tobacco dependence treatments, and provide continuing education (CE) credits and/or other incentives for participation. *Provide resources* such as ensuring ready access to tobacco quitlines (e.g., 1-800-QUIT-NOW) and other community resources, self-help materials, and information about effective tobacco use medications (e.g., establish a clinic fax-to-quit service, place medication information sheets in examination rooms). *Report* the provision of tobacco dependence interventions on report cards or evaluative standards for health care organizations, insurers, accreditation organizations, and physician group practices (e.g., HEDIS, The Joint Commission, and Physician Consortium for Performance Improvement). *Provide feedback* to clinicians about their performance, drawing on data from chart audits, electronic medical records, and computerized patient databases. Evaluate the degree to which clinicians are identifying, documenting, and treating patients who use tobacco.

Systems Strategy 3. Dedicate staff to provide tobacco dependence treatment, and assess the delivery of this treatment in staff performance evaluations

Action	Strategies for implementation
Clinical sites should communicate to all staff the importance of intervening with tobacco users and should designate a staff person (e.g., nurse, medical assistant, or other clinician) to coordinate tobacco dependence treatments. Nonphysician personnel may serve as effective providers of tobacco dependence interventions.	*Designate* a tobacco dependence treatment coordinator for every clinical site. *Delineate* the responsibilities of the tobacco dependence treatment coordinator (e.g., ensuring the systematic identification of smokers, ready access to evidence-based cessation treatments [e.g., quitlines], and scheduling of followup visits). *Communicate* to each staff member (e.g., nurse, physician, medical assistant, pharmacist, or other clinician) his or her responsibilities in the delivery of tobacco dependence services. Incorporate a discussion of these staff responsibilities into training of new staff.

Systems Strategy 4. Promote hospital policies that support and provide inpatient tobacco dependence services

Action	Strategies for implementation
Provide tobacco dependence treatment to all tobacco users admitted to a hospital.	*Implement* a system to identify and document the tobacco use status of all hospitalized patients. *Identify* a clinician(s) to deliver tobacco dependence inpatient consultation services for every hospital and reimburse them for delivering these services. *Offer* tobacco dependence treatment to all hospitalized patients who use tobacco. *Expand* hospital formularies to include FDA-approved tobacco dependence medications. *Ensure* compliance with The Joint Commission regulations mandating that all sections of the hospital be entirely smoke-free and that patients receive cessation treatments. *Educate* hospital staff that first-line medications may be used to reduce nicotine withdrawal symptoms, even if the patient is not intending to quit at this time.

Systems Strategy 5. Include tobacco dependence treatments (both counseling and medication) identified as effective in this Guideline as paid or covered services for all subscribers or members of health insurance packages

Action	Strategies for implementation
Provide all insurance subscribers, including those covered by managed care organizations (MCOs), workplace health plans, Medicaid, Medicare, and other government insurance programs, with comprehensive coverage for effective tobacco dependence treatments, including medication and counseling.	*Cover* effective tobacco dependence treatments (counseling and medication) as part of the basic benefits package for all health insurance packages. *Remove* barriers to tobacco treatment benefits (e.g., copays, utilization restrictions). *Educate* all subscribers and clinicians about the availability of covered tobacco dependence treatments (both counseling and medication), and encourage patients to use these services.

Chapter 6 Evidence and Recommendations

Background

The recommendations summarized in Chapters 2, 3, 4, and 5 are the result of a review and analysis of the existing tobacco treatment literature. This chapter reports that review and analysis and describes the effectiveness of various treatments, assessments, and implementation strategies. This chapter also addresses which treatments or assessments are effective, how they should be used, and how they should be implemented within a health care system.

The Panel identified topics that warranted new analyses for the 2008 update based on several criteria: they were important, supported by substantial new literature, and/or addressed issues not considered in prior Guidelines. The number of topics selected for new analyses was limited by the Public Health Service Guideline Update contract parameters. The 2008 Guideline Update Panel selected 11 topics for new analysis (see Table 1.1), based in part on input from tobacco control researchers and practitioners. These 11 topics and related categories are represented in Table 6.1. Type of outcome analyses varied across the different topics. In most analyses, long-term abstinence (6 months or more) was the outcome measure of interest; in others, it was the rate of smoker identification or intervention delivery. In addition to these new topics, Table 6.2 lists the topics that previously were analyzed for the 1996 and 2000 Guidelines. Importantly, the Guideline Update Panel reviewed all recommendations from the 1996 and 2000 Guidelines that did not undergo updated meta-analyses. For these prior recommendations, the Panel reviewed relevant literature since 1999 to determine whether the prior recommendation merited retention, modification, or deletion. See Appendix D for comparison of 2000 and 2008 Guideline recommendations.

The analyses reported in this chapter almost exclusively addressed treatments for cigarette smoking, as opposed to the use of other forms of tobacco, as the small number of studies on the use of noncigarette tobacco products, other than smokeless tobacco, precluded their separate analysis.

Finally, the Panel attempted to analyze treatment and assessment strategies that constitute distinct approaches that exist in current clinical practice.

The Panel chose categories within each analyzed topic according to three major criteria. First, some categories reflected generally accepted dimensions or taxonomies. An example of this is the categorical nature of the clinician types (physician, psychologist, nurse, and so on). Second, information on the category had to be available in the published literature. Many questions of theoretical interest had to be abandoned simply because the requisite research literature was not available. Third, the category had to occur with sufficient frequency to permit meaningful statistical analysis. Therefore, the cutpoints of some continuous variables (e.g., total amount of contact time) were determined so there were a sufficient number of studies within each analytical category to permit meaningful analysis.

In ideal circumstances, the Panel could evaluate each characteristic by consulting randomized controlled trials relevant to the specific categories in question. Unfortunately, with the exception of medication interventions, very few or no randomized controlled trials are designed to address the effects of specific treatment or assessment characteristics of interest. Moreover, treatment characteristics frequently are confounded with one another. For example, comparisons among clinicians often are confounded with the type of counseling and the format and intensity of the interventions. Therefore, direct, unconfounded comparisons of categories within a particular analysis type often were impossible. These characteristics nevertheless were analyzed because of their clinical importance, and because it was possible to reduce confounding by careful selection of studies and by statistical control of some confounding factors.

Table 6.1. Topics meta-analyzed for the 2008 Guideline update

Characteristics analyzed	Categories of those characteristics
Quitline	• No quitline intervention • Use of a proactive quitline • Use of a proactive quitline in combination with medication • Number of quitline sessions
Combining counseling and medication	• Medication alone • Counseling alone • Medication and counseling combined

Table 6.1. Topics meta-analyzed for the 2008 Guideline update (continued)

Characteristics analyzed	Categories of those characteristics
Medications	• Placebo medication • Bupropion SR • Clonidine • Nicotine gum • Nicotine inhaler • Nicotine lozenge • Nicotine nasal spray • Nicotine patch • Nortriptyline • Varenicline • Long-term medication • Single medication • Combination of medications • High-dose nicotine patch
Providing tobacco treatment as a health care insurance benefit	• Not providing coverage for tobacco treatment • Providing services as a covered insurance benefit
Systems features	• No intervention • Clinician training • Clinician training and reminder systems
Specific populations	• Adolescent smokers, pregnant smokers, smokers with psychiatric disorders, including substance use disorders and smokers with low socioeconomic status/limited formal education (see Chapter 7 for description)

Table 6.2. Topics meta-analyzed for the 1996 and 2000 Guidelines and included in the 2008 Guideline update (but not re-analyzed)

Characteristics analyzed	Categories of those characteristics
Screen for tobacco use	• No screening system in place • Screening system in place
Advice to quit	• No advice to quit • Physician advice to quit
Intensity of person-to-person clinical contact	• No person-to-person intervention • Minimal counseling (longest session ≤ 3 minutes in duration) • Low intensity counseling (longest session > 3 minutes and ≤ 10 minutes in duration) • Higher intensity counseling (longest session > 10 minutes) • Total amount of contact time • Number of person-to-person treatment sessions

Table 6.2. Topics meta-analyzed for the 1996 and 2000 Guidelines and included in the 2008 Guideline update (but not re-analyzed) (continued)

Characteristics analyzed	Categories of those characteristics
Type of clinician	• No clinician • Self-help materials only • Nonphysician health care clinician (e.g., psychologist, counselor, social worker, nurse, dentist, graduate student, pharmacist, tobacco treatment specialist) • Physician • Number of types of clinicians
Formats of psychosocial intervention	• No contact • Self-help/self-administered (e.g., pamphlet, audiotape, videotape, mailed information, computer program) • Individual counseling/contact • Group counseling/contact • Proactive telephone counseling/contact • Number of types of formats
Self-help interventions	• No self-help intervention • Number of self-help interventions • Self-help interventions
Types of counseling and behavioral therapies	• No counseling • No person-to-person intervention or minimal counseling • General: problemsolving/coping skills/relapse-prevention/stress-management approach • Negative affect/depression intervention • Weight/diet/nutrition intervention • Extratreatment social support intervention • Intratreatment social support intervention • Contingency contracting/instrumental contingencies • Rapid smoking • Other aversive smoking techniques • Cigarette fading/smoking reduction prequit • Acupuncture
Over-the-counter (OTC) medication	• Placebo OTC nicotine patch therapy • OTC nicotine patch therapy

Additional topics that were important and clinically relevant—but did not lend themselves to analysis due to a lack of long-term abstinence data—nevertheless were considered by the Panel through a review of the existing literature. The strength of evidence associated with these recommended actions for clinical interventions was at the "B" or "C" level (see below), reflecting the fact that they are not based primarily on meta-analyses.

This chapter addresses the treatment and assessment characteristics outlined in Tables 6.1 and 6.2 and is divided into three sections: (1) evidence for counseling and psychosocial interventions; (2) evidence for medication interventions; and (3) evidence for systems changes. For each topic, background information, clinical recommendations, and the basis for those recommendations are provided. As described in Chapter 1, each recommendation was given a strength-of-evidence classification based on the criteria shown in Table 6.3. Finally, for many topics, recommendations for further research are provided.

Table 6.3. Summary of strength of evidence for recommendations

Strength-of-evidence classification	Criteria
Strength of Evidence = A	Multiple well-designed randomized clinical trials, directly relevant to the recommendation, yielded a consistent pattern of findings.
Strength of Evidence = B	Some evidence from randomized clinical trials supported the recommendation, but the scientific support was not optimal. For instance, few randomized trials existed, the trials that did exist were somewhat inconsistent, or the trials were not directly relevant to the recommendation.
Strength of Evidence = C	Reserved for important clinical situations in which the Panel achieved consensus on the recommendation in the absence of relevant randomized controlled trials.

A. Counseling and Psychosocial Evidence

1. Screening and Assessment

Screen for Tobacco Use

Recommendation: All patients should be asked if they use tobacco and should have their tobacco use status documented on a regular basis. Evidence has shown that clinic screening systems, such as expanding the vital signs to include tobacco use status or the use of other reminder systems such as chart stickers or computer prompts, significantly increase rates of clinician intervention. (Strength of Evidence = A)

The Panel relied on the meta-analyses from the original 1996 Guideline to determine the impact of tobacco screening systems. Tobacco screening

systems were evaluated in terms of their impact on two outcomes: the rate of tobacco treatment by clinicians, and the rate of cessation by patients who smoke.

Identifying Tobacco Users: Impact on Clinical Intervention. Nine studies met the selection criteria and were meta-analyzed as part of the 1996 Guideline to assess the impact of screening systems on the rate of smoking cessation intervention by clinicians. The results of this meta-analysis are shown in Table 6.4. Implementing clinic systems designed to increase the assessment and documentation of tobacco use status markedly increases the rate at which clinicians intervene with their patients who smoke.

Table 6.4. Meta-analysis (1996): Impact of having a tobacco use status identification system in place on rates of clinician intervention with their patients who smoke (n = 9 studies)[a]

Screening system	Number of arms	Estimated odds ratio (95% C.I.)	Estimated rate of clinician intervention (95% C.I.)
No screening system in place to identify smoking status (reference group)	9	1.0	38.5
Screening system in place to identify smoking status	9	3.1 (2.2–4.2)	65.6 (58.3–72.6)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Identifying Tobacco Users: Impact on Tobacco Cessation. Three studies met the selection criteria and were meta-analyzed as part of the 1996 Guideline to assess the impact of identifying smokers on actual rates of smoking cessation. The results of this meta-analysis are shown in Table 6.5. These results, combined with the results from Table 6.4, show that having a clinic system in place that identifies smokers increases rates of clinician intervention but does not, by itself, produce significantly higher rates of smoking cessation.

Strategy A1 (see Chapter 3A) and Systems Strategy 1 (see Chapter 5) detail an approach for including tobacco use status as a vital sign with systematic prompts and reminders. Although the data assessing this intervention were gathered exclusively from cigarette smokers, the Panel believed

that these results are generalizable to all tobacco users. This approach is designed to produce consistent assessment and documentation of tobacco use. Evidence from controlled trials shows that this approach increases the probability that tobacco use is assessed and documented consistently.[54,232] However, documenting smoking status is not by itself sufficient to promote treatment by clinicians.[233] Systems changes beyond smoker identification strategies are likely to be needed to increase rates of cessation advice and intervention.[139,234-237]

Table 6.5. Meta-analysis (1996): Impact of having a tobacco use status identification system in place on abstinence rates among patients who smoke (n = 3 studies)[a]

Screening system	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No screening system in place to identify smoking status (reference group)	3	1.0	3.1
Screening system in place to identify smoking status	3	2.0 (0.8–4.8)	6.4 (1.3–11.6)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Specialized Assessment

Recommendation: Once a tobacco user is identified and advised to quit, the clinician should assess the patient's willingness to quit at this time. (Strength of Evidence = C)

If the patient is willing to make a quit attempt at this time, interventions identified as effective in this Guideline should be provided. (See Chapters 3A and 4.)

If the patient is unwilling to quit at this time, an intervention designed to increase future quit attempts should be provided. (See Chapter 3B.)

Recommendation: Tobacco dependence treatment is effective and should be delivered even if specialized assessments are not used or available. (Strength of Evidence = A)

Every individual entering a health care setting should receive an assessment that determines his or her tobacco use status and interest in quitting. The patient should be asked, "Are you willing to make a quit attempt at this time?" Such an assessment (willing or unwilling) is a necessary first step in treatment. In addition, every patient should be assessed for physical or medical conditions that may affect the use of planned treatments (e.g., medication).

The clinician also may want to perform specialized assessments of individual and environmental attributes that provide information for tailoring treatment and that predict quitting success. Specialized assessments refer to the use of formal instruments (e.g., questionnaires, clinical interviews, or physiologic indices such as carbon monoxide, serum nicotine/cotinine levels, and/or pulmonary function) that may be associated with cessation outcome (in addition, the reader may find other assessments relevant to medication use and specific populations when selecting treatment). Some of the variables targeted by specialized assessments that predict quitting success are listed in Table 6.6.

Several considerations should be kept in mind regarding the use of specialized assessments. First, there is little consistent evidence that a smoker's status on a specialized assessment is useful for treatment matching. The one exception is that persons who are highly nicotine dependent may benefit more from higher nicotine gum or lozenge doses (see Medication Evidence; Section B of Chapter 6). More importantly, the Panel found that, regardless of their standing on specialized assessments, all smokers have the potential to benefit from tobacco dependence treatments. Therefore, delivery of tobacco dependence treatments should not depend on the use of specialized assessments. Finally, tailored interventions based on specialized assessments do not consistently produce higher long-term quit rates than do nontailored interventions of equal intensity. Some promising studies exist, however, that suggest that individualizing self-help materials may be beneficial (see Individually Tailored and Stepped-Care Interventions, page 92).[238-245] In addition, the Panel recognizes that some effective interventions, such as general problemsolving (see Types of Counseling and Behavioral Therapies, on page 96), entail treatment tailoring based on a systematic assessment that occurs as an integral part of treatment.

Table 6.6. Variables associated with higher or lower abstinence rates

Variables associated with higher abstinence rates	
Variable	**Examples**
High motivation	Tobacco user reports a strong motivation to quit.
Ready to change	Tobacco user is ready to quit within a 1-month period.
Moderate to high self-efficacy	Tobacco user is confident in his or her ability to quit.
Supportive social network	A smoke-free workplace and home; friends who do not smoke in the quitter's presence.
Variables associated with lower abstinence rates	
Variable	**Examples**
High nicotine dependence	Tobacco user smokes heavily (≥ 20 cigarettes/day), and/or has first cigarette of the day within 30 minutes after waking in the morning.
Psychiatric comorbidity and substance use	Tobacco user currently has elevated depressive symptoms, active alcohol abuse, or schizophrenia.
High stress level	Stressful life circumstances and/or recent or anticipated major life changes (e.g., divorce, job change).
Exposure to other smokers	Other smokers in the household.

The existing evidence suggests that treatment can be effective despite the presence of risk factors for relapse (e.g., high nicotine dependence, other smokers in the home), but abstinence rates in smokers with these characteristics tend to be lower than rates in those without these characteristics.[246-248]

Future Research

The following topics regarding specialized assessment require additional research:

- Whether treatment adjustment based on specialized assessments can improve long-term abstinence rates

- Whether working to change the social network can improve abstinence rates (e.g., intervening with other smokers in the household to change their smoking patterns, teaching quitting support, or encouraging a smokefree home)

- Disparities in screening and assessment in specific populations

2. Treatment Structure and Intensity

Advice To Quit Smoking

Recommendation: All *physicians* should strongly advise every patient who smokes to quit because evidence shows that physician advice to quit smoking increases abstinence rates. (Strength of Evidence = A)

For these recommendations, the 2008 Guideline Panel relied on meta-analyses performed for the 1996 Guideline. Seven studies were included in the 1996 meta-analysis of the effectiveness of physician advice to quit smoking. In the studies used in this analysis, the modal length of clinician intervention was 3 minutes or less. Two studies in this analysis used interventions lasting about 5 minutes. Results of the meta-analysis on physician advice are shown in Table 6.7. This analysis shows that brief physician advice significantly increases long-term smoking abstinence rates. These results were also supported by a more recent, independent meta-analysis.[56]

Advice by physicians was examined in the Table 6.7 meta-analysis from the 1996 Guideline; there were too few studies to examine advice delivered by any other type of clinician, although one study found that advice to quit from health care providers in general did significantly increase quit rates.[249] The analysis for total amount of contact time (see Table 6.9) indicates that minimal counseling (advice) delivered by a variety of clinician types increases long-term abstinence rates. Also, studies have shown that dentists and dental hygienists can be effective in assessing and advising smokeless/spit tobacco users to quit[250] (see Chapter 7). Given the large number of smokers who visit a clinician each year, the potential public health impact of universal advice to quit is substantial.[56]

Table 6.7. Meta-analysis (1996): Effectiveness of and estimated abstinence rates for advice to quit by a physician (n = 7 studies)[a]

Advice	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No advice to quit (reference group)	9	1.0	7.9
Physician advice to quit	10	1.3 (1.1–1.6)	10.2 (8.5–12.0)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Future Research

The following topics regarding advice to quit require additional research:

- Effectiveness of advice to quit smoking given by clinicians other than physicians (e.g., nurses, nurse practitioners, pharmacists, dentists, dental hygienists, tobacco treatment specialists, physician's assistants)
- Cumulative effectiveness of combined advice from physicians and other types of clinicians

Intensity of Clinical Interventions

Recommendation: Minimal interventions lasting less than 3 minutes increase overall tobacco abstinence rates. Every tobacco user should be offered at least a minimal intervention, whether or not he or she is referred to an intensive intervention. (Strength of Evidence = A)

Recommendation: There is a strong dose-response relation between the session length of person-to-person contact and successful treatment outcomes. Intensive interventions are more effective than less intensive interventions and should be used whenever possible. (Strength of Evidence = A)

Recommendation: Person-to-person treatment delivered for four or more sessions appears especially effective in increasing abstinence rates. Therefore, if feasible, clinicians should strive to meet four or more times with individuals quitting tobacco use. (Strength of Evidence = A)

These recommendations are supported by three separate meta-analyses conducted for the 2000 Guideline: one involving session length, one involving total amount of contact time, and one involving the number of sessions.

Table 6.8. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for various intensity levels of session length (n = 43 studies)[a]

Level of contact	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No contact	30	1.0	10.9
Minimal counseling (< 3 minutes)	19	1.3 (1.01–1.6)	13.4 (10.9–16.1)
Low-intensity counseling (3-10 minutes)	16	1.6 (1.2–2.0)	16.0 (12.8–19.2)
Higher intensity counseling (> 10 minutes)	55	2.3 (2.0–2.7)	22.1 (19.4–24.7)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Session Length. Forty-three studies met selection criteria for comparison across various session lengths. Whenever possible, session length was categorized based on the maximum amount of time the clinician spent with a smoker addressing tobacco dependence in a single contact. Minimal counseling interventions were defined as 3 minutes or less, low-intensity counseling was defined as greater than 3 minutes to 10 minutes, and higher intensity counseling interventions were defined as greater than 10 minutes. Interventions could involve multiple patient-clinician contacts, with the session length determined for coding purposes as the length of time of the longest session. These levels of person-to-person contact were compared with a no-contact reference group involving study conditions in which subjects received no person-to-person contact (e.g., self-help-only conditions). There is a dose-response relation between session length and abstinence rates. As Table 6.8 shows, all three session lengths (minimal counseling, low-intensity counseling, and higher intensity counseling) significantly increased abstinence rates over those produced by no-contact conditions. However, there was a clear trend for abstinence rates to increase across these session lengths, with higher intensity counseling producing the highest rates.

Total Amount of Contact Time. Thirty-five studies met the selection criteria for the analysis assessing the impact of total contact time. The amount of contact time was calculated from the text as the total time accumulated (the number of sessions multiplied by the session length). When the exact time was not known for minimal and low-intensity interventions, they were assigned median lengths of 2 and 6.5 minutes, respectively. The total amount of contact time was then categorized as no-contact, 1–3 minutes, 4–30 minutes, 31–90 minutes, 91–300 minutes, and greater than 300 minutes. As Table 6.9 shows, any contact time significantly increased abstinence rates over those produced by no contact. However, there was a clear trend for abstinence rates to increase across contact time, up to the 90-minute mark. There was no evidence that more than 90 minutes of total contact time substantially increases abstinence rates.

Table 6.9. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for total amount of contact time (n = 35 studies)[a]

Total amount of contact time	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No minutes	16	1.0	11.0
1–3 minutes	12	1.4 (1.1–1.8)	14.4 (11.3–17.5)
4–30 minutes	20	1.9 (1.5–2.3)	18.8 (15.6–22.0)
31–90 minutes	16	3.0 (2.3–3.8)	26.5 (21.5–31.4)
91–300 minutes	16	3.2 (2.3–4.6)	28.4 (21.3–35.5)
> 300 minutes	15	2.8 (2.0–3.9)	25.5 (19.2–31.7)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Number of Sessions. Forty-six studies involving at least some person-to-person contact met selection criteria for the analysis addressing the impact of number of treatment sessions. Zero or one session was used as the reference group. As shown in Table 6.10, multiple treatment sessions increase smoking abstinence rates over those produced by zero or one session. The evidence suggests a dose-response relation between number of sessions and treatment effectiveness.

It is important to note that although the use of more intensive interventions (i.e., longer sessions, more sessions) may produce enhanced abstinence rates, these interventions may have limited reach (affect fewer smokers) and may not be feasible in some primary care settings. For instance,

not all smokers are interested in participating in an intensive intervention, and not all smokers may have access to or be able to afford services that can provide intensive interventions. Finally, the clinician can link the patient to additional treatment options, such as quitlines or other intensive cessation treatment programs, to provide additional person-to-person treatment.

Future Research

The following topics regarding intensity of person-to-person contact require additional research:

- Effects of treatment duration, timing, and spacing of sessions (i.e., the number of days or weeks over which treatment is spread). For instance, does front loading sessions (having the majority of the sessions during the first few weeks of a quit attempt) or spacing sessions throughout the quit attempt yield better long-term abstinence rates?
- Methods to increase the appeal and utilization of intensive treatments
- Effectiveness of intensive inpatient treatment programs

Table 6.10. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for number of person-to-person treatment sessions (n = 46 studies)[a]

Number of sessions	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
0–1 session	43	1.0	12.4
2–3 sessions	17	1.4 (1.1–1.7)	16.3 (13.7–19.0)
4–8 sessions	23	1.9 (1.6–2.2)	20.9 (18.1–23.6)
> 8 sessions	51	2.3 (2.1–3.0)	24.7 (21.0–28.4)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Type of Clinician

Recommendation: Treatment delivered by a variety of clinician types increases abstinence rates. Therefore, all clinicians should provide smoking cessation interventions. (Strength of Evidence = A)

Recommendation: Treatments delivered by multiple types of clinicians are more effective than interventions delivered by a single type of clinician. Therefore, the delivery of interventions by more than one type of clinician is encouraged. (Strength of Evidence = C)

Clinician Types. Twenty-nine studies met selection criteria for the 2000 meta-analysis examining the effectiveness of various types of clinicians providing tobacco use treatment. These analyses compared the effectiveness of interventions delivered by different types of clinicians with interventions in which there were no clinicians (e.g., when there was no intervention or the intervention consisted of self-help materials only). Tobacco use treatments delivered by any single type of health care provider, such as a physician or other clinician (e.g., nurse, psychologist, dentist, or counselor), or by multiple clinicians, increase abstinence rates relative to interventions in which there is no clinician (e.g., self-help interventions). None of the studies in these analyses involved medication, but they did involve psychosocial intervention, principally counseling. Results are shown in Table 6.11. Results suggest that physicians and other clinicians are similarly effective in delivering tobacco cessation counseling. New research reviewed since the 2000 Guideline suggests that trained peer counselors also may be effective.[251-253]

Number of Clinician Types. Thirty-seven studies met selection criteria for the 2000 analysis examining the effectiveness of multiple clinicians used in smoking cessation interventions. "Multiple clinicians" refers to the number of different *types* of clinicians (if a nurse and a physician each delivered parts of an intervention, two types of clinicians would be involved). Tobacco use treatments delivered by two or more types of clinicians increase abstinence rates relative to those produced by interventions in which there is no clinician (Table 6.12). However, the number of clinician types is confounded with treatment intensity. For instance, if an individual meets with a physician for a medication consultation and then talks to a health educator about the quit plan, that is two clinicians and two sessions. The number of contacts may be more important than the number of clinicians providing treatment.

Table 6.11. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for interventions delivered by different types of clinicians (n = 29 studies)[a]

Type of clinician	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No clinician	16	1.0	10.2
Self-help	47	1.1 (0.9–1.3)	10.9 (9.1–12.7)
Nonphysician clinician	39	1.7 (1.3–2.1)	15.8 (12.8–18.8)
Physician clinician	11	2.2 (1.5–3.2)	19.9 (13.7–26.2)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Table 6.12. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for interventions delivered by various numbers of clinician types (n = 37 studies)[a]

Number of clinician types	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No clinician	30	1.0	10.8
One clinician type	50	1.8 (1.5–2.2)	18.3 (15.4–21.1)
Two clinician types	16	2.5 (1.9–3.4)	23.6 (18.4–28.7)
Three or more clinician types	7	2.4 (2.1–2.9)	23.0 (20.0–25.9)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Future Research

The following topics regarding type of clinician require additional research:

- Effectiveness of specific types of clinicians (e.g., quitline counselors, trained peer counselors, nurses, physician assistants, pharmacists, social workers)
- Relative effectiveness of various numbers and types of clinicians, with the intensity of the intervention held constant

Formats of Psychosocial Treatments

Recommendation: Proactive telephone counseling, group counseling, and individual counseling formats are effective and should be used in smoking cessation interventions. (Strength of Evidence = A)

Recommendation: Smoking cessation interventions that are delivered in multiple formats increase abstinence rates and should be encouraged. (Strength of Evidence = A)

Recommendation: Tailored materials, both print and Web-based, appear to be effective in helping people quit. Therefore, clinicians may choose to provide tailored self-help materials to their patients who want to quit. (Strength of Evidence = B)

Format Types. Overall format type (delivery mode) recommendations rest on the 2000 Guideline meta-analysis, although new focused analyses of proactive quitlines were conducted for the 2008 update. Fifty-eight studies met selection criteria and were included in the 2000 meta-analysis comparing different types of formats (see Table 6.13). Tobacco use treatment delivered by means of proactive telephone counseling/contact (quitlines, call-back counseling), individual counseling, and group counseling/contact all increase abstinence rates relative to no intervention.

Self-Help. The 2000 format meta-analysis also evaluated the effectiveness of self-help interventions (e.g., pamphlets/booklets/mailings/manuals, videotapes, audiotapes, referrals to 12-step programs, reactive telephone hotlines/helplines [see Glossary], computer programs/Internet, and lists of community programs). Interventions delivered by means of widely varied self-help materials (whether as stand-alone treatments or as adjuvants) appear to increase abstinence rates relative to no intervention in this particular analysis. However, the effect of self-help was weak and typically not significant across analyses conducted for the 2000 Guideline (see Tables 6.13 and 6.15).

Number of Formats. Fifty-four studies met selection criteria and were included in the 2000 meta-analysis comparing the number of format types used for tobacco use treatment. The self-help treatments included in this analysis occurred either by themselves or in addition to other treatments. Tobacco use treatment that used three or four format types was especially effective. Results of this analysis are shown in Table 6.14.

Self-Help: Focused Analyses. Because the format meta-analysis revealed self-help to be of marginal effectiveness, another analysis was undertaken in 2000 to provide additional, focused information on self-help. Studies were accepted for the 2000 analysis if the presence of self-help materi-

als constituted the sole difference in treatment arms. In the main format analysis, some treatment arms differed on factors other than self-help *per se* (e.g., intensity of counseling). The treatments that accompanied self-help material in the focused analysis ranged from no advice or counseling to intensive counseling. The results of this analysis were comparable to those in the larger format analysis (i.e., self-help was of marginal effectiveness).

For the 2000 Guideline analysis, 21 studies met selection criteria to evaluate the effectiveness of providing multiple types of self-help interventions (e.g., pamphlets, videotapes, audiotapes, and reactive hotlines/helplines). The results provide little evidence that the provision of multiple types of self-help, when offered without any person-to-person intervention, significantly enhances treatment outcomes (see Table 6.15).

Two final 2000 meta-analyses addressed the impact of self-help brochures *per se*. In one analysis, brochures were used as the only intervention. In the other analysis, self-help brochures were used in addition to counseling. In neither analysis did self-help significantly boost abstinence rates.

Table 6.13. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for various types of formats (n = 58 studies)[a]

Format Number	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No format	20	1.0	10.8
Self-help	93	1.2 (1.02–1.3)	12.3 (10.9–13.6)
Proactive telephone counseling	26	1.2 (1.1–1.4)	13.1 (11.4–14.8)
Group counseling	52	1.3 (1.1–1.6)	13.9 (11.6–16.1)
Individual counseling	67	1.7 (1.4–2.0)	16.8 (14.7–19.1)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Table 6.14. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for number of formats (n = 54 studies)[a]

Number of formats[b]	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No format	20	1.0	10.8
One format	51	1.5 (1.2–1.8)	15.1 (12.8–17.4)
Two formats	55	1.9 (1.6–2.2)	18.5 (15.8–21.1)
Three or four formats	19	2.5 (2.1–3.0)	23.2 (19.9–26.6)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.
[b] Formats included self-help, proactive telephone counseling, group, or individual counseling.

Table 6.15. Meta-analysis (2000): Effectiveness of and estimated abstinence rates for number of types of self-help (n = 21 studies)[a]

Factor	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
No self-help	17	1.0	14.3
One type of self-help	27	1.0 (0.9–1.1)	14.4 (12.9–15.9)
Two or more types	10	1.1 (0.9–1.5)	15.7 (12.3–19.2)

[a] Go to *www.surgeongeneral.gov/tobacco/gdlnrefs.htm* for the articles used in this meta-analysis.

Quitlines. Both the substantial growth in quitline research and the implementation of a national network of tobacco quitlines (available through 1-800-QUIT-NOW) led the 2008 Guideline Panel to identify quitline effectiveness as a topic deserving focused meta-analyses. Nine studies met selection criteria and were analyzed for the 2008 Guideline update comparing the effectiveness of a quitline intervention versus minimal or no contact or self-help materials. This differs from the 2000 meta-analysis (Table 6.13) in that the current analysis focused on study arms that used quitline intervention alone rather than telephone counseling that may have occurred with other types of interventions. For the purpose of this analysis, quitlines are defined as telephone counseling in which at least some of the contacts are initiated by the quitline counselor to deliver tobacco use interventions, including call-back counseling. Quitlines significantly increase abstinence rates compared to minimal or no counseling interventions (Table 6.16).[254] In a second 2008 meta-analysis of quitlines, six studies were analyzed comparing the effect of adding quitline counseling to medication versus medication alone. The addition of quitline counseling to medication significantly improves abstinence rates

compared to medication alone (see Table 6.17). These analyses suggest a robust effect of quitline counseling and are consistent with a recent independent analysis[254] and with the recently released Centers for Disease Control and Prevention's *Guide to Community Preventive Services*.[92]

Table 6.16. Meta-analysis (2008): Effectiveness of and estimated abstinence rates for quitline counseling compared to minimal interventions, self-help, or no counseling (n = 9 studies)[a]

Intervention	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
Minimal or no counseling or self-help	11	1.0	8.5
Quitline counseling	11	1.6 (1.4–1.8)	12.7 (11.3–14.2)

Table 6.17. Meta-analysis (2008): Effectiveness of and estimated abstinence rates for quitline counseling and medication compared to medication alone (n = 6 studies)[a]

Intervention	Number of arms	Estimated odds ratio (95% C.I.)	Estimated abstinence rate (95% C.I.)
Medication alone	6	1.0	23.2
Medication and quitline counseling	6	1.3 (1.1–1.6)	28.1 (24.5–32.0)
