AIT and FC are controversial treatment options for autism and other disorders. Although two investigations indicated AIT may help some children with autism,[5,6] as yet there are no good controlled studies to support its use. In the case of FC, there are good scientific data showing it to be ineffective.[11–14] Moreover, as noted before, the potential for harm does exist, particularly if unsubstantiated allegations of abuse occur using FC. Many families incur substantial expense pursuing these treatments, and spend time and resources that could be used more productively on behavioral and educational interventions. When controversial or unproven treatments are being considered by a family, the pediatrician should provide guidance and assistance in obtaining and reviewing information. The pediatrician should ensure that the child's health and safety, and the family's financial and emotional resources are not compromised. It is important for the pediatrician to obtain current data on both AIT and FC as they become available. Until further information is available, the use of these treatments does not appear warranted at this time, except within research protocols. Information on communicating with families who choose an alternative medical approach for their child with chronic illness and disability is also available in the literature.[21]

The Adolescent's Right to Confidential Care When Considering Abortion (RE9614)

AMERICAN ACADEMY OF PEDIATRICS

Committee on Adolescence

ABSTRACT. In this statement, the American Academy of Pediatrics (AAP) reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. The AAP supports the recommendations presented in the report on mandatory parental consent to abortion by the Council on Ethical and Judicial Affairs of the American Medical Association. Adolescents should be strongly encouraged to involve their parents and other trusted adults in decisions regarding pregnancy termination, and the majority of them voluntarily do so. Legislation mandating parental involvement does not achieve the intended benefit of promoting family communication, but it does increase the risk of harm to the adolescent by delaying access to appropriate medical care. The statement presents a summary of pertinent current information related to the benefits and risks of legislation requiring mandatory parental involvement in an adolescent's decision to obtain an abortion. The AAP acknowledges and respects the diversity of beliefs about abortion and affirms the value of voluntary parental involvement in decision making by adolescents.

Assuring adolescent access to health care, including reproductive health care, has been a long-standing objective of the American Academy of Pediatrics (AAP). Assured access to timely medical care is especially important for pregnant adolescents because of the significant medical, personal, and social consequences of adolescent childbearing. The AAP strongly advocates for the prevention of unintended adolescent pregnancy by supporting comprehensive health and sexuality education, abstinence, and the use of contraception by sexually active youths. For two decades the AAP has been on record as supporting the access of minors to all options regarding undesired pregnancy, including the right to obtain an abortion. Membership surveys confirm this support.[1,2]

Under current federal constitutional law, minors have the right to obtain abortions without parental consent unless otherwise specified by state law. Legislation that mandates parental involvement (parental consent or notification) as a condition of service when a minor seeks an abortion has generated considerable controversy. Recent US Supreme Court rulings, although upholding the constitutional rights of minors to choose abortion, have held that it is not unconstitutional for states to impose requirements for parental involvement as long as "adequate provision for judicial bypass" is available for minors who think that this involvement would not be in their best interest.[3,4] Subsequently, there has been renewed activity to include mandatory parental consent or notification requirements in state and federal abortion-related legislation.

The American Medical Association, the Society for Adolescent Medicine, the American Public Health Association, the American College of Obstetricians and Gynecologists, the AAP, and other health professional organizations have reached a consensus that minors should not be compelled or required to involve their parents in their decisions to obtain abortions, although they should be encouraged to discuss their pregnancies with their parents and other responsible adults. These conclusions result from objective analyses of current data, which indicate that legislation mandating parental involvement does not achieve the intended benefit of promoting family communication but does increase the risk of harm to the adolescent by delaying access to appropriate medical care.[5-9]

In this statement, the AAP reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. The AAP supports the recommendations presented in the report on mandatory parental consent to abortion by the Council on Ethical and Judicial Affairs of the American Medical Association.[5] This statement does not duplicate the extensive analysis published in that report but presents a summary of pertinent current information related to the benefits and risks of legislation requiring mandatory parental involvement in an adolescent's decision to obtain an abortion. This statement does not discuss the philosophical or religious issues related to abortion. Beliefs about abortion are deeply personal and are shaped by class, culture, religion, and personal history, as well as the current social and political climate. The AAP acknowledges and respects the diversity of beliefs about abortion. This statement affirms the value of parental involvement in decision making by adolescents and the importance of productive family communication in general. The AAP is a foremost advocate of strong family relationships and holds that parents are generally supportive and act in the best interests of their children.

BACKGROUND

Statistical Trends

One million pregnancies occur annually among American teenagers. Of these, about 400 000 occur in minors younger than 18 years of age, of which 41% are terminated by elective abortion.[10] The percentage of pregnancies terminated by induced abortion in minors increased in the 1970s, plateaued in the early 1980s, and has decreased since 1985, particularly in younger girls. Whereas 46% of pregnant adolescents 15 years of age and younger obtained abortions in 1985, only 39% did so in 1988.[10] Postulated explanations for the decline include a shift in attitudes toward abortion among adolescents, increased legal and financial barriers to abortion, particularly for low-income adolescents, and increasing social acceptance of childbearing among unmarried adolescents. Birth rates among adolescents nationally are now the highest since the early 1970s. Approximately 80% of births to minors younger than 18 years of age are to unmarried adolescents.[11] Adoption ratios have declined during the last decade; approximately 2% to 4% of unmarried adolescents place their infants for adoption.[12]

Compared with those who choose childbirth, adolescents who choose abortion tend to come from higher socioeconomic backgrounds, have higher educational aspirations and achievements, have mothers with higher educational levels, have higher self-esteem, have greater feelings of control over life, have lower levels of anxiety, and are better able to conceptualize the future.[13-15]

State Laws

The status of legislation requiring mandatory parental involvement in a minor's abortion decision is currently in flux. As of 1992, 38 states had some form of specific legislation on record, highly variable among states in both content and degree of enforcement.[9,16] However, US Supreme Court rulings in 1992 on "undue burden" standards and requirements for judicial bypass procedures raise legal questions about the validity of many existing state statutes, while allowing new or revised clauses that could be held constitutional. Groups opposed to legal abortion view parental notification requirements for minors as politically feasible; thus, adolescent rights to confidential care have become part of a larger battle regarding access to abortion in general.[17] Continuing legislative activity can be anticipated. Of 308 abortion-related bills introduced in 41 states during 1992, 61 were related to parental consent or notification, confirming the need for health professionals to be prepared to protect the best interests of adolescents with objective data on this issue.

EFFECT OF LEGISLATION ON FAMILY COMMUNICATION

Basic principles of law and society hold that parents should be involved in and responsible for assuring medical care for their children, that parents ordinarily act in the best interests of their children, and that minors benefit from the advice and emotional support of their parents. Legislation mandating parental involvement in abortion decisions is promoted on the basis of its theoretical benefits on strengthening family responsibility and communication. Some who support reproductive choice may be ambivalent about parental notification requirements. Adults may fear that minors contemplating abortion are immature, isolated, or at risk of being coerced into decisions without adequate counseling. Many parents vote for notification clauses because they hope these laws will increase communication that otherwise might not happen.[18] The 1990 AAP membership survey showed that although 85% of members thought that mandatory parental notification for abortion would cause some adolescents to delay seeking care, 49% said there should be such laws,[2] suggesting that many AAP members assume there is benefit from such legislation. Because outcome analysis, as supported by the evidence that follows, shows a minimal benefit compared with a significant risk, there is clearly a need for current data to be better understood.

Voluntary Parental Involvement

Research confirms that pregnant minors do not make abortion decisions in isolation; they actively involve adults to whom they feel close. Even when not required to, the majority of minors seeking abortions voluntarily involve at least one parent in their decisions. A survey of 1519 unmarried pregnant minors in states where parental involvement is not mandatory found that 61% told one or both parents about their intent to have abortions. The younger the minor, the more likely she was to do so (90% of those 14 years old or younger, 74% of those 16 years old).[19] Among minors who did not involve a parent, virtually all involved at least one responsible adult other than clinic staff (such as another relative, teacher, counselor, professional, or clergy). A study of inner-city, black, pregnant teenagers younger than 18 years of age confirmed that more than 91% voluntarily consulted a parent or "parent surrogate" about pregnancy decisions. The term parent surrogate refers to a close adult who is fulfilling a parental role. This person was often a grandmother, aunt, or other relative who had "raised them" or with whom they lived, even if that adult was not the legal guardian.[20]

The importance of parent surrogates and extended families is significant when assessing the impact of attempts to legislate family communication. Most notification clauses are restricted to traditional definitions of biological parents or legal guardians and fail to address the complexity and diversity of modern family structures and adult support systems relevant to adolescents. For minors who are willing to involve parents or parent surrogates in their abortion decisions, legislation adds no benefit and actually may impede appropriate family communication channels.

Involuntary Parental Notification

Minors who choose not to inform parents about their intention to have abortions are disproportionately older (16 and 17 years old), white, and employed.[19] Very young adolescents almost always agree to voluntary parental involvement. In the unusual instance of resistance, the

possibility of incest or abuse should be carefully evaluated. The most frequent reasons minors cite for not telling parents include the belief that the knowledge would damage their relationship, the fear that it would escalate conflict or coercion, and the desire to protect a vulnerable parent from stress and disappointment.[19] Adolescents who are strongly opposed to informing parents tend to predict family reactions accurately.[21] Involuntary parental notification can precipitate a family crisis characterized by severe parental anger and rejection of the minor and her partner. One third of minors who do not inform parents already have experienced family violence and fear it will recur.[19] Research on abusive and dysfunctional families shows that violence is at its worst during a family member's pregnancy and during the adolescence of the family's children.[5] Although parental involvement in minors' abortion decisions may be helpful in many cases, in others it may be punitive, coercive, or abusive.[22]

Credible reviews of available data conclude that there is no evidence that mandatory parental involvement results in the benefits to the family intended by the legislation. No studies show that forced disclosure results in improved parent-child relationships, improved communication, or improved satisfaction with the decision about pregnancy outcome.[22-24]

The current data also indicate that such legislation does not increase the likelihood that parents will be involved. The percentages of minors who inform parents about their intent to have abortions are essentially the same in states with and without notification laws.[25] In states with such laws, adolescents who are not willing to inform parents use judicial bypass mechanisms,[26] go out of state to obtain services,[27] obtain clandestine care,[28] or delay care.[29,30]

ADOLESCENT COMPETENCY TO MAKE HEALTH CARE DECISIONS

Adolescents who are willing to involve parents in their abortion decisions will likely benefit from adult experience, wisdom, and support. Legislation requiring mandatory parental consent or notification for abortion presupposes, however, that pregnant minors are not competent to make informed decisions and therefore require legal protection. The age of 18 years is a convenient legal dividing line, but it has no scientific validity as the point at which individuals become competent decision makers. Summaries of well-designed research conclude that most minors 14 to 17 years of age are as competent as adults to provide consent to abortion. They are able to understand the risks and benefits of options and to make voluntary, rational, independent decisions.[31-33] Once pregnant, an adolescent by most state laws is considered an "emancipated minor" and is held responsible and competent to consent to her own medical treatment during the pregnancy and to the medical decisions regarding her fetus or newborn (eg, amniocentesis, genetic testing, life-saving treatment, and circumcision). No state laws require the minor's parent to consent to the minor's decision to continue the pregnancy when the parent thinks that terminating the pregnancy is in the minor's best interest or, with few exceptions, to place the infant for adoption. It is inconsistent, then, to presume that the minor is not legally competent to make decisions regarding pregnancy termination.[24,31,34]

Legal Issues

The legal issues involved in a minor's right to confidential abortion care have been well covered in other reviews.[35-38] The vast majority of court opinions and legal analyses hold that the justifications presented for mandatory parental involvement in a minor's abortion decision are not sufficiently compelling to outweigh the minor's right to privacy in deciding whether to terminate a pregnancy.[39] Teenagers perceive no difference in legal requirements for consent versus notification. Both abridge confidentiality. All analyses confirm that confidential care for adolescents is critical to improving their health. There is a "remarkable degree of consensus that adolescents should have access to confidential health services and that parental involvement, consent, or notification should not be a barrier to care."[9] There is substantial legal consensus that parental consent and notification laws, whether or not ruled constitutional, run counter to fundamental principles of family law, which ideally seek to protect the privacy of family decision making from government interference and to protect the best interests of the minor in the circumstances when the government does intervene in family affairs.[39]

CONCERNS ABOUT PSYCHOLOGICAL OR PHYSICAL CONSEQUENCES OF ABORTION DECISIONS

Some adults support mandatory parent notification, thinking that it will protect the adolescent from making a decision she might regret later. Most adolescents, however, express satisfaction with their ultimate pregnancy decisions, providing they think that the decisions were their own. No significant differences in the levels of later satisfaction with their decisions have been found between adolescents who choose abortion and those who bear children or between those who parent as opposed to those who place their infants for adoption; almost all think that they made the right choices for themselves.[40-42] The key determinant of this expressed satisfaction is the sense of "ownership" over the pregnancy decisions and the belief that their choices were not the results of coercion.[42] In other research, pregnant adolescents who chose not to communicate with parents were as satisfied with their decisions as those who did consult with parents and received support for their decisions.[20] Adolescents who communicated with nonsupportive parents were the ones more likely to express dissatisfaction with pregnancy decisions.

Extensive reviews conclude that there are no documented negative psychological or medical sequelae to elective, legal, first-trimester abortion among teenaged women.[43,44] No significant psychological sequelae have been substantiated, despite extensive searches of the scientific literature.[45-47] When facing an unwanted pregnancy, regardless of the ultimate outcome, most women experience a range of normal emotional reactions, including regret, mild depression, and anxiety. Adverse reactions after abortion are rare; most women experience relief and reduced depression and distress.[48] Some women may experience feelings of grief and guilt after termination of pregnancies, especially those who consider themselves deeply religious or who were ambivalent about their decisions, and they may benefit from appropriate therapeutic counseling.[49] The incidence of diagnosed psychiatric illness and hospitalization is considerably lower after abortion than after childbirth. Psychiatric disorders, when found, have been attributed to preexisting psychiatric illness, undergoing abortion under coercion or pressure, or concomitant highly stressful life circumstances, including abandonment.[46]

The medical risks of legal first-trimester abortion likewise are extremely low. Mortality risks seem to be five times greater for teenagers who continue their pregnancies than they are for teens who terminate them. Morbidity rates and medical complications from continuing a pregnancy are more adverse than those from abortion at all stages of gestation.[48,50] The scientific evidence indicates that legal abortion results in fewer deleterious sequelae for women compared with other possible outcomes of unwanted pregnancy. There is no rational basis for policies that put barriers in the way of an adolescent's selection of abortion because of concerns about physical or psychological consequences.

ADVERSE EFFECTS OF MANDATORY PARENTAL INVOLVEMENT LEGISLATION

Mandatory parental consent or notification laws do not protect the health of young women and, in fact, may do harm.

Adverse Health Impact

The most damaging impact of mandatory parental notification laws is that they can delay and obstruct the access of pregnant adolescents to timely professional advice and medical care.[5,48] Teenagers are twice as likely as adults to delay the diagnosis of first-trimester pregnancy. Adolescents are often confused about their right to confidential care, and even a perceived lack of confidentiality in health care regarding sexual issues deters them from seeking services.[51] Once the minor does present for pregnancy counseling, mandatory parental involvement laws can delay medical care further. After enactment of such statutes, court proceedings in Massachusetts delayed the termination of pregnancy by as much as 6 weeks; in Minnesota, the average delay was 1 to 3 weeks, and the proportion of second-trimester abortions in teens increased by 12%.[48] In Mississippi, a parental consent requirement increased by 19% the ratio of minors to adults who underwent their procedures after 12 weeks' gestation.[52] Later-trimester procedures (after 14 weeks) increase both the medical risks and financial costs to the patient, and a prolonged delay can eliminate abortion as an accessible option.[50]

It is likely that mandatory parental consent legislation decreases access to abortion by adolescents, although confounding variables make it difficult to ascertain causal effects on abortion rates. Both abortion rates and abortion ratios have decreased nationwide in states with and without parental consent statutes. In Minnesota, after parental consent laws were enacted in 1981, at first it seemed that abortion rates decreased disproportionately in 15- to 17-year-olds, but with no increase in birth rates, leading some to hypothesize that teenagers were more motivated to avoid pregnancy.[53] However, after the Supreme Court upheld Minnesota's consent laws in 1990,[3] abortion rates in minors fell to the lowest level in 10 years, and birth rates for the same age group rose to the highest level since 1980 (*St Paul Dispatch.* June 30, 1992).

Adverse Psychological and Social Impact

There is increasing evidence of the negative effects of delayed or denied abortion on both the emotional health of the mothers and the developmental status of the unwanted children. Later-stage abortions are associated with a greater risk of psychological sequelae for pregnant teenagers (compared with first-trimester abortions, which are without significant negative sequelae).[54] American studies have recently confirmed European research that women who are denied abortions only rarely give up their unwanted infants for adoption and may harbor resentment and anger toward their children for years. Despite strong social pressure not to acknowledge that a child is unwanted, more than one third of the women confessed to having strong negative feelings toward their children. Compared with the offspring of willing parents, the children of women who did not obtain requested abortions were much more likely to be troubled and depressed, to drop out of school, to commit crimes, and to have serious illnesses.[55,56] Compared with peers who terminate their pregnancies, adolescents who bear children are at significantly higher risk of educational deficits, economic disadvantage, and marital instability.[41,48]

Adverse Family Impact

As discussed, parental involvement can have adverse effects on both minors and their families, particularly if it takes on a coercive character. The risks of violence, abuse, coercion, unresolved conflict, and rejection are significant in nonsupportive or dysfunctional families when parents are informed of a pregnancy against the adolescent's considered judgment.[1,30] In *Hodgson vs Minnesota*, the majority of the Supreme Court found that mandatory parental involvement can result in family upheaval and can be dangerous for minors in homes where physical, emotional, or sexual abuse is present.[1,39]

Judicial Bypass

The option of obtaining a judicial bypass (a court proceeding in which a judge determines whether the adolescent is mature enough to make the decision to have an abortion or whether it is in her best interest not to inform parents) is viewed by some as a reasonable compromise to protect a concerned adolescent from harm while permitting states to impose mandatory parental involvement statutes.[5] The US Supreme Court ruled in 1990 that judicial bypass mechanisms are constitutionally required if state legislation is enacted, and they are ethically essential for adolescents at risk of abuse. However, judges who preside over bypass rulings testify unequivocally that this procedure is of no benefit to minors.[57,58] It has no effect on the ultimate decision with respect to abortion or on the process by which that decision is made. Of 12 000 petitions in Massachusetts and Minnesota, only 21 were denied, and half of the denials were overturned on appeal.[24] The judicial bypass process itself poses risks of medical and psychological harm. It is detrimental to medical well-being, because it causes further delays in access to medical treatment (from 4 days to several weeks), which increase the risk of complications from delayed or second-trimester procedures.[22]

It is detrimental to emotional well-being, because adolescents perceive the court proceedings as extremely burdensome, humiliating, and stressful.[24] The pregnant adolescent is required to divulge intimate details of her private life to dozens of strangers (clerks, bailiffs, court reporters, witnesses, and others) to obtain a brief (10-minute) hearing before a judge who has no firsthand knowledge of her case and typically no training in counseling adolescents or developmental issues.[39] Regardless of the Supreme Court ruling, many legal opinions hold that the judicial bypass process constitutes "undue burden" for adolescents seeking abortion care.[22,24,39]

CONCLUSIONS AND RECOMMENDATIONS

1. Adolescents should be strongly encouraged to involve their parents and other trusted adults in decisions regarding pregnancy termination, and the majority of them voluntarily do so. A minor's decision to involve parents is determined by the quality of the family relationship, not by laws. Family communication is inherently a family responsibility, and parents themselves create the emotional atmosphere that fosters productive dialogue. Adolescents who feel loved and supported by their parents normally will communicate with them in times of crisis. Studies show that adolescents are most likely to disclose their pregnancies if the family has a history of warmth, rapport, and involvement of parents in past problem solving.[25,26] As emphasized in previous AAP position statements, enhancing parental skills for listening, communicating, valuing, and nurturing throughout the childhood years is the most effective means of ensuring family involvement in adolescent decisions.[1,59] The pediatrician's most valued role may be to strengthen these family communication skills and supportive behaviors.

2. Concerned professionals should make every effort to ensure that a pregnant teenager receives adult guidance and support when considering all the options available, so she can make the decision that is in her best interest. This is best achieved by adhering to existing professional ethics and standards for obtaining meaningful informed consent.[60] Physicians should ensure that the minor patient has full information and has given careful consideration to the issues involved. They should encourage minors to consult with parents, other family members, or other trusted adults if parental support is not possible. The very young adolescent is especially needy in this regard. Ultimately, the pregnant patient's right to decide should be respected regarding who should be involved and what the outcome of the pregnancy will be, which is the approach most consistent with ethical, legal, and health care principles.

3. The AAP reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. Genuine concern for the best interests of minors argues strongly against mandatory parental consent and notification laws. Although the stated intent of mandatory parental consent laws is to enhance family communication and parental responsibility, there is no supporting evidence that the laws have these effects. No evidence exists that legislation mandating parental involvement against the adolescent's wishes has any added benefit in improving productive family communication or affecting the outcome of the decision. There is evidence that such legislation may have an adverse impact on some families and that it increases the risk of medical and psychological harm to the adolescent. Judicial bypass provisions do not ameliorate the risk.

4. The AAP reaffirms its support of measures that increase access to health care for children and youths, regardless of age or financial status, and opposes unnecessary regulations that limit or delay access to care. The documented impact of parental consent laws is to reduce minors' access to early legal abortion. Public policies should encourage sexually active adolescents to seek timely, professional health care. The threat of compelled parental notification against the adolescent's wishes, even if judicial bypass is available, is a strong disincentive to seeking care. The AAP holds that public policies can and should encourage voluntary involvement of parents or other mature adults, but specific laws mandating notification of biological parents or legal guardians as a condition of service are counterproductive.[57]

FREE

Pediatricians can play a key role in preventing and controlling HIV infection by promoting risk-reduction counseling and offering routine HIV testing to adolescent and young adult patients. Most sexually active youth do not feel that they are at risk of contracting HIV and have never been tested. Obtaining a sexual history and creating an atmosphere that promotes nonjudgmental risk counseling is a key component of the adolescent visit. In light of increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the Centers for Disease Control and Prevention recommends universal and routine HIV testing for all patients seen in health care settings who are 13 to 64 years of age. There are advances in diagnostics and treatment that help support this recommendation. This policy statement reviews the epidemiologic data and recommends that routine screening be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV. This statement addresses many of the real and perceived barriers that pediatricians face in promoting routine HIV testing for their patients. *Pediatrics* 2011;128:1023–1029

INTRODUCTION AND BACKGROUND

The HIV epidemic persists in the United States despite great progress in treatment and continued efforts to screen targeted populations. In 2006, an estimated 1 106 400 HIV-infected people were living in the United States, of whom 55 320 (5%) were adolescents and young adults aged 13 to 24 years.[1] Between 2005 and 2008, the estimated number of HIV/AIDS cases increased among 15- to 19-year-olds and 20- to 24-year-olds.[2] HIV continues to be among the top 10 leading causes of death in the 20- to 24-year age group.[3] Of the 1.1 million people living with HIV/AIDS in the United States, approximately 20% are unaware of their infection[4]; this is a group that accounts for 54% to 70% of new HIV infections.[5] In 2006, an estimated 48% of HIV-infected adolescents and young adults were unaware of their infection.[6,7] The American Academy of Pediatrics encouraged HIV testing of all sexually active youth in a 2001 policy statement.[8] This updated statement reflects advances in diagnostic testing, changes in epidemiology, and updated recommendations.

The risk of HIV infection varies with community prevalence rates, sexual behaviors, and concurrent substance use. The rate of new HIV

diagnoses per 100 000 population increases with age from 12.6 in the 15- to 19-year age group to 37.2 in the 20- to 24-year age group.[2] In 2007, 73% of 13- to 24-year-olds diagnosed with HIV/AIDS were male, and 27% were female.[9] As with adults, most adolescent cases occur through sexual transmission. Among young men, at least two-thirds of HIV transmissions occur via male-to-male sex, whereas heterosexual encounters are the primary means of transmission among female adolescents and young adults.[3] The greatest increase in new diagnoses has occurred among young minority men who have sex with men, which is a finding that necessitates new approaches to prevention. HIV infection disproportionately affects minorities, occurring 7 times more often in black people and 2.6 times more often in Latino people than in white people[10] and is more common in people living in the South and the Northeast.[3]

Drug and alcohol use contributes to high-risk sexual activity. The 2009 Youth Risk Behavior Survey found that 46% of high school students reported having engaged in sexual activity (62% by the 12th grade), and 22% had consumed alcohol or used drugs before their last sexual intercourse.[11] History of other sexually transmitted infections (STIs) can increase the risk of HIV acquisition,[12] and a recent survey found that 26% of adolescent girls (14–19 years of age) tested positive for an STI.[13]

Most sexually active adolescents and young adults do not feel that they are at risk of HIV infection and do not get tested. Although 65% of the high school students who took the survey reported being sexually active by the 12th grade and more than 85% had received HIV/AIDS education, only 13% had been tested for HIV.[11] Surveys of sexually active youth aged 15 to 19 years found that they do not believe that they are at risk of HIV infection, and fewer than one-third of them had been tested for HIV.[14] In contrast, surveys of older youth (18–25 years of age) have revealed that 48% have been tested for HIV at some point, but fewer than one-third of them have been tested in the preceding 12 months.[15] This sense of invulnerability is, in part, attributable to the adolescent's physical, psychological, and social development—factors that contribute to low testing rates. Adolescents also cite concerns about confidentiality, access to testing, and invasive blood procedures as barriers to testing.[16] A 2005 American Academy of Pediatrics survey revealed that nearly 50% of pediatricians recommend that all sexually active youth be screened for STIs; however, only 28% of them recommend that all adolescents be tested for HIV.[17]

In light of the increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the Centers for Disease Control and Prevention (CDC) recommends universal and routine HIV screening rather than targeted testing. Opt-out HIV testing, which refers to testing performed unless the patient declines,[18] should be routinely performed for all patients aged 13 to 64 years who are seen in health care settings; this testing is performed without a separate written informed consent or pretest counseling.[4] Individual states are changing local laws to meet these recommendations.[18] The complex issues of confidentiality, disclosure, and consent in adolescent care make implementation of these recommendations more challenging. Nevertheless, pediatricians can play a key role in preventing and controlling HIV infection by promoting risk reduction and offering HIV testing to their adolescent and young adult patients.

RISK ASSESSMENT AND COUNSELING

Because adolescents are a vulnerable population at increased risk of HIV infection, they should be routinely assessed for high-risk behaviors and screened for HIV. Pediatricians should also implement primary and secondary prevention strategies for STIs and HIV infection. Resources that facilitate assessment in a busy practice include the *Bright Futures* curriculum[19] and *Guidelines for Adolescent Preventive Services* (GAPS)[20] questionnaires. Although the new CDC recommendations deemphasize risk assessment and counseling as precursors for opt-out testing, these activities are critical components of routine adolescent visits. Adolescents may be more willing to disclose high-risk behaviors if pediatricians establish confidential, private discussions at each health maintenance visit.[21] Ideally, a confidentiality policy should be reviewed with adolescents and their parents in early adolescence (ie, before 14 years of age) and can be modeled on a sample provided by *Bright Futures*.[19]

Discussing same-sex and opposite-sex attractions, sexual identity, sexual activity, and exposure to sexual violence or abuse are key components of taking sexual histories and providing health guidance to adolescents.[22] Creating a supportive atmosphere and factual, nonjudgmental counseling is essential for reaching youth.

The US Preventive Services Task Force[23] and the American Academy of Pediatrics recognize that all youth are at current or future risk of STIs and HIV infection. Both groups recommend that all youth receive behavioral counseling to prevent STIs, including the recommendation that they delay sexual activity. Opportunities to discuss HIV and STIs with youth during routine health assessments are often missed, and youths of ethnic minorities are

less likely to receive regular preventive health care.[24] The expansion of adolescent vaccine requirements to include human papillomavirus vaccine has provided additional opportunities for risk counseling, because discussion regarding this vaccination affords a natural segue into discussions of other STIs and HIV.[25] School physicals and annual athletic preparticipation physical examinations provide other opportunities to discuss HIV and STIs, conduct risk assessments, and provide health guidance and offer testing; these examinations are often the only contact youth have with any health provider.[21]

The use of postexposure prophylaxis with antiretroviral drugs should be considered for adolescents who may have been exposed to HIV after an episode of high-risk sexual activity or needle use. Victims of sexual violence should have baseline HIV testing as well as STI screening and treatment and should be offered mental health counseling.[26] Guidelines for the use of postexposure prophylaxis in nonoccupational exposures are available,[27] and practitioners can get expert consultation from the AIDS Education and Training Centers National Clinicians Consultation Center (800-448-8765).

TESTING FOR HIV

Much progress has been made in the area of HIV testing, and rapid and less invasive diagnostic HIV tests are readily available[28] (http://www.cdc.gov/hiv/topics/testing/resources/factsheets/rtlab.htm). The gold standard for HIV diagnosis remains the detection of HIV antibody in serum by enzyme-linked immunoassay (EIA) followed by confirmatory Western blot or immunofluorescent assay. The sensitivity and specificity of current assays are more than 99%. False-positive EIA results, although uncommon, can occasionally occur. False-negative results can occur if testing is performed during the acute phase of infection, before the development of an antibody response, or in subjects with severe immunosuppression. The use of an oral fluid testing device that measures HIV antibody in mucosal transudate is well accepted by youth and is used in many outreach settings.[16] In addition, several point-of-care rapid HIV-1 antibody tests provide results in minutes to hours.[29] These tests have sensitivity and specificity rates similar to those for standard EIA. In routine care, a negative rapid antibody test result does not need confirmation; however, as with EIAs, positive results should be confirmed with a more specific test, such as a Western blot or immunofluorescent assay. If the rapid test or EIA result is positive but the Western blot result is indeterminate, the adolescent might be in the process of seroconversion, or the result could be false-positive; the test should be repeated, and a virologic test (eg, nucleic acid test; HIV RNA test, or viral load test) should be performed for confirmation.

Most laboratories that perform standard EIA testing will automatically repeat an EIA if the first result is positive, followed by a Western blot test if the repeat EIA result is positive and will not report the positive results unless the Western blot confirms positivity. However, the advantage of the rapid test is that the results can be given to the patient immediately with the caution that the results need to be confirmed. Pediatricians who see youth with initial positive rapid test results should discuss the results with the patient and obtain a confirmatory Western blot. A positive HIV test result should be discussed with the patient in person; positive results should not be given by telephone. Local health departments or case management agencies can assist with linking youth with appropriate care and counseling after diagnosis. HIV-infected youth should be cared for by providers with expertise in HIV medicine.[30] Reviewing negative HIV results with youth provides an opportunity for pediatricians to provide additional risk counseling. In high-risk situations such as sexual assault or other nonoccupational exposures, negative testing should be repeated in 3 months and postexposure prophylaxis considered as previously discussed.

Pediatricians should be aware that an estimated 50% of patients acutely infected with HIV present with symptoms to health care providers; however, few providers make the diagnosis at this time.[31] Symptoms of acute retroviral syndrome are outlined in Table 1. During the acute stages of infection, antibody testing might yield a negative or indeterminate result while RNA testing results are positive. HIV RNA (viral load) testing should be performed on patients with suspect symptoms of acute infection and a negative antibody test result. Influenza-like illness and aseptic meningitis are also frequent presentations of the acute retroviral syndrome, and HIV testing may be appropriate, especially during seasons in which influenza and aseptic meningitis are not prevalent. The decision to include HIV RNA testing in this clinical scenario is based on age, risk factors, social history, and prevalence of HIV in the geographic area.

IMPLEMENTATION OF HIV SCREENING

The CDC recommendation is to screen, through opt-out testing, all patients aged 13 to 64 years unless or until the HIV prevalence of their patient population is determined to be less than 0.1% (Table 2). Pediatricians who care for youth in areas that have low prevalence rates should continue targeted testing. Youth at risk include all sexually active

TABLE 1 Identifying and Diagnosing Acute HIV-1 Infection

Suspecting acute HIV infection: signs or symptoms of acute HIV infection with recent (within 2–6 wk) high HIV risk exposure[a]
Signs/symptoms/laboratory findings can include but are not limited to ≥1 of the following: fever, lymphadenopathy, skin rash, myalgia/arthralgia, headache, diarrhea, oral ulcers, leucopenia, thrombocytopenia, transaminase elevation, aseptic meningitis
High-risk exposures include sexual contact with a person infected with HIV or at risk of HIV, sharing of injection drug use paraphernalia, or contact of potentially infectious blood with mucous membranes or breaks in skin[a]
Differential diagnosis: EBV and non-EBV (eg, CMV)–related infectious mononucleosis syndromes, influenza, viral hepatitis, streptococcal infection, syphilis
Evaluation/diagnosis of acute/primary HIV infection
HIV antibody EIA (rapid test if available)
Reactive EIA must be followed by Western blot
Negative EIA result or reactive EIA with negative or indeterminate Western blot should be followed by a virologic test[b]
A positive virologic test result in this setting is consistent with acute HIV infection
Positive quantitative or qualitative HIV RNA test results should be confirmed with subsequent documentation of seroconversion

EBV indicates Epstein-Barr virus; CMV, cytomegalovirus.

[a] In some settings, behaviors conducive to acquisition of HIV infection might not be ascertained or might not be perceived as "high risk" by the health care provider, the patient, or both. Thus, symptoms and signs consistent with acute retroviral syndrome should motivate consideration of this diagnosis even in the absence of reported high-risk behaviors.

[b] p24 antigen or HIV RNA assay. The p24 antigen is less sensitive but more specific than HIV RNA tests; HIV RNA tests are generally preferred. HIV RNA tests include quantitative branched DNA (bDNA) or reverse-transcriptase polymerase chain reaction (RT-PCR) or qualitative transcription-mediated amplification (APTIMA [GenProbe, San Diego, CA]).

Data source: modified from Panel on Antiretroviral Guidelines for Adults and Adolescents. Department of Health and Human Services. Guidelines for the use of antiretroviral agents in HIV-1-infected adults and adolescents. Available at: www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf.

TABLE 2 CDC Recommendations on Consent and Pretest Information

Screening should be voluntary and undertaken only with the patient's knowledge and understanding that HIV testing is planned
Patients should be informed verbally or in writing that HIV testing will be performed unless they decline (opt-out screening). Verbal or written information should include an explanation of HIV infection and the meanings of positive and negative test results, and the patient should be offered an opportunity to ask questions and to decline testing. With such notification, consent for HIV screening should be incorporated into the patient's general informed consent for medical care on the same basis as are other screening or diagnostic tests; a separate consent form for HIV testing is not recommended
Easily understood informational materials should be made available in the languages of the commonly encountered populations within the service area. The competence of interpreters and bilingual staff to provide language assistance to patients with limited English proficiency must be ensured
If a patient declines an HIV test, the decision should be documented in the medical record

Data source: Branson BM, Handsfield HH, Lampe MA, et al; Centers for Disease Control and Prevention. *MMWR Recomm Rep.* 2006;55(RR-14):1–17.[4]

adolescents. Youth at high risk, which include those who use intravenous drugs, exchange sex for money, or have sex with multiple partners or are men who have sex with men, should be tested yearly. Pediatricians should be aware of their local HIV prevalence data, because some communities have very high rates of HIV, which places youth at disproportionate risk(www.cdc.gov/hiv/topics/surveillance/resources/slides/2007report_tables). Because 13% of pregnancies occur in youth aged 15 to 19 years, routine HIV testing and early identification can also positively affect prevention of mother-to-child transmission of HIV.

The US Preventive Services Task Force strongly recommends HIV testing of at-risk adults and adolescents and all pregnant women; however, it has made no recommendation for or against routine screening.[32] Its accompanying review of the evidence discusses that, depending on the setting, many patients will be missed with risk-based screening and that there is good evidence for routine screening of patients seen in high-risk or high-prevalence settings, including STI clinics, correctional facilities, and adolescent clinics with high STI rates.[33] Although several studies have shown the cost-effectiveness of routine HIV screening, data addressing this issue in youth are insufficient.[34–36]

Nearly half of recently identified infected people had their first HIV test within 1 year of being diagnosed with AIDS. These so-called late testers are generally young, heterosexual, poorly educated, and black or Latino, and they are more likely to be identified through a health care setting than through targeted testing.[4] Early testing plays an important role in the health of the individual adolescent and the community. There is evidence that at least 20% of newly diagnosed youth seroconverted within the previous 6 months.[37] This early phase of illness is a time of high viremia, during which the risk of infectivity and transmission is greatest. People who are aware of their HIV status are more likely to practice safer sex or remain abstinent.[38] Patients who are diagnosed and treated earlier have a slower progression to AIDS, are more likely to restore immunologic function, and are less likely to transmit HIV to others.[39]

The health care setting has many advantages as a site of HIV testing for youth. Adolescents are more likely to agree to be tested if it is recommended by a physician,[40] and youth who are diagnosed at a health care facility are more likely to enter into HIV care in a timely fashion.[37] The 2007 National Health Interview Survey found that among adults who received an HIV test, more than 80% did so in doctors' offices, hospitals, emergency departments, and clinics compared with test-

ing at HIV counseling and testing centers or STI clinics.[41]

The use of acute care settings to improve testing rates is attractive to youth, because they are more likely to use urgent care settings for their health care needs.[42] In the years before diagnosis, many HIV-infected adults seek care for HIV-related symptoms in acute care settings.[43] Implementation of rapid HIV testing in the emergency department setting has improved testing rates and greatly benefits youth who prefer rapid testing. A recent study in a large pediatric emergency department used a multisystems approach to implement routine screening with rapid HIV testing. More than 50% of youth were offered HIV testing, and only 13% opted out.[44] Effective implementation in emergency care settings requires commitment by emergency department staff, education, training, and an effective means of reminding staff to routinely perform the test (eg, electronic prompts).

PERCEIVED BARRIERS TO ROUTINE TESTING

Research has found that youth might forgo reproductive health services if parental consent is required.[45] Laws concerning consent and confidentiality for HIV care and treatment vary among states; thus, physicians need to familiarize themselves with local laws. Public health statutes and legal precedents allow for medical evaluation and treatment of minors with certain illnesses—particularly STIs—without parental knowledge or consent. Consent and confidentiality laws, even for the treatment of STIs, may have special provisions in some states for teenagers in foster care. Minors can now consent to HIV testing in all states, although the age of consent varies (www.guttmacher.org/statecenter/spibs/spib_OMCL.pdf).[46] Although these state laws might be in the process of being changed, pediatricians need to know and abide by the laws in effect in their jurisdiction. The Compendium of State HIV Testing Laws from the National HIV/AIDS Clinicians' Consultation Center (www.nccc.ucsf.edu) can help clinicians seeking clarification of how their state laws and the CDC recommendations apply in clinical practice. The compendium comprehensively presents clinicians with regular updates to each state's HIV testing laws. Excellent tools are also available to assist providers in implementing HIV testing in their adolescent practices (www.adolescentaids.org/healthcare/acts.php).[47] Reimbursement and disclosure to parents via insurance billing are issues that require additional attention. At present, health insurance coverage of HIV screening is variable.[18] Health advocates, insurers, and states must influence policies around confidentiality and insurance coverage that can address the aforementioned issues.

If pediatricians are unable to ensure confidentiality for HIV testing for adolescent patients in their office setting, they should identify and refer youth to confidential community-based HIV testing. Pediatricians should familiarize themselves with available resources in their communities. A CDC Web site (www.hivtest.org) provides assistance in finding local testing sites.

Disclosure of the HIV status of an adolescent should be held to the same legal and ethical standards as those for an adult. An important concern for HIV-positive adolescents is the limits of confidentiality related to notification of sexual partners. Partner-notification services can play a key role in preventing and controlling the HIV epidemic in the United States. Physicians should be familiar with state laws, and they should use reasonable means to persuade an infected person to voluntarily inform his or her partner(s). Physicians who intend to disclose their adolescent patient's HIV status to sexual partners or parents should inform the patient of their intent before testing and should describe the circumstances under which disclosure would occur. Optimally, adolescents should have the support of a parent or guardian when faced with a diagnosis of HIV; however, each case should be approached individually. Disclosure of HIV-infection status is regulated by state laws, and disclosure to school authorities without an adolescent's consent generally is not indicated.[48]

CONCLUSIONS AND RECOMMENDATIONS

1. Routine HIV screening should be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%.
2. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV (eg, substance use).
3. High-risk youth should be tested annually for HIV. Adolescents tested for other STIs should be tested for HIV at the same visit.
4. Emergency departments and urgent care facilities in high-prevalence areas should implement routine HIV testing, which will provide an excellent opportunity to reach youth who do not seek primary care services often.
5. Physicians should recognize the symptoms of the acute retroviral syndrome, such as mononucleosis-like syndromes, and consider including HIV RNA testing (viral load) in the diagnostic workup of youth when the appropriate risk factors are present.

6. Although parental involvement in adolescent health care is always desirable, consent of the adolescent should be sufficient to provide testing and treatment for HIV infection or STIs. Pediatricians should make use of free and confidential community-based testing programs if there are cost or confidentiality concerns.
7. Pediatricians should assess sexual and substance use behaviors, an essential component of routine adolescent care, regardless of perceived risk. Standardized assessment tools and a confidentiality protocol can be helpful.
8. Pediatricians are encouraged to create an environment of tolerance and facilitate open discussion of gender and sexual orientation.
9. Opt-out HIV testing is preferred if allowed by state laws, and rapid HIV testing has similar sensitivity to EIAs and can provide immediate notification of preliminary results. Physicians must follow the guidelines of their local jurisdictions for routine HIV opt-out testing in adolescents and are encouraged to advocate for change when such jurisdictions create barriers for implementation of opt-out testing.
10. A negative HIV test result should be used as an opportunity to counsel adolescents on sexual and drug use behaviors to reduce future risk.
11. For adolescents with a positive HIV test result, it is critical to arrange linkages to age-appropriate HIV specialty care, including prenatal care when appropriate.
12. Pediatricians are encouraged to advocate for the dissemination of accurate, evidence-based prevention education, access to confidential HIV and STI testing and counseling, and HIV treatment for adolescents.
13. Preventive care screening should include universal coverage and adequate payment for HIV testing and related counseling. Physicians should advocate for confidential billing practices related to HIV and STI testing in adolescent and young adults.

Advanced Practice in Neonatal Nursing

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Fetus and Newborn

ABSTRACT

The participation of advanced practice registered nurses in neonatal care continues to be accepted and supported by the American Academy of Pediatrics. Recognized categories of advanced practice neonatal nursing are the neonatal clinical nurse specialist and the neonatal nurse practitioner. *Pediatrics* 2009;123:1606–1607

NCNS—neonatal clinical nurse specialist

INTRODUCTION

The American Academy of Pediatrics (AAP) endorses the role of the advanced practice registered nurse (APRN) and the current training and credentialing process developed by the National Association of Neonatal Nurses.[1,2] These guidelines were specifically designed to educate APRNs at the graduate level to manage critically ill and convalescing infants. These guidelines and standards include requirements for the completion of a graduate-level education program of study and supervised practice beyond the level of basic nursing. This preparation includes the attainment of a master's degree in the neonatal nursing specialty. The neonatal nurse practitioner (NNP) curriculum must have included a minimum of 200 neonatal-specific didactic hours plus a minimum of 600 directly supervised hours with critically ill neonates/infants in level II and III NICUs.[1–5] Currently credentialed NNPs who have graduated from non–master's degree programs or certificate programs should be allowed to maintain their practice and be encouraged to complete a formal graduate education.[6] The AAP supports the documented competency of the master's degree–prepared APRN for entry into practice as an NNP. Some APRNs may wish to pursue the highest level of educational preparation in nursing, either the doctor of philosophy (PhD) or the doctor of nurse practice (DNP). However, the AAP does not consider such a degree to be necessary for clinical practice.

Included in the category of neonatal APRNs are the following[1,2]:

- Neonatal clinical nurse specialist (NCNS): a registered nurse with a master's degree who, through study and supervised practice at the graduate level, has become expert in the theory and practice of neonatal nursing. The NCNS is responsible for fostering continuous quality improvement in neonatal nursing care and developing and educating staff. The NCNS models expert nursing practice and applies and promotes evidence-based nursing practice.
- NNP: a registered nurse with clinical expertise in neonatal nursing who has obtained a master's degree with supervised clinical experience in the management of newborn infants and their families. The NNP manages patients in collaboration with a physician, usually a pediatrician or neonatologist. Using the acquired knowledge of pathophysiology, pharmacology, and physiology, the NNP may exercise independent judgment in the assessment, diagnosis, and management of infants and in the performance of certain procedures. The NNP may also be responsible for education of staff, research, and developing standards of nursing care.[6,7]

The spectrum of duties performed by the neonatal APRN will vary among institutions and may be governed by state regulations. Each of these roles currently requires advanced education and a master's degree. Nationally recognized certification examinations and requirements for maintenance education exist for each category.[8] Credentialing for practice is currently governed by individual states. Inpatient care privileges are granted by the individual institution. Each institution needs to develop a procedure for the initial granting and subsequent maintenance of privileges, ensuring that the proper professional credentials are in place. That procedure is best developed by the collaborative efforts of the nursing administration and the medical staff.

RECOMMENDATIONS

1. Medical care by the APRN for patients receiving level III newborn intensive care is provided in collaboration with, or under the supervision of, a physician, usually a neonatologist.
2. Medical care by the APRN for patients receiving level I and II care is provided in collaboration with, or under the supervision of, a physician with special interest and experience in neonatal medicine, usually a pediatrician or neonatologist.
3. Determination of whether the APRN practices in collaboration with, or under the supervision of, a physician should be determined in accordance with the board of nursing regulations in the state in which the APRN is practicing.[8]
4. The APRN should be certified by a nationally recognized organization and should maintain that certification.
5. The APRN should maintain clinical expertise and knowledge of current therapy by participating in continuing education and other scholarly activities as recommended by the National Certification Corporation.[9]
6. The APRN should comply with hospital policy regarding credentialing and recredentialing.[10]

Policy Statement

Pediatrics **Volume 81, Number 5** **May, 1988, p 736**

Age Limits of Pediatrics (RE8116)

AMERICAN ACADEMY OF PEDIATRICS

Council on Child and Adolescent Health

The purview of pediatrics includes the physical and psychosocial growth, development, and health of the individual. This commitment begins prior to birth when conception is apparent and continues throughout infancy, childhood, adolescence, and early adulthood, when the growth and developmental processes are generally completed. The responsibility of pediatrics may therefore begin with the fetus and continue through 21 years of age. There are special circumstances (eg, a chronic illness and/or disability) in which, if mutually agreeable to the pediatrician, the patient, and when appropriate the patient's family, the services of the pediatrician may continue to be the optimal source of health care past the age of 21 years.

Reaffirmed 9/92, 1/97
The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

AAP Principles Concerning Retail-Based Clinics

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Retail-Based Clinic Policy Work Group

THE AMERICAN Academy of Pediatrics (AAP) opposes retail-based clinics (RBCs) as an appropriate source of medical care for infants, children, and adolescents and strongly discourages their use, because the AAP is committed to the medical home model. The medical home model provides accessible, family-centered, comprehensive, continuous, coordinated, compassionate, and culturally effective care for which the pediatrician and the family share responsibility.[1] Given that the RBC is not a medical home model, the AAP is particularly concerned with the effects of the following attributes of an RBC on health care for children and adolescents:

- Fragmentation of care.
- The possible effects on quality of care.
- Provision of episodic care to children with special health care needs and chronic diseases, who may not be readily identifiable.
- Lack of access to and maintenance of a complete, accessible, central health record that contains all pertinent patient information.
- The use of tests for the purposes of diagnosis without proper follow-up.
- Possible public health issues that could occur when patients with contagious diseases are in a commercial, retail environment with little or no isolation (eg, fevers, rashes, mumps, measles, strep throat, etc).
- Seeing children with "minor" conditions, as will often be the case in an RBC, is misleading and problematic. Many pediatricians use the opportunity of seeing the child for something minor to address issues in the family, discuss any problems with obesity or mental health issues, catch up on immunizations, identify undetected illness, and continue strengthening the relationship with the child and family. These visits are important and provide an opportunity to work with patients and families to deal with a variety of other issues.

The AAP acknowledges that the shifting economic and organizational dynamics of the current health care system will likely support the continued existence and expansion of RBCs. However, the aforementioned concerns and the overall effects these clinics will have on pediatric practice have led the AAP to respond with the following principles:

1. Supporting the medical home model: RBCs should support the medical home model by referring the patient back to the pediatrician or other primary care physician for all future care. In the event that the patient does not have a relationship with a pediatrician or primary care physician, RBCs should have the means to assist the family in establishing contact with one within a medical

Abbreviations
AAP—American Academy of Pediatrics
RBC—retail-based clinic

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

home. Third-party payers are encouraged to provide appropriate incentives to plan members to access the medical home as the best practice model for pediatric primary care.

2. Communication: The AAP recommends that RBCs promptly communicate with the patient's pediatrician or other primary care physician within 24 hours of the visit. At a minimum, the following information should be included: patient's name, date of birth, at least 2 additional pieces of identifying information (eg, parents' name and/or address), reason for visit, diagnosis and disposition, findings, laboratory results (if any), and an indication as to whether any follow-up is needed.
3. Using evidence-based medicine: The AAP recommends that all those providing care to children follow all AAP clinical guidelines as well as those guidelines developed by other medical organizations that have the support and endorsement of the AAP. RBCs should be required to participate in ongoing quality-improvement and quality-assurance processes, as is required of pediatric and other primary care practices. RBCs must meet all requirements related to quality assurance and ensure full compliance with state licensure requirements for oversight or collaborative protocols relative to scope of practice.
4. Contagious diseases: By providing medical care to individuals in a retail-based setting, RBCs must take the necessary precautions to prevent the spread of contagious diseases. Although the RBC may have policies that limit the scope of services, this may not prevent individuals with contagious diseases from seeking care at RBCs. This presents a potential public health hazard to retail staff and customers who may come in contact with a contagious individual. RBCs should be subject to and comply with all health care facility standards (eg, hygiene, safety, regulations of the Occupational Safety and Health Administration, policies and procedures for children with communicable diseases, etc).
5. Financial incentives: The AAP is opposed to waiving or lowering copays or offering financial incentives for visits to RBCs in lieu of visits to pediatricians' or other primary care physicians' offices. The AAP believes that the medical home model is the optimal standard of care, and RBCs are not medical homes. Payer incentives should not promote fragmentation of care but instead should recognize and reward systems of care that promote continuous, coordinated, and comprehensive care.

Abusive Head Trauma in Infants and Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Cindy W. Christian, MD, Robert Block, MD, and the Committee on Child Abuse and Neglect

ABSTRACT

Shaken baby syndrome is a term often used by physicians and the public to describe abusive head trauma inflicted on infants and young children. Although the term is well known and has been used for a number of decades, advances in the understanding of the mechanisms and clinical spectrum of injury associated with abusive head trauma compel us to modify our terminology to keep pace with our understanding of pathologic mechanisms. Although shaking an infant has the potential to cause neurologic injury, blunt impact or a combination of shaking and blunt impact cause injury as well. Spinal cord injury and secondary hypoxic ischemic injury can contribute to poor outcomes of victims. The use of broad medical terminology that is inclusive of all mechanisms of injury, including shaking, is required. The American Academy of Pediatrics recommends that pediatricians develop skills in the recognition of signs and symptoms of abusive head injury, including those caused by both shaking and blunt impact, consult with pediatric subspecialists when necessary, and embrace a less mechanistic term, abusive head trauma, when describing an inflicted injury to the head and its contents. *Pediatrics* 2009;123:1409–1411

AHT—abusive head trauma

HISTORY

The recognition of child abuse in modern medicine began in the 19th century, with the work of the French forensic physician Ambroise Tardieu,[1,2] who described a wide array of physical and sexual injuries to children, including meningeal hemorrhage and brain injuries in fatally abused infants. More than 80 years later, American physicians began describing the clinical and radiologic manifestations of child abuse. Pediatrician and radiologist John Caffey[3,4] first described the association of chronic subdural hemorrhages and long-bone fractures in 1946, but it was not until 1972 that he published a seminal paper describing the radiologic and clinical features attributed to shaking injuries. Ludwig and Warman[5] first published the term "shaken baby syndrome" in their review of 20 infants and young toddlers injured by shaking, none of whom showed evidence of impact injury to the head. In 1987, Duhaime et al[6] reported that victims of fatal shaken baby syndrome, and many of those who survived their trauma, showed evidence of blunt impact to the head at the time of diagnosis. The importance of impact in acceleration/deceleration injury was supported by their basic biomechanical models, and they concluded that most serious abusive head injuries required an impact to the head. The relative importance of impact as a contributor to the head injury sustained by abused children became a source of controversy. Biomechanical modeling has since been used to both support and refute the contributions of shaking or impact to abusive head trauma (AHT).[7,8] In reality, all models and theories have known limitations, and many clinicians and researchers acknowledge that precise mechanisms for all abusive injuries remain incompletely understood.[9] Efforts to better understand the mechanisms and causations of injury have improved the gathering of objective data in the clinical realm. Case investigations, including meticulous medical history taking, examinations, and medical workups, have expanded and improved. Medical diseases that can mimic the presentation of AHT are recognized, and screening is performed when indicated. Social welfare, law enforcement, and legal professionals have become better educated about AHT. Clinical research has expanded, and biomechanical modeling of injuries has improved.

Case histories clearly support the conclusion that shaking occurs in some injury scenarios. Shaking was the most commonly reported mechanism of injury described in a series of AHT cases in which perpetrators admitted abuse (68% of 81 cases).[10] Shaking alone was described in 32 cases, and only 4 of the victims showed evidence of impact injury. Although this indicates incomplete admission to the injury mechanism in some cases, the commonality of a described shaking mechanism along with the infrequency of impact evidence supports shaking as an important mechanism of AHT. In addition, blunt impact trauma or impact combined with shaking can result in infant head injuries.[11] In severe and fatal cases, concomitant cervical spine injury can sometimes be found.[12] Secondary brain injury resulting from hypoxia, ischemia, and metabolic cascades contributes to poor outcomes.[13,14] Shaken baby

syndrome is a subset of AHT. Injuries induced by shaking and those caused by blunt trauma have the potential to result in death or permanent neurologic disability, including static encephalopathy, mental retardation, cerebral palsy, cortical blindness, seizure disorders, and learning disabilities. Medical and biomechanical research, clinical and pathologic experience, and radiologic advances have improved our understanding of the range of mechanisms that contribute to brain injury from AHT, yet controversy remains.

DISCUSSION

Few pediatric diagnoses engender as much debate as AHT, in part because of the social and legal consequences of the diagnosis. The diagnosis can result in children being removed from their homes, parents losing their parental rights, and adults being imprisoned for their actions. Controversy is fueled because the mechanisms and resultant injuries of accidental and abusive head injury overlap, the abuse is rarely witnessed, an accurate history of trauma is rarely offered by the perpetrator, there is no single or simple test to determine the accuracy of the diagnosis, and the legal consequences of the diagnosis can be so significant.[15] Because the civil and criminal justice systems are often involved in cases of AHT, the scientific debates related to mechanism and causation of injury often are argued during courtroom proceedings. On occasion, the courtroom allows for scientific theory to be confirmed or refuted,[16] but in reality, the American justice system is not designed to determine scientific truth but, rather, to balance contested facts and bring closure to a dispute. Medical terminology should accurately reflect the medical diagnosis. The term "shaken baby syndrome" has become synonymous in public discourse with AHT in all its forms.[17] The term is sometimes used inaccurately to describe infants with impact injury alone or with multiple mechanisms of head and brain injury and focuses on a specific mechanism of injury rather than the abusive event that was perpetrated against a helpless victim. Legal challenges to the term "shaken baby syndrome" can distract from the more important questions of accountability of the perpetrator and/or the safety of the victim. The goal of this policy statement is not to detract from shaking as a mechanism of AHT but to broaden the terminology to account for the multitude of primary and secondary injuries that result from AHT, some of which contribute to the often-permanent and significant brain damage sustained by abused infants and children.

The term "shaken baby syndrome" has become recognized by the public; prevention strategies for curtailing the incidence of AHT have been developed and researched, and some states have mandated shaken baby syndrome education for parents of all newborn infants.[18] Because it may not be obvious to parents that shaking can be harmful to infants, the newborn nursery is an appropriate venue for this education. The American Academy of Pediatrics supports prevention efforts that reduce the frequency of AHT and recognizes the utility of maintaining the use of the term "shaken baby syndrome" for prevention efforts. Just as the public commonly uses the term "heart attack" and not "myocardial infarction," the term "shaken baby syndrome" has its place in the popular vernacular. However, for medical purposes, the American Academy of Pediatrics recommends adoption of the term "abusive head trauma" as the diagnosis used in the medical chart to describe the constellation of cerebral, spinal, and cranial injuries that result from inflicted head injury to infants and young children.

THE ROLE OF THE PEDIATRICIAN

As mandated reporters of suspected child abuse and neglect, pediatricians carry the burden of recognizing and responding to medical manifestations of AHT. The diagnosis is sometimes obvious, but injuries in many symptomatic infants are unrecognized by unsuspecting physicians.[19] In addition, physicians do not always report to child welfare agencies injuries that are highly suspicious for abuse, which puts children at further risk for injury.[20,21] To protect abused infants and prevent future severe neurologic injury, pediatricians must remain cognizant of the possibility of AHT in infants who present with both subtle and overt neurologic symptoms and take seriously the ethical and legal mandates to report suspected child abuse to governmental agencies for investigation. Pediatricians also have a responsibility to consider alternative hypotheses when presented with a patient with findings suggestive of AHT. A medical diagnosis of AHT is made only after consideration of all the clinical data. On some occasions, the diagnosis is apparent early in the course of the evaluation, because some infants and children have injuries to multiple organ systems that could only be the result of inflicted trauma. On other occasions, the diagnosis is less certain, and restraint is required until the medical evaluation has been completed. However, as physicians, we have an obligation to make a working diagnosis, as we do with many other diagnoses, and take the legally mandated steps for further investigation when indicated. Pediatricians often find it helpful to consult a subspecialist in the field of child abuse pediatrics to ensure that the medical evaluation has been complete and the diagnosis is accurate. Subspecialists in radiology, ophthalmology, neurosurgery, neurology, and other fields should also be consulted when necessary to ensure a complete and accurate evaluation. When child protective services or law enforcement is involved in an investigation, the pediatrician is required to interpret medical information for nonmedical professionals in an understandable manner that accurately reflects the medical data. Pediatricians also have a responsibility to the family of the abused child. The diagnosis of child abuse has enormous social, psychological, and legal implications for families. The role of the pediatrician is not to apportion blame or investigate potential criminal activity but to identify the medical problem, treat the child's injuries, and offer honest medical information to parents and families. Finally, pediatricians can work to prevent AHT by supporting prevention efforts in the community and in practice. Pediatricians may help prevent AHT by providing anticipatory guidance to new parents about the dangers of shaking or impact and providing methods for dealing

with the frustration of a crying infant. They can also stress the importance of leaving a young infant or toddler in the care of adults whom the parents trust will not harm their child and can participate in comprehensive community-based prevention efforts. AHT commonly results in permanent neurologic damage and carries tremendous family and societal costs. With an aim toward prevention, the American Academy of Pediatrics recommends the following.

RECOMMENDATIONS

1. Pediatricians should be alert to the signs, symptoms, and head injury patterns associated with AHT.
2. Pediatricians should know how to begin a thorough and objective medical evaluation of infants and children who present for medical care with signs and symptoms of potential AHT. Consultants in radiology, ophthalmology, neurosurgery, and other subspecialties are important partners in the medical evaluation and can assist in interpreting data and reaching a diagnosis.
3. Pediatricians should consider consulting a subspecialist in the field of child abuse pediatrics to ensure that the medical evaluation of the patient has been complete and that the diagnosis is accurate.
4. Pediatricians should use the term "abusive head trauma" rather than a term that implies a single injury mechanism, such as shaken baby syndrome, in their diagnosis and medical communications.
5. Pediatricians should continue to educate parents and caregivers about safe approaches to calming and coping with crying infants and the dangers of shaking, striking, or impacting an infant's head.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Access to Optimal Emergency Care for Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine

ABSTRACT

Millions of pediatric patients require some level of emergency care annually, and significant barriers limit access to appropriate services for large numbers of children. The American Academy of Pediatrics has a strong commitment to identifying barriers to access to emergency care, working to surmount these obstacles, and encouraging, through education and system changes, improved levels of emergency care available to all children.

INTRODUCTION

Millions of infants, children, adolescents, and young adults seek emergency care every year in the United States. Many individuals may not receive appropriate acute care in a timely fashion because of numerous obstacles. Emergency departments (EDs) are the nation's safety net. EDs provide comprehensive acute care 24 hours a day, 7 days a week.[1–3] Factors that weaken this safety net disproportionately affect vulnerable populations. Access to appropriate pediatric emergency medical care is important for children, because substantial morbidity may occur if care is delayed.

Problems That Restrict Access to Care

A. Lack of universal understanding and application of a definition of "emergency."

B. Lack of reasonable access to alternative sources of health care so that the ED is left as the only place that will see everyone.

C. ED crowding and diversion of emergency medical services (EMS).

D. Lack of universal access to enhanced or basic 911 services and wireless 911 service for cellular phones, with reliance in some areas on local 10-digit emergency telephone numbers.

E. The misconception that freestanding urgent care centers provide comprehensive emergency services and that all EDs are equally equipped to care for children.

F. Variability in the availability of appropriate equipment, supplies, and medications in emergency departments for children of all ages.[4]

G. Variability in pediatric training and experience among physicians and nurses staffing EDs.

H. Lack of pediatric training and experience for prehospital EMS and interhospital transport personnel.

EMSC—Emergency Medical Services for Children

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

I. Lack of evidence-based guidelines for care efficacy and safety within all levels of emergency medical services for children.

J. Lack of access to pediatric emergency medical care in many regions of the country.

K. Lack of reliable access to pediatric medical subspecialists, pediatric surgical specialists, and mental health professionals.

L. Lack of, or failure to initially identify, the medical home, or failure to return the child to the medical home after ED discharge.

M. Lack of or inadequate reimbursement for primary care for large numbers of children.

N. Managed care protocols that bypass regional emergency services for children.

O. Managed care protocols designed to reduce the use of emergency facilities without providing appropriate alternatives for care.

P. Failure by payers to use the "prudent-layperson" standard for definition of emergency.

Q. Retroactive denial of third-party payment when diagnostic signs and/or symptoms suggest an emergent condition but the final diagnosis (often established after evaluation and treatment) is "nonemergent."

R. Denial of payment for services to insured patients for any reason (eg, preexisting or chronic conditions).

S. Increasing legislation and managed care initiatives related to emergency access for children that often require complex and time-consuming telephone calls and documentation.

T. Fears borne by families of ill or injured children regarding immigration issues, social service agency intervention for child custody concerns, and other legal or financial concerns.

U. Language and education barriers to understanding appropriate utilization of less emergent sources of care.

Since the American Academy of Pediatrics (AAP) published the original policy statement on access to emergency care in 1992[5] and a revision in 2000,[6] several substantial advances have occurred.

Advances That Promote Access to Emergency Care

- Significant increases in the number of emergency medicine residents and residency programs that include specific training and experience in pediatric emergencies.
- Development of dual pediatrics-emergency medicine residency training programs.
- Significant increases in pediatric emergency medicine fellowship programs.
- Increased availability of physicians with specific training and certification in pediatric emergency care.
- A substantial and ongoing increase in the presence of board-certified emergency medicine physicians in EDs throughout the country.
- Increasing numbers of providers at all levels taking pediatric emergency courses such as Pediatric Advanced Life Support (PALS),[7] Advanced Pediatric Life Support (APLS),[8] the Neonatal Resuscitation Program (NRP),[9] and the Emergency Nursing Pediatric Course (ENPC).[10]
- Improvements in pediatric education for EMS providers and the Pediatric Education for Prehospital Professionals (PEPP) program.[11]
- Many available resources covering school and child care emergencies[12,13] (see additional publications at http://bolivia.hrsa.gov/emsc and www.aap.org and courses at www.nasn.org).
- Publication of the Institute of Medicine 1993[14] and 2006[3] reports on pediatric emergency care.
- Development of models and educational materials on access to pediatric emergency medical care through the Emergency Medical Services for Children (EMSC) program of the Health Resources and Services Administration's Maternal and Child Health Bureau (see http://bolivia.hrsa.gov/emsc).[15]
- Publication of new manuals and texts that provide education and information about access to pediatric emergency care.[16]
- Publication of statements and guidelines for pediatric facility categorization, emergency centers, office preparedness, urgent care centers, and prehospital and interfacility transport[17–20] (including a policy statement currently in development from the AAP on preparation of the offices of pediatricians and pediatric primary care providers).
- Institutional adoption of pediatric facility standards, such as Emergency Departments Approved for Pediatrics [EDAP], through legislation or voluntary participation.[21]
- Development of model legislation for emergency care for children.
- Formation of the Pediatric Emergency Care Applied Research Network (PECARN) as a means to promote evidence-based approaches to care.[21]

Despite this progress in access to emergency care, more advances are needed.

RECOMMENDATIONS

The AAP recommends that every child in need have access to quality pediatric emergency medical care. Efforts must be made at local, state, and federal levels to:

1. Improve prompt and appropriate access to pediatric emergency medical care for all children regardless of socioeconomic status, ethnic origin, immigration status, type of insurance, location, or health status.
2. Increase public, professional, and government awareness about the magnitude of the problem of access to pediatric emergency medical care for children.
3. Fund, support, and promote the further development and improvement of EMS for children at federal, state, and local levels.
4. Improve awareness, dissemination, and use of the large body of resources available through the Health Resources and Services Administration's Maternal and Child Health Bureau's EMSC program and provide ongoing funding support for future resource development, education, research, and outcomes evaluation by the EMSC program, as recommended in the 2006 Institute of Medicine report.[3]
5. Improve optimal emergency care for children throughout every aspect of the EMSC continuum, from injury prevention to tertiary-level pediatric emergency and critical care to rehabilitation, and ultimately coordinate emergency care through the medical home.
6. Promote the development of evidence-based guidelines and other strategies, such as medication dosing guidelines, to improve care consistency and quality and to reduce errors in the emergency care of children.
7. Fund, support, and further develop research efforts directed at all aspects of pediatric emergency care to provide the foundation for evidence-based standards for efficacious and safe patient care.
8. Encourage the implementation of enhanced (emergency-access) 911 systems and wireless 911 services for cellular phones.
9. Improve collaboration between schools, child care facilities, mental health professionals, medical homes, and local EMS to facilitate easy access into the EMS system.
10. Encourage collaborative efforts by emergency care physicians and primary care physicians to identify a medical home for every child. If a medical home is not identified, the ED should initiate the process of locating a medical home for follow-up and ongoing care after discharge.
11. Encourage the use of the emergency information form (EIF) published by the AAP and American College of Emergency Physicians (http://aappolicy.aappublications.org/cgi/content/full/pediatrics;104/4/e53) for children with special health care needs.
12. Encourage all EDs to establish transfer agreements with facilities with higher levels of pediatric care to ensure timely access to pediatric emergency and subspecialty tertiary care for critically ill and injured children.
13. Encourage state and local EMS system and ED preparedness for pediatric emergencies and care of children in disasters.
14. Encourage the availability of existing pediatric medical subspecialists, pediatric surgical specialists, and mental health professionals who have special skills and expertise that are required for comprehensive and optimal care of critically ill and injured children.
15. For pediatric surgical specialists and pediatric medical subspecialists who are in short supply, encourage the expansion of training programs to ensure the future availability of these professionals necessary to provide specialized pediatric care.
16. Support and facilitate the practice of telemedicine to optimize the delivery of care for services that can be delivered via telemedicine.
17. Encourage managed care organizations to accept the prudent-layperson definition of an emergency and to provide reimbursement for services mandated by the Emergency Medical Treatment and Active Labor Act (42 USC §1395dd).
18. Payers should cover the expense of language-translation services required to provide emergency care.

The AAP membership and leadership, as advocates for children, can and should make a strong commitment to assist pediatricians and families in making decisions about seeking timely and appropriate emergency care.

Training Guidelines for Pediatric Cardiology Fellowship Programs

Thomas P. Graham, Jr, MD, FACC, FAHA, FAAP, *Chair*; and Robert H. Beekman, III, MD, FACC, FAHA, FAAP, *Co-Chair*

INTRODUCTION

Pediatric cardiology is a complex, multifaceted specialty composed of diverse clinical and academic subspecialty areas. It is characterized by rapid growth of subspecialty areas and swift incorporation of new information from the clinical and laboratory sciences. It is important, therefore, to define the fellowship training required to launch a successful career in pediatric cardiology. The following document represents the first broad-based effort to do so.

In 2000, the Society of Pediatric Cardiology Training Program Directors (SPCTPD) embarked on the process of defining fellowship training guidelines. The process itself was broad-based and inclusive. All pediatric cardiology training program directors were invited to nominate members to participate in the training guidelines task forces; in turn, each task force was comprised of all nominated members who agreed to participate. Therefore, all training programs were provided an opportunity to actively participate.

In 2002, the American College of Cardiology (ACC) approved and published the Revised Recommendations in Adult Cardiovascular Medicine Core Cardiol-

* AHA CVDY representative

† AAP representative

‡ Former task force member during writing effort.

This document was approved by the American College of Cardiology Foundation Board of Trustees in June 2005, by the American Heart Association Science Advisory and Coordinating Committee in July 2005, and by the American Academy of Pediatrics Board in July 2005.

When citing this document, the American Academy of Pediatrics would appreciate the following citation format: Beekman RH III, Graham TP, et al. ACCF/AHA/AAP recommendations for training in pediatric cardiology: a report of the American College of Cardiology Foundation/American Heart Association/American College of Physicians Task Force on Clinical Competence (ACC/AHA/AAP Committee on Pediatric Cardiology). *Pediatrics*. 2005;116:1256–1278.

ogy Training.[1] As the SPCTPD was concluding its training guideline development, plans were formalized to use a similar process through the ACC Pediatric Cardiology/Congenital Heart Disease Committee and the ACC Training Program Directors Committee. Accordingly, a steering committee was developed with original authors of the Pediatric Cardiology Training Guidelines to form a liaison with the ACC, the American Heart Association (AHA), and the Section on Pediatric Cardiology and Cardiac Surgery of the American Academy of Pediatrics (AAP) to agree on the final guidelines and to publish them widely.

These guidelines are written with the planned goal of serving as a practical resource for directors of pediatric cardiology training programs. We also hope that this document will prove useful to the Residency Review Committee (RRC) for pediatric training programs in the revision of requirements for the accreditation of pediatric cardiology programs. The general requirements, clinical competencies, and oversight for fellows in pediatric cardiology would remain the same as outlined by the Accreditation Council for Graduate Medical Education (ACGME).

GENERAL CONSIDERATIONS

The guidelines proposed in this document address overall recommendations for training in pediatric cardiology and important subspecialties within the field of pediatric cardiology. Although we understand that the pediatric RRC sets minimum standards for accreditation of fellowship programs, this document endeavors to define a more comprehensive set of guidelines for pediatric cardiology fellowship training. Fellowship training guidelines are presented for: general pediatric cardiology (including inpatient care and consultations); echocardiography and noninvasive imaging; electrophysiology; cardiac catheterization and intervention; cardiac intensive care; adult congenital heart disease; and research participation. Each section other than general pediatric cardiology specifies "core" and "advanced" training experiences. *Core* recommendations are intended to be common training experiences for all pediatric cardiology trainees regardless of long-term career goals. *Advanced* recommendations are additional training experiences for trainees intending to develop a clinical or academic area of special competence. All guidelines are recommended experiences, and not absolute mandates, as it is recognized that each training program has unique strengths and that clinical and academic variation across training programs provides important diversity for the specialty.

Table 1 summarizes the approximate time commitment (in months) recommended for core training in the task force reports that follow. Variations in these time commitments should be allowed, as pediatric cardiology programs vary widely in size, organization, and emphasis. For example, in some programs, fellows may get considerable cardiac intensive care unit training during their general inpatient experiences and not require a two- to four-month standalone rotation. Thus, the training guidelines must provide programs with flexibility to address individual trainee clinical and/or research training needs during a core fellowship of 36 months' duration.

TABLE 1. Core Training Recommendations

Experience	Time Commitment (in months)
General experience (inpatient)	3–6
Echocardiography/imaging	4–6
Cardiac catheterization	3–4 (estimate*)
Electrophysiology	2–3
Cardiac intensive care	2–4
Adult congenital heart disease	0–2 (estimate*)
Research	12–18
Total	36

* Task Force identified experience-based recommendations. See individual section for numbers.

The training program must possess the faculty expertise, patient volume, and inpatient/outpatient facilities to provide meaningful trainee experiences as outlined in this document. All faculty should be board certified or possess suitable equivalent qualifications. Recommendations for trainee and faculty evaluation are those outlined in the "general and special requirements" as published by the ACGME, and training should take place within a program that is accredited by the ACGME.

A comment about trainee research participation is appropriate. The field of pediatric cardiology is absolutely dependent upon research (basic and clinical) for meaningful progress. There is a critical need for the development of physician-scientists in our specialty to assure such future progress. Therefore, it is key that training programs begin to prepare trainees for a successful investigative career. Such preliminary research training will in most instances require 18 months or more. The balancing of clinical and research training will continue to be a major issue for training programs. It is highly probable that trainees who want to pursue a physician-scientist career will require at least four years of fellowship to begin the academic process and to finish training in the clinical areas. The authors are in complete agreement with the newly published American Board of Pediatrics (ABP) Training Requirements for subspecialty certification concerning scholarly activity, meaningful accomplishments in research, scholarship oversight, and differing pathways to train physician-scientists.

APPENDIX

The authors of this section declare they have no relationships with industry pertinent to this topic.

Task Force 1: General Experiences and Training

Hugh D. Allen, MD, FACC, FAHA, FAAP, *Chair*; J. Timothy Bricker, MD, FACC, FAAP; Michael D. Freed, MD, FACC, FAHA, FAAP; Roger A. Hurwitz, MD, FACC, FAAP; Tim C. McQuinn, MD, FAAP; Richard M. Schieken, MD, FACC, FAHA, FAAP; William B. Strong, MD, FACC, FAAP; and Kenneth G. Zahka, MD, FACC, FAAP

INTRODUCTION

The goals of pediatric cardiology training include acquiring the cognitive and procedural expertise required to provide high-quality care to children with cardiovascular disease, acquiring the academic skills to make meaningful scholarly contributions to the specialty, and, importantly, to develop the capacity for ongoing self-education beyond the years of formal training.

The general training of pediatric cardiology fellows builds on the general clinical and academic skills acquired during residency training. The pediatric cardiology fellow should be given broad exposure to clinical activities in pediatric cardiology inpatient and outpatient care, pediatric cardiology inpatient and outpatient consultations, and in preventive cardiology. The academic skills of formal presentation, small-group teaching, literature review, data analysis, and study design are also components of the general training guidelines.

CLINICAL TRAINING

A fundamental goal of clinical training is to acquire bedside diagnostic skill and the ability to provide high-qualilty consultative inpatient and outpatient pediatric cardiology care. The core skills of history-taking and physical examination are the only means for correctly initiating diagnostic and management options appropriate to the individual patient, and these must be heavily stressed at all points of patient contact. Pediatric cardiology fellows should be observed by faculty while performing key portions of the history and physical examination, and to also have the opportunity to observe faculty perform history-taking and physical examination, so that meaningful discussion of useful strategies and techniques may develop. Consultation services, general inpatient wards, and outpatient clinics all provide excellent opportunities for such interaction.

The pediatric cardiology fellow must have the opportunity to provide not only inpatient and outpatient consultation services but also direct patient care in both inpatient and outpatient settings. There must be a continuity of care in the outpatient clinic so that fellows can begin to appreciate the course of pediatric cardiac disease over time and its cumulative impact on individual patients and their families. The combined time commitment of the general inpatient and inpatient consultation services should be no less than three months. The continuity outpatient clinic should begin early in fellowship and continue throughout training, preferably on a biweekly basis. Both inpatient and outpatient experiences should include exposure to the management of the adult patient with congenital heart disease.

There are many ways for general inpatient and outpatient practices to be organized. In the delivery of high-level inpatient and outpatient care the pediatric cardiologist must demonstrate effective team leadership, accurate and efficient medical record keeping, sensitivity to medical ethical issues, an ability to communicate with and support patients and their families through stressful decisions and experiences, and show strict compliance with federal regulatory statutes. The general inpatient and outpatient training environment for pediatric cardiology fellows must provide full opportunity for observation, acquisition, and application of these skills by the trainee.

During the course of inpatient and outpatient activities the pediatric cardiology fellow will become familiar with a core knowledge base, as outlined in Table 1, at a minimum.

DIDACTIC CONTENT

The Core Curriculum

The program should offer courses, seminars, workshops, and/or laboratory experiences to provide appropriate background in basic and fundamental disciplines related to the heart and cardiovascular system. A lecture series encompassing a core curriculum in clinical and basic science topics must be provided for pediatric cardiology fellows. It should be designed so that the spectrum of topics presented will be completed at least once in the three years of accredited fellowship training. Pediatric cardiology fellows should contribute formal presentations of selected topics in the core curriculum, both to strengthen their knowledge base and to develop formal presentation skills. General areas to be covered in the core curriculum include those listed in Table 1.

TABLE 1. Core Knowledge Base

Anatomy and physiology of congenital heart defects (e.g., tetralogy of Fallot, hypoplastic left heart syndrome, ventricular septal defect)
Cardiac, autonomic and noncardiac causes of syncope and near-syncope
Cardiac MRI/CT
Cardiac sequelae of chronic hepatic disease
Cardiac sequelae of chronic renal disease
Cardiac sequelae of HIV/AIDS
Cardiac sequelae of obstructive sleep apnea
Cardiac sequelae of oncologic therapy
Cardiomyopathy, heart failure, and transplantation in the pediatric patient
Cardiopulmonary bypass
Cardiovascular pharmacology
Cardiovascular physiology and anatomy
Cardiovascular sequelae and follow-up in Marfan, William, DiGeorge, Turner, and Noonan syndromes
Cardiovascular sequelae of pregnancy and the impact of congenital heart disease
Cardiovascular sequelae of rheumatologic disease
Cardiovascular sports medicine
Care of the single ventricle patient
Cellular electrophysiology (e.g., action potentials and ion channels)
Chest pain
Clinical electrophysiology (e.g., mechanisms of arrhythmias, pacemakers, ablative therapy)
Coagulation and anticoagulation
Diagnosis and management of arrhythmias
Diagnosis and management of elevated pulmonary vascular resistance
Diagnosis and management of intravascular/intracardiac thrombosis
Diagnosis and management of left-to-right shunt lesions
Diagnosis and management of patent ductus arteriosus in premature infants
Diagnosis and management of right to left shunt lesions
Diagnosis and management of valvular heart disease, including artificial heart valves
Diagnostic evaluation of heart murmurs
Differential diagnosis and management of cardiac tumors
Differential diagnosis and management of pericardial effusion and pericardial tamponade
Embryonic, fetal, and postnatal cardiovascular development
Endocarditis
Exercise testing
Fetal/neonatal/perinatal cardiovascular physiology
Genetics of cardiovascular diseases of childhood
Hyperlipidemia
Hypertension
Kawasaki disease
Medical ethics
Normal cardiovascular anatomy and physiology, including exercise physiology
Obesity
Pericarditis and pericardial effusions
Physics of echocardiography and Doppler analysis
Physiology and natural history of congenital heart disease
Population health
Preventive cardiology, including prevention of adult acquired heart disease
Quality assurance and process improvement methodology
Rationale, expectations, and methods of screening for congenital heart disease in neonates with trisomy of chromosome 21, 18, or 13
Rationale, expectations, and methods of screening for congenital heart disease infants of diabetic pregnancies
Rationale, expectations, and methods of screening for congenital heart disease in the presence of neonatal emergencies such as gastroschisis, omphalocele, congenital diaphragmatic hernia, or cardiorespiratory failure leading to extracorporeal membrane oxygenation
Rheumatic fever
Risk factors in childhood and adolescence
Segmental cardiac analysis
Statistics and study design

Additional Conferences

Preoperative conferences with the cardiovascular surgical service are essential. Journal clubs are a recommended element of an academic environment and provide an excellent venue for participatory evaluation of study design and data analysis. Quality assurance evaluation and morbidity/mortality conferences should be held periodically. Multidisciplinary clinical and research conferences are highly desirable; according to the strengths of the institution, contributors might include neonatology, cardiothoracic surgery, adult cardiology, cardiac pathology, physiology, pharmacology, pulmonology, intensive care, cardiac anesthesiology, cardiovascular radiology, clinical genetics, molecular genetics, tissue engineering, stem cell biology, or developmental biology. In all of these conferences, pediatric cardiology fellows should be provided with active roles appropriate to their level of knowledge and training.

TEACHING AND EVALUATION SKILLS

It is a fundamental responsibility in academic medicine that those with the most experience must teach. The pediatric cardiology fellow will often be the most clinically experienced house officer on a team of residents, interns, and/or medical students. The fellow in that setting should be expected to provide lectures/seminars to the team of house officers. The pediatric cardiology fellow should also be allowed the opportunity to practice clinical leadership, organizational skills, and impromptu educational activities as appropriate to his/her demonstrated level of knowledge and training. There should be occasion for observation and critique of these skills by the attending physician as well as demonstration of these skills to the fellow by the attending.

Pediatric cardiology fellows should develop formal evaluation of trainees and training skills during their fellowship. To do so, they should participate in feedback to residents, students, and cardiology attendings throughout their rotations regarding their own educational and technical progress and the progress of other team members. Accurate self-evaluation is the most valuable skill of all and should be nurtured in all phases of pediatric cardiology training.

APPENDIX

The authors of this section declare they have no relationships with industry pertinent to this topic.

Task Force 2: Pediatric Training Guidelines for Noninvasive Cardiac Imaging

Endorsed by the American Society of Echocardiography and the Society of Pediatric Echocardiography

Stephen P. Sanders, MD, FACC, *Chair*; Steven D. Colan, MD, FACC; Timothy M. Cordes, MD, FACC, FAAP; Mary T. Donofrio, MD, FACC, FAAP; Gregory J. Ensing, MD, FACC; Tal Geva, MD, FACC; Thomas R. Kimball, MD, FACC, FAAP; David J. Sahn, MD, MACC, FAAP; Norman H. Silverman, MD, FACC, FAHA; Mark S. Sklansky, MD, FACC; and Paul M. Weinberg, MD, FACC, FAAP

INTRODUCTION

Noninvasive imaging, including echocardiography and magnetic resonance imaging (MRI), is a primary means for elucidating the anatomy and physiology of childhood heart disease. Competence in performance and interpretation of echocardiography and MRI is now essential to the practice of pediatric cardiology. Depending upon one's individual career goals, varying levels of expertise may be expected to be achieved during fellowship training. This document defines the levels of knowledge and expertise that pediatric cardiology trainees should acquire in echocardiography and MRI during training, and it offers guidelines for achieving these levels of competence.

Training guidelines have been previously published for pediatric echocardiography,[1] fetal echocardiography,[2] and pediatric transesophageal echocardiography.[3] Those documents were reviewed and considered during preparation of these guidelines. The guidelines presented here differ in some instances from previous recommendations because this task force recognizes that training programs have changed significantly over the decade since the last guidelines were promulgated.

PEDIATRIC ECHOCARDIOGRAPHY

Echocardiography, as used in this document, includes two-dimensional imaging of the heart and related structures, M-mode echocardiography for assessment of chamber size and function, color M-mode and Doppler tissue and flow mapping, pulsed and continuous-wave spectral Doppler flow analysis, and other variations of these basic modalities used to assess the structure and function of the heart and related organs, including new technologies such as three-dimensional echocardiography as they become available.

Facilities and Environment

The pediatric echocardiography laboratory should serve a hospital with inpatient and outpatient facilities, neonatal and pediatric intensive care units, a pediatric cardiac catheterization/interventional laboratory, and an active pediatric cardiac surgical program. The pediatric echocardiography laboratory should be under the supervision of a full-time pediatric cardiologist-echocardiographer qualified to direct a laboratory, and whose primary responsibility is supervision of the laboratory. The laboratory must perform a sufficient number of pediatric transthoracic, pediatric transesophageal, and fetal echocardiograms[1,4] each year to allow trainees sufficient exposure to both normal and abnormal examinations.

LEVELS OF EXPERTISE

Training goals defined here are to enable trainees to achieve one of two levels of expertise in echocardiography as appropriate for career goals.

Core

- Understanding of the general physical properties of ultrasound and clinical ultrasound technology.
- Ability to perform and interpret transthoracic echocardiography in normal infants, children and adolescents, and in those with childhood heart disease, with consultation as needed.
- Basic introduction to the principles of performing and interpreting transesophageal and fetal echocardiograms. Physicians with *core* expertise only are not expected to perform transesophageal and fetal echocardiograms independently.

Advanced

- Special expertise in performance and interpretation of transthoracic echocardiography in all forms of congenital and acquired pediatric heart disease, including the adult with congenital heart disease, enabling the practitioner to function independently.
- Ability to perform and interpret transesophageal and fetal echocardiography independently.
- Ability to supervise training and performance of sonographers, fellows, and other physicians.

TRAINING GUIDELINES

Core training should be achieved by all pediatric cardiology fellows during core clinical training, typically during four to six months dedicated to echocardiography over the course of the standard three-year training program. This level of expertise is anticipated to be sufficient for those fellows who do not plan to pursue echocardiography as an area of subspecialization.

Advanced training requires an additional 9 to 12 months of training and may be achieved through a dedicated experience in pediatric echocardiography after completion of core pediatric echocardiography instruction. This level of training is appropriate for those physicians who intend to be dedicated pediatric echocardiographers.

TRAINING GOALS

Successful completion of each training level should result in competence in the following specific areas.

Core

- Understanding of the physical properties of ultrasound.
- Proper, safe, and facile use of ultrasound instruments.
- Knowledge of the limitations of echocardiography.
- Recognition of cardiac structures displayed by echocardiography and the correlation between echocardiographic images and cardiac anatomy.
- Interpretation of Doppler flow information and deduction of cardiovascular physiology.
- Performance and interpretation of complete transthoracic two-dimensional and M-mode echocardiograms, Doppler color-flow mapping, and pulsed- and continuous-wave spectral Doppler flow analysis in normal pediatric patients and in those with childhood heart disease, with consultation as needed.
- Assessment of systolic, diastolic, and regional myocardial function in normal pediatric patients and those with childhood heart disease, with consultation as needed.
- Ability to review critically published clinical research in echocardiography.

Advanced

In addition to *core* competencies, other goals include:

- Independent performance and interpretation of complete transthoracic two-dimensional and M-mode echocardiograms, Doppler color-flow mapping, and pulsed- and continuous-wave spectral Doppler flow analysis in normal pediatric patients and in those with childhood heart disease.
- Independent assessment of systolic, diastolic and regional myocardial function in normal pediatric patients and in those with congenital or acquired heart disease, to include stress echocardiographic studies.
- Special expertise in the performance and interpretation of pediatric transthoracic, pediatric transesophageal, and fetal echocardiography.
- Training of sonographers and junior pediatric cardiology trainees.
- Participation in basic or clinical research in echocardiography, including presenting original data at one or more scientific meetings.

TRAINING METHODS

Each level of training may be achieved by the methods outlined in the following text or by comparable alternative methods. A summary of the recommended minimum number of procedures is found in Table 1.

TABLE 1. Echocardiography Training—Recommended Minimum Procedure Numbers

Core training	
TTE perform and interpret (≤1 year of age)	150 (50)
TTE review	150
Advanced training*	
TTE perform and interpret (≤1 year of age)	200 (50)
TTE review	200
TEE perform and interpret	50
Fetal echocardiogram	50

* Numbers are in addition to those obtained during core training.
TEE = transesophageal echocardiogram; TTE = transthoracic echocardiogram.

Core

Each trainee should perform and interpret at least 150 pediatric echocardiograms, including at least 50 in patients one year of age or younger, under the supervision of the laboratory director or other qualified staff pediatric cardiologist-echocardiographer(s). Each trainee should also review at least 150 additional pediatric echocardiograms.

In addition, the laboratory director or other staff pediatric cardiologist-echocardiographer(s) should conduct regular laboratory conferences with the trainee(s) to present illustrative cases and to teach proper interpretation and the limitations of echocardiography. Pathological specimens, models, or photographs for echocardiographic-anatomic correlation are excellent teaching aids that should be incorporated wherever possible.

Integration of echocardiography into the clinical practice of pediatric cardiology should be demonstrated on inpatient and outpatient rotations and at medical-surgical management conferences.

Research training for pediatric cardiology trainees should include active participation in reviews of scientific journal articles that pertain to echocardiography.

Advanced

Each *advanced*-level trainee should perform and interpret at least 200 additional pediatric transthoracic echocardiograms and review, or perform and interpret, another 200 pediatric echocardiograms. As with core training, at least 50 of these should be done in infants one year of age or younger. Each trainee should perform a significant number of echocardiograms independently (one-third to one-half of the exams), with subsequent review and critique of the examination by the responsible staff pediatric cardiologist-echocardiographer. Teaching methods outlined in the previous text should be continued here.

Each *advanced*-level trainee should perform and interpret at least 50 pediatric transesophageal echocardiograms, including manipulation of the transducer and registration of images, under direct supervision by a dedicated pediatric cardiologist-echocardiographer. The trainee should perform intubation of the esophagus in at least 20 patients under the direct supervision of a pediatric cardiologist-echocardiographer or anesthesiologist experienced in the procedure. An ideal environment for learning pediatric transesophageal echocardiography is the operating suite during performance of intraoperative

examinations, but the training experience should not be limited to this venue and should include the intensive care unit, cardiac catheterization suite, and outpatient examinations.

Each *advanced* trainee should perform and/or review at least 50 fetal echocardiograms. The trainee must master the fundamental skills of determining fetal position, situs, cardiac anatomy, and cardiac rhythm under the supervision of a dedicated pediatric cardiologist-echocardiographer. The trainee should observe and participate in the discussion of the findings with the parents by the staff echocardiographer responsible for the examination. As the trainee's experience progresses, a significant proportion (30% to 50%) of studies should be performed independently, including cases with normal and abnormal cardiac anatomy and rhythm, with supervision by a dedicated pediatric cardiologist-echocardiographer. Each trainee should understand how to recognize and approach fetal heart failure, and he or she should understand the association of fetal heart disease with extracardiac structural abnormalities, syndromes, and chromosomal abnormalities.

Research training for pediatric cardiology trainees should include, at a minimum, active participation in reviews of scientific journal articles that pertain to echocardiography. In addition, participation in basic or clinical research in echocardiography should be encouraged.

Each *advanced*-level trainee should be given responsibility for participating in the training of sonographers and junior pediatric cardiology fellows, initially with supervision of the laboratory director and then independently and also presenting echocardiography-related teaching conferences and formal didactic lectures.

EVALUATION

The laboratory director, in consultation with the teaching staff, should evaluate each trainee in writing on a regular basis. Trainees should maintain a log of all echocardiograms performed and reviewed, including the age of the patient and the diagnosis. The log should be reviewed regularly by both the laboratory director and the training program director to ensure that each trainee is obtaining adequate and balanced experience.

The evaluation should be reviewed with each trainee and a written copy provided. If a trainee does not appear to be progressing adequately during the rotation, a meeting should be scheduled as soon as possible to inform the trainee and to discuss potential remedial measures. The evaluation should be based on achievement of the expected levels of competence in the areas outlined in the previous text.

Direct observation of the trainee during performance of echocardiograms provides information about imaging skills and understanding of the ultrasound instruments. Conferences in which echocardiograms are presented provide an opportunity to assess skills in interpretation of images and Doppler recordings. The trainees' understanding of research design and methods and ability to review research can be critically evaluated during journal club meetings or other venues for medical literature review. Teaching skills and effectiveness can be evaluated by direct observation and from evaluations by sonographers and more junior trainees and by performance at teaching conferences prepared and delivered by trainees.

Pediatric Cardiovascular Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) as used in this document includes anatomic and functional cardiovascular MRI in congenital and acquired pediatric heart disease as well as in the adult with congenital heart disease. At present, there are no specific guidelines for training or credentialing in pediatric cardiovascular MRI. It is likely that the training guidelines for pediatric cardiovascular MRI proposed here will require amendment as the field evolves. These guidelines must be considered as goals and should not be considered as requirements.

LEVELS OF EXPERTISE

Trainees may achieve one of two levels of expertise in pediatric cardiovascular MRI as appropriate for career goals.

Core

- Familiarity with the general physical principles upon which MRI is based.
- Ability to view and understand MR images in normal infants, children, and adolescents and those with childhood heart disease.
- Introduction to commonly used imaging protocols and MRI terminology.

Advanced

- Thorough understanding of clinical MRI instruments and the imaging protocols used for cardiovascular imaging and physiological analysis (e.g., quantitative analysis of ventricular function and blood flow).
- Ability to independently perform and interpret all types of MRI in childhood heart disease and congenital heart disease at all ages.
- Ability to supervise training of technologists, fellows, and other physicians.

TRAINING GUIDELINES

Training in pediatric cardiovascular MRI should occur within a pediatric cardiology fellowship program and/or a pediatric radiology training program accredited by the Accreditation Council for Graduate Medical Education (ACGME). The MR laboratory should serve a hospital with both inpatient and outpatient facilities, neonatal and pediatric intensive care units, a pediatric cardiac catheterization/interventional laboratory, and an active pediatric cardiac surgical program. The MRI laboratory should be under the supervision of a full-time cardiologist and/or radiologist qualified in cardiovascular MRI, and it must perform a sufficient number of annual examinations to allow each trainee sufficient exposure to both normal and abnormal examinations.

Core training should be achieved by all pediatric cardiology fellows during the core clinical years of the program. This level of expertise may be sufficient for those fellows who plan to practice clinical pediatric cardiology with access to a pediatric cardiologist or radiologist with special expertise in pediatric cardiovascular MRI.

Advanced training requires a minimum of six months of instruction in addition to *core* training. This level of training is appropriate for those physicians who intend to have special expertise in pediatric cardiovascular MRI and is recommended for directors of pediatric cardiovascular MRI laboratories.

TRAINING GOALS

Successful completion of each training level should result in competence in the following specific areas.

Core

- Physical principles of MRI and physiologic analysis.
- Limitations of, and contraindications to, MRI.
- Recognition of cardiac structures displayed by MRI and the correlation between MR images and cardiac anatomy.
- Basic familiarity with commonly used imaging protocols, their clinical uses, and MRI terminology.
- Critical review of published clinical research in pediatric cardiovascular MRI.

Advanced

- Thorough understanding of MRI physics, instrumentation, nomenclature, and safety.
- Special expertise in the performance and interpretation of pediatric cardiovascular MRI, including all commonly used imaging and flow analysis protocols.
- Training of technologists and junior pediatric cardiology trainees.
- Management of and quality assurance for the MRI laboratory.
- Basic or clinical research in pediatric cardiovascular MRI, including presenting original data at one or more scientific meetings.

TRAINING METHODS

Each level of training may be achieved by the methods outlined in the following text or by comparable alternative methods.

Core

Pediatric cardiology trainees should gain exposure to cardiovascular MRI through active review of scientific journal articles that pertain to pediatric cardiovascular MRI, discussion with cardiologists and radiologists who perform cardiovascular MRI, and, if possible, review of cardiovascular MRI examinations.

Advanced

During a fellowship in pediatric cardiovascular MRI, each trainee should perform and/or interpret at least 100 cardiovascular MRI examinations in patients with congenital or acquired childhood heart disease, including adult patients with congenital heart disease. As the trainee's experience progresses, an increasing proportion of these examinations should be performed independently, with review and critique by the laboratory director.

Research training should include continued critical review of the pediatric cardiovascular MRI literature and an opportunity to perform basic or clinical research leading to publication or presentation of scientific data.

Each trainee should be given responsibility for participating in the training of technologists and junior pediatric cardiology fellows, initially with supervision of the laboratory director and subsequently independently. In addition, each trainee should have opportunities to observe and participate in the management of the laboratory, especially quality improvement initiatives.

EVALUATION

The laboratory director, in consultation with the teaching staff, should evaluate each trainee in writing. The evaluation should be reviewed with each trainee and a written copy provided. The trainee should maintain a log of all examinations performed and reviewed, including the age of the patient, diagnosis, and role of the trainee in the examination.

APPENDIX

The authors of this section declare they have no relationships with industry pertinent to this topic.

Task Force 3: Training Guidelines for Pediatric Cardiac Catheterization and Interventional Cardiology

Endorsed by the Society for Cardiovascular Angiography and Interventions

Robert H. Beekman, III, MD, FACC, FAAP, *Chair*;
William E. Hellenbrand, MD, FACC; Thomas R. Lloyd, MD, FACC;
James E. Lock, MD, FACC, FAAP; Charles E. Mullins, MD, FACC, FAHA, FAAP;
Jonathan J. Rome, MD, FACC; and David F. Teitel, MD

INTRODUCTION

The purpose of this document is to recommend minimum training experiences in cardiac catheterization for clinical fellows in pediatric cardiology training programs. Training guidelines in cardiac catheterization are well-established in adult cardiovascular medicine,[1,2] and they have been considered recently in pediatric cardiology as well.[3,4]

Pediatric cardiac catheterization is a unique specialty encompassing a wide range of diagnostic and therapeutic techniques applied to a diverse group of congenital and acquired cardiovascular disorders. A physician who performs a pediatric cardiac catheterization must possess the technical skills and clinical judgment to safely and accurately perform a thorough diagnostic cardiac catheterization and angiographic study. Furthermore, an interventional pediatric cardiologist must also assess the indications for a catheter intervention, including the risks of performing or not performing the procedure (i.e., requires knowledge of the natural history of the defect), and must skillfully perform the appropriate catheter intervention. It is appropriate, therefore, to delineate minimal training requirements in cardiac catheterization for pediatric cardiology trainees.

There are no studies relating training experiences to subsequent clinical skill in pediatric cardiac catheterization. Therefore, the recommendations in Task Force 3 represent the opinions of the authors. To help guide this process, all Accreditation Council for Graduate Medical Education (ACGME)-accredited pediatric cardiology training programs were surveyed in 2001 to inquire about current practices and opinions regarding fellow training in pediatric cardiac catheterization and intervention. Thirty-two programs responded. The responses represented the opinions of fellowship directors (n = 21), catheterization laboratory directors (n = 15), and division directors (n = 13) (in some programs one individual holds more than one position). This document draws on this Training Program Survey to help define training guidelines in this specialty.

FACILITIES AND ENVIRONMENT

Training in cardiac catheterization should occur within a pediatric cardiology fellowship program that is accredited by the ACGME. The cardiac catheterization laboratory should serve a hospital with inpatient and outpatient facilities, neonatal and pediatric intensive care units, and an active pediatric cardiac surgical program. The pediatric cardiac catheterization laboratory should be under the supervision of a full-time pediatric cardiologist, whose primary responsibility is supervision of the laboratory. The laboratory must perform a sufficient number of cardiac catheterizations and interventional procedures to provide each trainee with an acceptable experience.

The cardiac catheterization program must have a regular teaching conference in which diagnostic data (hemodynamic and angiographic) and therapeutic outcomes are formally discussed. In addition, each program that provides *advanced* interventional training must have a regular morbidity and mortality conference in which all adverse outcomes of catheter interventions are systematically reviewed. Participants in this conference should include cardiology faculty, clinical fellows, and preferably pediatric cardiothoracic surgeons and cardiac anesthesiologists. Active participation in these conferences by all clinical cardiology fellows, particularly those at *advanced* levels, is essential to clinical training that emphasizes quality outcomes.

LEVELS OF EXPERTISE

In this report we discuss *core* training for all fellows, and *advanced* training for fellows desiring special expertise in cardiac catheterization and interventional cardiology. The *core* training is recommended for all clinical fellows during their core clinical experience. It is intended to be sufficient for fellows who do not plan a career in interventional pediatric cardiology, but who may be required to perform simple diagnostic studies and to interpret catheterization and angiographic data in their clinical practices. (Cardiologists who provide "diagnostic only" catheterization services must coordinate the care closely with interventional cardiologists and surgeons at referral centers to minimize the need for repeat catheterization procedures.) The *advanced* training provides expertise in both diagnostic and interventional catheterization procedures, and it is intended to qualify a fellow to embark upon a career in cardiac catheterization and intervention.

Core Training: Goals and Methods

Core training in cardiac catheterization refers to the training experiences recommended for all clinical cardiology fellows, regardless of specific career goals. In the Training Program Survey, there was unanimous support for core training in cardiac catheterization for all clinical fellows. The goal of such

TABLE 1. Recommended Body of Knowledge Covered During Core Training

- Indications for and risks of cardiac catheterization and angiography
- Indications for and risks of therapeutic catheter procedures
- Interpretation of pressure waveforms
- Interpretation of O_2 saturation data
- Fick principle and shunt calculations
- Vascular resistance calculations
- Cardiac angiography: basic techniques/angles/interpretation
- Radiation safety

core training is to introduce fellows to the field of cardiac catheterization and the risks and benefits of catheter-based procedures, to teach basic diagnostic catheterization skills, and to provide a basic knowledge of hemodynamics, angiography, and radiation safety. A core curriculum in pediatric cardiac catheterization should include the topics and experiences outlined in Table 1.

The core training should involve each clinical fellow in a minimum of 100 cardiac catheterizations, at least 20 of which include an interventional component (Table 2). These experiences should familiarize the fellow to the indications for cardiac catheterization and intervention, femoral vessel access techniques, basic catheter manipulations, hemodynamic measurements and calculations, and angiographic interpretations. Participation by the fellow as either the primary operator or the primary assistant is satisfactory involvement. A log book should be maintained by the fellow to document the experience and outcomes of catheterization.

Advanced Training: Goals and Methods

Advanced training in cardiac catheterization refers to the training recommended for pediatric cardiology fellows who intend to pursue a career in pediatric cardiac catheterization and interventional cardiology. Therefore, the advanced training goal is to prepare the trainee to independently perform diagnostic and therapeutic catheter procedures with excellent outcomes. Prerequisite to these advanced training experiences is the successful completion of core training. Advanced training should involve each fellow in a minimum of 200 catheterization procedures, at least 100 of which are interventional. The minimum recommended numbers of procedures are specified in Table 3 (and are in addition to those obtained during the core training). The procedure types and numbers in Table 3 are recommended guidelines, not mandates, as it is understood that some qualified programs may not perform every procedure. Participation by the fellow as either the primary operator or the primary assistant is satisfactory involvement.

TABLE 2. Core Training—Recommended Minimum Case Numbers*

Total cardiac catheterizations	100
Interventional procedures	20
Type of intervention	
Balloon septostomy†	5
Other	Not specified

* Numbers represent the median response from the Training Program Survey.
† Fluoroscopic orechocardiographic guidance.

TABLE 3. Advanced Training—Recommended Minimum Case Numbers*

Total cardiac catheterizations	200
Interventional procedures	100
Type of intervention	
Balloon septostomy†	5
Transseptal puncture	10
Pulmonary valve dilation	10 (5 newborns)
Aortic valve dilation	10 (5 newborns)
Pulmonary artery dilation	10
Pulmonary artery stent	10
Coarctation dilation	10
Coarctation stent	5
Collateral occlusion	10
Ductus arteriosus occlusion	10
Atrial septal defect occlusion	10

* Numbers represent the median response from the Training Program Survey.
† Fluoroscopic or echocardiographic guidance.

A minimum number of procedures is necessary, but this is not sufficient to prepare a trainee for a career in cardiac catheterization and intervention. Also important to a successful career, and perhaps more crucial, are technical facility and good clinical judgment. During advanced training the trainee must acquire sophisticated skills in complex catheter manipulations, wire and sheath exchanges, device implantation techniques, and retrievals. Furthermore, good clinical judgment regarding the indications for and against intervention require a thorough knowledge of the natural history of congenital cardiac defects,[5,6] and of the medical, catheter, and surgical options available for treatment. It is the responsibility of the training program director to assure that each advanced trainee graduates with the technical skills, clinical judgment, and cognitive knowledge to pursue an independent career in pediatric cardiac catheterization.

A log book is to be maintained by the advanced fellow to document the nature and outcome of each diagnostic and interventional procedure he or she participated in throughout training. The fellow should also participate actively in regular cardiac catheterization teaching and morbidity conferences where outcomes and complications of interventional procedures are thoroughly discussed (see the previous text). Finally, it is strongly recommended that the advanced fellow participate in at least one clinical research project related to cardiac catheterization and/or interventional cardiology.

Advanced training in pediatric cardiac catheterization requires a dedicated 12-month experience, at a minimum. Some fellowship programs may be able to offer the recommended advanced training experiences during a 3- or 3.5-year training program. Nevertheless, even in those programs additional training provides the fellow an opportunity to enhance technical skills and clinical judgment in this very complex specialty. The authors of this document believe that the highest-quality training is obtained during a fourth-year experience. Three or 3.5 years of training may be satisfactory for some individuals if all advanced training guidelines are achieved, and partic-

Task Force 4: Recommendations for Training Guidelines in Pediatric Cardiac Electrophysiology

Endorsed by the Heart Rhythm Society

Victoria L. Vetter, MD, FACC, FAHA, *Chair*; Michael J. Silka, MD, FACC; George F. Van Hare, MD, FACC, FAAP; and Edward P. Walsh, MD, FACC

INTRODUCTION

The field of clinical cardiac electrophysiology has rapidly expanded over the past 30 years. Advances in the diagnosis and treatment of pediatric cardiac rhythm disorders, and the increasing trend in medicine in general to develop criteria or guidelines for competence and training in specific fields, have led to the need to develop guidelines for training in pediatric clinical cardiac electrophysiology (CCEP).

The American College of Cardiology (ACC), American Heart Association (AHA), and Heart Rhythm Society (formerly NASPE) have addressed training guidelines in adult CCEP.[1–3] The extensive body of literature regarding adult CCEP training and basic electrophysiology (EP) knowledge provides an important background and should be applied in an appropriately modified form to pediatric CCEP training.[4–21] Recognizing the considerable differences in the pediatric and adult cardiology populations, guidelines that are unique to the pediatric and congenital heart disease population must be developed. Canadian recommendations for training in pediatric EP have been published.[22] It should be recognized that pediatric patients are unique, as recognized by the separate training programs and board certification for pediatricians and internists, and for adult and pediatric cardiologists. In addition, the pediatric electrophysiologist will have experience and expertise in groups unique to pediatric cardiac electrophysiology, including the fetus with in utero arrhythmias, the child with a structurally normal heart and supraventricular tachycardia, ventricular tachycardia, or other arrhythmias, the child with preoperative or postoperative arrhythmias after surgery for congenital heart disease, and the adult with congenital heart disease, both in the pre- and postoperative states. This unique group of adults with congenital heart disease is best served by those with a combined knowledge of congenital heart disease and age-specific disease processes, whether this be provided by a combination of pediatric and adult cardiologists or single individuals with broad training or dual training in pediatric and adult cardiology.

FACILITIES AND ENVIRONMENT

Training should be obtained in an Accreditation Council for Graduate Medical Education (ACGME)-accredited pediatric cardiology training program. Recommendations for catheter ablation facilities have been published.[2,9] Pediatric catheterization laboratory facilities should be available with the appropriate EP equipment to perform EP studies and catheter ablation. These facilities should ensure a safe, sterile, and effective environment for invasive EP studies and implantation of pacemakers and arrhythmia control devices. In many settings, the operating room can be used for the pacing/arrhythmia control devices. Although experience at outside institutions, including adult programs, may be valuable, no more than two to four months of the one-year advanced training should be spent at other institutions. In particular, added experience in pacemaker and implantable cardioverter-defibrillator (ICD) implantation, as well as in ventricular tachycardia studies, may be acquired at a certified adult CCEP program, provided that it is within the previously noted time frame.

At least one board-certified pediatric cardiologist with advanced CCEP skills should be identified as the director of the core and advanced Electrophysiology Training Program. Because there is currently no pediatric EP examination, consideration should be given for one pediatric EP faculty member to take the NASPExAM, or its successor examination. For advanced training of fellows, at least one faculty member should be skilled in the implantation of pacemakers and ICDs.

LEVELS OF EXPERTISE

In this report we discuss *core* training for all fellows and *advanced* training for fellows desiring special expertise in pediatric CCEP. The *core* training is recommended for all clinical fellows during their core clinical experience. It is intended to be sufficient for fellows who do not plan a career in EP. The *advanced* training provides expertise in both diagnostic and therapeutic EP and it is intended to qualify a fellow to embark upon a career in pediatric CCEP. Within the *advanced* level are two tracks related to expertise in pacemaker/ICD care: track 1 physicians prescribe and follow patients who require pacemaker/ICD care; track 2 physicians will also be skilled in device implantation.

Core Training: Goals and Methods

Core EP training is required of all trainees to be a competent pediatric cardiologist. The goal is to enable all trainees to be skilled in electrocardiographic (ECG) interpretation, including standard, ambulatory (Holter), exercise ECGs, and transtelephonic ECGs.

Additionally, the trainee should understand the indications for and the use of noninvasive diagnostic techniques including exercise testing, 24-h ambulatory and event monitors, and tilt table testing and should have a general understanding of their interpretation. All trainees should be able to properly interpret cardiac arrhythmias and manage arrhythmias in the acute care setting. There should be an understanding of the use of non-pharmacologic methods and pharmacologic agents to treat arrhythmias, including drug interactions and proarrhythmic potential. The trainee should understand the indications for the selection of patients for specialized electrophysiologic studies, including ablation. In addition, the trainee should obtain a basic understanding of the indications for, and the information obtained from, invasive EP studies. This should include an understanding of the use of information obtained from these testing modalities for the management of the patient's clinical condition. The trainee should have skills in the interpretation of basic EP information obtained from electrophysiology study (EPS).

Participation in at least 10 EPS cases including catheter placement and analysis of electrophysiologic tracings are needed to acquire these skills. The trainee should understand the evaluation of patients with syncope, palpitations, chest pain, and irregular heart rhythms. All trainees should understand the indications for pacemaker placement, know the differences in pacing modes, understand and be able to perform basic pacemaker interrogation, reprogram and troubleshoot pacemakers, recognizing basic malfunctions such as capture failure, sensing malfunctions, and battery end of service characteristics. Participation by the trainee in at least 20 pacemaker evaluations is recommended to develop these skills. The trainee should receive instruction in the insertion, management, and follow-up of temporary pacemakers, including measurement of pacing and sensing thresholds. He or she should understand the general indications for consideration of the use of arrhythmia control devices (ICDs and anti-tachycardia devices) and know when to refer these patients for more advanced EP evaluation. The trainee should understand the indications and techniques for elective and emergency cardioversion. Four elective direct current cardioversions are required.

The core training to obtain the previously described skills and knowledge should occur in the first three years of pediatric cardiology training and be equivalent to two to three months of concentrated study, but may be acquired throughout the three years as needed to obtain designated competence skills (Table 1).

Advanced Training (Year 4 ± Year 5): Goals and Methods

The goal of *advanced* training is to enable the pediatric electrophysiologist to perform, interpret, and train others to conduct and interpret specific procedures at a high skill level. Tables 2 and 3 describe the competence skills necessary for advanced-level training. The recommended minimum procedures are summarized in Table 4 for both core and advanced training.

Advanced-level skills involve understanding the evaluation and management of common arrhythmias, from the fetus to young adult. In addition, advanced understanding of complex arrhythmia management, especially in the postoperative period after repair of congenital heart defects and in special

TABLE 1. Core Competence Skills

- Interpretation of ECGs, Holters, exercise testing, and event monitors with arrhythmia recognition
- Recognition of developmental changes in cardiac rates and rhythm with age and of "normal" variants of rhythm
- Management of arrhythmias in the acute care setting, including uses of pharmacologic agents, cardioversion with esophageal or intracardiac pacing, and direct current cardioversion
- Management of common chronic arrhythmias such as infant supraventricular tachycardia
- Evaluation of the patient with documented arrhythmia, symptoms of arrhythmia (palpitations, increased or decreased heart rate, irregular heart rhythm), and syncope or presyncope
- Treatment of patients with all forms of syncope
- Evaluation of patients with long QT syndrome or family history of sudden death and management of these patients
- Knowledge of indications for use of noninvasive EP testing
- Knowledge of indications for invasive EP studies and general understanding of information obtained from EPS, including interpretation of basic EP information
- Knowledge of indications for catheter ablation, understanding of procedure and complications of procedure
- Knowledge of indications for pacing, anti-tachycardia device, and ICD placement
- Knowledge of pacing modes, basic pacemaker interrogation, reprogramming, and trouble-shooting for loss of capture, under or over sensing, battery end of life
- Temporary transvenous and transcutaneouspacing
- Evaluation of EP literature

TABLE 2. Advanced EP Clinical Competence Skills

Advanced competence skills include core basic skills plus:

- Management of all types of cardiac arrhythmias in all ages from the fetus to young adult
- Evaluation and management of patients with specific arrhythmia syndromes including long QT syndrome, Brugada syndrome, and right ventricular dysplasia
- Evaluation of patients with family history of sudden cardiac death
- Management of complex arrhythmias, especially in postoperative congenital heart disease patients
- Evaluation of patient with syncope including, when appropriate, performance of tilt table testing with appropriate interpretation and management of patient
- Performance of esophageal EPS
- Knowledge of the indications, risks, and benefits of EPS/catheter ablation
- Interpretation and use of EPS data
- Technical and cognitive skills to perform EPS/catheter ablation, using current mapping technology and techniques
- Advanced knowledge of selection of pacemaker type, programming, follow-up, and trouble-shooting
- Advanced knowledge of pacemakers and implantable cardioverter-defibrillators
- Intraoperative evaluation and programming of pacemakers and ICDs

TABLE 3. Advanced EP Research Competence Skills

- Evaluation of EP literature
- Development of clinical research skills
- Completions of EP project which results in an abstract and/or manuscript
- Grant submission is encouraged

groups such as long QT syndrome, Brugada syndrome, and right ventricular dysplasia, should be attained. Evaluation and management of the patient with all forms of syncope should be accomplished, including the performance of tilt table testing when appropriate. In those programs that employ tilt testing, participation in at least 10 procedures in a pediatric or adult laboratory is advisable. A thorough understanding of pathophysiology and therapy of syncope and tilt testing should be required of all trainees. Advanced-level trainees should develop the cognitive skills to evaluate the patient with a family history of sudden cardiac arrest or death. Skill and experience should be encouraged in pediatric EPS interpretation and use of the EP data to make management and therapeutic decisions. Experience with esophageal EPS should be obtained with participation in 10 procedures. The indications, risks, and benefits of these procedures should be known.

Advanced-level trainees will develop technical and cognitive skills and experience in the performance of invasive diagnostic and therapeutic CCEP. At least 75 diagnostic intracardiac EPS should be performed, of which at least 10 should be patients with ventricular tachycardia. At least 40 of these diagnostic procedures must be in patients who are 12 years of age or younger, and at least 10 should be in patients with repaired or palliated congenital heart disease. In addition, participation in at least 40 catheter ablation procedures is required. The diagnostic portion of a catheter ablation procedure may be used to satisfy the requirement for participation in 75 diagnostic procedures. Participation should include scrubbing for the case, catheter manipulation, analysis, review of tracings, and generation of a report.

Advanced understanding of pacemaker indications, optimal pacemaker choices, and follow-up of pacemaker patients should be obtained. The Heart Rhythm Society has recommended two tracks for those caring for pacemaker patients. Track 1 involves electrophysiologists who will be involved in prescribing and following pacemaker and ICD patients. Track 2 individuals prescribe, implant, and follow patients with pacemakers and ICDs. In both tracks, advanced understanding of pacemaker and ICD indications, optimal pacemaker choices, and evaluation or follow-up of 75 pacemaker/ICD patients should be obtained. In addition, attendance—including intraoperative testing of 35 pacemaker or ICD implants (20 new, 10 revisions, 5 ICDs)—is required. To implant pacemakers and ICDs, direct participation in a total of at least 50 pacemaker and device implants is required, of which a reasonable number should be complex devices including ICDs. As new technology develops, the number of device implants necessary to achieve competence may change. Participation should include scrubbing for the surgery, catheter manipulation, participation in intraoperative testing, and generation of a report. As the skills for implanting devices in smaller children are specific to pediatric EP, at least 15 of these implantation procedures should be in children less than 12 years of age. Also, experience with implantation in patients with repaired congenital heart disease is essential.

Advanced-level pediatric electrophysiologists should have all the skills noted in the previous text, but they may or may not perform the implantation of pacemakers and ICDs. If the pediatric clinical cardiac electrophysiologist does not actually perform these

TABLE 4. Core and Advanced Training: Recommended Minimum Experiences

Level of Training	Core Pediatric Cardiology Training	Advanced Pediatric EP Training
Training time	2 to 3 months equivalent	12 months or more post general PC training*
ECG interpretation	500†	1,500
Ambulatory ECG interpretation	50	200
Exercise ECG	10	40
Tilt table tests	2	10
Transesophageal EPS/temporary postoperative epicardial wire study	5	10
Intracardiac EPS	10	75‡
Intracardiac EPS 12 years of age or less		40
Intracardiac EPS in repaired congenital heart disease		10
Catheter ablation	5	40
Catheter ablation 12 years of age of age or less		20
Catheter ablation in repaired congential heart disease		10
DC cardioversion	4	10
Pacemaker + ICD		
Evaluations/follow-up	20	50
Intraoperative evaluation pacemakers and devices		35 (20 new, 10 revisions, 5 ICDs)
Track 2: implant pacemaker and complex devices		50 (15 in ages 12 yrs or less)

* 4 to 6 months of this training could be obtained during a regular 3-year pediatric cardiology training program if it did not interfere with other required training.
† ECG reading may be performed throughout three-year fellowship.
‡ The diagnostic portion of an ablation procedure may be used to satisfy this requirement.

procedures, they should participate in the intraoperative evaluation and postoperative care. Advanced-level training is expected for any pediatric electrophysiologist who implants pacemakers and ICDs. An additional one to two years after the general cardiology training program is required to achieve advanced-level training. Supplementary training may be required to achieve track 2 implantation competence. Part of this experience with implantation may be gained in an outside program or an affiliated adult CCEP training program. Until specific pediatric pacemaker and ICD certification is available, consideration should be given for advanced trainees implanting pacemakers and ICDs to take the NASPE examination.

Specific Program Content (Core and Advanced Levels)

Trainees will be expected to develop an appropriate level of knowledge and experience in the following areas:

- Basic cellular and whole organ EP related to normal physiology and cardiac arrhythmias in all pediatric and adult congenital patients.
- Pharmacologic principles underlying the use of antiarrhythmic drugs and the effects of various conditions encountered in pediatrics on the use of those drugs (prematurity, developmental biologic changes, including those in volume of distribution, hepatic and renal clearance, drug interactions, and congestive heart failure).
- Management of pediatric and adult patients with congenital heart disease and cardiac arrhythmias; knowledge of presentation and natural history of the variety of arrhythmias encountered in pediatric electrophysiology practice; understanding of the effects of various management strategies on the physiology and psychology of the pediatric and congenital heart patient.
- Expertise in the use of the ECG and other noninvasive specialized testing, including ambulatory monitoring, transtelephonic monitoring, exercise stress testing, and tilt table testing to evaluate cardiac arrhythmias and symptoms.
- An understanding of the indications, contraindications, and potential risks and benefits of intracardiac EPS and esophageal EPS. Core-level trainees should have a general understanding of the information provided by EPS and recognize basic information provided such as site of heart block, identification of mechanism of the arrhythmia, and location of accessory pathways or focal arrhythmia sites. Advanced-level trainees should have experience with esophageal EPS for the treatment and evaluation of arrhythmias. Advanced trainees should also develop an advanced understanding of intracardiac EPS interpretation and use of the data for management. In addition, advanced trainees should develop the advanced cognitive and technical skills to perform EPS.
- Proficiency in the use of esophageal, temporary postoperative epicardial wire, and intracardiac EPS for diagnosis and treatment should be achieved. This includes the ability to manipulate catheters, knowledge of EP equipment and catheters, and ability to perform the full spectrum of programmed electrical stimulation and intracardiac mapping and to interpret the results.
- Advanced trainees should develop the full spectrum of cognitive and technical skills in all types of catheter ablation in children and young adults with congenital heart disease. Advanced trainees should develop skills in the indications for and

APPENDIX. Author Relationships With Industry and Others

potential complications of catheter ablation and should be prepared to treat any of these complications. During the four years of training, the advanced trainee should develop skills in transseptal perforation by participating in at least 10 transseptal procedures. Trainees should have exposure to and develop skills in manipulation of ablation catheters for antegrade ablation; retrograde (transaortic) ablation experience is also highly desirable.

Core-level trainees should have a basic knowledge and understanding of the use of pacemakers and ICDs in pediatric and congenital heart patients. In addition, the core trainee should develop an understanding of pacemakers and skills in evaluation of pacemaker problems that may occur. Advanced-level trainees should have advanced knowledge in the evaluation and management of pacemakers and ICDs. In addition, advanced trainees will participate in implantation (either intraoperative evaluation or actual implant depending on whether track 1 or 2 is chosen) of pacemakers and ICDs, and provide expert understanding and management of implanted pacemakers and ICDs. In addition, advanced-level trainees should have an understanding and experience in using pacemakers and ICDs for noninvasive EPS and internal cardioversion. All levels should have skills in introducing temporary transvenous pacemakers. All levels should have experience with transcutaneous pacing. Both levels should have the skill to use transthoracic temporary postoperative epicardial wires for the recording of electrograms. Advanced trainees should have knowledge and experience in using these wires to convert arrhythmias.

Core-level trainees should have a basic understanding of the indications for and use of cardiac surgery to treat arrhythmias. Advanced level trainees should provide expert mapping and other EP knowledge at the surgical procedure.

Specific formal instruction topics should be covered in a core lecture series and in a journal club format. There should be regularly scheduled conferences regarding EPS interpretation, application of the EPS to the patient's clinical management, and conferences on interpretation of standard and ambulatory ECGs.

EVALUATION AND DOCUMENTATION OF COMPETENCE

The program director is expected to maintain adequate records of each individual's training experiences and performance of various procedures for appropriate documentation for levels 1 or 2. The trainees should maintain records of participation in the form of a log book containing clinical information, procedure performed, and outcomes, listing any complications encountered. Finally, formal written evaluations should occur at least every three months.

Track 2 will develop skills in implantation of pacemakers and ICDs, including extraction.

Task Force 5: Requirements for Pediatric Cardiac Critical Care

Thomas Kulik, MD, *Chair*; Therese M. Giglia, MD, FACC;
Keith C. Kocis, MD, FACC, FAAP; Larry T. Mahoney, MD, FACC; Steven M. Schwartz, MD;
Gil Wernovsky, MD, FACC, FAAP; and David L. Wessel, MD, FAHA

INTRODUCTION

Although pediatric cardiac critical care, as a distinct field of interest, is a relatively recent development, treating critically ill patients has always been a substantial part of clinical pediatric cardiology. In addition, even pediatric cardiologists who do not provide primary care for critically ill patients will be asked to consult on such patients. It therefore seems appropriate to specify what knowledge and skills relevant to the care of critically ill patients should be taught in a pediatric cardiology fellowship program.

FACILITIES AND ENVIRONMENT

Not all pediatric cardiac training programs have a separate pediatric cardiac intensive care unit (ICU), and in some training programs the primary care of hemodynamically compromised cardiac patients is provided by physicians other than pediatric cardiologists. However, this should not preclude trainees from attaining the specified requirements through interaction with pediatric cardiologists, pediatric intensivists, neonatologists, pediatric cardiac surgeons, and other practitioners. Because the advanced practitioner must be board eligible or board certified in pediatric cardiology, it is implied that the pediatric cardiology training be done in an Accreditation Council for Graduate Medical Education (ACGME)-approved training program. The additional nine months of advanced training specified below should take place in an institution in which at least 250 pediatric cardiac procedures per year (this number is by consensus of the authors), utilizing cardiopulmonary bypass, are performed.

LEVELS OF EXPERTISE

In formulating the core training requirements, it was expected that all board-certified pediatric cardiologists should be proficient in the following: 1) the evaluation and (at least) initial stabilization of the hemodynamically compromised pediatric patient with heart disease; and 2) consultation with surgeons, pediatric intensivists, neonatologists, and others regarding the medical, and preoperative and postoperative management of pediatric patients with heart disease.

It is unrealistic to expect all pediatric cardiac trainees to be expert (and stay expert) in the most advanced aspects of pediatric cardiac critical care. In many centers the critical care management of pediatric cardiac patients is provided primarily by pediatric intensivists, neonatologists, or pediatric cardiac surgeons, rather than by cardiologists. However, given that most pediatric cardiologists will occasionally be responsible for situations such as those previously noted, it is important that they can provide appropriate care until consultation with those more experienced in pediatric cardiac intensive care can be obtained. In some cases the pediatric cardiologist may be the only source of expertise (e.g., in understanding the limitations of echocardiography in delineating the anatomy/physiology of a hemodynamically compromised postoperative patient). Hence, it is important that the pediatric cardiologist be familiar with critical care-related issues, often specific to a given cardiac lesion, when providing consultation in the context of the critically ill patient. Thus, *core* requirements apply to *all* trainees seeking board certification in pediatric cardiology.

Advanced requirements, which are more comprehensive, apply to practitioners who will undertake primary responsibility for the comprehensive management of critically ill pediatric patients with congenital or acquired heart disease.

These documents specify training guidelines in pediatric cardiac critical care for pediatric cardiology trainees. The advanced guidelines specify training requirements only for practitioners who are board eligible/board certified in pediatric cardiology. These guidelines do not address what might be a suitable course of training for cardiac critical care for practitioners with primary training in a discipline other than pediatric cardiology.

CORE TRAINING: GOALS AND METHODS

General Requirements

At the end of the pediatric cardiology fellowship, the board-eligible pediatric cardiologist should reliably be able to do the following:

1) Evaluate and treat neonates and infants with critical structural cardiac disease. Evaluation and treatment includes:
   a) Establishing an accurate anatomic diagnosis and ascertaining the relevant cardio-pulmonary physiology.
   b) Providing appropriate medical therapy to stabilize the patient (provide for adequate oxygen delivery and organ perfusion).
   c) Knowing what medical and surgical treatments are appropriate for the condition and what the short- and long-term outcomes of these therapies are.

   In particular, the trainee should have sufficient training and experience to be efficient in managing these patients:
   - Neonates and infants with ductal-dependent left and right-sided obstructive lesions.
   - Neonates with d-transposition of the great arteries.
   - Neonates with total anomalous pulmonary venous connection with obstruction.
   - Infants with anomalous origin of the left coronary artery.
2) Evaluate and treat neonates, infants, and older patients with other forms of critical cardiac disease.

   In particular, the trainee should have sufficient training and experience to be efficient in evaluating and treating these patients:
   - Patients with primary myocardial dysfunction.
   - Patients with acutely compromised cardiopulmonary status due to myocarditis or cardiomyopathy (including that due to rheumatic fever, Kawasaki disease, and so on).
   - Patients with acutely symptomatic arrhythmias.
   - Patients with acutely compromised cardiopulmonary status due to endocarditis.
   - Patients with pericardial effusion.
   - Patients having a hypercyanotic episode ("tet spell").
   - Neonates and infants with increased pulmonary vascular resistance, with or without structural abnormality of the heart.
3) Provide care, or consultation for those providing primary care, for cardiac patients with illness of non-cardiac origin.

   For example, a cyanotic patient with respiratory syncitial virus pneumonitis requires care somewhat different than a patient with a normal heart.
4) Provide consultation for those caring for postoperative cardiac patients.

   In particular, the pediatric cardiologist should be able to do the following:
   - Provide interpretation of diagnostic studies, such as echocardiograms and heart catheterization, including clearly delineating the limitations of such studies.
   - Diagnose and treat acutely symptomatic arrhythmias.
   - Provide consultation regarding therapies to maximize oxygen delivery and cardiac output.
   - Provide consultation regarding pharmacologic and other therapies for patients with "single ventricle" physiology.
   - Provide consultation regarding therapy for patients with increased pulmonary vascular resistance.

SPECIFIC AREAS OF KNOWLEDGE AND COMPETENCE

The following section lists certain areas of special importance.

1. Cardiopulmonary physiology, especially as it applies to cardiac patients in the ICU setting.
   a) Determinants of, and means of influencing, oxygen delivery, cardiac output, and vascular resistance.
   b) The physiology of the patient with a single ventricle, including determinants of, and means of influencing, systemic arterial oxygen saturation, systemic perfusion, and myocardial work.
   c) The physiology of the patient with a ductal-dependent left-sided obstructive lesion, including determinants of, and means of influencing, systemic arterial oxygen saturation, systemic perfusion, and myocardial work.
   d) The physiology of the patient with a fixed restriction of pulmonary blood flow, including determinants of, and means of influencing, systemic arterial oxygen saturation, systemic perfusion, and myocardial work.
   e) The physiology associated with d-transposition of the great arteries.
   f) The physiology of cardiopulmonary interaction, including how mechanical ventilation affects cardiac output.
2. Cardiovascular pharmacology.

   The trainee should learn the actions, mechanisms of action, side effects, and clinical use of:
   a) Inotropic agents (e.g., digoxin, adrenergic agonists, phosphodiesterase inhibitors).
   b) Vasodilators/antihypertensive agents (e.g., alpha adrenergic antagonists, angiotensin-converting enzyme inhibitors, calcium channel antagonists, beta adrenergic antagonists).
   c) Commonly used antiarrhythmic drugs (e.g., digoxin, procainamide, lidocaine, amiodarone).
   d) Inhaled nitric oxide.
   e) Prostaglandin E_1.
   f) Neuromuscular blocking agents (e.g., pancuronium, succinylcholine).
   g) Analgesics and sedatives (e.g., morphine, fentanyl, ketamine, benzodiazepines).

h) Anticoagulants (unfractionated and low molecular weight heparin, warfarin).
i) Diuretics (e.g., furosemide, chlorothiazide).
j) Prostacyclin and other pulmonary vasodilators.

3. The relationship between cardiac structure, function, and clinical state.
   The trainee should learn:
   a) How cardiac structural abnormalities (e.g., obstruction of the atrial septum in hypoplastic left heart syndrome) affect cardiopulmonary function, physiology, and hence the clinical state of the patient.
   b) Methods (e.g., echocardiography, invasive pressure measurements, arterial blood gas analysis, magnetic resonance imaging) to determine and measure cardiac structure, function, and physiology in the ICU patient, and the limitations of these techniques.
   c) Indications for remedy of structural lesions (in both unoperated and operated patients), and appropriate means of therapy (surgical, catheter-based intervention).
4. Diagnosis and therapy of arrhythmias, especially those occurring in ICU patients.
   In particular, the trainee should be familiar with the use of atrial and ventricular pacing leads or transesophageal electrocardiography for diagnosing and treating arrhythmias, and the diagnosis and therapy of junctional ectopic tachycardia.
5. Airway management skills.
6. Provision of analgesia and sedation.
7. Conduct of cardiopulmonary resuscitation.
8. Commonly used modes of mechanical ventilation and their application in patients with heart disease.
9. Common complications that occur in cardiac patients in the ICU, and how they may be prevented and treated.
   The trainee should be familiar with factors that predispose to common postoperative complications (e.g., catheter-related sepsis, pathological thrombosis, surgically-induced heart block), appropriate diagnostic techniques, and therapy for these complications.
10. Familiarity with extracorporeal membrane oxygenation and other cardiac support systems.
11. Indications for, and general principles, for providing "end-of-life" or "palliative" care.

REQUIRED TRAINING PERIOD FOR CORE TRAINING

In training programs where pediatric cardiology fellows provide primary care of pediatric cardiac patients in the ICU (generally programs that have a separate cardiac ICU), a minimum of two months' full-time experience in the ICU is recommended. For programs where pediatric cardiology fellows act as consultants for cardiac patients in the intensive care setting, at least four months' experience providing such consultation is recommended.

Trainees will be evaluated by the appropriate supervising faculty, and both written and oral feedback will be provided to the trainee. Written evaluations, addressing specific areas of competence, will be developed at each training site.

ADVANCED TRAINING: GOALS AND METHODS

Advanced training in pediatric cardiac intensive care is intended to prepare practitioners who will undertake primary responsibility for the comprehensive management of critically ill patients with congenital or acquired heart disease. Because this discipline stands at the nexus of pediatric cardiology and pediatric critical care, some physicians with primary training in fields other than pediatric cardiology work in this area. This document describes an appropriate advanced practitioner training program only for physicians board eligible or board certified in pediatric cardiology; it does not specify what an appropriate training program should be for those trained in other disciplines (e.g., critical care medicine [CCM] or pediatric anesthesiology).

GENERAL REQUIREMENTS

1. The advanced practitioner must be board certified/board eligible in pediatric cardiology.
2. Advanced practitioners must have (at least) nine months of clinical training beyond the core training as outlined in the previous text. (This excludes practitioners doubly boarded in pediatric cardiology and pediatric CCM.) Practitioners with training in (only) pediatric cardiology are therefore expected, in addition to having three years of pediatric cardiology training, to have one month of training in anesthesia, four months' experience predominantly in general pediatric CCM, and at least four months' experience caring for pediatric cardiac patients in the ICU setting (a total of 9 months).

The practitioner must have sufficient experience in managing term and pre-term neonates both preoperatively and postoperatively.

SPECIFIC AREAS OF KNOWLEDGE AND COMPETENCE

Specific requirements for advanced training include all of those for core training (listed in the previous text), as well as the following:

1. Mechanical ventilation.
   a) Indications for and utilization of commonly employed modes of mechanical ventilation, as well as more advanced modes of ventilation (e.g., high-frequency oscillatory ventilation).
   b) Optimal ways of providing gas exchange for patients with congenital heart disease, taking into account factors such as the effect of airway pressure on venous return, the impact of fiO_2 on pulmonary vascular resistance, arterial O_2 saturation, and systemic perfusion.
   c) Pulmonary toxicity related to barotrauma, volutrauma, and high levels of inspired oxygen, and how to minimize such toxicity.
2. Indications for, application of, and complications related to mechanical support for the failing cardiopulmonary system. Current systems that provide such support include extracorporeal life

support, ventricular support devices, and intra-aortic balloon pumps. Expertise in at least one form of mechanical support should result from advanced-level training.
3. Performance of invasive procedures often required in managing critically ill cardiac patients. These procedures include advanced techniques for intravascular access (e.g., subclavian vein and internal jugular venous cannulation), insertion of chest tubes, pericardiocentesis, and so on.
4. Utilization of more advanced cardiovascular pharmacologic therapy (e.g., esmolol for therapy of hypertension, vasopressin for therapy of hypotension).
5. Advanced skills in evaluation and treatment of arrhythmias (e.g., utilization of epicardial electrodes and transesophageal leads for diagnosis and treatment of rhythm abnormalities, use of pharmacologic agents to treat arrhythmias, and so on).
6. Advanced management of pulmonary hypertension.
7. Diagnosis and treatment of less frequently encountered/more complex postoperative complications, including lesion-specific complications. Such complications include significant residual cardiac lesions, paralyzed hemi-diaphragm(s), large airway obstruction, compartment syndrome following femoral arterial cannulation for cardiopulmonary bypass, prolonged chest tube drainage, and so on. The practitioner should be familiar with indications for invasive evaluation (e.g., heart catheterization or bronchoscopy) and invasive therapy (e.g., additional cardiac surgery, interventional catheterization, tracheostomy).
8. Evaluation and management of multisystem organ failure.
9. Postoperative management of orthotopic heart transplant patients, and management of acute rejection.
10. Diagnosis and management of renal failure, including indications for renal replacement therapy.
11. Diagnosis and management of forms of neurological dysfunction, sometimes seen in patients with critical heart disease (seizures, stroke, global ischemia, increased intracranial pressure).
12. Available means of providing nutritional support, and the most appropriate means for a given patient.
13. Transfusion management, and recognition and treatment of common transfusion-related complications.

APPENDIX

Dr. David L. Wessel declared that he had the following relationships with industry relevant to this topic—Pfizer (consultant and research grant); INO Therapeutics (consultant and scientific advisory board). The other authors of this report declared that they have no relationships with industry pertinent to this topic.

Task Force 6: Training in Transition of Adolescent Care and Care of the Adult With Congenital Heart Disease

Daniel J. Murphy, Jr, MD, FACC, FAAP, *Chair*; and Elyse Foster, MD, FACC, FAHA

INTRODUCTION

The number of adults with congenital heart disease (CHD) has increased significantly over the past 20 years. Palliative surgery and, more recently, non-surgical and medical interventions have permitted even those with the most complex lesions to reach adulthood. The recent Bethesda Conference estimated that there are approximately 420,000 CHD patients in the U.S., based on models that exclude simple congenital lesions such as bicuspid aortic valve, small atrial or ventricular septal defect, and mild pulmonary stenosis. Of those patients, approximately three-fourths have lesions that are moderately complex and one-fourth have lesions of great complexity.

Establishing an adequate system for the care of these individuals is a challenging task that can best be accomplished through an integrative approach that draws on the skills and knowledge base of both pediatric and medical (adult) cardiologists within an adult CHD center. Many adults with CHD continue to be cared for by pediatric cardiologists, who are well trained to deal with the often complex problems associated with CHD, but are generally unprepared to manage unique problems of adults with CHD, including long-term complications and adult health care issues such as pregnancy and overlay of acquired disease. Thus, basic knowledge of issues unique to adults with CHD as well as knowledge of the indications for referral to a specialized adult CHD (ACHD) center is required of all pediatric cardiologists.

The American College of Cardiology (ACC) has published training guidelines for Adult Cardiovascular Medicine Core Cardiology Training II (COCATS 2) which include recommendations regarding care of adult patients with CHD. These recommendations were developed with the recognition that appropriate training and education for adult cardiologists is currently deficient in CHD, but that eventually the numbers and complexity of such adult patients will demand that many be cared for in adult settings by cardiologists with an internal medicine-

adult cardiology background.[1] It will be at least a decade or more before the graduates of adult cardiology training programs are sufficiently numerous and adequately trained to staff specialized adult congenital centers as recommended in the 32nd Bethesda Conference.[2] Medical/pediatric residents with double boards in adult and pediatric cardiology would provide excellent training to care for these patients. Meanwhile, for the foreseeable future, significant numbers of adults will need to receive all or a part of their cardiac care from pediatric cardiologists with training in adult issues.

Even if in the future the majority of adults with CHD are cared for in specialized ACHD centers, staffed primarily by specially trained adult cardiologists, there are compelling reasons for the pediatric cardiology training curriculum to address issues relating to ACHD. The Bethesda Conference recommended that such centers maintain a liaison with pediatric cardiology programs for purposes of patient care, education, and support. For example, as surgical treatments evolve, the postoperative course changes, requiring new forms of surveillance and follow-up; the lessons learned from adolescents will shape the care of adults with CHD, and only close coordination between pediatric cardiologists and specialists in ACHD will optimize that care.

This report suggests an approach to the training of pediatric cardiologists. These guidelines will emphasize the importance of preparing young patients with CHD for transition to adult care, the need for pediatric cardiologists to understand the outcomes of CHD in the adult patient, and will serve as a guide for pediatric cardiologists who will participate directly in the care of adults with CHD.

LEVELS OF TRAINING

Core Training (Level 1)

We differentiate three levels of training and expected expertise in the care of adults with CHD. Core training represents the level of knowledge appropriate for all trainees in pediatric cardiology and indicates the knowledge content that each graduate of such a program should acquire. This level of knowledge should be tested in the Subspecialty Certification Examination in Pediatric Cardiology and will provide the graduate with sufficient expertise to care for adolescents with CHD and prepare them for transition to ACHD care. In addition to the basic science and clinical knowledge included in every pediatric cardiology curriculum, certain additional knowledge areas should be included:

- general knowledge
- natural history of cardiac defects
- postoperative residua, long-term issues
- understanding care in the adult setting
- transition issues
- adolescent medicine
- outpatient experience
- lectures as part of core curriculum
- indications for and access to local/regional expert consultation
- adolescent and young adult medical care issues
- contraception, gynecologic issues, pregnancy
- physical activity, sports, and activity counseling
- education, health and general
- insurability
- employment
- psychosocial issues

Advanced Training (Level 2): Special Expertise in Adults With CHD

The COCATS 2 guidelines for adult cardiology fellows suggest at least one year of concentrated exposure for those trainees who wish to care independently for adult patients with CHD. Certain knowledge areas should be included:

Basic Science

Pathophysiology of acquired heart disease with a strong emphasis on heart failure, arrhythmias, and coronary atherosclerosis.

Adult Medical Care Issues

- coronary artery disease, hypertension, lipid management, chronic obstructive pulmonary disease
- contraception, gynecologic issues, management during pregnancy and delivery
- physical activity, sports, and activity counseling
- education, health and general
- insurability
- employment
- psychosocial issues
- palliative care

In addition to didactic materials, training should include the following activities and aims:

- Participation in a regular (at least weekly) clinic organized for the care of adults with CHD—at least 10 patients per week; and participation in the perioperative care of adult patients with CHD including direct observation of surgical repair.
- Program requirements.

To train effectively at level 2, a pediatric cardiology program should include at least one faculty member with a career commitment to the care of adult patients with CHD.

Advanced Training (Level 3): Advanced Expertise in Adults With CHD

The COCATS 2 guidelines recommend an additional year of continued participation in clinical practice relating to ACHD to achieve advanced level 3 training. In addition to the guidelines for advanced level 2 training, level 3 should include active participation in clinical and/or laboratory research in

conjunction with clinical activities and direct participation in additional cardiac catheterization and echocardiographic procedures in adults with CHD.[1]

APPENDIX

The authors of this section declare they have no relationships with industry pertinent to this topic.

Task Force 7: Training Guidelines for Research in Pediatric Cardiology

D. Woodrow Benson, Jr, MD, PhD, *Chair*; H. Scott Baldwin, MD, FACC, FAHA; Larry T. Mahoney, MD, FACC, FAHA; and Tim C. McQuinn, MD, FAAP

Historically, pediatric cardiology has been a dynamic clinical field where a rapid transfer of knowledge from the research laboratory to the bedside occurred regularly. Conversely, many problems on which laboratory effort was focused were first identified at the bedside. This pattern continues today, and there is every reason to believe it will accelerate in the future. Research in pediatric cardiology is defined in broad terms because it is anticipated that future advances in the care of pediatric patients with cardiovascular disease will go beyond current practice and come from diverse areas of biomedical science. If the pediatric cardiologist is to maintain clinical competence and improve clinical knowledge in step with the progress of biomedical science, it is crucial that he or she thoroughly understands the concepts, methods, and pitfalls of the research process. It is important that every pediatric cardiology trainee participate directly in research as training that is limited to practical experience can teach only the status quo, and the status quo cannot improve patient care. The guidelines that follow are based in part on recommendations published in 1995 and revised in 2002[1,2] and a Task Force Report on Pediatric Cardiovascular Diseases.[3]

In addition to direct involvement in research, every trainee should gain practical experience in review of published data, research design, data analysis, and logical deduction. The research experience plays a unique role in developing the skills in continuing self-education essential to all pediatric cardiologists. Trainees contemplating a career in investigative cardiology bear a special responsibility to prepare effectively to advance understanding in the broad area of clinical, translational, and basic cardiovascular science as well as population science, behavioral science, quality of care, and outcomes research.

Because the research experience is such an integral component, pediatric cardiology training should be carried out in institutions in which the opportunity to participate in research is available. The training site should be one that provides an atmosphere of intellectual inquiry and support of the investigational process.

GENERAL STANDARDS

The training institution must have staff and facilities for research. Opportunities for research for the trainees should be available not only within the clinical cardiology division, but also within biomedical science, epidemiological, or other clinical programs of the institution. Availability of expertise in cardiac development, cardiovascular genetics, epidemiology, outcome evaluation, biostatistics, population science, behavioral science, quality of care, outcomes research, and biomedical ethics should be readily available. There should be a critical mass of investigators, and it is expected that cardiovascular investigation be well represented. Not all investigators need to be clinical cardiologists, but at least one full-time faculty member from each training program should have demonstrated skill and research productivity as an investigator.

DURATION OF RESEARCH TRAINING

For trainees planning careers in education and patient care, the core research training should include substantial research time devoted to a specific research project or projects. In most cases, this will encompass a full 12 months of the training period. For those planning a career with a major emphasis on investigation, an additional one to two years beyond the core research training, working directly with an experienced funded mentor, is needed in most cases.

CONTENT OF TRAINING PROGRAM

Research training is an important part of the core instruction of every trainee. Those planning a substantive commitment to clinical, translational, or basic cardiovascular research, as well as population science, behavioral science, quality of care, and outcomes research, will need advanced research training.

Core Research Training

It is anticipated that in most instances core research training will be devoted to a specific project or projects with a clinical or translational research focus. Such research training must be carried out under the supervision of an experienced investigator and according to approved principles of biomedical ethics and institutional rules for patient protection. It must be recognized that such research is difficult because of the complexity of achieving valid scien-

tific conclusions while working with a diverse population and simultaneously protecting the interests of each patient. Advanced educational activities as outlined by the American Board of Pediatrics may meet the core research training objectives when appropriately planned, supervised, and evaluated by faculty with expertise in this area.

Components of Core Research Training

With appropriate mentoring, the trainee should develop skills in at least the following areas:

1. Literature study, to ascertain the exact state of knowledge before undertaking new investigation.
2. Formulation of hypothesis and specific goals, ensuring that the hypothesis is testable, that the goals are appropriate, and that statistical power is achievable.
3. Development of the research plan and the protocol, including study design, recruitment of subjects, ethical considerations, informed consent and protection of privacy, data collection modes, full description of procedures, and institutional approval of human investigation, where appropriate.
4. Data collection, including preparation of data forms.
5. Development of analytic methods or procedural skills, as required, and particularly the handling of artifacts, missing data, outliers, and statistical inference.
6. Presentation of results, preferably both oral and written, emphasizing that no investigation is complete until it is reported in peer-reviewed journals.
7. Risk-benefit analysis, regarding both patient (subject) risk and benefit and societal risk and benefit.
8. Health policy implications of research.

In the case of multiple center clinical trials, participation in the full range of special activities outlined here is required. The clinician lacking expertise in these areas may be unable to interpret critical reports bearing directly on his or her practice. New data might be accepted uncritically or important advances recognized tardily. The training program should provide frequent opportunities for faculty and trainees to review and analyze small- and large-scale clinical and basic research reports in depth. Core research training in the eight skill areas in the previous text could be most easily obtained as part of a master's program in Clinical Investigation, Public Health, or some other structured program.

Advanced Research Training

Trainees preparing for research careers in pediatric cardiology need an extensive foundation in scientific investigation. Some trainees may have obtained extensive research preparation in combined MD/PhD programs, but may lack the special skills appropriate to their personal research goals. These may be obtained during a postdoctoral research fellowship or as part of the cardiology traineeship. Advanced research training should be a mentored investigational experience with a productive and active scientist, MD or PhD, working in the appropriate fields of clinical, epidemiological, genetic, developmental, or biomolecular investigation as well as population science, behavioral science, quality of care, and outcomes research.

Trainees who aim for a career in investigative cardiology but who have not had the opportunity to obtain a PhD or equivalent training prior to embarking on their cardiology traineeships should have the opportunity and be encouraged to obtain the essential coursework and laboratory experience necessary for a productive research career. Several types of individual or institutional research training grants are important resources to support such training.

The advanced research training previously outlined constitutes only the beginning of the education of an independent cardiovascular investigator. Individuals who pursue this path will require additional research mentoring as junior faculty, and compensation during the prolonged period of research training and mentoring should be sufficient to allow a substantial time commitment to this training. To prepare for a successful investigative career, mentored training during and following fellowship of two to five years is usually necessary. Current models to support young faculty during these critical times of career development include the American Heart Association Scientist Development Grant and the National Heart, Lung, and Blood Institute K08 or K23 awards.

The fundamental demonstration of successful training for a pediatric cardiology investigator is successful competition for external funding obtained via peer-reviewed mechanisms. Advanced research training plans should be formulated with this goal in mind.

EVALUATION

Evaluation of a trainee's research progress and research skills should be subjective as well as objective, based on agreed-upon criteria and standards, and should be ongoing throughout the training period. Each trainee's competence and understanding should be documented at the completion of training. The American Board of Pediatrics requirements for research oversight should guide the evolution process.

Trainees should be strongly encouraged to publish substantive results, thereby providing an evaluation by peer-reviewed journals.

FLEXIBILITY

It must be appreciated that the education of future investigative cardiologists is a continuing process and that they usually remain in an educational institution where they are immersed in clinical cardiology. They often have unique demands that might require altering the sequence and exposure of clinical training, consistent with their previous clinical experience. Therefore, the program director should be afforded latitude in the assignment of responsibilities for the three years of training while guaranteeing

full clinical competence. Blocked research time of 12 to 18 months with clinical duties limited to one-half day per week plus weekend and night call during this time is highly desirable.

SUMMARY

It is vital to the future intellectual health of cardiovascular medicine and the welfare of pediatric patients with cardiovascular disease that all future pediatric cardiologists be familiar with the principles and tools of research. Training in research requires the intense involvement of productive and established investigators. Those trainees preparing for a career in investigative cardiology require a carefully developed but flexible educational plan that will permit them to be successful in their research careers over an extended period.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Achieving Quality Health Services for Adolescents

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Adolescence

ABSTRACT

In recent years, there has been an increased national focus on assessing and improving the quality of health care. This statement provides recommendations and criteria for assessment of the quality of primary care delivered to adolescents in the United States. Consistent implementation of American Academy of Pediatrics recommendations (periodicity of visits and confidentiality issues), renewed attention to professional quality-improvement activities (access and immunizations) and public education, and modification of existing quality-measurement activities to ensure that quality is delivered are proposed as strategies that would lead to improved care for youth. *Pediatrics* 2008;121:1263–1270

INTRODUCTION

In recent years, there has been an increased national focus on assessing and improving the quality of health care.[1,2] In a recently published policy statement, "Principles for the Development and Use of Quality Measures," the AAP's Steering Committee on Quality Improvement and Management and the Committee on Practice and Ambulatory Medicine provided a guide for pediatricians on the appropriate uses of quality measures and the criteria on which they should be based.[3] The Institute of Medicine (IOM) has identified health care quality as a national priority and has framed 4 consumer-oriented perspectives on health care needs: staying healthy, getting better, living with illness or disability, and coping with the end of life. The IOM has also addressed quality issues from the perspective of concern for safety, effectiveness, patient centeredness, and timeliness of care and with regard to equity across population subgroups.[4,5]

Access, affordability, cultural effectiveness, communication, and empathy are important attributes of quality care for all age groups. The American Academy of Pediatrics (AAP) has included quality of care in its strategic priorities. Providing quality care for children and adolescents requires that pediatricians maintain relationships with families and with community institutions such as schools or child care providers while maintaining the relationship with their patient. In providing quality care for adolescents, pediatricians must also help patients and their families as teenagers develop autonomy, responsibility, and an adult identity. Thus, adolescent services should also be developmentally appropriate.[6,7] Confidentiality, both in determining whether youth receive what they need and whether there are opportunities for private one-on-one time during health care visits, is a major factor that affects quality of care for many youth.[8,9]

Most adolescents are healthy. However, the preventable health problems of adolescents make specific screening and counseling services important. Most adult chronic diseases have origins during childhood and adolescence.[10,11] Reduction of risky behavior has great potential for reducing preventable adolescent and adult morbidity and mortality, and primary care clinicians can play a critical role in preventing adverse outcomes and promoting healthy lifestyles. Nonetheless, many youth are at high risk of early unintended pregnancy, sexually transmitted infections (STIs), and tobacco, alcohol, and substance use.[12] Alcohol, substance abuse, drunk driving, sexual activity, depression, suicide, smoking, violence, and guns are the primary causes of morbidity and mortality among adolescents.[13,14] Anticipatory guidance, screening, and counseling to reduce health risks are the centerpiece of pediatric and adolescent preventive care; nonetheless, the content of care delivered to many youth does not meet guidelines for care or the perceived needs of adolescent patients.[15]

With passage of the State Children's Health Insurance Program (SCHIP), commitment has been building to ensure that children and adolescents are part of national, state, and local efforts to improve health care quality. The expansion of health insurance coverage and emergence of new quality measures for children and youth create opportunities to assess and improve health services for America's 40 million adolescents. In 2002, the US Congress

mandated that the Agency for Healthcare Research and Quality (AHRQ) produce an annual report on health care disparities in the United States. The National Healthcare Disparities Report includes a broad set of performance measures used to monitor the nation's progress toward improved health care quality for all Americans and builds on the conceptual framework of reports from the IOM. In addition, in 2002, the AHRQ issued a call for measures for inclusion in its National Quality Measures Clearinghouse. Although performance measurement can help move efforts to improve preventive services for adolescents, federal quality and disparity measures are often restricted to those that can be obtained easily from hospital or other administrative databases. In addition, in 2006, the AHRQ issued the National Healthcare Quality Report,[6] which provided additional data on adolescent care and emphasized the need for assessment and measurements. Despite expert and consumer agreement about the importance of adolescent preventive care for health care system accountability and performance reporting, there are few current measurement methods.[2,16–19]

This statement provides recommendations and criteria for assessment of the quality of adolescent care and the need for comprehensive efforts to improve the quality of primary care delivered to adolescents in the United States. Because much of adolescent morbidity and mortality is preventable, this statement focuses on quality issues that relate to staying healthy—preventive care themes. Quality issues for acute, specialty, and hospital care needs, issues for children with special health care needs, and end-of-life issues, although important, are outside the scope of this review. As the federal government addresses increased attention to measurement and to development of quality indicators, better implementation of AAP guidelines,[12] renewed attention to professional quality-improvement activities and public education, and modification of existing quality-measurement activities to ensure that quality care is delivered are proposed as strategies that will lead to better care for youth.

ADOLESCENT HEALTH STATUS AND RISKY BEHAVIORS

The state of America's youth with regard to progress toward achieving national health objectives is mixed. Adolescents engage in high-risk behaviors that cause significant morbidity and mortality. Adolescents and young adults have higher incidences of substance abuse, unprotected sex, reckless driving, and violent behavior compared with adults. Unintentional injuries are the leading cause of death for children, adolescents, and young adults, and alcohol use plays a role in many injuries. Homicide and suicide are the next leading causes of death for adolescents.[15] Violence affects adolescents as both perpetrators and victims. Adolescents are susceptible to intimate partner violence as well, with between 9% and 60% of adolescents having experienced some form of dating violence, and as many as 21% of child abuse cases are perpetrated against adolescents.[20]

Risky and healthy behaviors that affect adult morbidity also have their origins during the adolescent years. According to the Centers for Disease Control and Prevention (CDC), more than half of all teenagers report having had sex, many do not use appropriate barrier protection, and 25% of all annual STI cases in the United States occur in adolescents. Nearly 13.4% of students in the United States had smoked at least 1 cigarette in the previous 30 days, and 23% have reported current cigarette use. Most American adolescents have consumed alcohol at least once in their lifetimes, almost half (43.3%) had consumed alcohol at least once in the previous 30 days, and more than 1 (25.5%) in 4 reported having consumed 5 or more alcoholic drinks on at least 1 occasion in the preceding month. The recommended daily fruit and vegetable intake in the United States is 5 servings per day; however, only 20.1% of adolescents eat the recommended amount. In addition, most adolescents engage in physical activities at lower-than-recommended levels.[15]

PRIMARY CARE ACCESS AND UTILIZATION

Adolescents are among those least likely to have access to health care, and they have the lowest rate of primary care use of any age group in the United States.[9,13] Adolescents and young adults, especially those in poverty, are more likely to be uninsured than any other age group, and many are underinsured with coverage that does not include preventive care, counseling, or other needed services.[13,21] More than 12 million (14.1%) infants, children, and young adults are uninsured, and an estimated 7 of those 12 million are either adolescents or young adults.[22] Although implementation of the SCHIP has improved access to care for more than 2 million previously uninsured children and adolescents, tremendous variation remains across states.[23]

More than 85% of adolescents in the United States report having a regular source of health care. Most families identify a pediatrician or family practitioner as a source of primary care, and most adolescents report having seen their clinician within the last year.[9,24] A study by the AAP Department of Practice and Research in 2003 found that pediatricians' share of visits from adolescents (ages 12–18) increased from 32.3% to 38.5% during a 10-year study period from 1991 to 2000.[25] For many reasons, including barriers to care for adolescents and lack of provider training and incentives, few adolescents receive recommended comprehensive preventive counseling and screening services on key topics such as alcohol use, depression, sexual activity, smoking, injury prevention, physical activity, and diet.[11,22,26,27]

Currently, even adolescents who receive health care often do not receive adequate preventive counseling, health promotion, or screening. Most physicians perform recommended preventive services at low rates, few adolescent visits are for preventive care, and many adolescent visits do not include health counseling or guidance.[11,26–28] Moreover, nearly half of the visits between adolescents and their doctors do not include an opportunity for the teenager to talk privately with the physician. Almost 1 in 3 adolescent girls and 1 in 4 boys report having missed needed care, almost 4 of 10 girls report

having been too embarrassed to talk about an issue with their physician, and fewer than half who thought they should talk about prevention of pregnancy or STIs had ever done so with their doctor.[9,28] Thus, a substantial proportion of visits could not have provided confidential counseling or screening for preventable risky behaviors.

Data from the National Committee for Quality Assurance (NCQA) in the Health Plan Employer Data and Information Set (HEDIS) are used to determine if adolescents have had an annual well visit as a measure of quality for health maintenance organizations' delivery of preventive care. However, this measure provides information only about how many continuously enrolled adolescents have had a visit that was administratively coded as a well visit. The measure does not provide information about whether counseling and/or screening was provided, whether there was an opportunity for a private and confidential encounter, or whether preventive services were provided outside the context of well visits.[29,30] In addition, few health plans score more than 50% on this measure,[31] despite the higher proportion of visits reported by either parents or adolescents. Adolescents might report a higher proportion of well visits because they believe that the care they receive during school or sports physical encounters is equivalent to regular preventive care. However, sports physicals, especially station-based examinations, are generally not comprehensive, high-quality preventive care encounters. Most station examinations do not include psychosocial screening to identify behavioral and other risks. Station examinations also do not allow for attention to longer-term risks of morbidity and mortality, because they are primarily focused on safety, orthopedic fitness, and risk of death from sports.[32] Station examinations also lack confidentiality. Without comprehensive screening, there are many missed opportunities for early diagnosis and treatment.[32]

Appropriate measures of quality also require definition of adolescents' expectations for the content of care delivered to them. Adolescents cite confidentiality, cost, and convenience as key determinants of their use of and satisfaction with care.[7,10] Confidentiality is the key for addressing many types of preventable problems, because fear of disclosure, diagnosis, and treatment may cause adolescents to delay or avoid needed care. Although most physicians support providing confidential care to adolescents, some are uncomfortable with the family negotiations that may surround independent care and decision-making, and few routinely arrange alternative billing or other systems to facilitate adolescents' using their practices confidentially. Nevertheless, several studies have shown that adolescents are both interested in and willing to talk with clinicians about recommended preventive counseling and screening topics, especially during private, confidential health care visits.[9,10,28,29]

ACCESS TO QUALITY CARE FOR ADOLESCENTS

For health services to meet adolescents' needs, they should meet criteria for both the system of health service delivery and the specific services provided.[7,33] Systems factors affect or facilitate adolescents actually receiving services. They are not services themselves but, rather, form the infrastructure of service delivery. These factors include health service organization and financing as well as various domains of access, including availability, affordability, confidentiality, visibility, convenience, flexibility, and coordination.[7] In contrast, services are a measure of the therapeutic interactions received and reflect service capacity, content, and utilization. Services variables also include quality.

Seven criteria for access to care have been proposed by the Society for Adolescent Medicine,[7] including:

- Availability: age-appropriate services and trained clinicians must be available in all communities.
- Visibility: health services for adolescents must be recognizable and convenient and should not require complex planning by adolescents or their parents.
- Quality: a basic level of service must be provided to all youth, and adolescents should be satisfied with the care they receive.
- Confidentiality: adolescents should be encouraged to involve their families in health decisions, but confidentiality must be ensured.
- Affordability: public and private insurance programs must provide adolescents with preventive and other services designed to promote healthy behaviors and decrease morbidity and mortality.
- Flexibility: services, clinicians, and delivery sites must cater to developmental, cultural, ethnic, and social diversity among adolescents.
- Coordination: service providers must ensure that comprehensive services are available to adolescents.

The developmental characteristics of adolescents make these 7 criteria critical for adolescents' health. Similarly, the preventable health problems of adolescents make the availability and visibility of certain preventive services—including family planning and reproductive health services, diagnosis and treatment of STIs and HIV, mental health counseling and treatment, and substance abuse counseling and treatment—critically important for those in this age group. Confidentiality, or the lack thereof, affects quality of care. In a recent survey, 58% of high school students reported health concerns that they wanted to keep private from their parents, approximately only one third of the respondents knew they were legally entitled to receive confidential care for specific health issues, and 68% reported concerns about the confidentiality of services provided in school-based clinics.[34]

The specific services that should be provided to adolescents are summarized by the AAP in its recommendations for clinical preventive services[35] and in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*,[12] which recommend comprehensive preventive counseling and screening services, including annual preventive health care visits for adolescents between 11 and 21 years of age. Such visits should include confidential screening (through trigger questionnaires, clinical inter-

views, or other means), early identification, appropriate preventive care interventions, and referrals for behavioral, emotional, and medical risk; education and counseling on behavioral, emotional, and medical risks to health; and recommended immunizations. Ideally, these health services should be provided in the context of a medical home that provides coordinated care for youth and their families. When school-based health clinics serve as medical homes and provide primary care, they should be expected to meet similar criteria for the quality of the care they provide. In contrast, sports physicals conducted in schools, especially station-style examinations, undermine the primary care relationship and are unlikely to provide quality comprehensive care. Thus, school or other policies should not encourage supplanting routine well visits or the primary care relationship with sports physicals. In addition, forms used by schools and athletic teams for preparticipation sports examinations should incorporate preventive health assessment tools into their content.

It is also important to stress the implementation of office systems that prompt annual screening of adolescents. Preventive health prompts that alert the clinician or other members of the health care team when adolescents present for urgent care visits that preventive health services are due and systems that remind clinicians to address specific content can systematically increase the delivery of preventive services.[36]

Education and counseling include encouraging good health habits and providing guidance on avoiding risky behaviors (specifically, promotion of healthy eating, physical activity, and exercise; responsible sexual behaviors; avoidance of tobacco, alcohol, and other substances; use of seat belts and protective helmets; avoidance of drunk driving, interpersonal violence, and weapons; and other injury-prevention strategies). Screening, followed by target counseling or interventions for those found to be at risk, includes assessment for hypertension and hyperlipidemia, obesity, eating disorders, substance abuse, sexual orientation, sexual activity, pregnancy, HIV and other STIs and cervical cancer, school performance and learning disorders, depression and suicidality, involvement in or victimization from violence or abuse, and tuberculosis. In addition to AAP policies, similar components for adolescent preventive services have also been set forth by the American Medical Association, American Academy of Family Physicians, and the US Maternal and Child Health Bureau (MCHB).[12,35,37,38]

Recommendations for delivery of clinical preventive services to adolescents include counseling families to reinforce the importance of setting clear expectations for adolescent behavior, review firearm safety and access issues, and address the importance of parents as role models for healthy behavior.[12,35,37] Recent evidence also supports the importance of providing anticipatory guidance to parents, because it helps support their role in promoting positive youth development and helping develop protective factors in the lives of adolescents.[39]

EMERGING QUALITY MEASURES FOR ADOLESCENT CARE

The IOM conceptual framework for quality addresses 4 consumer-oriented perspectives on health needs: staying healthy, getting better, living with illness or disability, and coping with the end of life.[2] These concepts are crossed by 4 components of health care quality: safety, effectiveness, patient centeredness, and timeliness, each of which has had policy prominence in its own way. In addition, the IOM has identified equity across populations as a cross-cutting issue.[2,4] Equity refers to providing care that does not vary in quality because of personal characteristics such as gender, ethnicity, geographic location, and socioeconomic status. The IOM has also delineated criteria to apply in thinking about individual quality measures: the overall importance of the aspect of quality being measured, the scientific soundness of the measure, and the feasibility of measurement.[4]

During the 1990s, numerous observers remarked on the lack of valid or reliable quality measures for children's health care.[40,41] In response, federal and private-sector funders invested in the development, testing, and implementation of quality measures for children's health care. Access (as in provider capacity), immunization rates, and the rates at which children and adolescents have well visits are used by the NCQA as quality indicators for health maintenance organizations, but these measures provide no information about the provision of preventive counseling and screening and do not take into account the fact that preventive services are often provided outside of well visits. Mangione-Smith and McGlynn,[41] of the Rand Corporation, have developed extensive chart-based measures of care quality for children and youth. The AHRQ and CDC have also helped develop other valid and reliable adolescent quality measures that could be used for public health or managed care surveillance. The AHRQ has also called for a research agenda in quality measurement for children's health care, the National Initiative for Children's Health Care Quality has been founded, and the AAP has launched several quality-improvement initiatives for pediatric practice.[19,36]

The Child and Adolescent Health Measurement Initiative (CAHMI) was established in 1998 by the Foundation for Accountability to provide leadership and resources for quality of health care for children and adolescents. The CAHMI collaboration includes the NCQA, the AAP, Children Now, the CDC, the AHRQ, the MCHB, and others.[36] The CAHMI has developed and studied 3 measures for children and youth services quality: a child development measure for children between 0 and 48 months of age; a measure for identification of children with chronic illness or special health needs; and an adolescent preventive care measure, called the Young Adult Health Care Survey (YAHCS),[29] for teenagers 14 to 18 years of age, which assesses whether adolescents are receiving recommended health care services. This YAHCS has also been endorsed by the National Quality Forum.

Adolescents have been found to be more valid and reliable than chart review and other data sources in reporting their experiences with preventive care.[30,42] The YAHCS items have been shown to be valid (compared with audiotaped visits) and more accurate than chart data about processes of care.[42] The YAHCS items have also been shown to be reliable[30] in measuring quality of

adolescent preventive care. The YAHCS measurement scales have also demonstrated strong construct validity (mean factor loading = .64) and reliability (mean Cronbach's α = .77).[29]

The YAHCS items ask adolescents directly about the health care they received in the previous 12 months. In fact, because many of the discussions during adolescents' visits are conducted privately between adolescents and their clinicians, adolescents are likely to be a better source of some kinds of information than either their parents or their charts. The 7 YAHCS quality measures address key aspects of recommended preventive care, including (1) screening and counseling for risky behavior (smoking, alcohol use, violence, and guns); (2) screening and counseling for sexual activity and STIs and pregnancy prevention; (3) screening and counseling for mental health and depression; (4) promotion of healthy lifestyle issues (diet, weight, and exercise); (5) private and confidential health care; (6) perceived helpfulness and effectiveness of visits; and (7) adolescents' rating of their clinician's communication and an overall rating of care. The YAHCS also asks about adolescents' health care use, health status, and participation in risky behaviors, because this information can be helpful in assessing whether an adolescent's needs are being met.

The YAHCS is also aligned with the AAP preventive care policies as well as with guidelines from the American Medical Association, American Academy of Family Physicians, MCHB, and *Healthy People 2010*. Average preventive counseling and screening scores from the YAHCS range from 18.2% for discussing risky behavior topics to 50.4% for discussing diet, weight, and exercise topics.[29] The YAHCS can be used to bridge efforts to measure the performance of health care plans and clinicians, target and improve health care quality, and assess and improve public health.

Health plan accreditation and quality assessment, state policies and surveillance systems, and tracking of quality and disparities by the AHRQ have few measures for adolescent care. The AAP is concerned that the gaps in the proposed measure set reflect inconsistent measurement development and will fail to document quality in important domains such as health status and outcomes of care. Thus, it is critical that the gaps in reporting be seen as mandates for improved measure specification and data collection and not as a de facto standard in our expectations for future reporting. Better implementation of AAP policies, renewed attention to professional quality-improvement activities and public education, and modification of existing quality-measurement activities to ensure that quality care is delivered are proposed as strategies that would lead to better care for youth.

OPPORTUNITIES AND CHALLENGES FOR PRIMARY CARE

The system of primary care for adolescents in the United States is changing along with broader changes in the content, organization, and financing of all health services. These changing patterns in the organization of health care may both improve and hinder the care received by adolescents. Similarly, changes in the science of medicine, as well as in technology both in and out of health care may have significant implications for health care delivery to children and their families. The growth of large, integrated health care delivery systems may lead to greater community orientation and more explicit consideration of adolescents' needs. On the other hand, consolidation of services may lead to fewer opportunities and may not result in greater attention to the quality of care delivered or studies of prevention or treatment effectiveness.

Large systems may threaten the quality of health care for children and adolescents. If service delivery systems are not appropriately designed for them, adolescents' ability to use health care may suffer. Regulations of the Health Insurance Portability and Accountability Act (HIPAA) allow states with permissive confidentiality policies to continue them. However, the HIPAA is also expected to make confidential care more difficult to deliver in some areas. Some clinicians may interpret and view HIPAA regulations as restrictive barriers to delivering preventive health care services to adolescents rather than as protective of confidential care. A focus on costs may erode support for many services. Primary care clinicians may have less opportunity to provide anticipatory guidance, behavioral assessment and interventions, or health promotion and disease-prevention counseling.

Adolescents are often unable to anticipate or plan for their needs. Thus, to serve adolescents appropriately, services must be available in a wide range of health care settings, including community-based adolescent health, family planning, and public health clinics; school-based and school-linked health clinics; physicians' offices and physicians' offices affiliated with health maintenance organizations; health maintenance organizations; and hospitals. Without multiple entry points and a diversity of care resources, adolescents are less likely to connect with the appropriate care resources.

Computer technology and the Internet have affected the practice of medicine in the method and speed of access to information and in the nature of communication among physicians, patients, and other members of the health care team. These technological advances provide opportunities for distance education and support for patients. However, the media and the Internet also may lead to misinformation for physicians and patients. Many consumers have difficulty critically appraising health-related information. The education of primary care clinicians must include training in the informatics of health care and the potential promise and problems inherent in technological change.

Coordinated efforts to address disparities in quality should be part of the quality agenda for adolescents' health. This must include measures and surveillance that can identify disparities based on age as well as sensitivity to cultural differences in interpretation and performance of quality measures. However, there are concerns about both the relevancy and appropriateness of the measure set proposed by AHRQ in tracking quality and disparities for pediatric and adolescent health care. Overreliance on clinical or administrative data will fail to document qual-

ity in important domains such as health status and outcomes of care. In addition, if the national initiatives simply report on available data, they may fail to truly address quality and may lead clinicians and others to focus their attention on what is now measured rather than on what is truly important in improving health care.

CONCLUSIONS AND RECOMMENDATIONS

The IOM refers to the discrepancy between the health care that Americans receive and the health care that Americans should receive as a "quality chasm." Adolescents, although traditionally thought of as healthy, are not exempt from this problem. Adolescents have unique health care needs that are not always addressed, and young people often face significant barriers to obtaining needed health care, including lack of insurance, financial difficulty, and lack of (or perceived lack of) confidentiality. Most adolescent morbidity and mortality is attributable to preventable risk factors, and AAP guidelines for quality adolescent health care include screening and counseling to promote healthy behaviors and prevent risky behaviors and for the provision of confidential care.

The AAP believes that it is possible to raise awareness about these issues and ensure that primary care for children and adolescents provides comprehensive service packages and sufficient support to allow clinicians to identify and coordinate services for the common biomedical, behavioral, and educational problems of children.

Public policy must help support improvements in our health care system so that more children and adolescents receive quality care. Employer-sponsored insurance often leaves uncovered some of the services, such as reproductive health or mental health services, that adolescents need the most. Public insurance programs, including Medicaid and the SCHIP, provide an opportunity to increase the number of children with insurance coverage. The first challenge for these programs, as has been the case for Medicaid, is to enroll eligible children and adolescents. However, as the SCHIP expands insurance coverage to a greater proportion of poor and near-poor youth, understanding and addressing the nonfinancial factors that affect access and quality of care become increasingly important. To be effective, these programs must address the reasons that adolescents miss needed care, such as lack of confidentiality or the ability to choose clinicians who are geographically and culturally accessible.

Meaningful measures that assess the quality of primary care have been developed but have been slow to enter the field, with actual use in the health care system itself far from optimal. Child and adolescent health has unique characteristics that differentiate it from adult health and require the development of specific measures. First, children's growth is rapid and presents challenges that often require distinct measures for different age groups. In addition, children have different patterns of health, illness, and disability. They have fewer chronic conditions than adults do; thus, quality measurement for children with chronic illness requires noncategorical approaches to assessment. Children also depend on adults for access to care, adherence to recommended treatments, and continuity of care. Quality-measurement and -improvement initiatives need to be developed to specifically address the transition of care from adolescence into adulthood. As adolescents assume responsibility for their own health behaviors, the importance of confidential screening and counseling requires clinicians to derive information directly from youth.

Improving the health of children and adolescents is a quality-of-care issue, a professional education issue, and a personal and family responsibility issue. National and community solutions and coordinated efforts are needed to improve health care systems and improve the quality of preventive health care delivered to youth; to help promote improvements in quality through support of professional and consumer education campaigns; and to support quality-improvement initiatives in states, managed care plans, and communities.

Families have a special role to play in advocating for their teenagers' health. Most parents or guardians want a professional they trust, such as their pediatrician, to promote healthy, responsible behavior and provide accurate information about health risks so that youth at risk can be identified and offered appropriate help. Thus, every adolescent's parent or guardian should be supportive of ensuring that their teenager has private, confidential time during their health care encounters so that important, preventable issues are addressed.

Pediatricians need to provide care that includes effective counseling skills and must have the right incentives to work with adolescents and their families. This depends on understanding the adolescent's health-behavior choices in context and helping patients make the healthiest choices for themselves. Skills such as motivational interviewing[43] and tailoring behavior-change counseling to patients' stage of change can help physicians counsel youth and their families more effectively.[44]

There are few current federal initiatives to improve care for adolescents. The MCHB funds the Office of Adolescent Health, interdisciplinary adolescent health training programs, and implementation of comprehensive preventive care guidelines. In addition, the Bureau of Primary Care, the CDC, and some states have supported adolescent prevention services quality-improvement initiatives. However, concerted and sustained federal and state efforts will be needed to ensure quality services for most of our nation's youth.

Public health surveillance and health care quality-assurance activities should use measures that assess adolescents' experiences with care, ensuring that confidential counseling opportunities are provided (rather than by relying on parental report). Use of adolescent self-report to assess the content of primary care delivered to youth via managed care quality assurance and public health surveillance systems has the potential to improve the quality of adolescent care.

The AAP recommends the following:

1. All children and adolescents should receive comprehensive, confidential (as appropriate) primary care as recommended by AAP guidelines,[12] including screen-

ing, counseling, and physical and laboratory evaluations.

2. All children and adolescents should be covered by health insurance that provides benefits and care in accordance with AAP guidelines[12] and that provides coverage and access to pediatric specialists for care identified as medically necessary during recommended screening and health supervision visits.
3. State governments should ensure that adolescent confidentiality is preserved and/or protected as HIPAA regulations and electronic health records undergo implementation.
4. Private-sector and government payers should develop policies and contract standards to promote access to adolescent care and availability of confidential services for adolescents and should provide other incentives for delivery of high-quality care to adolescents.
5. Public education should help parents and other consumers understand what constitutes high-quality adolescent primary care so that consumers can be better advocates for confidential and private screening and counseling in settings they trust to help keep their children healthy.
6. Pediatricians and other adolescent health care clinicians should be provided professional education about effective strategies for delivery of high-quality adolescent primary care.
7. Feasible, valid, and reliable quality measures should be developed and implemented that use adolescent self-reported data to help assess the quality of preventive care provided to youth. In addition, existing measures that were developed in association with initiatives designed to improve the care delivered to adolescent patients should be catalogued and improved for use by external quality-measurement organizations

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Active Healthy Living: Prevention of Childhood Obesity Through Increased Physical Activity

Council on Sports Medicine and Fitness and Council on School Health

ABSTRACT

The current epidemic of inactivity and the associated epidemic of obesity are being driven by multiple factors (societal, technologic, industrial, commercial, financial) and must be addressed likewise on several fronts. Foremost among these are the expansion of school physical education, dissuading children from pursuing sedentary activities, providing suitable role models for physical activity, and making activity-promoting changes in the environment. This statement outlines ways that pediatric health care providers and public health officials can encourage, monitor, and advocate for increased physical activity for children and teenagers.

INTRODUCTION

In 1997, the World Health Organization declared obesity a global epidemic with major health implications.[1] According to the 1999–2000 National Health and Nutrition Examination Survey (www.cdc.gov/nchs/nhanes.htm), the prevalence of overweight or obesity in children and youth in the United States is over 15%, a value that has tripled since the 1960s.[2] The health implications of this epidemic are profound. Insulin resistance, type 2 diabetes mellitus, hypertension, obstructive sleep apnea, nonalcoholic steatohepatitis, poor self-esteem, and a lower health-related quality of life are among the comorbidities seen more commonly in affected children and youth than in their unaffected counterparts.[3–7] In addition, up to 80% of obese youth continue this trend into adulthood.[8,9] Adult obesity is associated with higher rates of hypertension, dyslipidemia, and insulin resistance, which are risk factors for coronary artery disease, the leading cause of death in North America.[10]

Assessment of Overweight

Ideally, methods of measuring body fat should be accurate, inexpensive, and easy to use; have small measurement error; and be well documented with published reference values. Direct measures of body composition, such as underwater weighing, magnetic resonance imaging, computed axial tomography, and dual-energy radiograph absorptiometry, provide an estimate of total body fat mass. These techniques, however, are used mainly in tertiary care centers for research purposes. Anthropometric measures of relative fatness may be inexpensive and easy to use but rely on the skill of the measurer, and their relative accuracy must be validated against a "gold-standard" measure of adiposity. Such indirect methods of

estimating body composition include measuring weight and weight for height, body mass index (BMI), waist circumference, skinfold thickness, and ponderal index.[11] Of these, perhaps the most convenient is BMI, which can be calculated according to the following formulas (www.cdc.gov/growthcharts):

$$\text{BMI} = \text{weight (kg)}/(\text{height})\ (\text{m}^2) \text{ or}$$

$$\text{BMI} = \text{weight (kg)}/\text{height (cm)}/\text{height (cm)} \times 10\,000$$

$$\text{BMI} = \text{weight (lb)}/\text{height (in)}/\text{height (in)} \times 703$$

BMI varies with age and gender. It typically increases during the first months of life, decreases after the first year, and increases again around 6 years of age.[11] A specific BMI value, therefore, should be evaluated against age- and gender-specific reference values. In the United States, such reference charts based on early 1970s survey data of children 2 to 20 years of age are readily available for clinical use.[12] Children and youth with a BMI greater than the 95th percentile are classified as overweight or obese, and those between the 85th and 95th percentiles are designated at risk of overweight.[13] Although BMI tends to underestimate overweight in tall individuals and overestimate overweight in short individuals and those with high lean body mass (ie, athletes), it generally correlates well with more precise measures of adiposity in individuals with BMI in the 95th percentile or greater.[14]

Factors Contributing to Obesity

Some children have medical conditions associated with obesity and/or require pharmacologic treatments resulting in significant weight gain. Others (1%–2% of obese children) have underlying genetic conditions such as Down, Prader-Willi, or Bardet-Biedle syndrome, which can be associated with obesity. Rarely, single-gene disorders, including congenital leptin deficiency and defects in the melanocortin 4 receptor, cause morbid childhood obesity.

Observations in twin, sibling, and family studies suggest that children are more likely to be overweight if relatives are similarly affected and that heritability may play a role in as many as 25% to 85% of cases. However, to suggest that only genetic factors have caused the recent global epidemic of childhood obesity would not be realistic. It is more likely that most of the world's population carries a combination of genes that may have evolved to cope with food scarcity. In obesogenic environments in which calorie-dense foods are readily available and low-energy expenditure is commonplace, this genetic predisposition would be maladaptive and could lead to an obese population.[11]

Nutritional factors contributing to the increase in obesity rates include, in no particular order, (1) insufficient infant breastfeeding, (2) a reduction in cereal fiber, fruit, and vegetable intake by children and youth, and (3) the excessive consumption of oversized fast foods and soda, which are encouraged by fast-food advertising during children's television programming and a greater availability of fast foods and sugar-containing beverages in school vending machines.[15,16] Although nutritional issues have a significant role to play, this statement focuses on factors associated with decreased energy expenditure, namely excessive sedentary behaviors and lack of adequate physical activity.

Children and youth are more sedentary than ever with the widespread availability of television, videos, computers, and video games. Data from the 1988–1994 National Health and Nutrition Examination Survey indicated that 26% of American children (up to 33% of Mexican American and 43% of non-Hispanic black children) watched at least 4 hours of television per day, and these children were less likely to participate in vigorous physical activity. They also had greater BMIs and skinfold measurements than those who watched <2 hours of television per day.[17]

Not only are the rates of sedentary activities rising, but participation in physical activity is not optimal. In a 2002 Youth Media Campaign Longitudinal Survey, 4500 children 9 to 13 years of age and their parents were polled about physical activity levels outside of school hours. The report indicated that 61.5% of 9- to 13-year-olds did not participate in any organized physical activities and 22.6% did not partake in nonorganized physical activity during nonschool hours.[18]

Youth at Risk of Decreased Physical Activity

Particular individuals at increased risk of having low levels of physical activity have been identified and include children who are from ethnic minorities (especially girls) in the preadolescent/adolescent age groups, children living in poverty, children with disabilities, children residing in apartments or public housing, and children living in neighborhoods where outdoor physical activity is restricted by climate, safety concerns, or lack of facilities.[19,20] According to the Centers for Disease Control and Prevention (www.cdc.gov/nccdphp/sgr/adoles.htm), inactivity is twice as common among females (14%) as males (7%) and among black females (21%) as white females (12%). In a meta-analysis that evaluated physical activity and cardiorespiratory fitness, 6- to 7-year-olds were more active in moderate to vigorous physical activity (46 minutes/day) compared with 10- to 16-year-olds (16–45 minutes/day). Boys were approximately 20% more active than girls, and mean activity levels decreased with age by 2.7% per year in boys compared with 7.4% per year in girls.[21] Many reasons are stated for the general lack of physical activity among children and youth. These reasons include inactive role models (eg, parents and other caregivers), competing demands/time pressures, unsafe environments, lack of

recreation facilities or insufficient funds to begin recreation programs, and inadequate access to quality daily physical education (PE).

Physical Activity in Schools

Children and youth spend most of their waking hours at school, so the availability of regular physical activity in that setting is critical. Although the *Healthy People 2010* report recommends increasing the amount of daily PE for all students in a larger proportion of US schools, such changes do not seem to be forthcoming.[19] In 2000, a school health policies and program study[22] looked at a nationally representative sample of private and public schools and found that only 8% of American elementary schools, 6.4% of middle schools, and 5.8% of high schools with existing PE requirements provided daily PE classes for all grades for the entire year. In addition, although approximately 80% of states have policies calling for students to participate in PE in all schools, 40% of elementary schools, 52% of middle schools, and 60% of high schools allow exemption from PE classes, particularly for students with permanent physical disabilities and those having religious reasons.[22] The National Association of State Boards of Education recommends 150 minutes per week of PE for elementary students and 225 minutes per week for middle and high school students.[23] Unfortunately, these requirements are not being implemented. In a study of 814 third-grade students from 10 different US data-collection sites, the mean duration of PE was 33 minutes twice a week, with only 25 minutes per week at a moderate to vigorous intensity level.[24] In addition, 1991–2003 Youth Risk Behavior Surveillance data showed that although the percentage of high school students enrolled in PE class remained constant (48.9%–55.7%), the percentage of students with daily PE attendance decreased from 41.6% in 1991 to 25.4% in 1995 and remained stable thereafter (25.4%–28.4%).[25]

Management of the Obese Child

The successful treatment of obesity in the pediatric age group has been somewhat obscure to date. Studies have shown that younger children seem to respond better to treatment than adolescents and adults.[11,26] Reasons given for this include greater motivation, more influence of the family on behavioral change, and the ability to take advantage of longitudinal growth, which allows children to "grow into their weight." Treatment programs that include nutritional intervention in combination with exercise have higher success rates than diet modification alone. Indeed, a research program that included dietary modification, exercise, and family-based behavioral modification demonstrated enhanced weight loss and better maintenance of lost weight over 5 years.[27] Successful activity-related interventions include a reduction in sedentary behavior and an increase in energy expenditure. Improvements in BMI have been shown to occur when television viewing is restricted.[28] In this regard, the American Academy of Pediatrics (AAP) recommends no more than 2 hours of quality television programming per day for children older than 2 years.[29] Lifestyle-related physical activity, as opposed to calisthenics or programmed aerobic exercise, seems to be more important for sustained weight loss.[30] Such treatment programs should be individually tailored to each child, and their success should be measured not just in terms of weight loss but also in terms of the effects of the programs on associated morbidities.

Health Benefits of Physical Activity

Regular physical activity is important in weight reduction and improving insulin sensitivity in youth with type 2 diabetes.[31] Aerobic exercise has been shown in a prospective randomized, controlled study of 64 children (9–11 years old) with hypertension to reduce systolic and diastolic blood pressure over 8 months.[32] Resistance training (eg, weight lifting) after aerobic exercise seems to prevent the return of blood pressure to preintervention levels in hypertensive adolescents.[33] Weight loss through moderate aerobic exercise has been shown to reduce the hyperinsulinemia, hepatomegaly, and liver enzyme elevation seen in patients with steatohepatitis.[6,34] Regular physical activity is also beneficial psychologically for all youth regardless of weight. It is associated with an increase in self-esteem and self-concept and a decrease in anxiety and depression.[35]

Prevention of Overweight in Children and Youth

Given the challenges of reversing existing obesity in the pediatric population, preventive tactics are likely to be the key to success. Unfortunately, controlled prevention trials have been somewhat disappointing to date. In a systematic Cochrane Database review,[36] 3 of 4 long-term studies combining dietary education with physical activity showed no difference in overweight, and 1 long-term physical activity intervention study showed a slight reduction in overweight. However, the randomized control design may not be ideal for the study of most health-promotion interventions. This is because these are typically population-based programs, which tend to be complex, are delivered over long periods of time, and present some difficulties in controlling all variables.[11] Solution-oriented research, which evaluates promising interventions, often in a quasi-experimental manner, may be more appropriate in the long run.[37] It is unlikely, however, that any single strategy will be sufficient to reverse current trends in pediatric obesity. Success is more likely to be achieved by the implementation of sustainable, economically viable, culturally acceptable active-living policies that can be integrated into multiple sectors of society.

Increasing Physical Activity Levels in Children and Youth

Physical activity needs to be promoted at home, in the community, and at school, but school is perhaps the most encompassing way for all children to benefit. As of June 2005, there is a new opportunity for pediatricians to get involved with school districts. Section 204 of the Child Nutrition and WIC [Supplemental Nutrition Program for Women, Infants, and Children] Reauthorization Act of 2004 (Public Law 108–265) requires that every school receiving funding through the National School Lunch and/or Breakfast Program develop a local wellness policy that promotes the health of students, with a particular emphasis on addressing the problem of childhood obesity. By the 2006–2007 school year, each school or school district is required to set goals for healthy nutrition, physical activity, and other strategies to promote student wellness. Parents, students, school personnel, and members of the community are required to be involved in the policy development. Pediatricians can take advantage of this requirement to get involved. In light of the school wellness policy, many schools are looking to modify their present PE programs to improve their physical activity standards.

In past years, PE classes used calisthenics and sport-specific skill acquisition to promote fitness. This approach did not meet the needs of all students, such as those with obesity or physical disabilities. PE curricula and instruction should emphasize the knowledge, attitudes, and motor and behavioral skills required to adopt and maintain lifelong habits of physical activity.[38] Cross-sectional school-based studies have shown modest correlation between physical activity and lower BMI, although long-term follow-up data are lacking. In an observational study of 9751 kindergarten students, an increase in PE instruction time was associated with a significant reduction in BMI among overweight girls.[39] Project SPARK (Sports, Play, and Active Recreation for Kids Curriculum) looked at increasing physical activity through modified PE and classroom-based teaching on health and skill fitness. Physical activity levels increased during PE classes, and fitness levels in girls improved as a result.[40] It is interesting to note that, despite a significant increase in PE class time, there was no interference with academic attainment, and some achievement test results improved. A recent review of the literature suggests that school-based physical activity programs may modestly enhance academic performance in the short-term, but additional research is required to establish any long-term improvements. There does not seem to be sufficient evidence to suggest that daily physical activity detracts from academic success.[41]

An increase in school PE participation alone is not likely to be sufficient to reverse the childhood obesity epidemic. A 2-year study of elementary students showed that those who had enhanced physical activity education as well as modified PE classes to increase lifestyle aerobic activity increased their physical activity inside the classroom, but lower levels were noted outside the classroom in their leisure time, and no improvements on fitness testing or body fat percentage were seen.[42] The PLAY (Promoting Lifestyle Activity for Youth) program, which encourages the accumulation of 30 to 60 minutes of moderate to vigorous physical activity daily beyond school time and during regular school hours outside of PE classes, has been shown to increase the physical activity levels of children, especially girls.[43] Children can increase their physical activity levels in many other ways during school and nonschool hours, including active transportation, unorganized outdoor free play, personal fitness and recreational activities, and organized sports. Parents of children in organized sports should be encouraged to stimulate their children to be physically active on days when they are not participating in these sports and not rely solely on the sports to provide all their away-from-school physical activity. This should include participation in physical activities with the entire family. Communities designed with green spaces and biking trails help provide families the means to enjoy such active lifestyles.

During late childhood and adolescence, strength training may be additionally beneficial. Youth taking part in this type of exercise may gain strength, improve sport performance, and derive long-term health benefits.[44] Obese children often prefer strength training because it does not require agility or aerobic ability, and the benefits become apparent within as little as 2 to 3 weeks. Because of their added body mass, overweight participants also tend to be stronger than their peers, giving them a relative psychological advantage. Recent studies have shown that obese students are more compliant and increase their free fat mass when weight training is added to aerobic exercise or a standardized energy-reduction diet.[45,46]

Recommended physical activity levels for children and youth vary somewhat in different countries. The Centers for Disease Control and Prevention and the United Kingdom Health Education Authority recommend that children and youth accumulate at least 60 minutes daily of moderate to vigorous physical activity in a variety of enjoyable individual and group activities.[47,48] Health Canada guidelines recommend increasing physical activity above the current level by at least 30 minutes (10 minutes vigorous) and reducing sedentary activity by the same amount per day. Each month, physical activity should be increased and sedentary behavior should be decreased by 15 minutes until at least 90 minutes more active time and 90 minutes less inactive time are accumulated (www.paguide.com). The Canadian Paediatric Society has endorsed these recommendations and emphasizes a wide variety of activities as part of recreation, transportation, chores, work, and

planned exercise to encourage lifestyle changes that may last a lifetime.[49]

Age-Appropriate Recommendations for Physical Activity

Clinicians should encourage parents to limit sedentary activity and make physical activity and sport recommendations to parents and caregivers that are consistent with the developmental level of the child.[50] The following are guidelines from the AAP for different age groups.

Infants and Toddlers

There is insufficient evidence to recommend exercise programs or classes for infants and toddlers as a means of promoting increased physical activity or preventing obesity in later years. The AAP has recommended that children younger than 2 years not watch any television. The AAP suggests that parents be encouraged to provide a safe, nurturing, and minimally structured play environment for their infant.[51] Infants and toddlers should also be allowed to develop enjoyment of outdoor physical activity and unstructured exploration under the supervision of a responsible adult caregiver. Such activities include walking in the neighborhood, unorganized free play outdoors, and walking through a park or zoo.

Preschool-Aged Children (4–6 Years)

Free play should be encouraged with emphasis on fun, playfulness, exploration, and experimentation while being mindful of safety and proper supervision. Preschool-aged children should take part in unorganized play, preferably on flat surfaces with few variables and instruction limited to a show-and-tell format. Appropriate activities might include running, swimming, tumbling, throwing, and catching. Preschoolers should also begin walking tolerable distances with family members. In addition, parents should reduce sedentary transportation by car and stroller and, as applies to all age groups, limit screen time to <2 hours per day.

Elementary School–Aged Children (6–9 Years)

In this age group, children improve their motor skills, visual tracking, and balance. Parents should continue to encourage free play involving more sophisticated movement patterns with emphasis on fundamental skill acquisition. These children should be encouraged to walk, dance, or jump rope and may enjoy playing miniature golf. There is little difference between the sexes in weight, height, endurance, and motor skill development at this age; thus, co-ed participation is not contraindicated. Organized sports (soccer, baseball) may be initiated, but they should have flexible rules and short instruction time, allow free time in practices, and focus on enjoyment rather than competition. These children have a limited ability to learn team strategy.

Middle School–Aged Children (10–12 Years)

Preferred physical activities that focus on enjoyment with family members and friends should be encouraged as with previous groups. Emphasis on skill development and increasing focus on tactics and strategy as well as factors promoting continued participation are needed. Fully developed visual tracking, balance, and motor skills are typical in late childhood. Middle school–aged children are better able to process verbal instruction and integrate information from multiple sources so that participation in complex sports (football, basketball, ice hockey) is more feasible. Puberty may begin at different rates, making some individuals bigger and stronger than others. Basing placement in contact and collision sports on maturity rather than chronologic age may result in less risk of injury and enhanced chance of success, especially for those at lower Tanner stages. Weight training may be initiated, provided that the program is well supervised, that small free weights are used with high repetitions (15–20), that proper technique is demonstrated, and that shorter sets using heavier weights and maximum lifts (squat lifts, clean and jerk, dead lifts) are avoided.[44]

Adolescents

Adolescents are highly social and influenced by their peers. Identifying activities that are of interest to the adolescent, especially those that are fun and include friends, is crucial for long-term participation. Physical activities may include personal fitness preferences (eg, dance, yoga, running), active transportation (walking, cycling), household chores, and competitive and noncompetitive sports. Ideally, enrollment in competitive contact and collision sports should be based on size and ability instead of chronologic age. Weight training may continue, and as the individual reaches physical maturity (Tanner stage 5), longer sets using heavier weights and fewer repetitions may be safely pursued while continuing to stress the importance of proper technique.

Office-Based Physical Activity Assessment

An accurate assessment of an individual child's physical activity level by history or questionnaire is difficult and fraught with methodologic problems. It may be easier for parents to recall the number of times per week their child plays outside for at least 30 minutes than to estimate the average daily minutes spent in physical activity. In addition, asking parents about the number of hours per day their child spends in front of a television, video game, or computer screen may be simpler to quantify and track than time spent in active play. Pedometers may also be helpful, because they provide a simple and more objective method of measuring activity, are inexpensive, and have a "gadget appeal" among youngsters. It has been recommend that adults accumulate 10 000 steps per day to follow a healthy lifestyle.[52] Require-

ments are less clearly defined in children, but guidelines range from 11 000 to 12 000 steps per day for girls and 13 000 to 15 000 steps per day for boys.[53,54]

CONCLUSIONS

The prevalence of pediatric obesity has reached epidemic proportions. It is unlikely that the medical profession alone will be able to solve this serious health problem. The promotion of decreased caloric intake and increased energy expenditure will need to take place within all aspects of society. Among the most difficult but most important challenges for society are making exercise alternatives as attractive, exciting, and enjoyable as video games for children, convincing school boards that PE and other school-based physical activity opportunities are as important to long-term productivity as are academics, changing both supplier and consumer attitudes about food selection and portion sizes, and reengineering living environments to promote physical activity.

RECOMMENDATIONS

Research has shown the importance of social, physical, and cultural environments in determining the extent to which people are able to be active in all facets of daily life, including work, education, family life, and leisure.[55] Creating active school communities is an ideal way to ensure that children and youth adopt active, healthy lifestyles. These communities require a collaborative framework between families, schools, community recreation leaders, and health care professionals. Physicians can be instrumental in the development of active school communities by advocating for policy changes at the community, state, and national levels that support healthy nutrition, reducing sedentary time, and increasing physical activity levels while providing education and health supervision about regular physical activity and reduced sedentary time to families in their practices.

ADVOCACY

In addition to promoting healthy nutrition recommendations suggested by the AAP Committee on Nutrition, physicians and health care professionals and their national organizations should advocate for:

- Social marketing that promotes increased physical activity.
- The appropriate allocation of funding for quality research in the prevention of childhood obesity.
- The development and implementation of a school wellness counsel on which local physician representation is encouraged.
- A school curriculum that teaches children and youth the health benefits of regular physical activity.
- Comprehensive community sport and recreation programs that allow for community and school facilities to be open after hours and make physical activities available to all children and youth at reasonable costs; access to recreation facilities should be equally available to both sexes.
- The reinstatement of compulsory, quality, daily PE classes in all schools (kindergarten through grade 12) taught by qualified, trained educators. The curricula should emphasize enjoyable participation in physical activity that helps students develop the knowledge, attitudes, motor skills, behavioral skills, and confidence required to adopt and maintain healthy active lifestyles. These classes should allow participation by all children regardless of ability, illness, injury, and developmental disability, including those with obesity and those who are disinterested in traditional competitive team sports. Commitment of adequate resources for program funding, trained PE personnel, safe equipment, and facilities is also recommended.
- The provision of a variety of physical activity opportunities in addition to PE, including the protection of children's recess time and the requirement of extracurricular physical activity programs and nonstructured physical activity before, during, and after school hours, that address the needs and interests of all students.
- The reduction of environmental barriers to an active lifestyle through the construction of safe recreational facilities, parks, playgrounds, bicycle paths, sidewalks, and crosswalks.

PROMOTING A HEALTHY LIFESTYLE

Physicians and health care professionals should promote active healthy living within each family unit by:

- Serving as role models through the adoption of an active lifestyle.
- Inquiring about nutritional intake, calculating and plotting BMI, identifying obesity-related comorbidities, and promoting healthy eating as suggested by the AAP Committee on Nutrition.
- Documenting the number of hours per day spent on sedentary activities and limiting screen (television, video game, and computer) time according to AAP guidelines.
- Determining physical activity levels of the child and family members at regular health care visits.
- Tabulating the amount of physical activity the child or youth does each day at home, school, or child care as part of transportation, work, recreation, and unorganized sports, which should include determining the actual minutes of PE and recess-related physical activity achieved at school each week. In addition, the

number of times per week spent in outdoor play for at least 30 minutes and/or the number of daily steps achieved (monitored by using a pedometer) should be documented. Specific involvement in organized sports and dance also should be noted.

- Encouraging children and adolescents to be physically active for at least 60 minutes per day, which does not need to be acquired in a continuous fashion but rather may be accumulated by using smaller increments. Events should be of moderate intensity and include a wide variety of activities as part of sports, recreation, transportation, chores, work, planned exercise, and school-based PE classes. These activities should be primarily unstructured and fun if they are to achieve best compliance.
- Identifying any barriers the child, youth, or parent might have against increasing physical activity, which might include lack of time, competing interests, perceived lack of motor skills, and fear of injury on the part of the child. Parents might be additionally concerned about financial and safety issues. Efforts must then be made to work with the family to educate them regarding the importance of lifelong physical activity and to identify potential strategies to overcome some of their barriers.
- Recommending that parents become good role models by increasing their own level of physical activity. Parents should also incorporate physical activities that family members of all ages and abilities can do together. They should encourage children to play outside as much as possible. Safety should be promoted by the use of appropriate protective equipment (bicycle helmets, life jackets, etc).
- Advising parents to support their children and youth in developmentally and age-appropriate sports and recreational activities. The child's favorite types of physical activity should be a priority. These might best occur in the school setting during extracurricular activities, in which parents/grandparents can take part as leaders and coaches.
- Suggesting that overweight children partake in activities that take advantage of their tall stature and muscle strength, such as water-based sports and strength training, rather than those that require weight bearing (eg, jumping, jogging).
- Recommending that parents of overweight children and youth play a supporting, accepting, and encouraging role in returning them to healthier lifestyles to increase self-esteem.
- Encouraging youth to promote physical activities for their peers and become role models and leaders for younger students.

FREE

The American Academy of Pediatrics and the Centers for Disease Control and Prevention are amending previous recommendations and making additional recommendations for the use of tetanus toxoid, reduced-content diphtheria toxoid, and acellular pertussis vaccine (Tdap). Review of the results from clinical trials and other studies has revealed no excess reactogenicity when Tdap is given within a short interval after other tetanus- or diphtheria-containing toxoid products, and accrual of postmarketing adverse-events reports reveals an excellent safety record for Tdap. Thus, the recommendation for caution regarding Tdap use within any interval after a tetanus- or diphtheria-containing toxoid product is removed. Tdap should be given when it is indicated and when no contraindication exists. In further efforts to protect people who are susceptible to pertussis, the American Academy of Pediatrics and Centers for Disease Control and Prevention recommend a single dose of Tdap for children 7 through 10 years of age who were underimmunized with diphtheria-tetanus-acellular pertussis (DTaP). Also, the age for recommendation for Tdap is extended to those aged 65 years and older who have or are likely to have contact with an infant younger than 12 months (eg, health care personnel, grandparents, and other caregivers). *Pediatrics* 2011;128:809–812

INTRODUCTION

The American Academy of Pediatrics (AAP)[1] and the Centers for Disease Control and Prevention (CDC)[2] currently recommend a single dose of tetanus toxoid, reduced-diphtheria toxoid, and reduced-content acellular pertussis vaccine (Tdap) instead of tetanus and diphtheria toxoid vaccine (Td) for adolescents aged 11 through 18 years of age who have completed the recommended pediatric-formulation diphtheria and tetanus toxoids and whole-cell pertussis vaccine (DTP)/diphtheria-tetanus-acellular pertussis vaccine (DTaP) series in childhood; the adolescent dose of Tdap should preferably be given at a preventive care visit at 11 through 12 years of age. The CDC currently recommends a single dose of Tdap to replace a single decennial Td booster for adults 19 through 64 years of age who have not previously received Tdap and as soon as is feasible for health care providers who have direct patient contact.[2] Two Tdap vaccines are licensed in the United States—Boostrix (GlaxoSmithKline Biologicals, Research Triangle Park, NC), for persons 10 through 64 years of age, and Adacel (Sanofi Pasteur, Swiftwater, PA),

for persons 11 through 64 years of age. On October 27, 2010, the Advisory Committee on Immunization Practices (ACIP) of the CDC amended recommendations and made additional recommendations for use in those who have not received Tdap previously: (1) whenever indicated, regardless of interval since the last tetanus- or diphtheria-containing vaccine; (2) for children 7 through 10 years of age who did not receive the full recommended series of DTaP before 7 years of age; and (3) for certain adults aged 65 years and older. The CDC policy changes are published.[3]

The ACIP Pertussis Working Group, composed of liaison members from multiple organizations, including the AAP Committee on Infectious Diseases, reviewed published and unpublished data on Tdap immunogenicity and safety from vaccine trials and other relevant experiences in formulating its recommendations. The working group also considered the current epidemiology of pertussis, the need to protect vulnerable infants through encouragement and expansion of cocooning,[4,5] and data and expert opinion on barriers to receipt of Tdap. This vaccine policy statement expands previous AAP recommendations for Tdap[4] and will be incorporated into the 2012 *Red Book*.

No Minimum Interval Between Td and Tdap Is Necessary

At the time of licensure of Tdap in 2005, there were few data on the reactogenicity of Tdap after a short interval from another tetanus toxoid– or diphtheria toxoid–containing vaccine. Thus, Tdap was recommended with a minimum interval of 5 years for standard use, and an interval as short as 2 years was acceptable when potential risk of pertussis was high.

Confirming adult immunization status by review of immunization records or recall is difficult and is an important barrier to achieving the vaccine coverage needed for this group. Accumulating data demonstrate no increased risk of severe local reactions or serious adverse events for adolescents or adults who receive Tdap at short intervals after tetanus toxoid– or diphtheria toxoid–containing vaccines. Together, these findings support removal of any cautionary minimum interval regarding any tetanus toxoid– or diphtheria toxoid–containing vaccine when Tdap is indicated. Reports reviewed for safety of short intervals included Canadian children and adolescents with a DTP/DTaP/Td-to-Tdap interval as low as 2 years[6]; French adults 18 to 76 years of age with a Td/Td-inactivated polio vaccine (IPV)-to-Tdap/Td-IPV interval of 28 days to 2 years[7]; and health care personnel vaccinated in an institutional respiratory illness outbreak with tetanus toxoid (TT)- or Td-to-Tdap interval of less than 2 years.[8] The number of subjects in these studies is small; therefore, data do not exclude a significant but rare event. In addition, a postlicensure retrospective cohort study found that medically attended local reactions after Tdap were low (2.6 events per 10 000 Tdap vaccinations) and comparable with those after Td.[9] Since licensure, evidence on safety of Tdap in persons 10 through 64 years of age has been collected through the Vaccine Safety Datalink (VSD) and has revealed no association with several predetermined adverse neurologic events, including encephalopathy/encephalitis/meningitis, paralytic syndromes, seizure, cranial nerve disorder, or Guillain-Barré syndrome.[10] Postmarketing data from the Vaccine Adverse Events Reporting System (VAERS) 2 years after licensure also support the safety of Tdap.

Children 7 Through 10 Years of Age Who Were Not Fully Immunized With DTaP Should Be Given Tdap

At the time of recommendation of universal Tdap for adolescents,[1,2] the AAP and ACIP recommended that children 7 through 10 years of age with a history of incomplete childhood immunization with DTP/DTaP should be given Td to complete the tetanus and diphtheria toxoid series, because Tdap is not licensed in the United States for children younger than 10 years. Although data on immunogenicity of Tdap in undervaccinated or completely unvaccinated children 7 through 10 years of age are limited, 2 studies of use of Tdap in place of the fifth dose of DTaP have shown similar immunogenicity to DTaP.[11,12] Lower rates of local reactions also were reported after Tdap in place of the fifth DTaP.[11–13] If a child 7 through 10 years of age is not fully immunized against pertussis (ie, has not received 5 doses of DTP/DTaP or 4 doses when the fourth dose was administered after the fourth birthday) or has an unknown or uncertain immunization history, a single dose of Tdap should be given. Only 1 dose of Tdap is recommended at this time, because Tdap vaccines are not licensed for multiple doses. If further doses of Td-containing vaccine are required, they are given on a catch-up schedule. Although Tdap could be substituted for any 1 of the 3 doses, the preferred 3-dose schedule would be Tdap followed by Td at 4 weeks and 6 to 12 months. Either Tdap product (Boostrix or Adacel) can be used for the underimmunized child 7 through 10 years of age. At this time, it is recommended that children who receive Tdap at 7 through 10 years of age should not be given the usual adolescent Tdap dose at the 11- through 12-year visit but should be given a booster dose of Td 10 years after their last dose of Td-containing vaccine (Tdap or Td). At the present time, only 1 dose of Tdap should be administered. A repeat dose is not advised.

Certain Adults Aged 65 Years and Older Should be Given Tdap

The objective for vaccinating adults aged 65 years and older is to protect

them from pertussis and to improve the cocooning of young infants who are too young to be protected by the DTaP series and who are at substantial risk of severe disease, hospitalization, and death should they be exposed and infected with *Bordetella pertussis*. Multiple studies have found that family members and extended family members, including grandparents, are source cases for most infants with pertussis. In 1 study of more than 1000 children 0 through 3 years of age, 35% of the children were cared for by grandparent(s) at least during one 3-month period. Health care personnel also are at potential risk of acquiring and transmitting pertussis. Although Tdap vaccines are not licensed for persons 65 years and older, unpublished immunogenicity and safety data as well as Vaccine Adverse Events Reporting System data are supportive of the recommendation that persons 65 years and older in the high-risk setting of potential transmission to young infants should be given Tdap. On February 23, 2011, the ACIP made provisional recommendations that all health care personnel, regardless of age, receive a single dose of Tdap as soon as is feasible if they have not previously received Tdap and regardless of the time since the last dose of Td. At this time, the CDC does not recommend immunizing all persons aged 65 years and older. However, there are no contraindications to immunizing persons in this age group, and anyone desiring vaccine can be immunized.

RECOMMENDATIONS

Recommendations for changes in and additional uses of Tdap:

- There is no minimum interval required or advised between receipt of a tetanus toxoid– or diphtheria toxoid–containing vaccine and Tdap when Tdap is otherwise indicated.
- A single dose of Tdap should be given to children 7 through 10 years of age who have incomplete or unknown pertussis vaccine history. Additional vaccines may be required on the basis of a catch-up schedule.
- A single dose of Tdap should be given to adults of any age (including those aged 65 years or older) who have not received Tdap previously, who are health care personnel, or who have or anticipate having close contact with an infant younger than 12 months, such as grandparents and other caregivers.
- A single dose of Tdap may be given in place of Td to any person aged 65 years or older who has not received Tdap previously.

At the time of the ACIP vote on these changes in Tdap recommendations in October 2010, the Vaccines for Children Program advisors concurred with coverage of Tdap for use relevant to the program. Tdap is set forth in the Vaccine Injury Table for eligibility to receive compensation under the Vaccine Injury Compensation Act. Because Tdap is a "covered" vaccine, such eligibility extends to the added recommendations mentioned here (www.hrsa.gov/vaccinecompensation).

abstract

Attention-deficit/hyperactivity disorder (ADHD) is the most common neurobehavioral disorder of childhood and can profoundly affect the academic achievement, well-being, and social interactions of children; the American Academy of Pediatrics first published clinical recommendations for the diagnosis and evaluation of ADHD in children in 2000; recommendations for treatment followed in 2001. *Pediatrics* 2011;128: 1007–1022

Summary of key action statements:

1. The primary care clinician should initiate an evaluation for ADHD for any child 4 through 18 years of age who presents with academic or behavioral problems and symptoms of inattention, hyperactivity, or impulsivity (quality of evidence B/strong recommendation).
2. To make a diagnosis of ADHD, the primary care clinician should determine that *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* criteria have been met (including documentation of impairment in more than 1 major setting); information should be obtained primarily from reports from parents or guardians, teachers, and other school and mental health clinicians involved in the child's care. The primary care clinician should also rule out any alternative cause (quality of evidence B/strong recommendation).
3. In the evaluation of a child for ADHD, the primary care clinician should include assessment for other conditions that might coexist with ADHD, including emotional or behavioral (eg, anxiety, depressive, oppositional defiant, and conduct disorders), developmental (eg, learning and language disorders or other neurodevelopmental disorders), and physical (eg, tics, sleep apnea) conditions (quality of evidence B/strong recommendation).
4. The primary care clinician should recognize ADHD as a chronic condition and, therefore, consider children and adolescents with ADHD as children and youth with special health care needs. Management of children and youth with special health care needs should follow the principles of the chronic care model and the medical home (quality of evidence B/strong recommendation).

5. Recommendations for treatment of children and youth with ADHD vary depending on the patient's age:
   a. For *preschool-aged children (4–5 years of age)*, the primary care clinician should prescribe evidence-based parent- and/or teacher-administered behavior therapy as the first line of treatment (quality of evidence A/strong recommendation) and may prescribe methylphenidate if the behavior interventions do not provide significant improvement and there is moderate-to-severe continuing disturbance in the child's function. In areas where evidence-based behavioral treatments are not available, the clinician needs to weigh the risks of starting medication at an early age against the harm of delaying diagnosis and treatment (quality of evidence B/recommendation).
   b. For *elementary school–aged children (6–11 years of age)*, the primary care clinician should prescribe US Food and Drug Administration–approved medications for ADHD (quality of evidence A/strong recommendation) and/or evidence-based parent- and/or teacher-administered behavior therapy as treatment for ADHD, preferably both (quality of evidence B/strong recommendation). The evidence is particularly strong for stimulant medications and sufficient but less strong for atomoxetine, extended-release guanfacine, and extended-release clonidine (in that order) (quality of evidence A/strong recommendation). The school environment, program, or placement is a part of any treatment plan.
   c. For *adolescents (12–18 years of age)*, the primary care clinician should prescribe Food and Drug Administration–approved medications for ADHD with the assent of the adolescent (quality of evidence A/strong recommendation) and may prescribe behavior therapy as treatment for ADHD (quality of evidence C/recommendation), preferably both.
6. The primary care clinician should titrate doses of medication for ADHD to achieve maximum benefit with minimum adverse effects (quality of evidence B/strong recommendation).

INTRODUCTION

This document updates and replaces 2 previously published clinical guidelines from the American Academy of Pediatrics (AAP) on the diagnosis and treatment of attention-deficit/hyperactivity disorder (ADHD) in children: "Clinical Practice Guideline: Diagnosis and Evaluation of the Child With Attention-Deficit/Hyperactivity Disorder" (2000)[1] and "Clinical Practice Guideline: Treatment of the School-aged Child With Attention-Deficit/Hyperactivity Disorder" (2001).[2] Since these guidelines were published, new information and evidence regarding the diagnosis and treatment of ADHD has become available. Surveys conducted before and after the publication of the previous guidelines have also provided insight into pediatricians' attitudes and practices regarding ADHD. On the basis of an increased understanding regarding ADHD and the challenges it raises for children and families and as a source for clinicians seeking to diagnose and treat children, this guideline pays particular attention to a number of areas.

Expanded Age Range

The previous guidelines addressed diagnosis and treatment of ADHD in children 6 through 12 years of age. There is now emerging evidence to expand the age range of the recommendations to include preschool-aged children and adolescents. This guideline addresses the diagnosis and treatment of ADHD in children 4 through 18 years of age, and attention is brought to special circumstances or concerns in particular age groups when appropriate.

Expanded Scope

Behavioral interventions might help families of children with hyperactive/impulsive behaviors that do not meet full diagnostic criteria for ADHD. Guidance regarding the diagnosis of problem-level concerns in children based on the *Diagnostic and Statistical Manual for Primary Care* (DSM-PC), *Child and Adolescent Version*,[3] as well as suggestions for treatment and care of children and families with problem-level concerns, are provided here. The current DSM-PC was published in 1996 and, therefore, is not consistent with intervening changes to *International Classification of Diseases, Ninth Revision, Clinical Modification* (ICD-9-CM). Although this version of the DSM-PC should not be used as a definitive source for diagnostic codes related to ADHD and comorbid conditions, it certainly may continue to be used as a resource for enriching the understanding of ADHD manifestations. The DSM-PC will be revised when both the DSM-V and ICD-10 are available for use.

A Process of Care for Diagnosis and Treatment

This guideline and process-of-care algorithm (see Supplemental Fig 2 and Supplemental Appendix) recognizes evaluation, diagnosis, and treatment as a continuous process and provides recommendations for both the guideline and the algorithm in this single publication. In addition to the formal recommendations for assessment, diagnosis, and treatment, this guideline

provides a single algorithm to guide the clinical process.

Integration With the Task Force on Mental Health

This guideline fits into the broader mission of the AAP Task Force on Mental Health and its efforts to provide a base from which primary care providers can develop alliances with families, work to prevent mental health conditions and identify them early, and collaborate with mental health clinicians.

The diagnosis and management of ADHD in children and youth has been particularly challenging for primary care clinicians because of the limited payment provided for what requires more time than most of the other conditions they typically address. The procedures recommended in this guideline necessitate spending more time with patients and families, developing a system of contacts with school and other personnel, and providing continuous, coordinated care, all of which is time demanding. In addition, relegating mental health conditions exclusively to mental health clinicians also is not a viable solution for many clinicians, because in many areas access to mental health clinicians to whom they can refer patients is limited. Access in many areas is also limited to psychologists when further assessment of cognitive issues is required and not available through the education system because of restrictions from third-party payers in paying for the evaluations on the basis of them being educational and not health related.

Cultural differences in the diagnosis and treatment of ADHD are an important issue, as they are for all pediatric conditions. Because the diagnosis and treatment of ADHD depends to a great extent on family and teacher perceptions, these issues might be even more prominent an issue for ADHD. Specific cultural issues are beyond the scope of this guideline but are important to consider.

METHODOLOGY

As with the 2 previously published clinical guidelines, the AAP collaborated with several organizations to develop a working subcommittee that represented a wide range of primary care and subspecialty groups. The subcommittee included primary care pediatricians, developmental-behavioral pediatricians, and representatives from the American Academy of Child and Adolescent Psychiatry, the Child Neurology Society, the Society for Pediatric Psychology, the National Association of School Psychologists, the Society for Developmental and Behavioral Pediatrics, the American Academy of Family Physicians, and Children and Adults With Attention-Deficit/Hyperactivity Disorder (CHADD), as well as an epidemiologist from the Centers for Disease Control and Prevention (CDC).

This group met over a 2-year period, during which it reviewed the changes in practice that have occurred and issues that have been identified since the previous guidelines were published. Delay in completing the process led to further conference calls and extended the years of literature reviewed in order to remain as current as possible. The AAP funded the development of this guideline; potential financial conflicts of the participants were identified and taken into consideration in the deliberations. The guideline will be reviewed and/or revised in 5 years unless new evidence emerges that warrants revision sooner.

The subcommittee developed a series of research questions to direct an extensive evidence-based review in partnership with the CDC and the University of Oklahoma Health Sciences Center. The diagnostic review was conducted by the CDC, and the evidence was evaluated in a combined effort of the AAP, CDC, and University of Oklahoma Health Sciences Center staff. The treatment-related evidence relied on a recent evidence review by the Agency for Healthcare Research and Quality and was supplemented by evidence identified through the CDC review.

The diagnostic issues were focused on 5 areas:

1. ADHD prevalence—specifically: (*a*) What percentage of the general US population aged 21 years or younger has ADHD? (*b*) What percentage of patients presenting at pediatricians' or family physicians' offices in the United States meet diagnostic criteria for ADHD?
2. Co-occurring mental disorders—of people with ADHD, what percentage has 1 or more of the following co-occurring conditions: sleep disorders, learning disabilities, depression, anxiety, conduct disorder, and oppositional defiant disorder?
3. What are the functional impairments of children and youth diagnosed with ADHD? Specifically, in what domains and to what degree do youth with ADHD demonstrate impairments in functional domains, including peer relations, academic performance, adaptive skills, and family functioning?
4. Do behavior rating scales remain the standard of care in assessing the diagnostic criteria for ADHD?
5. What is the prevalence of abnormal findings on selected medical screening tests commonly recommended as standard components of an evaluation of a child with suspected ADHD? How accurate are these tests in the diagnosis of ADHD compared with a reference standard (ie, what are the psychometric properties of these tests)?

The treatment issues were focused on 3 areas:

1. What new information is available

regarding the long-term efficacy and safety of medications approved by the US Food and Drug Administration (FDA) for the treatment of ADHD (stimulants and nonstimulants), and specifically, what information is available about the efficacy and safety of these medications in preschool-aged and adolescent patients?

2. What evidence is available about the long-term efficacy and safety of psychosocial interventions (behavioral modification) for the treatment of ADHD for children, and specifically, what information is available about the efficacy and safety of these interventions in preschool-aged and adolescent patients?
3. Are there any additional therapies that reach the level of consideration as evidence based?

Evidence-Review Process for Diagnosis

A multilevel, systematic approach was taken to identify the literature that built the evidence base for both diagnosis and treatment. To increase the likelihood that relevant articles were included in the final evidence base, the reviewers first conducted a scoping review of the literature by systematically searching literature using relevant key words and then summarized the primary findings of articles that met standard inclusion criteria. The reviewers then created evidence tables that were reviewed by content-area experts who were best able to identify articles that might have been missed through the scoping review. Articles that were missed were reviewed carefully to determine where the abstraction methodology failed, and adjustments to the search strategy were made as required (see technical report to be published). Finally, although published literature reviews did not contribute directly to the evidence base, the articles included in review articles were cross-referenced with the final evidence tables to ensure that all relevant articles were included in the final evidence tables.

For the scoping review, articles were abstracted in a stratified fashion from 3 article-retrieval systems that provided access to articles in the domains of medicine, psychology, and education: PubMed (www.ncbi.nlm.nih.gov/sites/entrez), PsycINFO (www.apa.org/pubs/databases/psycinfo/index.aspx), and ERIC (www.eric.ed.gov). English-language, peer-reviewed articles published between 1998 and 2009 were queried in the 3 search engines. Key words were selected with the intent of including all possible articles that might have been relevant to 1 or more of the questions of interest (see the technical report to be published). The primary abstraction included the following terms: "attention deficit hyperactivity disorder" or "attention deficit disorder" or "hyperkinesis" and "child." A second, independent abstraction was conducted to identify articles related to medical screening tests for ADHD. For this abstraction, the same search terms were used as in the previous procedure along with the additional condition term "behavioral problems" to allow for the inclusion of studies of youth that sought to diagnose ADHD by using medical screening tests. Abstractions were conducted in parallel fashion across each of the 3 databases; the results from each abstraction (complete reference, abstract, and key words) were exported and compiled into a common reference database using EndNote 10.0.[4] References were subsequently and systematically deduplicated by using the software's deduplication procedure. References for books, chapters, and theses were also deleted from the library. Once a deduplicated library was developed, the semifinal database of 8267 references was reviewed for inclusion on the basis of inclusion criteria listed in the technical report. Included articles were then pulled in their entirety, the inclusion criteria were reconfirmed, and then the study findings were summarized in evidence tables. The articles included in relevant review articles were revisited to ensure their inclusion in the final evidence base. The evidence tables were then presented to the committee for expert review.

Evidence-Review Process for Treatment

In addition to this systematic review, for treatment we used the review from the Agency for Healthcare Research and Quality (AHRQ) Effective Healthcare Program "Attention Deficit Hyperactivity Disorder: Effectiveness of Treatment in At-Risk Preschoolers; Long-term Effectiveness in All Ages; and Variability in Prevalence, Diagnosis, and Treatment."[5] This review addressed a number of key questions for the committee, including the efficacy of medications and behavioral interventions for preschoolers, children, and adolescents. Evidence identified through the systematic evidence review for diagnosis was also used as a secondary data source to supplement the evidence presented in the AHRQ report. The draft practice guidelines were developed by consensus of the committee regarding the evidence. It was decided to create 2 separate components. The guideline recommendations were based on clear characterization of the evidence. The second component is a practice-of-care algorithm (see Supplemental Fig 2) that provides considerably more detail about how to implement the guidelines but is, necessarily, based less on available evidence and more on consensus of the committee members. When data were lacking, particularly in the

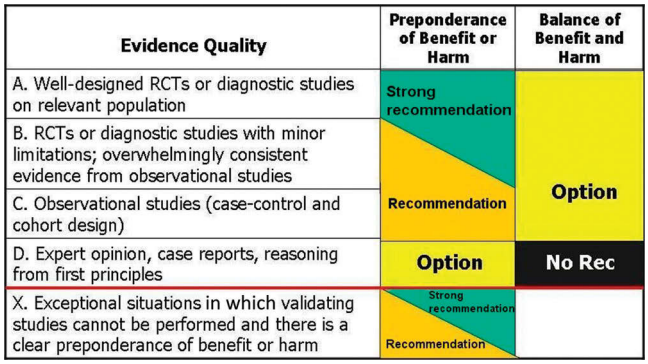

FIGURE 1

Integrating evidence-quality appraisal with an assessment of the anticipated balance between benefits and harms if a policy is conducted leads to designation of a policy as a strong recommendation, recommendation, option, or no recommendation. The evidence is discussed in more detail in a technical report that will follow in a later publication. RCT indicates randomized controlled trial; Rec, recommendation.

process-of-care algorithmic portion of the guidelines, a combination of evidence and expert consensus was used. Action statements labeled "strong recommendation" or "recommendation" were based on high- to moderate-quality scientific evidence and a preponderance of benefit over harm.[6] Option-level action statements were based on lesser-quality or limited data and expert consensus or high-quality evidence with a balance between benefits and harms. These clinical options are interventions that a reasonable health care provider might or might not wish to implement in his or her practice. The quality of evidence supporting each recommendation and the strength of each recommendation were assessed by the committee member most experienced in epidemiology and graded according to AAP policy (Fig 1).[6]

The guidelines and process-of-care algorithm underwent extensive peer review by committees, sections, councils, and task forces within the AAP; numerous outside organizations; and other individuals identified by the subcommittee. Liaisons to the subcommittee also were invited to distribute the draft to entities within their organizations. The resulting comments were compiled and reviewed by the chairperson, and relevant changes were incorporated into the draft, which was then reviewed by the full committee.

ABOUT THIS GUIDELINE

Key Action Statements

In light of the concerns highlighted previously and informed by the available evidence, the AAP has developed 6 action statements for the evaluation, diagnosis, and treatment of ADHD in children. These action statements provide for consistent and quality care for children and families with concerns about or symptoms that suggest attention disorders or problems.

Context

This guideline is intended to be integrated with the broader algorithms developed as part of the mission of the AAP Task Force on Mental Health.[7]

Implementation: A Process-of-Care Algorithm

The AAP recognizes the challenge of instituting practice changes and adopting new recommendations for care. To address the need, a process-of-care algorithm has been developed and has been used in the revision of the AAP ADHD toolkit.

Implementation: Preparing the Practice

Full implementation of the action statements described in this guideline and the process-of-care algorithm might require changes in office procedures and/or preparatory efforts to identify community resources. The section titled "Preparing the Practice" in the process-of-care algorithm and further information can be found in the supplement to the Task Force on Mental Health report.[7] It is important to document all aspects of the diagnostic and treatment procedures in the patients' records. Use of rating scales for the diagnosis of ADHD and assessment for comorbid conditions and as a method for monitoring treatment as described in the process algorithm (see Supplemental Fig 2), as well as information provided to parents such as management plans, can help facilitate a clinician's accurate documentation of his or her process.

Note

The AAP acknowledges that some primary care clinicians might not be confident of their ability to successfully diagnose and treat ADHD in a child because of the child's age, coexisting conditions, or other concerns. At any point at which a clinician feels that he or she is not adequately trained or is uncertain about making a diagnosis or continuing with treatment, a referral to a pediatric or mental health subspecialist should be made. If a diagnosis of ADHD or other condition is made by a subspecialist, the primary care clinician should develop a management strategy with the subspecialist that ensures that the child will continue to receive appropriate care consistent with a medical home model wherein the pediatrician part-

ners with parents so that both health and mental health needs are integrated.

KEY ACTION STATEMENTS FOR THE EVALUATION, DIAGNOSIS, TREATMENT, AND MONITORING OF ADHD IN CHILDREN AND ADOLESCENTS

Action statement 1: The primary care clinician should initiate an evaluation for ADHD for any child 4 through 18 years of age who presents with academic or behavioral problems and symptoms of inattention, hyperactivity, or impulsivity (quality of evidence B/strong recommendation).

Evidence Profile

- **Aggregate evidence quality:** B.
- **Benefits:** In a considerable number of children, ADHD goes undiagnosed. Primary care clinicians' systematic identification of children with these problems will likely decrease the rate of undiagnosed and untreated ADHD in children.
- **Harms/risks/costs:** Children in whom ADHD is inappropriately diagnosed might be labeled inappropriately, or another condition might be missed, and they might receive treatments that will not benefit them.
- **Benefits-harms assessment:** The high prevalence of ADHD and limited mental health resources require primary care pediatricians to play a significant role in the care of their patients with ADHD so that children with this condition receive the appropriate diagnosis and treatment. Treatments available have shown good evidence of efficacy, and lack of treatment results in a risk for impaired outcomes.
- **Value judgments:** The committee considered the requirements for establishing the diagnosis, the prevalence of ADHD, and the efficacy and adverse effects of treatment as well as the long-term outcomes.
- **Role of patient preferences:** Success with treatment depends on patient and family preference, which has to be taken into account.
- **Exclusions:** None.
- **Intentional vagueness:** The limits between what can be handled by a primary care clinician and what should be referred to a subspecialist because of the varying degrees of skills among primary care clinicians.
- **Strength: strong recommendation.**

The basis for this recommendation is essentially unchanged from that in the previous guideline. ADHD is the most common neurobehavioral disorder in children and occurs in approximately 8% of children and youth[8–10]; the number of children with this condition is far greater than can be managed by the mental health system. There is now increased evidence that appropriate diagnosis can be provided for preschool-aged children[11] (4–5 years of age) and for adolescents.[12]

Action statement 2: To make a diagnosis of ADHD, the primary care clinician should determine that *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (DSM-IV-TR) criteria have been met (including documentation of impairment in more than 1 major setting), and information should be obtained primarily from reports from parents or guardians, teachers, and other school and mental health clinicians involved in the child's care. The primary care clinician should also rule out any alternative cause (quality of evidence B/strong recommendation).

Evidence Profile

- **Aggregate evidence quality:** B.
- **Benefits:** The use of DSM-IV criteria has lead to more uniform categorization of the condition across professional disciplines.
- **Harms/risks/costs:** The DSM-IV system does not specifically provide for developmental-level differences and might lead to some misdiagnoses.
- **Benefits-harms assessment:** The benefits far outweigh the harm.
- **Value judgments:** The committee took into consideration the importance of coordination between pediatric and mental health services.
- **Role of patient preferences:** Although there is some stigma associated with mental disorder diagnoses resulting in some families preferring other diagnoses, the need for better clarity in diagnoses was felt to outweigh this preference.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

As with the findings in the previous guideline, the DSM-IV criteria continue to be the criteria best supported by evidence and consensus. Developed through several iterations by the American Psychiatric Association, the DSM-IV criteria were created through use of consensus and an expanding research foundation.[13] The DSM-IV system is used by professionals in psychiatry, psychology, health care systems, and primary care. Use of DSM-IV criteria, in addition to having the best evidence to date for criteria for ADHD, also affords the best method for communication across clinicians and is established with third-party payers. The criteria are under review for the development of the DSM-V, but these changes will not be available until at least 1 year after the publication of this current guideline. The diagnostic criteria have not changed since the previous guideline and are presented in Supplemental Table 2. An anticipated change in the DSM-V is increasing the age limit for when ADHD needs to have first presented from 7 to 12 years.[14]

Special Circumstances: Preschool-aged Children (4–5 Years Old)

There is evidence that the diagnostic criteria for ADHD can be applied to preschool-aged children; however, the subtypes detailed in the DSM-IV might not be valid for this population.[15–21] A review of the literature, including the multisite study of the efficacy of methylphenidate in preschool-aged children, revealed that the criteria could appropriately identify children with the condition.[11] However, there are added challenges in determining the presence of key symptoms. Preschool-aged children are not likely to have a separate observer if they do not attend a preschool or child care program, and even if they do attend, staff in those programs might be less qualified than certified teachers to provide accurate observations. Here, too, focused checklists can help physicians in the diagnostic evaluation, although only the Conners Comprehensive Behavior Rating Scales and the ADHD Rating Scale IV are DSM-IV–based scales that have been validated in preschool-aged children.[22]

When there are concerns about the availability or quality of nonparent observations of a child's behavior, physicians may recommend that parents complete a parent-training program before confirming an ADHD diagnosis for preschool-aged children and consider placement in a qualified preschool program if they have not done so already. Information can be obtained from parents and teachers through the use of validated DSM-IV–based ADHD rating scales. The parent-training program must include helping parents develop age-appropriate developmental expectations and specific management skills for problem behaviors. The clinician may obtain reports from the parenting class instructor about the parents' ability to manage their children, and if the children are in programs in which they are directly observed, instructors can report information about the core symptoms and function of the child directly. Qualified preschool programs include programs such as Head Start or other public prekindergarten programs. Preschool-aged children who display significant emotional or behavioral concerns might also qualify for Early Childhood Special Education services through their local school districts, and the evaluators for these programs and/or Early Childhood Special Education teachers might be excellent reporters of core symptoms.

Special Circumstances: Adolescents

Obtaining teacher reports for adolescents might be more challenging, because many adolescents will have multiple teachers. Likewise, parents might have less opportunity to observe their adolescent's behaviors than they had when their children were younger. Adolescents' reports of their own behaviors often differ from those of other observers, because they tend to minimize their own problematic behaviors.[23–25] Adolescents are less likely to exhibit overt hyperactive behavior. Despite the difficulties, clinicians need to try to obtain (with agreement from the adolescent) information from at least 2 teachers as well as information from other sources such as coaches, school guidance counselors, or leaders of community activities in which the adolescent participates. In addition, it is unusual for adolescents with behavioral/attention problems not to have been previously given a diagnosis of ADHD. Therefore, it is important to establish the younger manifestations of the condition that were missed and to strongly consider substance use, depression, and anxiety as alternative or co-occurring diagnoses. Adolescents with ADHD, especially when untreated, are at greater risk of substance abuse.[26] In addition, the risks of mood and anxiety disorders and risky sexual behaviors increase during adolescence.[12]

Special Circumstances: Inattention or Hyperactivity/Impulsivity (Problem Level)

Teachers, parents, and child health professionals typically encounter children with behaviors relating to activity level, impulsivity, and inattention who might not fully meet DSM-IV criteria. The DSM-PC[3] provides a guide to the more common behaviors seen in pediatrics. The manual describes common variations in behavior as well as more problematic behaviors at levels of less impairment than those specified in the DSM-IV.

The behavioral descriptions of the DSM-PC have not yet been tested in community studies to determine the prevalence or severity of developmental variations and problems in the areas of inattention, hyperactivity, or impulsivity. They do, however, provide guidance to clinicians regarding elements of treatment for children with problems with mild-to-moderate inattention, hyperactivity, or impulsivity. The DSM-PC also considers environmental influences on a child's behavior and provides information on differential diagnosis with a developmental perspective.

Action statement 3: In the evaluation of a child for ADHD, the primary care clinician should include assessment for other conditions that might coexist with ADHD, including emotional or behavioral (eg, anxiety, depressive, oppositional defiant, and conduct disorders), developmental (eg, learning and language disorders or other neurodevelopmental disorders), and physical (eg, tics, sleep apnea) conditions (quality of evidence B/strong recommendation).

Evidence Profile

- **Aggregate evidence quality:** B.
- **Benefits:** Identifying coexisting conditions is important for developing the most appropriate treatment plan.
- **Harms/risks/costs:** The major risk is misdiagnosing the conditions and providing inappropriate care.
- **Benefits-harms assessment:** There is a preponderance of benefit over harm.
- **Value judgments:** The committee members took into consideration the common occurrence of coexisting conditions and the importance of addressing them in making this recommendation.
- **Role of patient preferences:** None.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

A variety of other behavioral, developmental, and physical conditions can coexist in children who are evaluated for ADHD. These conditions include, but are not limited to, learning problems, language disorder, disruptive behavior, anxiety, mood disorders, tic disorders, seizures, developmental coordination disorder, or sleep disorders.[23,24,27–38] In some cases, the presence of a coexisting condition will alter the treatment of ADHD. The primary care clinician might benefit from additional support and guidance or might need to refer a child with ADHD and coexisting conditions, such as severe mood or anxiety disorders, to subspecialists for assessment and management. The subspecialists could include child psychiatrists, developmental-behavioral pediatricians, neurodevelopmental disability physicians, child neurologists, or child or school psychologists.

Given the likelihood that another condition exists, primary care clinicians should conduct assessments that determine or at least identify the risk of coexisting conditions. Through its Task Force on Mental Health, the AAP has developed algorithms and a toolkit[39] for assessing and treating (or comanaging) the most common developmental disorders and mental health concerns in children. These resources might be useful in assessing children who are being evaluated for ADHD. Payment for evaluation and treatment must cover the fixed and variable costs of providing the services, as noted in the AAP policy statement "Scope of Health Care Benefits for Children From Birth Through Age 26.[40]

Special Circumstances: Adolescents

Clinicians should assess adolescent patients with newly diagnosed ADHD for symptoms and signs of substance abuse; when these signs and symptoms are found, evaluation and treatment for addiction should precede treatment for ADHD, if possible, or careful treatment for ADHD can begin if necessary.[25]

Action statement 4: The primary care clinician should recognize ADHD as a chronic condition and, therefore, consider children and adolescents with ADHD as children and youth with special health care needs. Management of children and youth with special health care needs should follow the principles of the chronic care model and the medical home (quality of evidence B/strong recommendation).

Evidence Profile

- **Aggregate evidence quality:** B.
- **Benefits:** The recommendation describes the coordinated services most appropriate for managing the condition.
- **Harms/risks/costs:** Providing the services might be more costly.
- **Benefits-harms assessment:** There is a preponderance of benefit over harm.
- **Value judgments:** The committee members considered the value of medical home services when deciding to make this recommendation.
- **Role of patient preferences:** Family preference in how these services are provided is an important consideration.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

As in the previous guideline, this recommendation is based on the evidence that ADHD continues to cause symptoms and dysfunction in many children who have the condition over long periods of time, even into adulthood, and that the treatments available address symptoms and function but are usually not curative. Although the chronic illness model has not been specifically studied in children and youth with ADHD, it has been effective for other chronic conditions such as asthma,[23] and the medical home model has been accepted as the preferred standard of care.[41] The management process is also helped by encouraging strong family-school partnerships.[42]

Longitudinal studies have found that, frequently, treatments are not sustained despite the fact that long-term outcomes for children with ADHD indicate that they are at greater risk of significant problems if they discontinue treatment.[43] Because a number of parents of children with ADHD also have ADHD, extra support might be necessary to help those parents provide medication on a consistent basis and institute a consistent behavioral program. The medical home and chronic illness approach is provided in the process algorithm (Supplemental Fig 2). An important process in ongoing care is bidirectional communication with teachers and other school and mental health clinicians involved in the child's care as well as with parents and patients.

Special Circumstances: Inattention or Hyperactivity/Impulsivity (Problem Level)

Children with inattention or hyperactivity/impulsivity at the problem level (DSM-PC) and their families might also benefit from the same chronic illness and medical home principles.

Action statement 5: Recommendations for treatment of children and youth with ADHD vary depending on the patient's age.

Action statement 5a: For *preschool-aged children (4–5 years of age)*, the primary care clinician should prescribe evidence-based parent- and/or teacher-administered behavior therapy as the first line of treatment (quality of evidence A/strong recommendation) and may prescribe methylphenidate if the behavior interventions do not provide significant improvement and there is moderate-to-severe continuing disturbance in the child's function. In areas in which evidence-based behavioral treatments are not available, the clinician needs to weigh the risks of starting medication at an early age against the harm of delaying diagnosis and treatment (quality of evidence B/recommendation).

Evidence Profile

- **Aggregate evidence quality:** A for behavior; B for methylphenidate.
- **Benefits:** Both behavior therapy and methylphenidate have been demonstrated to reduce behaviors associated with ADHD and improve function.
- **Harms/risks/costs:** Both therapies increase the cost of care, and behavior therapy requires a higher level of family involvement, whereas methylphenidate has some potential adverse effects.
- **Benefits-harms assessment:** Given the risks of untreated ADHD, the benefits outweigh the risks.
- **Value judgments:** The committee members included the effects of untreated ADHD when deciding to make this recommendation.
- **Role of patient preferences:** Family preference is essential in determining the treatment plan.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

Action statement 5b: For *elementary school-aged children (6–11 years of age)*, the primary care clinician should prescribe FDA-approved medications for ADHD (quality of evidence A/strong recommendation) and/or evidence-based parent- and/or teacher-administered behavior therapy as treatment for ADHD, preferably both (quality of evidence B/strong recommendation). The evidence is particularly strong for stimulant medications and sufficient but less strong for atomoxetine, extended-release guanfacine, and extended-release clonidine (in that order) (quality of evidence A/strong recommendation). The school environment, program, or placement is a part of any treatment plan.

Evidence Profile

- **Aggregate evidence quality:** A for treatment with FDA-approved medications; B for behavior therapy.
- **Benefits:** Both behavior therapy and FDA-approved medications have been demonstrated to reduce behaviors associated with ADHD and improve function.
- **Harms/risks/costs:** Both therapies increase the cost of care, and behavior therapy requires a higher level of family involvement, whereas FDA-approved medications have some potential adverse effects.
- **Benefits-harms assessment:** Given the risks of untreated ADHD, the benefits outweigh the risks.
- **Value judgments:** The committee members included the effects of untreated ADHD when deciding to make this recommendation.
- **Role of patient preferences:** Family preference, including patient preference, is essential in determining the treatment plan.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

Action statement 5c: For *adolescents (12–18 years of age)*, the primary care clinician should prescribe FDA-approved medications for ADHD with the assent of the adolescent (quality of evidence A/strong recommendation) and may prescribe behavior therapy as treatment for ADHD (quality of evidence C/recommendation), preferably both.

Evidence Profile

- **Aggregate evidence quality:** A for medications; C for behavior therapy.
- **Benefits:** Both behavior therapy and FDA-approved medications have been demonstrated to reduce behaviors associated with ADHD and improve function.
- **Harms/risks/costs:** Both therapies increase the cost of care, and behavior therapy requires a higher level of family involvement, whereas FDA-approved medications have some potential adverse effects.
- **Benefits-harms assessment:** Given the risks of untreated ADHD, the benefits outweigh the risks.
- **Value judgments:** The committee members included the effects of untreated ADHD when deciding to make this recommendation.
- **Role of patient preferences:** Family preference, including patient preference, is essential in determining the treatment plan.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation/ recommendation.**

Medication

Similar to the recommendations from the previous guideline, stimulant medications are highly effective for most children in reducing core symptoms of ADHD.[44] One selective norepinephrine-reuptake inhibitor (atomoxetine[45,46]) and 2 selective α_2-adrenergic agonists (extended-release guanfacine[47,48] and extended-release clonidine[49]) have also demonstrated efficacy in reducing core symptoms. Because norepinephrine-reuptake inhibitors and α_2-adrenergic agonists are newer, the evidence base that supports them—although adequate for FDA approval—is considerably smaller than that for stimulants. None of them have been approved for use in preschool-aged children. Compared with stimulant medications that have an effect size [effect size = (treatment mean − control mean)/control SD] of approximately 1.0,[50] the effects of the nonstimulants are slightly weaker; atomoxetine has an effect size of approximately 0.7, and extended-release guanfacine and extended-release clonidine also have effect sizes of approximately 0.7.

The accompanying process-of-care algorithm provides a list of the currently available FDA-approved medications for ADHD (Supplemental Table 3). Characteristics of each medication are provided to help guide the clinician's choice in prescribing medication.

As was identified in the previous guideline, the most common stimulant adverse effects are appetite loss, abdominal pain, headaches, and sleep disturbance. The results of the Multimodal Therapy of ADHD (MTA) study revealed a more persistent effect of stimulants on decreasing growth velocity than have most previous studies, particularly when children were on higher and more consistently administered doses. The effects diminished by the third year of treatment, but no compensatory rebound effects were found.[51] However, diminished growth was in the range of 1 to 2 cm. An uncommon additional significant adverse effect of stimulants is the occurrence of hallucinations and other psychotic symptoms.[52] Although concerns have been raised about the rare occurrence of sudden cardiac death among children using stimulant medications,[53] sudden death in children on stimulant medication is extremely rare, and evidence is conflicting as to whether stimulant medications increase the risk of sudden death.[54–56] It is important to expand the history to include specific cardiac symptoms, Wolf-Parkinson-White syndrome, sudden death in the family, hypertrophic cardiomyopathy, and long QT syndrome. Preschool-aged children might experience increased mood lability and dysphoria.[57] For the nonstimulant atomoxetine, the adverse effects include initial somnolence and gastrointestinal tract symptoms, particularly if the dosage is increased too rapidly; decrease in appetite; increase in suicidal thoughts (less common); and hepatitis (rare). For the nonstimulant α_2-adrenergic agonists extended-release guanfacine and extended-release clonidine, adverse effects include somnolence and dry mouth.

Only 2 medications have evidence to support their use as adjunctive therapy with stimulant medications sufficient to achieve FDA approval: extended-release guanfacine[26] and extended-release clonidine. Other medications have been used in combination off-label, but there is currently only anecdotal evidence for their safety or efficacy, so their use cannot be recommended at this time.

Special Circumstances: Preschool-aged Children

A number of special circumstances support the recommendation to initiate ADHD treatment in preschool-aged children (ages 4–5 years) with behavioral therapy alone first.[57] These circumstances include:

- The multisite study of methylphenidate[57] was limited to preschool-aged children who had moderate-to-severe dysfunction.
- The study also found that many children (ages 4–5 years) experience improvements in symptoms with behavior therapy alone, and the overall evidence for behavior therapy in preschool-aged children is strong.
- Behavioral programs for children 4 to 5 years of age typically run in the form of group parent-training programs and, although not always compensated by health insurance, have a lower cost. The process algorithm (see Supplemental pages s15-16) contains criteria for the clinician to use in assessing the quality of the behavioral therapy. In addition, programs such as Head Start and Children and Adults With Attention Deficit Hyperactivity Disorder (CHADD) (www.chadd.org) might provide some behavioral supports.

Many young children with ADHD might still require medication to achieve maximum improvement, and medication is not contraindicated for children 4 through 5 years of age. However, only 1 multisite study has carefully assessed medication use in preschool-aged children. Other considerations in the recommendation about treating children 4 to 5 years of age with stimulant medications include:

- The study was limited to preschool-aged children who had moderate-to-severe dysfunction.
- Research has found that a number of young children (4–5 years of age) experience improvements in symptoms with behavior therapy alone.
- There are concerns about the possi-

ble effects on growth during this rapid growth period of preschool-aged children.

- There has been limited information about and experience with the effects of stimulant medication in children between the ages of 4 and 5 years.

Here, the criteria for enrollment (and, therefore, medication use) included measures of severity that distinguished treated children from the larger group of preschool-aged children with ADHD. Thus, before initiating medications, the physician should assess the severity of the child's ADHD. Given current data, only those preschool-aged children with ADHD who have moderate-to-severe dysfunction should be considered for medication. Criteria for this level of severity, based on the multisite-study results,[57] are (1) symptoms that have persisted for at least 9 months, (2) dysfunction that is manifested in both the home and other settings such as preschool or child care, and (3) dysfunction that has not responded adequately to behavior therapy. The decision to consider initiating medication at this age depends in part on the clinician's assessment of the estimated developmental impairment, safety risks, or consequences for school or social participation that could ensue if medications are not initiated. It is often helpful to consult with a mental health specialist who has had specific experience with preschool-aged children if possible.

Dextroamphetamine is the only medication approved by the FDA for use in children younger than 6 years of age. This approval, however, was based on less stringent criteria in force when the medication was approved rather than on empirical evidence of its safety and efficacy in this age group. Most of the evidence for the safety and efficacy of treating preschool-aged children with stimulant medications has been from methylphenidate.[57] Methylphenidate evidence consists of 1 multisite study of 165 children and 10 other smaller single-site studies that included from 11 to 59 children (total of 269 children); 7 of the 10 single-site studies found significant efficacy. It must be noted that although there is moderate evidence that methylphenidate is safe and efficacious in preschool-aged children, its use in this age group remains off-label. Although the use of dextroamphetamine is on-label, the insufficient evidence for its safety and efficacy in this age group does not make it possible to recommend at this time.

If children do not experience adequate symptom improvement with behavior therapy, medication can be prescribed, as described previously. Evidence suggests that the rate of metabolizing stimulant medication is slower in children 4 through 5 years of age, so they should be given a lower dose to start, and the dose can be increased in smaller increments. Maximum doses have not been adequately studied.[57]

Special Circumstances: Adolescents

As noted previously, before beginning medication treatment for adolescents with newly diagnosed ADHD, clinicians should assess these patients for symptoms of substance abuse. When substance use is identified, assessment when off the abusive substances should precede treatment for ADHD (see the Task Force on Mental Health report[7]). Diversion of ADHD medication (use for other than its intended medical purposes) is also a special concern among adolescents[58]; clinicians should monitor symptoms and prescription-refill requests for signs of misuse or diversion of ADHD medication and consider prescribing medications with no abuse potential, such as atomoxetine (Strattera [Ely Lilly Co, Indianapolis, IN]) and extended-release guanfacine (Intuniv [Shire US Inc, Wayne, PA]) or extended-release clonidine (Kapvay [Shionogi Inc, Florham Park, NJ]) (which are not stimulants) or stimulant medications with less abuse potential, such as lisdexamfetamine (Vyvanse [Shire US Inc]), dermal methylphenidate (Daytrana [Noven Therapeutics, LLC, Miami, FL]), or OROS methylphenidate (Concerta [Janssen Pharmaceuticals, Inc, Titusville, NJ]). Because lisdexamfetamine is dextroamphetamine, which contains an additional lysine molecule, it is only activated after ingestion, when it is metabolized by erythrocyte cells to dexamphetamine. The other preparations make extraction of the stimulant medication more difficult.

Given the inherent risks of driving by adolescents with ADHD, special concern should be taken to provide medication coverage for symptom control while driving. Longer-acting or late-afternoon, short-acting medications might be helpful in this regard.[59]

Special Circumstances: Inattention or Hyperactivity/Impulsivity (Problem Level)

Medication is not appropriate for children whose symptoms do not meet DSM-IV criteria for diagnosis of ADHD, although behavior therapy does not require a specific diagnosis, and many of the efficacy studies have included children without specific mental behavioral disorders.

Behavior Therapy

Behavior therapy represents a broad set of specific interventions that have a common goal of modifying the physical and social environment to alter or change behavior. Behavior therapy usually is implemented by training parents in specific techniques that improve their abilities to modify and

TABLE 1 Evidence-Based Behavioral Treatments for ADHD

Intervention Type	Description	Typical Outcome(s)	Median Effect Size[a]
Behavioral parent training (BPT)	Behavior-modification principles provided to parents for implementation in home settings	Improved compliance with parental commands; improved parental understanding of behavioral principles; high levels of parental satisfaction with treatment	0.55
Behavioral classroom management	Behavior-modification principles provided to teachers for implementation in classroom settings	Improved attention to instruction; improved compliance with classroom rules; decreased disruptive behavior; improved work productivity	0.61
Behavioral peer interventions (BPI)[b]	Interventions focused on peer interactions/relationships; these are often group-based interventions provided weekly and include clinic-based social-skills training used either alone or concurrently with behavioral parent training and/or medication	Office-based interventions have produced minimal effects; interventions have been of questionable social validity; some studies of BPI combined with clinic-based BPT found positive effects on parent ratings of ADHD symptoms; no differences on social functioning or parent ratings of social behavior have been revealed	

[a] Effect size = (treatment median − control median)/control SD.

[b] The effect size for behavioral peer interventions is not reported, because the effect sizes for these studies represent outcomes associated with combined interventions. A lower effect size means that they have less of an effect. The effect sizes found are considered moderate.

Adapted from Pelham W, Fabiano GA. *J Clin Child Adolesc Psychol.* 2008;37(1):184–214.

shape their child's behavior and to improve the child's ability to regulate his or her own behavior. The training involves techniques to more effectively provide rewards when their child demonstrates the desired behavior (eg, positive reinforcement), learn what behaviors can be reduced or eliminated by using planned ignoring as an active strategy (or using praising and ignoring in combination), or provide appropriate consequences or punishments when their child fails to meet the goals (eg, punishment). There is a need to consistently apply rewards and consequences as tasks are achieved and then to gradually increase the expectations for each task as they are mastered to shape behaviors. Although behavior therapy shares a set of principles, individual programs introduce different techniques and strategies to achieve the same ends.

Table 1 lists the major behavioral intervention approaches that have been demonstrated to be evidence based for the management of ADHD in 3 different types of settings. The table is based on 22 studies, each completed between 1997 and 2006.

Evidence for the effectiveness of behavior therapy in children with ADHD is derived from a variety of studies[60–62] and an Agency for Healthcare Research and Quality review.[5] The diversity of interventions and outcome measures makes meta-analysis of the effects of behavior therapy alone or in association with medications challenging. The long-term positive effects of behavior therapy have yet to be determined. Ongoing adherence to a behavior program might be important; therefore, implementing a chronic care model for child health might contribute to the long-term effects.[63]

Study results have indicated positive effects of behavior therapy when combined with medications. Most studies that compared behavior therapy to stimulants found a much stronger effect on ADHD core symptoms from stimulants than from behavior therapy. The MTA study found that combined treatment (behavior therapy and stimulant medication) was not significantly more efficacious than treatment with medication alone for the core symptoms of ADHD after correction for multiple tests in the primary analysis.[64] However, a secondary analysis of a combined measure of parent and teacher ratings of ADHD symptoms revealed a significant advantage for the combination with a small effect size of $d = 0.26$.[65] However, the same study also found that the combined treatment compared with medication alone did offer greater improvements on academic and conduct measures when ADHD coexisted with anxiety and when children lived in low socioeconomic environments. In addition, parents and teachers of children who were receiving combined therapy were significantly more satisfied with the treatment plan. Finally, the combination of medication management and behavior therapy allowed for the use of lower dosages of stimulants, which possibly reduced the risk of adverse effects.[66]

School Programming and Supports

Behavior therapy programs coordinating efforts at school as well as home might enhance the effects. School programs can provide classroom adaptations, such as preferred seating, modified work assignments, and test modifications (to the location at which it is administered and time allotted for taking the test), as well as behavior plans as part of a 504 Rehabilitation Act Plan or special education Individualized Education Program (IEP) under the "other health impairment" designation as part of the Individuals With

Disability Education Act (IDEA).[67] It is helpful for clinicians to be aware of the eligibility criteria in their state and school district to advise families of their options. Youths documented to have ADHD can also get permission to take college-readiness tests in an untimed manner by following appropriate documentation guidelines.[68]

The effect of coexisting conditions on ADHD treatment is variable. In some cases, treatment of the ADHD resolves the coexisting condition. For example, treatment of ADHD might resolve oppositional defiant disorder or anxiety.[68] However, sometimes the co-occurring condition might require treatment that is in addition to the treatment for ADHD. Some coexisting conditions can be treated in the primary care setting, but others will require referral and comanagement with a subspecialist.

Action statement 6: Primary care clinicians should titrate doses of medication for ADHD to achieve maximum benefit with minimum adverse effects (quality of evidence B/strong recommendation).

Evidence Profile

- **Aggregate evidence quality:** B.
- **Benefits:** The optimal dose of medication is required to reduce core symptoms to or as close to the levels of children without ADHD.
- **Harms/risks/costs:** Higher levels of medication increase the chances of adverse effects.
- **Benefits-harms assessment:** The importance of adequately treating ADHD outweighs the risk of adverse effects.
- **Value judgments:** The committee members included the effects of untreated ADHD when deciding to make this recommendation.
- **Role of patient preferences:** The families' preferences and comfort need to be taken into consideration in developing a titration plan.
- **Exclusions:** None.
- **Intentional vagueness:** None.
- **Strength: strong recommendation.**

The findings from the MTA study suggested that more than 70% of children and youth with ADHD respond to one of the stimulant medications at an optimal dose when a systematic trial is used.[65] Children in the MTA who were treated in the community with care as usual from whomever they chose or to whom they had access received lower doses of stimulants with less frequent monitoring and had less optimal results.[65] Because stimulants might produce positive but suboptimal effects at a low dose in some children and youth, titration to maximum doses that control symptoms without adverse effects is recommended instead of titration strictly on a milligram-per-kilogram basis.

Education of parents is an important component in the chronic illness model to ensure their cooperation in efforts to reach appropriate titration (remembering that the parents themselves might be challenged significantly by ADHD).[69,70] The primary care clinician should alert parents and children that changing medication dose and occasionally changing a medication might be necessary for optimal medication management, that the process might require a few months to achieve optimal success, and that medication efficacy should be systematically monitored at regular intervals.

Because stimulant medication effects are seen immediately, trials of different doses of stimulants can be accomplished in a relatively short time period. Stimulant medications can be effectively titrated on a 3- to 7-day basis.[65]

It is important to note that by the 3-year follow-up of 14-month MTA interventions (optimal medications management, optimal behavioral management, the combination of the 2, or community treatment), all differences among the initial 4 groups were no longer present. After the initial 14-month intervention, the children no longer received the careful monthly monitoring provided by the study and went back to receiving care from their community providers. Their medications and doses varied, and a number of them were no longer taking medication. In children still on medication, the growth deceleration was only seen for the first 2 years and was in the range of 1 to 2 cm.

CONCLUSION

Evidence continues to be fairly clear with regard to the legitimacy of the diagnosis of ADHD and the appropriate diagnostic criteria and procedures required to establish a diagnosis, identify co-occurring conditions, and treat effectively with both behavioral and pharmacologic interventions. However, the steps required to sustain appropriate treatments and achieve successful long-term outcomes still remain a challenge. To provide more detailed information about how the recommendations of this guideline can be accomplished, a more detailed but less strongly evidence-based algorithm is provided as a companion article.

AREAS FOR FUTURE RESEARCH

Some specific research topics pertinent to the diagnosis and treatment of ADHD or developmental variations or problems in children and adolescents in primary care to be explored include:

- identification or development of reliable instruments suitable to use in primary care to assess the nature or degree of functional impairment in children/adolescents with ADHD and monitor improvement over time;
- study of medications and other therapies used clinically but not approved by the FDA for ADHD, such as

electroencephalographic biofeedback;

- determination of the optimal schedule for monitoring children/adolescents with ADHD, including factors for adjusting that schedule according to age, symptom severity, and progress reports;
- evaluation of the effectiveness of various school-based interventions;
- comparisons of medication use and effectiveness in different ages, including both harms and benefits;
- development of methods to involve parents and children/adolescents in their own care and improve adherence to both behavior and medication treatments;
- standardized and documented tools that will help primary care providers in identifying coexisting conditions;
- development and determination of effective electronic and Web-based systems to help gather information to diagnose and monitor children with ADHD;
- improved systems of communication with schools and mental health professionals, as well as other community agencies, to provide effective collaborative care;
- evidence for optimal monitoring by some aspects of severity, disability, or impairment; and
- long-term outcomes of children first identified with ADHD as preschool-aged children.

SUBCOMMITTEE ON ATTENTION DEFICIT HYPERACTIVITY DISORDER (OVERSIGHT BY THE STEERING COMMITTEE ON QUALITY IMPROVEMENT AND MANAGEMENT, 2005–2011)

WRITING COMMITTEE

Mark Wolraich, MD, Chair – *(periodic consultant to Shire, Eli Lilly, Shinogi, and Next Wave Pharmaceuticals)*
Lawrence Brown, MD – *(neurologist; AAP Section on Neurology; Child Neurology Society) (Safety Monitoring Board for Best Pharmaceuticals for Children Act for National Institutes of Health)*
Ronald T. Brown, PhD – *(child psychologist; Society for Pediatric Psychology) (no conflicts)*
George DuPaul, PhD – *(school psychologist; National Association of School Psychologists) (participated in clinical trial on Vyvanse effects on college students with ADHD, funded by Shire; published 2 books on ADHD and receives royalties)*
Marian Earls, MD – *(general pediatrician with QI expertise, developmental and behavioral pediatrician) (no conflicts)*
Heidi M. Feldman, MD, PhD – *(developmental and behavioral pediatrician; Society for Developmental and Behavioral Pediatricians) (no conflicts)*
Theodore G. Ganiats, MD – *(family physician; American Academy of Family Physicians) (no conflicts)*
Beth Kaplanek, RN, BSN – *(parent advocate, Children and Adults With Attention Deficit Hyperactivity Disorder [CHADD]) (no conflicts)*
Bruce Meyer, MD – *(general pediatrician) (no conflicts)*
James Perrin, MD – *(general pediatrician; AAP Mental Health Task Force, AAP Council on Children With Disabilities) (consultant to Pfizer not related to ADHD)*
Karen Pierce, MD – *(child psychiatrist; American Academy of Child and Adolescent Psychiatry) (no conflicts)*
Michael Reiff, MD – *(developmental and behavioral pediatrician; AAP Section on Developmental and Behavioral Pediatrics) (no conflicts)*
Martin T. Stein, MD – *(developmental and behavioral pediatrician; AAP Section on Developmental and Behavioral Pediatrics) (no conflicts)*
Susanna Visser, MS – *(epidemiologist) (no conflicts)*

CONSULTANT

Melissa Capers, MA, MFA – *(medical writer) (no conflicts)*

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

David G. Jaimovich, MD, and the Committee on Hospital Care and Section on Critical Care

Admission and Discharge Guidelines for the Pediatric Patient Requiring Intermediate Care

ABSTRACT. During the past 3 decades, the specialty of pediatric critical care medicine has grown rapidly, leading to a number of pediatric intensive care units opening across the country. Many patients who are admitted to the hospital require a higher level of care than routine inpatient general pediatric care, yet not to the degree of intensity of pediatric critical care; therefore, an intermediate care level has been developed in institutions providing multidisciplinary subspecialty pediatric care. These patients may require frequent monitoring of vital signs and nursing interventions, but usually they do not require invasive monitoring. The admission of the pediatric intermediate care patient is guided by physiologic parameters depending on the respective organ system involved relative to an institution's resources and capacity to care for a patient in a general care environment. This report provides admission and discharge guidelines for intermediate pediatric care. Intermediate care promotes greater flexibility in patient triage and provides a cost-effective alternative to admission to a pediatric intensive care unit. This level of care may enhance the efficiency of care and make health care more affordable for patients receiving intermediate care. ***Pediatrics*** **2004; 113:1430–1433;** ***coordination of care, admission, discharge, multidisciplinary, intermediate care.***

The purpose of this statement is to provide lists of criteria that may be incorporated into multidisciplinary guidelines for the admission and discharge of children requiring intermediate care. Because of the continuous and rapidly changing developments in critical care pediatrics, these criteria may require periodic revision. Equally important, because of significant differences in personnel, facilities, and diagnostic and treatment capabilities from hospital to hospital, no single set of criteria will apply to every institution providing intermediate care.

Intermediate care is provided in acute care hospitals to a patient population with a severity of illness that does not require intensive care but does require greater services than those provided by routine inpatient general pediatric care. These patients may require frequent monitoring of vital signs and/or nursing interventions but usually will not require invasive monitoring. The development of intermediate care services has been proposed as an appropriate means to enhance resource utilization for intermediately ill patients.[1–4] In light of the recent emphasis on cost containment, intermediate care promotes flexibility in patient triage, provides pediatric patients with monitoring and therapies tailored to their severity of illness, and may be a cost-effective alternative to admission to a pediatric intensive care unit. Patients with a low risk of, but potential for, significant deterioration and who are admitted for routine monitoring are excellent candidates for intermediate care.

Intermediate care is ideally provided in facilities that have a pediatric intensive care unit.[5] However, these resources may not be widely available, particularly in geographically remote regions, where tertiary pediatric centers may be several hours and hundreds of miles away. Therefore, this statement is also intended to provide guidance for the care of children requiring intermediate care in hospitals without a pediatric intensive care unit. These hospitals should ensure that the resources, facilities, and personnel needed to provide care beyond the level of a general pediatric medical-surgical unit are available; furthermore, they should have the ability to immediately stabilize a child who becomes critically ill. In addition, these hospitals should identify facilities with pediatric intensive care units to which patients can be transferred if their condition worsens.[6] Established transfer policies with these facilities can ensure timely and effective transition of care for these patients.

In a hospital that has a pediatric intensive care unit, these intermediate care admission and discharge guidelines should be compatible with the admission and discharge guidelines for the hospital's pediatric intensive care unit.[6] This statement provides a framework for individual hospitals to establish admission and discharge criteria for intermediate pediatric care. It is intended that these guidelines be modified by individual institutions, depending on the availability of resources, personnel, and equipment necessary to evaluate and treat a seriously ill child.

Physiologic parameters may be added to these guidelines according to individual patient care unit and institutional policies so that triage may be pro-

The recommendations in this report do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

vided appropriately into and out of intermediate care. These criteria will need to be studied in relation to outcomes over the next several years, such as is done for pediatric intensive care units nationwide. Until that time these criteria, based on expert opinion, may assist hospitals and physicians in creating a safe environment for children with a higher intensity of service needs.

GUIDELINES FOR THE PATIENT REQUIRING INTERMEDIATE CARE

I. Respiratory Diseases

Patients with moderate pulmonary or airway disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with the potential need for endotracheal intubation.
B. Patients requiring minimal support with mechanical ventilation delivered by mature and stable tracheostomy. This would apply primarily to children with chronic respiratory insufficiency.
C. Patients with progressive pulmonary (lower or upper airway) disease of moderate severity with risk of progression to respiratory failure or with obstruction potential.
D. Patients acutely requiring supplemental oxygen (fraction of inspired oxygen ≥ 0.5), regardless of cause.
E. Stable tracheotomy patients.
F. Patients requiring frequent (at intervals <2 hours), intermittent, or continuous nebulized medications (according to institutional guidelines).
G. Patients requiring apnea work-up and cardiorespiratory monitoring.

II. Cardiovascular Diseases

Patients with moderate cardiovascular disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with non–life-threatening dysrhythmias with or without the need for cardioversion.
B. Patients with non–life-threatening cardiac disease requiring low-dose intravenous inotropic or vasodilator therapy.
C. Patients undergoing high-risk cardiac procedures who require close monitoring and who do not have hemodynamic or respiratory compromise.
D. Patients who have undergone closed-heart cardiovascular and intrathoracic surgical procedures, including patent ductus-arteriosis repair, vascular shunts, permanent pacemaker placement, and open thoracotomy who do not have hemodynamic or respiratory compromise.

III. Neurologic Diseases

Patients with non–life-threatening neurologic disease requiring multidisciplinary intervention, frequent monitoring, and neurologic assessment not more than every 2 hours, including but not limited to the following, may be admitted:

A. Patients with seizures who are responsive to therapy but require continuous cardiorespiratory monitoring and who do not have hemodynamic compromise but have the potential for respiratory compromise.
B. Patients with altered sensorium in whom neurologic deterioration or depression is unlikely and neurologic assessment is required.
C. Postoperative neurosurgical patients requiring cardiorespiratory monitoring.
D. Patients with acute inflammation or infections of the central nervous system without neurologic deficiency or other complications.
E. Patients with head trauma without progressive neurologic signs or symptoms.
F. Patients with progressive neuromuscular dysfunction without altered sensorium requiring cardiorespiratory monitoring.

IV. Hematologic/Oncologic Diseases

Patients with potentially unstable hematologic or oncologic disease or non–life-threatening bleeding requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with severe anemia without hemodynamic or respiratory compromise.
B. Patients with moderate complications of sickle cell crisis, such as respiratory distress, without acute chest syndrome.
C. Patients with thrombocytopenia, anemia, neutropenia, or solid tumor who are at risk of cardiopulmonary compromise but who are currently stable and, as a result, require close cardiorespiratory monitoring.

V. Endocrine/Metabolic Diseases

Patients with potentially unstable endocrine or metabolic disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with moderate diabetic ketoacidosis (blood glucose concentration <500 mg/dL or pH ≥ 7.2) requiring continuous insulin infusion therapy without altered sensorium.
B. Patients with other moderate electrolyte and/or metabolic abnormalities (requiring cardiac monitoring and therapeutic intervention), such as:
   1. Hypokalemia (blood potassium concentration <2.0 mEq) and hyperkalemia (blood potassium concentration >6.0 mEq)
   2. Hyponatremia and hypernatremia with alterations in clinical status (ie, seizures or altered mental status)
   3. Hypocalcemia or hypercalcemia.
   4. Hypoglycemia or hyperglycemia.
   5. Moderate metabolic acidosis requiring bicarbonate infusion.
C. Patients with inborn errors of metabolism requiring cardiorespiratory monitoring.

VI. Gastrointestinal Diseases

Patients with potentially unstable gastrointestinal disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with acute gastrointestinal bleeding but who do not have hemodynamic or respiratory instability.
B. Patients with a gastrointestinal foreign body or other gastrointestinal problem requiring emergency endoscopy but who do not have cardiorespiratory compromise.
C. Patients who have chronic gastrointestinal or hepatobiliary insufficiency but do not have coma, hemodynamic, or respiratory instability.

VII. Surgery

All patients requiring multidisciplinary intervention and frequent monitoring who have undergone surgical procedures but who do not have hemodynamic or respiratory instability, including but not limited to the following, may be admitted:

A. Patients who have undergone cardiovascular surgery.
B. Patients who have undergone thoracic surgery.
C. Patients who have undergone neurosurgical procedures.
D. Patients who have undergone upper or lower airway surgery.
E. Patients who have undergone craniofacial surgery.
F. Patients who have had thoracic or abdominal trauma.
G. Patients being treated for multiple traumatic injuries.

VIII. Renal Diseases

Patients with potentially unstable renal disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients with hypertension without seizures, encephalopathy, or other symptoms, but who require frequent intermittent therapeutic intravenous or orally administered medication.
B. Patients with noncomplicated nephrotic syndrome (regardless of cause) with chronic hypertension requiring frequent blood pressure monitoring.
C. Patients with renal failure, regardless of cause.
D. Patients requiring chronic hemodialysis or peritoneal dialysis.

IX. Multisystem and Other Diseases

Patients with potentially unstable multisystem disease requiring multidisciplinary intervention and frequent monitoring, including but not limited to the following, may be admitted:

A. Patients requiring the application of special technologic needs, including:
   1. Use of respiratory assistance, such as continuous positive airway pressure, bilevel positive airway pressure, or chronic home ventilation.
   2. Tracheostomy care requiring frequent pulmonary hygiene and suctioning.
   3. Pleural or pericardial drains after initial stabilization (for patients who do not have respiratory or hemodynamic compromise).
   4. Medications or resource needs in excess of those provided in the general patient care unit.
B. Patients who are direct admissions from another health care facility outside the hospital (may be directly admitted for intermediate care).
C. Patients with uncomplicated toxic ingestion who do not have cardiovascular or respiratory compromise and who require cardiorespiratory monitoring.

DISCHARGE AND TRANSFER GUIDELINES FOR THE INTERMEDIATE CARE PATIENT

Patients will be evaluated and considered for transfer to general care or special care units when the disease process has reversed or the physiologic condition that prompted admission has resolved and the need for multidisciplinary intervention and treatment is no longer present.

The decision to transfer or discharge to home will be made on the basis of the following criteria:

A. If patient's condition deteriorates and he or she requires care beyond the capabilities of the unit providing intermediate care, he or she should be admitted or readmitted to a pediatric intensive care unit.
B. Patient should be transferred to a floor or specialty care unit or discharged from the hospital, as appropriate, if the following criteria apply:
   1. Patient has stable hemodynamic parameters for at least 6 to 12 hours.
   2. Patient has stable respiratory status and has been extubated with evidence of acceptable gas exchange for more than 4 hours.
   3. Patient has minimal oxygen requirements as evidenced by a fraction of inspired oxygen of 0.4 or less.
   4. Intravenous inotropic support, vasodilators, and antiarrhythmic drugs are no longer required, or, when applicable, low doses of these medications may be administered to otherwise stable patients in a designated patient care unit.
   5. Cardiac arrhythmias are controlled for a reasonable period of time but not less than 24 hours.
   6. Patient has neurologic stability with control of seizures for a reasonable period of time.
   7. All invasive hemodynamic monitoring devices have been removed (eg, arterial lines).
   8. Patient who had required chronic mechanical ventilation and has experienced resolution of the acute illness that required intermediate or

intensive care has now returned to baseline clinical status.
9. Patient will require peritoneal dialysis or hemodialysis on a routine basis and therefore may receive these treatments as an outpatient or in a designated patient care unit.
10. The need for multidisciplinary intervention is predictable and compatible with policies of the receiving patient care unit.
11. The health care team, after careful multidisciplinary assessment and together with the patient's family, decides that there would be no benefit to keeping the child hospitalized or that the course of treatment is medically futile.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT
Guidance for the Clinician in Rendering Pediatric Care

Jonathan D. Klein, MD, MPH, and the Committee on Adolescence

Adolescent Pregnancy: Current Trends and Issues

ABSTRACT. The prevention of unintended adolescent pregnancy is an important goal of the American Academy of Pediatrics and our society. Although adolescent pregnancy and birth rates have been steadily decreasing, many adolescents still become pregnant. Since the last statement on adolescent pregnancy was issued by the Academy in 1998, efforts to prevent adolescent pregnancy have increased, and new observations, technologies, and prevention effectiveness data have emerged. The purpose of this clinical report is to review current trends and issues related to adolescent pregnancy, update practitioners on this topic, and review legal and policy implications of concern to pediatricians. *Pediatrics* 2005; 116:281–286; *pregnancy, contraceptives, childbearing, adolescent parents.*

ABBREVIATIONS. AAP, American Academy of Pediatrics; STD, sexually transmitted disease.

INTRODUCTION

Adolescent pregnancy in the United States is a complex issue affecting families, health care professionals, educators, government officials, and youths themselves.[1,2] Since 1998, when the last statement on this topic was issued by the American Academy of Pediatrics[3] (AAP), efforts to prevent adolescent pregnancy have increased,[1] and new observations, technologies, and prevention effectiveness data have emerged. The purpose of this clinical report is to provide pediatricians with recent data on adolescent sexuality, contraceptive use, and childbearing as well as information about preventing adolescent pregnancy in their communities and in clinical practice. This report does not address diagnosis of pregnancy or management of the transition to prenatal care. Information about counseling pregnant youth is provided in the AAP policy statement "Counseling the Adolescent About Pregnancy Options,"[4] and from the Alan Guttmacher Institute,[5] and information about early prenatal care is available from the American College of Obstetricians and Gynecologists (www.acog.org).

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

doi:10.1542/peds.2005-0999

SEXUAL ACTIVITY

The proportion of American adolescents who are sexually active has decreased in recent years; however, rates are still high enough to warrant concern.[6–9] Currently, more than 45% of high school females and 48% of high school males have had sexual intercourse.[6] The average age of first intercourse is 17 years for girls and 16 years for boys.[10] However, approximately one fourth of all youth report having had intercourse by 15 years of age.[11,12] Younger teenagers are especially vulnerable to coercive and nonconsensual sex. Involuntary sexual activity has been reported by 74% of sexually active girls younger than 14 years and 60% of those younger than 15 years.[10,11] Sexually active youth, similar to older unmarried adults, usually have monogamous, short-lived relationships with successive partners. Current surveys indicate that 11% of high school females and 17% of high school males report having had 4 or more sexual partners.[7] In addition to intercourse, many adolescents report having had oral sex or engaging in kissing, touching, or other mutual stimulation; however, data on these other behaviors are reported rarely.[13]

There are several predictors of sexual intercourse during the early adolescent years, including early pubertal development, a history of sexual abuse, poverty, lack of attentive and nurturing parents, cultural and family patterns of early sexual experience, lack of school or career goals, substance abuse, and poor school performance or dropping out of school.[1,2,6,11,12,14] Factors associated with a delay in the initiation of sexual intercourse include living with both parents in a stable family environment, regular attendance at places of worship, and higher family income.[11,12,15,16] Recently, parental supervision, setting expectations, and parent/child "connectedness" have been recognized as clearly associated with decreasing risky sexual behavior and other risky behaviors among adolescents.[14,16]

CONTRACEPTIVE USE

Despite increasing use of contraception by adolescents at the time of first intercourse,[10–12,17,18] 50% of adolescent pregnancies occur within the first 6 months of initial sexual intercourse.[11] The human immunodeficiency virus (HIV) epidemic and public health education efforts have led more adolescents to use barrier contraceptives; nonetheless, in 2003, among high school students who reported that they

had ever had sexual intercourse, only 63% reported having used a condom the last time they had intercourse.[6] Despite HIV prevention guidelines, initiation of prescription contraceptives is often accompanied by decreased condom use, especially among adolescents who do not perceive themselves to be at risk of sexually transmitted diseases (STDs).[19] Many adolescents who currently report using prescription contraceptives delayed seeing a clinician for a contraceptive prescription until they had been sexually active for 1 year or more.[10] Adolescent women, similar to adult women, have changed contraceptive methods in recent years, with decreases in pill use and increases in injectable contraceptive use.[20] Factors associated with more consistent contraceptive use among sexually active youth include academic success in school, anticipation of a satisfying future, and being involved in a stable relationship with a sexual partner.[21] The Centers for Disease Control and Prevention unambiguously recommends both abstinence and the use of barrier contraceptives for individuals who choose to be sexually active.[22] However, some groups continue to question the effectiveness of condoms.[23] Youth who participated in programs that provided information about abstinence, condoms, and/or contraception; who were engaged in one-on-one discussions about their own behavior; who were given clear messages about sex and condom or contraceptive use; and who were provided condoms or contraceptives have been found to increase consistent condom and contraception use without increasing sexual activity.[1]

TRENDS IN ADOLESCENT CHILDBEARING

Each year, approximately 900 000 teenagers become pregnant in the United States,[1] and despite decreasing rates, more than 4 in 10 adolescent girls have been pregnant at least once before 20 years of age.[1] Most of these pregnancies are among older teenagers (ie, those 18 or 19 years of age).[1,24] Approximately 51% of adolescent pregnancies end in live births, 35% end in induced abortion, and 14% result in miscarriage or stillbirth.[1,2,11,15,24] Historically, the highest adolescent birth rates in the United States were during the 1950s and 1960s, before the legalization of abortion and the development of many of the current forms of contraception.[20] After the legalization of abortion in 1973, birth rates for US females 15 to 19 years of age decreased sharply until 1986. Rates increased steadily until 1991; since then, the birth rate among teenagers has decreased every year since 1991.[1,24,25] Since 1991, the rate has decreased 35% for 15- to 17-year-olds and 20% for 18- to 19-year-olds.[23] Rates for 10- to 14-year-olds were 1.4 per 1000 in 1992 and have gradually decreased to 0.7 per 1000 in 2002.[26]

Although birth rates have been decreasing steadily for white and black teenagers in recent years, 1996 is the first year that birth rates decreased for Hispanic teenagers; Hispanic adolescents also have had the highest overall birth rates and smallest decreases in recent years.[25,27]

Once a teenager has had 1 infant, she is at increased risk of having another. Approximately 25% of adolescent births are not first births.[1,2,9,28]

ADOLESCENT PARENTS AND THEIR PARTNERS

Adolescent childbearing is usually inconsistent with mainstream societal demands for attaining adulthood through education, work experience, and financial stability. Poverty is correlated significantly with adolescent pregnancy in the United States. Although 38% of adolescents live in poor or low-income families, as many as 83% of adolescents who give birth and 61% who have abortions are from poor or low-income families. At least one third of parenting adolescents (both males and females) are themselves products of adolescent pregnancy. Although it is difficult to establish causal links between childhood maltreatment and subsequent adolescent pregnancy, in some studies as many as 50% to 60% of those who become pregnant in early or midadolescence have a history of childhood sexual or physical abuse.[10,11]

The problem of adolescent pregnancy is often assumed to be both an adolescent and an adult problem, because many partners of childbearing youth are adults. The percentage of adolescent pregnancies in which the father is an adult is unclear; studies report a range from 7% to 67%.[29–33] Adult men having sexual relationships with adolescents is problematic, because many of these relationships may be abusive or coercive. Adolescents who have sex with older men are also more likely to contract HIV infection or other STDs.[30,31,33,34] Although more than two thirds of adolescent girls' sexual partners are the same age or within a few years older and the sexual activity is consensual in nature, some partners are more than 4 years older.[35] Sexual relationships between adults and minors may be coercive or exploitative, with detrimental consequences for the health of both the teenager and her children.[30,36] Although some states and local jurisdictions have changed statutory rape laws and their enforcement, mandated reporting of all sexual activity as statutory rape or as child abuse has not been effective at changing behavior, does not allow for clinical judgment, and has the effect of deterring some of the adolescents most in need from seeking health care.[36,37]

Adolescent fathers are similar to adolescent mothers; they are more likely than their peers who are not fathers to have poor academic performance, higher school drop-out rates, limited financial resources, and decreased income potential.[37–39] Some fathers disappear from the lives of their adolescent partners and children,[40] but many others attempt to stay involved, and many young fathers struggle to be involved in their children's lives.[40,41] Current programs in adolescent pregnancy and parenting are exploring ways to reach and engage young fathers in the lives of their children.

RATES OF UNMARRIED CHILDBEARING

The birth rate to unmarried female adolescents has been increasing steadily for most of the last 30 years. In 2001, 78.9% of all births to adolescents occurred outside of marriage.[24] The increasing birth rate of

unmarried adolescents is primarily attributable to higher rates of births to unmarried white adolescents. However, adolescents account for a smaller percentage of total out-of-wedlock births now (26% in 2001) than they did in 1970 (50%).[24] Births to unmarried teenagers reflect a larger societal trend toward single parenthood, because birth rates for unmarried adults have also increased.[25,42,43] Although some reports have suggested that rates of marriage among childbearing teenagers are increasing, few teenagers or young adults who become pregnant are married before their infant is born.[44]

UNINTENDED VERSUS INTENDED PREGNANCY

More than 90% of 15- to 19-year-olds (and half of all adults) describe their pregnancies as being unintended. More than half of unintended adolescent pregnancies end in induced or spontaneous abortion,[43,44] compared with 35% of adolescent pregnancies overall.[21] On the other hand, some adolescent pregnancies are intended, and some young women are motivated to become pregnant and have children. Similar to adults, adolescents give many reasons for wanting to have children; the reason that some adolescents are motivated to be mothers at an early age is unclear.[1] Recent data suggest that many young women are ambivalent about becoming pregnant, and this is associated with less consistent and less effective contraceptive use.[45]

COMPARISON WITH INTERNATIONAL STATISTICS

Even with recent decreases, the United States has the highest adolescent birth rate among comparable industrialized countries despite sexual activity rates that are similar or higher among Western European teenagers than among teenagers in the United States.[5,17,21,25,46] For every 1000 females 15 to 19 years of age in 1992, 4 in Japan gave birth, 8 in the Netherlands gave birth, 33 in the United Kingdom gave birth, 41 in Canada gave birth, and 61 in the United States gave birth.[21] The higher birth rate for American adolescents compared with their peers in other countries is not attributable solely to high birth rates among American minority groups; non-Hispanic white adolescents in the United States also have a higher birth rate than do teenagers observed in any other developed country.[5,10,47] The reasons for this contrast are unclear, but European teenagers may have greater access to and acceptance of contraception. The contrast also may be related to universal sexuality education that exists in some European countries. Welfare benefits tend to be more generous in Europe than in the United States; thus, it is unlikely that the current welfare system motivates or explains American teenagers' decisions to have children.

MEDICAL RISKS OF ADOLESCENT PREGNANCY

Pregnant adolescents younger than 17 years have a higher incidence of medical complications involving mother and child than do adult women, although these risks may be greatest for the youngest teenagers.[17,48] The incidence of having a low birth weight infant (<2500 g) among adolescents is more than double the rate for adults, and the neonatal death rate (within 28 days of birth) is almost 3 times higher.[49] The mortality rate for the mother, although low, is twice that for adult pregnant women.[15,17]

Adolescent pregnancy has been associated with other medical problems including poor maternal weight gain, prematurity (birth at <37 weeks' gestation), pregnancy-induced hypertension, anemia, and STDs. Approximately 14% of infants born to adolescents 17 years or younger are preterm versus 6% for women 25 to 29 years of age.[49] Young adolescent mothers (14 years and younger) are more likely than other age groups to give birth to underweight infants, and this is more pronounced in black adolescents.[1,50–53]

Biological factors that have been associated consistently with negative pregnancy outcomes are poor nutritional status, low prepregnancy weight and height, parity, and poor pregnancy weight gain.[51,52] Many social factors have also been associated with poor birth outcomes, including poverty, unmarried status, low educational levels, smoking, drug use, and inadequate prenatal care.[54] Both biological and social factors may contribute to poor outcomes in adolescents. Adolescents also have high rates of STDs, substance use, and poor nutritional intake, all of which contribute to the risk of preterm delivery.[52] Interventions, such as prenatal intake of folic acid as a strategy for prevention of spina bifida, can be effective at decreasing observed disparities between adolescents and older women.[55]

PSYCHOSOCIAL COMPLICATIONS OF ADOLESCENT PREGNANCY

The psychosocial problems of adolescent pregnancy include school interruption, persistent poverty, limited vocational opportunities, separation from the child's father, divorce, and repeat pregnancy. When pregnancy does interrupt an adolescent's education, a history of poor academic performance usually exists.[56] Having repeat births before 18 years of age has a negative effect on high school completion. Factors associated with increased high school completion for pregnant teenagers include race (black teenagers fare better than do white teenagers), being raised in a smaller family, presence of reading materials in the home, employment of the teenager's mother, and having parents with higher educational levels.[54,56,57]

Research suggests that long-term negative social outcomes are not inevitable. Several long-term follow-up studies indicate that 2 decades after giving birth, most former adolescent mothers are not welfare-dependent; many have completed high school, have secured regular employment, and do not have large families.[51,57] Comprehensive adolescent pregnancy programs seem to contribute to good outcomes, as do home-visitation programs designed to promote good child health outcomes.[51,58]

CHILDREN OF ADOLESCENT PARENTS

Research during the past decade confirms the common belief that children of adolescent mothers do

not fare as well as those of adult mothers. These children have increased risks of developmental delay, academic difficulties, behavioral disorders, substance abuse, early sexual activity, depression, and becoming adolescent parents themselves.[57,59]

Adolescent mothers may not possess the same level of maternal skills as do adults. There is debate in the literature regarding the association of maternal age and child abuse. Some studies indicate that young maternal age is a risk factor for abuse, including fatalities, and others indicate the presence of reporting biases that may confound the findings.[60–63]

Although the current political climate tends to require that adolescent mothers live at home with their own families to qualify for government assistance, there is evidence that intensive involvement of families in rearing children of older adolescents may not be beneficial for either the adolescent or her child.[54,64] Many adolescent parenting programs are exploring ways to involve the families of the parenting adolescent in child care activities that are helpful.

ADOLESCENT PREGNANCY PREVENTION

Many models of adolescent pregnancy-prevention programs exist.[65–68] Most successful programs include multiple and varied approaches to the problem and include abstinence promotion and contraception information, contraceptive availability, sexuality education, school-completion strategies, and job training. Primary-prevention (first pregnancy) and secondary-prevention (repeat pregnancy) programs are both needed, with particular attention to adolescents who are at highest risk of becoming pregnant and innovative programs that include males.[69–72] Parents, schools, religious institutions, physicians, social and government agencies, and adolescents all have roles in successful prevention programs.

Efforts to prevent adolescent pregnancy at both the national and local levels have increased in recent years, and there has been increasing evidence that several different kinds of programs may help decrease sexual risk taking and pregnancy among teenagers. Recent studies have found that some sexuality- and HIV-education programs have sustained positive effects on behavior, and at least 1 program that combines sexuality education and youth development has been shown to decrease pregnancy rates for as long as 3 years.[1] Additionally, both community learning programs and sexuality- and HIV-education programs have been found to decrease sexual risk taking and/or pregnancy, and short clinic-based interventions involving educational materials coupled with counseling also may increase contraceptive use.[1]

Despite encouraging trends, efforts to prevent pregnancy must be constantly renewed as children enter into adolescence. By 2010, the population of adolescent girls 15 to 19 years of age is expected to increase by 10%; thus, decreasing pregnancy rates may not mean fewer pregnancies or births. Nonetheless, condom use has increased slightly, and adolescent contraceptive users have increasingly adopted long-acting hormonal methods, which have the lowest failure rates; thus, overall contraceptive effectiveness among teenagers has been improving.[73]

Current research indicates that encouraging abstinence and urging better use of contraception are compatible goals. Evidence shows that sexuality education that discusses contraception does not increase sexual activity, and programs that emphasize abstinence as the safest and best approach, while also teaching about contraceptives for sexually active youth, do not decrease contraceptive use. Some program models have resulted in better protective and preventive health behaviors.

CLINICAL CONSIDERATIONS FOR THE PEDIATRICIAN

1. Encourage adolescents to postpone early sexual activity and encourage parents to educate their children and adolescents about sexual development, responsible sexuality, decision-making, and values.
2. Be sensitive to issues relating to adolescent sexuality and be prepared to obtain a developmentally appropriate confidential sexual history from all adolescent patients. Because medical complications are possible, offer confidential screenings for sexual activity and pregnancy risk as well as for STD risk and abuse as a routine part of all adolescent care encounters.
3. Help ensure that all adolescents have knowledge of and access to contraception including barrier methods and emergency contraception supplies. As stated in the AAP policy statement "Folic Acid for the Prevention of Neural Tube Defects,"[74] recommend folic acid supplementation for all women of childbearing age who are capable of becoming pregnant, especially sexually active women who do not plan to use effective contraception or abstain from sexual intercourse.
4. Encourage and participate in community efforts to delay onset of sexual activity and to prevent first and subsequent adolescent pregnancies and advocate for implementation and investments in evidence-based programs that provide comprehensive information and services to youth. These efforts may vary widely from one community to another but should be directed at the specific needs of youth in that community.
5. Be aware of options and resources for adolescents and advocate for comprehensive medical and psychosocial support for all pregnant adolescents in the community. When diagnosing pregnancy, discuss pregnancy options or refer the patient for counseling; discuss adoption, abortion, and prenatal care; and provide follow-up. Tailor prenatal care to the medical, social, nutritional, and educational needs of the adolescent and include child care and contraceptive information.
6. Assess the adolescent mother's abilities to care for her children and have resources available for referral and assistance before neonatal discharge.
7. Advocate for the inclusion of the adolescent mother's partner and/or father of her child in pregnancy and parenting programs when appropriate.

These programs should provide access to education and vocational training, parenting skills classes, and contraceptive education.

8. Serve as a resource for the pregnant teenager and her infant, the teenager's family, and the father of the infant to ensure that optimal health care is obtained and appropriate support is provided.

Age Terminology During the Perinatal Period

ABSTRACT. Consistent definitions to describe the length of gestation and age in neonates are needed to compare neurodevelopmental, medical, and growth outcomes. The purposes of this policy statement are to review conventional definitions of age during the perinatal period and to recommend use of standard terminology including gestational age, postmenstrual age, chronological age, corrected age, adjusted age, and estimated date of delivery. ***Pediatrics*** **2004;114:1362–1364;** ***gestational age, postmenstrual age, chronological age, menstrual age, conceptional age, postconceptual age, corrected age, adjusted age, estimated date of delivery, estimated date of confinement.***

INTRODUCTION

Consistent definitions to describe the length of gestation and age in neonates are needed to compare neurodevelopmental, medical, and growth outcomes. The terms "gestational age," "postmenstrual age," "corrected age," and "postconceptional age" have frequently been defined unconventionally,[1,2] misapplied,[3–5] or left undefined.[6,7] Inconsistent use of terminology limits the accurate interpretation of data on health outcomes for newborn infants, especially for those born preterm or conceived using assisted reproductive technology. The purposes of this statement are to review conventional definitions of age during the perinatal period and to recommend standard terminology.

"Gestational age" (or "menstrual age") is the time elapsed between the first day of the last normal menstrual period and the day of delivery (Fig 1).[8–10] The first day of the last menstrual period occurs approximately 2 weeks before ovulation and approximately 3 weeks before implantation of the blastocyst. Because most women know when their last period began but not when ovulation occurred, this definition traditionally has been used when estimating the expected date of delivery. As long as menstrual dates are remembered accurately, this method of estimating the date of delivery is reliable.[11] Minor inaccuracy (4–6 days) in the expected date of delivery determined from menstrual dates is attributable to inherent biological variability in the relative timing of onset of the last menstrual period, fertilization of the egg, and implantation of the blastocyst.[12] Additional inaccuracy (weeks) may occur in women who have menstrual cycles that are irregular or variable in duration or if breakthrough bleeding occurs around the time of conception. Gestational age is conventionally expressed as completed weeks. Therefore, a 25-week, 5-day fetus is considered a 25-week fetus. To round the gestational age of such a fetus to 26 weeks is inconsistent with national and international norms.[2] The term "gestational age" should be used instead of "menstrual age" to describe the age of the fetus or newborn infant.

"Chronological age" (or "postnatal" age) is the time elapsed after birth (Fig 1). It is usually described in days, weeks, months, and/or years. This is different from the term "postmenstrual age." Postmenstrual age is the time elapsed between the first day of the last menstrual period and birth (gestational age) plus the time elapsed after birth (chronological age). Postmenstrual age is usually described in number of weeks and is most frequently applied during the perinatal period beginning after the day of birth. Therefore, a preterm infant born at a gestational age of 33 weeks who is currently 10 weeks old (chronological age) would have a postmenstrual age of 43 weeks. When postmenstrual age is quantitated in weeks and days for postnatal management reasons, a 33-week, 1-day gestational age infant who is 10 weeks, 5 days chronological age would have a postmenstrual age of 43 weeks, 6 days.

"Corrected age" (or "adjusted age") is a term most appropriately used to describe children up to 3 years of age who were born preterm (Fig 1). This term is preferred to "corrected gestational age" or "gestational age" and represents the age of the child from the expected date of delivery.[13,14] Corrected age is calculated by subtracting the number of weeks born before 40 weeks of gestation from the chronological age. Therefore, a 24-month-old, former 28-week gestational age infant has a corrected age of 21 months according to the following equation:

$$24 \text{ months} - [(40 \text{ weeks} - 28 \text{ weeks}) \times 1 \text{ month}/4 \text{ weeks}]$$

Corrected age and chronological age are not synonymous in preterm infants. Additionally, the term "corrected age" should be used instead of "adjusted age."

"Conceptional age" is the time elapsed between the day of conception and the day of delivery. (The term "conceptual age" is incorrect and should not be

doi:10.1542/peds.2004-1915

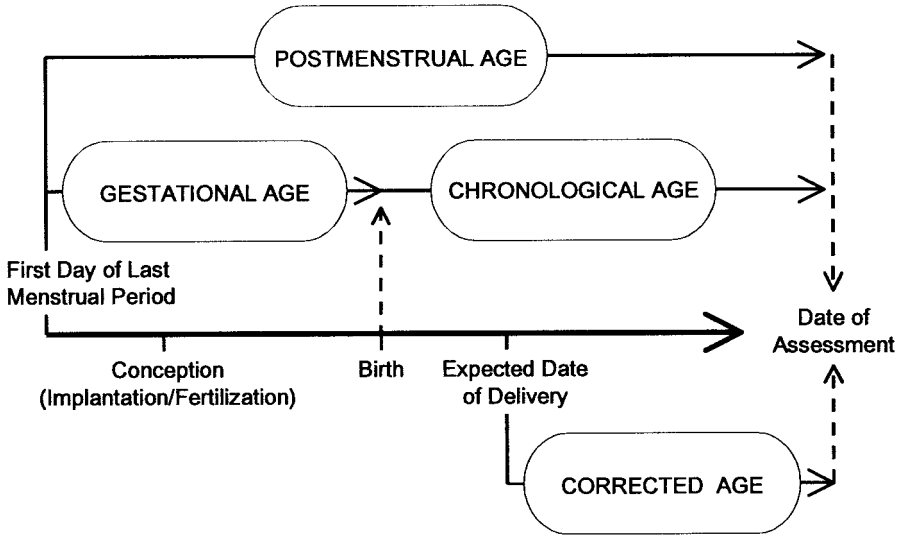

Fig 1. Age terminology during the perinatal period.

used.) Because assisted reproductive technologies accurately define the date of fertilization or implantation, a precise conceptional age can be determined in pregnancies resulting from such technologies. Much of the variability inherent in other methods of gestational age determination,[11–13] except for that attributed to timing of implantation, is eliminated when the date of conception is determined during assisted reproductive procedures. The convention for calculating gestational age when the date of conception is known is to add 2 weeks to the conceptional age.[10] Therefore, gestational age is 2 weeks longer than conceptional age; they are not synonymous terms. When describing the age of a fetus or neonate, "gestational age" is the term conventionally applied. This is particularly important for interpreting outcome studies of preterm infants. As an example, a preterm infant conceived using assisted reproductive technology who has a conceptional age of 25 weeks has a gestational age of 27 weeks. Outcomes for this infant should be compared with those of 27-week gestational age infants, not 25-week gestational age infants. To avoid confusion, the term "gestational age" should be used. The terms "conceptional age" and "postconceptional age," reflecting the time elapsed after conception, should not be used.

Gestational age is often determined by the "best obstetric estimate," which is based on a combination of the first day of last menstrual period, physical examination of the mother, prenatal ultrasonography, and history of assisted reproduction. The best obstetric estimate is necessary because of gaps in obstetric information and the inherent variability (as great as 2 weeks) in methods of gestational age estimation.[8,10,14–19] Postnatal physical examination of the infant is sometimes used as a method to determine gestational age if the best obstetric estimate seems inaccurate. Therefore, methods of determining gestational age should be clearly stated so that the variability inherent in these estimations can be considered when outcomes are interpreted.[8,10,14–19]

RECOMMENDATIONS

1. Standardized terminology should be used when defining ages and comparing outcomes of fetuses and newborns. The recommended terms (Table 1) are:
   - Gestational age (completed weeks): time elapsed between the first day of the last menstrual period and the day of delivery. If pregnancy was achieved using assisted reproductive technology, gestational age is calculated by adding 2 weeks to the conceptional age.
   - Chronological age (days, weeks, months, or years): time elapsed from birth.
   - Postmenstrual age (weeks): gestational age plus chronological age.
   - Corrected age (weeks or months): chronological age reduced by the number of weeks born before 40 weeks of gestation; the term should be used only for children up to 3 years of age who were born preterm.
2. During the perinatal period neonatal hospital stay, "postmenstrual age" is preferred to describe

TABLE 1. Age Terminology During the Perinatal Period

Term	Definition	Units of Time
Gestational age	Time elapsed between the first day of the last menstrual period and the day of delivery	Completed weeks
Chronological age	Time elapsed since birth	Days, weeks, months, years
Postmenstrual age	Gestational age + chronological age	Weeks
Corrected age	Chronological age reduced by the number of weeks born before 40 weeks of gestation	Weeks, months

the age of preterm infants. After the perinatal period, "corrected age" is the preferred term.
3. "Conceptional age," "postconceptional age," "conceptual age," and "postconceptual age" should not be used in clinical pediatrics.
4. Publications reporting fetal and neonatal outcomes should clearly describe methods used to determine gestational age.

Ambient Air Pollution: Health Hazards to Children

ABSTRACT. Ambient (outdoor) air pollution is now recognized as an important problem, both nationally and worldwide. Our scientific understanding of the spectrum of health effects of air pollution has increased, and numerous studies are finding important health effects from air pollution at levels once considered safe. Children and infants are among the most susceptible to many of the air pollutants. In addition to associations between air pollution and respiratory symptoms, asthma exacerbations, and asthma hospitalizations, recent studies have found links between air pollution and preterm birth, infant mortality, deficits in lung growth, and possibly, development of asthma. This policy statement summarizes the recent literature linking ambient air pollution to adverse health outcomes in children and includes a perspective on the current regulatory process. The statement provides advice to pediatricians on how to integrate issues regarding air quality and health into patient education and children's environmental health advocacy and concludes with recommendations to the government on promotion of effective air-pollution policies to ensure protection of children's health. *Pediatrics* 2004;114:1699–1707; *air pollution, adverse effects, children, asthma, environmental health.*

ABBREVIATIONS. $PM_{2.5}$, particulate matter with a median aerodynamic diameter less than 2.5 μm; PM_{10}, particulate matter with a median aerodynamic diameter less than 10 μm; EPA, Environmental Protection Agency; HAP, hazardous air pollutant; AQI, air quality index.

INTRODUCTION

Although it has been 3 decades since passage of the Clean Air Act in 1970 (Pub L No. 91–604), the air in many parts of the United States is far from clean. Air quality has improved in some areas but decreased in others.[1] In addition, there are important health effects from air pollutants at levels once considered safe. Children and infants are among the most susceptible to many of the air pollutants.

In 2002, approximately 146 million Americans were living in areas where monitored air failed to meet the 1997 National Ambient Air Quality Standards for at least 1 of the 6 "criteria air pollutants": ozone, particulate matter, sulfur dioxide, nitrogen dioxide, carbon monoxide, and lead (Table 1).[1] Although the standards for ozone and particulate matter were revised in 1997, legal barriers have delayed timely implementation.[2] Recent reports have identified adverse health effects at levels near or below the current standards for ozone, particulate matter, and nitrogen dioxide. Thus, the 1997 federal standards may not adequately protect children. Additionally, numerous other toxic air pollutants are of public health concern.[3]

Outdoor air pollution is also a major problem in developing countries. The World Health Organization found that the air quality in large cities in many developing countries is remarkably poor and that very large numbers of people in those countries are exposed to ambient concentrations of air pollutants well above the World Health Organization guidelines for air quality (www.who.int/ceh/publications/en/11airpollution.pdf).

Scientific understanding of the health effects of air pollution, including effects on children, has increased in the last decade. This statement updates a 1993 American Academy of Pediatrics (AAP) statement titled "Ambient Air Pollution: Respiratory Hazards to Children."[4]

EFFECTS OF AIR POLLUTION ON CHILDREN

Children are more vulnerable to the adverse effects of air pollution than are adults. Eighty percent of alveoli are formed postnatally, and changes in the lung continue through adolescence.[5] During the early postneonatal period, the developing lung is highly susceptible to damage after exposure to environmental toxicants.[5–7]

Children have increased exposure to many air pollutants compared with adults because of higher minute ventilation and higher levels of physical activity.[8] Because children spend more time outdoors than do adults, they have increased exposure to outdoor air pollution.[9,10]

Infants, children, the elderly, and those with cardiopulmonary disease are among the most susceptible to adverse health effects from criteria pollutants.[11–15] Lead is neurotoxic, especially during early childhood. Carbon monoxide interferes with oxygen transport through the formation of carboxyhemoglobin. Other criteria pollutants (ozone, sulfur dioxide, particulate matter, nitrogen dioxide) have respiratory effects in children and adults, including increased respiratory tract illness, asthma exacerbations, and decreased lung function (eg, changes in peak flow).[11–12] In adults, particulate air pollution is associated with respiratory and cardiovascular hos-

* People residing in regions with pollutant concentrations above the primary standard may experience adverse health effects from poor air quality.

pitalizations, cardiovascular mortality,[16] and lung cancer.[17] Air pollution also has effects on indirect health indicators such as health care utilization and school absences.[11–13]

Although numerous studies have shown that outdoor air pollution exacerbates asthma, the effect of outdoor air pollution on the development of asthma has been less clear. Recently, a prospective study found that the risk of developing asthma was not greater, overall, in children living in communities with high levels of ozone or particulate air pollution. However, in communities with high levels of ozone, there was an increased risk of developing asthma in a small subset of children involved in heavy exercise (participation in 3 or more team sports per year [relative risk: 3.3; 95% confidence interval: 1.9–5.8]). This increased risk with heavy exercise was not seen in low-ozone communities. Time spent outside was also associated with new cases of asthma in high-ozone communities (relative risk: 1.4; 95% confidence interval: 1.0–2.1) but not in low-ozone communities.[18] Additional studies are needed to define the role of outdoor air pollution in the development of asthma.

Children in communities with higher levels of urban air pollution (acid vapor, nitrogen dioxide, particulate matter with a median aerodynamic diameter less than 2.5 μm [$PM_{2.5}$], and elemental carbon [a component of diesel exhaust]) had decreased lung function growth, and children who spent more time outdoors had larger deficits in the growth rate of lung function.[19,20] Ambient air pollution (especially particulate matter with a median aerodynamic diameter less than 10 μm [PM_{10}]) has also been associated with several adverse birth outcomes, as discussed in the next section.

Levels of ozone and particulate matter are high enough in many parts of the United States to present health hazards to children.[1] Additionally, National Ambient Air Quality Standards for nitrogen dioxide may not be protective. Findings on these pollutants are summarized here.

Ozone

Ambient ozone is formed by the action of sunlight on nitrogen oxides and reactive hydrocarbons, both of which are emitted by motor vehicles and industrial sources. The levels tend to be highest on warm, sunny, windless days and often peak in midafternoon, when children are most likely to be playing outside.

Ozone is a powerful oxidant and respiratory tract irritant in adults and children, causing shortness of breath, chest pain when inhaling deeply, wheezing, and cough.[11] Children have decreases in lung function, increased respiratory tract symptoms, and asthma exacerbations on days with higher levels of ambient ozone.[11,21–23] Increases in ambient ozone have been associated with respiratory or asthma hospitalizations,[24,25] emergency department visits for asthma,[26] and school absences for respiratory tract illness.[27] In Atlanta, Georgia, summertime children's emergency department visits for asthma increased 37% after 6 days when ozone levels exceeded 0.11 ppm.[25] In southern California, school absences for respiratory tract illness increased 63% in association with a 0.02-ppm increase in ozone.[27]

In healthy adults, ozone causes airway inflammation and hyperreactivity, decrements in pulmonary function, and increased respiratory tract symptoms.[11] Ozone exposures at concentrations of 0.12 ppm or higher can result in decrements in lung function after subsequent challenge with aeroallergen.[28] Although most of the controlled studies of ozone exposure have been performed with adults, it is reasonable to believe that the results of these findings could be extended to children.

Ozone may be toxic at concentrations lower than 0.08 ppm, the current federal regulatory standard. Field studies suggest potential thresholds of between 0.04 and 0.08 ppm (1-hour average) for effects on lung function.[29–31] Recent studies of hospitalizations for respiratory tract illness in young children and emergency department visits for asthma suggest that the effects of ozone may occur at ambient concentrations below 0.09 ppm.[32,33] Another study found associations of ozone and respiratory symptoms in children with asthma at levels below the current US Environmental Protection Agency (EPA) standards.[34] If these findings are confirmed, the ozone standards may need additional revision.

In addition to studies on short-term effects, 2 recent studies of college freshmen suggest that increasing cumulative childhood exposure to ozone may affect lung function when exposed children reach young adulthood, particularly in measures of flow in small airways.[35,36] Early childhood exposures may, therefore, be particularly important.[35]

Particulate Matter

PM_{10} is small enough to reach the lower respiratory tract and has been associated with a wide range of serious health effects. PM_{10} is a heterogeneous

mixture of small solid or liquid particles of varying composition found in the atmosphere. Fine particles ($PM_{2.5}$) are emitted from combustion processes (especially diesel-powered engines, power generation, and wood burning) and from some industrial activities. Coarse particles (diameter between 2.5 and 10 μm) include windblown dust from dirt roads or soil and dust particles created by crushing and grinding operations. Toxicity of particles may vary with composition.[37,38]

Particle pollution contributes to excess mortality and hospitalizations for cardiac and respiratory tract disease.[14,39–41] The mechanism for particulate matter–associated cardiac effects may be related to disturbances in the cardiac autonomic nervous system, cardiac arrhythmias, or increased blood concentrations of markers of cardiovascular risk (eg, fibrinogen).[16,42]

Daily changes in mortality rates and numbers of people hospitalized are linked to changes in particulate air pollution.[14,39–41] These studies and others have estimated that for every 10 $\mu g/m^3$ increase in PM_{10}, there is an increase in the daily mortality rate between 0.5% and 1.6%. Effects were seen even in cities with mean annual PM_{10} concentrations between 25 and 35 $\mu g/m^3$. These recent studies suggest that even the current federal standards for $PM_{2.5}$ (24-hour standard = 65 $\mu g/m^3$; annual standard = 15 $\mu g/m^3$) and PM_{10} (24-hour standard = 150 $\mu g/m^3$; annual standard = 50 $\mu g/m^3$) should be lowered to protect public health. In 2002, California adopted more stringent standards for particulate matter: the annual average standard for $PM_{2.5}$ is 12 $\mu g/m^3$ and for PM_{10} is 20 $\mu g/m^3$.[43]

In children, particulate pollution affects lung function[44–46] and lung growth.[19] In a prospective cohort of children living in southern California, children with asthma living in communities with increased levels of air pollution (especially particulates, nitrogen dioxide, and acid vapor) were more likely to have bronchitis symptoms. In this study, bronchitis symptoms refers to a parental report of "one or more episodes of 'bronchitis' in the past 12 months" or report that, "apart from colds, the child usually seems to be congested in the chest or able to bring up phlegm").[47] The same mix of air pollutants was also associated with deficits in lung growth (as measured by lung function tests).[19] Recent studies in different countries have also found associations between ambient air pollution (especially particulates and/or carbon monoxide) and postneonatal infant mortality (attributable to respiratory causes and possibly sudden infant death syndrome),[48,49] low birth weight,[50–53] and preterm birth.[51,54–56]

The relative contribution of fine versus coarse particles to adverse health effects is being investigated. In studies of cities on the East Coast, fine particles seem to be important.[57] In other areas, coarse particles have a stronger or similar effect.[58] Several studies have found that fine particles from power plants and motor vehicles[59] or industrial sources[60] may be more closely associated with mortality.

Nitrogen Dioxide

Nitrogen dioxide is a gaseous pollutant produced by high-temperature combustion. The main outdoor sources of nitrogen dioxide include diesel and gasoline-powered engines and power plants. Levels of nitrogen dioxide around urban monitors have decreased over the past 20 years. Currently, all areas of the country meet the national air quality standard for nitrogen dioxide of 0.053 ppm (100 $\mu g/m^3$), measured as an annual arithmetic mean. However, national emissions (overall production) of nitrogen oxides have actually increased in the past 20 years because of an increase in nitrogen oxide emissions from diesel vehicles.[1] This increase is of concern, because nitrogen oxide emissions contribute to ground-level ozone (smog) and other environmental problems such as acid rain.[1]

Controlled-exposure studies of people with asthma have found that short-term exposures (30 minutes) to nitrogen dioxide at concentrations as low as 0.26 ppm can enhance the allergic response after subsequent challenge with allergens.[61,62] These findings are of concern, because some urban communities that are in compliance with the federal standards for nitrogen dioxide (annual average) may experience substantial short-term peak concentrations (1-hour average) that exceed 0.25 ppm. Confirmation of these studies is needed.

Epidemiologic studies have reported relationships between increased ambient nitrogen dioxide and risks of respiratory tract symptoms[63,64] and asthma exacerbations.[65] As noted previously, children with asthma living in communities with increased levels of air pollution (especially nitrogen dioxide, acid vapor, and particulates) were more likely to have bronchitis symptoms.[47] The same mix of air pollutants was also associated with deficits in lung growth (as measured by lung function tests).[19] These effects were increased in children who spent more time outdoors.

The epidemiologic studies of health effects associated with nitrogen dioxide should be interpreted with caution. Increased levels of ambient nitrogen dioxide may be a marker for exposure to traffic emissions or other combustion-related pollution. An independent role of nitrogen dioxide cannot be clearly established because of the high covariation between ambient nitrogen dioxide and other pollutants. Nonetheless, these studies illustrate that adverse respiratory tract effects are seen in urban areas where traffic is a dominant source of air pollution.

Traffic-Related Pollution

Motor vehicles pollute the air through tailpipe exhaust emissions and fuel evaporation, contributing to carbon monoxide, $PM_{2.5}$, nitrogen oxides, hydrocarbons, other hazardous air pollutants (HAPs), and ozone formation. Motor vehicles represent the principal source of air pollution in many communities, and concentrations of traffic pollutants are greater near major roads.[66] Recently, investigators (primarily in Europe and Japan) have found increased adverse health effects among those living near busy roads.

Studies examining associations between adverse respiratory tract health and traffic have been reviewed.[67] Increased respiratory tract complications in children (eg, wheezing, chronic productive cough, and asthma hospitalizations) have been associated with residence near areas of high traffic density (particularly truck traffic).[68–71] Other investigators have linked various childhood cancers to proximity to traffic.[72–74]

Diesel exhaust, a major source of fine particulates in urban areas, is carcinogenic. Numerous studies have found an association between occupational exposure to diesel exhaust and lung cancer.[75] On the basis of extensive toxicologic and epidemiologic evidence, national and international health authorities, including the EPA and the International Agency for Research on Cancer, have concluded that there is considerable evidence of an association between exposure to diesel exhaust and an increased risk of lung cancer.[76,77] Additionally, fine particles in diesel exhaust may enhance allergic and inflammatory responses to antigen challenge and may facilitate development of new allergies.[78,79] Thus, diesel exhaust exposure may worsen symptoms in those with allergic rhinitis or asthma.

School buses operate in proximity to children, and most of the nation's school bus fleets run on diesel fuel. The EPA and some state agencies are establishing programs to eliminate unnecessary school bus idling and to promote use of cleaner buses to decrease children's exposures to diesel exhaust and the amount of air pollution created by diesel school buses (www.epa.gov/cleanschoolbus). A recent pilot study found that a child riding inside a school bus may be exposed to as much as 4 times the level of diesel exhaust as someone riding in a car.[80] These findings underscore the importance of advocating for school districts to replace diesel buses or retrofit them with pollution-reducing devices and limit school bus idling where children congregate as soon as possible.

Other Air Pollutants

Airborne levels of lead, sulfur dioxide, and carbon monoxide have decreased dramatically because of the implementation of control measures. However, levels of these pollutants may still be high near major sources. For example, high lead levels may be found near metals-processing industries, high sulfur dioxide levels may occur near large industrial facilities (especially coal-fired power plants), and high levels of carbon monoxide may occur in areas with heavy traffic congestion.[1]

In addition to criteria air pollutants, there are numerous other air pollutants produced by motor vehicles, industrial facilities, residential wood combustion, agricultural burning, and other sources that are hazardous to children. More than 50000 chemicals are used commercially, and many are released into the air. For most of these chemicals, data on toxicity are sparse.[81] Some pollutants remain airborne or react in the atmosphere to produce other harmful substances. Other air pollutants deposit into and contaminate land and water. Some toxic air pollutants such as lead, mercury, and dioxins degrade slowly or not at all. These pollutants may bioaccumulate in animals at the top of the food chain, including humans. Children can be exposed to toxic air pollutants through contaminated air, water, soil, and food.[3] One example of a persistent pollutant emitted into ambient air that leads to exposure through another route is mercury, a developmental neurotoxicant.[82] Industrial emissions, especially from coal-fired power plants, are the leading source of environmental mercury. Although the levels of airborne mercury may not be hazardous, mercury deposits into soil and surface waters and ultimately accumulates in fish.[82]

The HAPs, often referred to as "toxic air contaminants" or "air toxics," refer to 188 pollutants and chemical groups known or suspected to cause serious health effects including cancer, birth defects, and respiratory tract and neurologic illness.[3,83] The Clean Air Act directs the EPA to regulate HAPs, which include compounds such as polycyclic aromatic hydrocarbons, acrolein, and benzene from fuel or fuel combustion; solvents such as hexane and toluene; hexavalent chromium from chrome-plating facilities; perchloroethylene from dry-cleaning plants; asbestos; metals (eg, mercury and cadmium); and persistent organic pollutants such as polychlorinated biphenyls. In 2001, diesel exhaust was listed as a mobile-source HAP. Many of these compounds are included in a priority list of 33 HAPs that are of special concern because of their widespread use and potential carcinogenicity and teratogenicity.[81] The priority list and general sources of these compounds are available on the EPA Web site (www.epa.gov/ttn/atw/nata).

Limited monitoring data suggest that concentrations of some HAPs may exceed the goals of the Clean Air Act in many cities.[84] Mobile sources (on- and off-road vehicles) account for approximately half of the emissions[3] but may contribute to 90% of the cancer risk (www.scorecard.org/env-releases/hap/us.tcl). A number of studies assessing health risks have found that estimated levels of some of the HAPs are a potential public health problem in many parts of the United States.[3,84–86] For example, estimated concentrations of benzene, formaldehyde, and 1,3-butadiene may contribute to extra cases of cancer (at least 1 extra case per million population exposed) in more than 90% of the census tracts in the contiguous United States. Additionally, the most recent national cancer-risk assessment for HAPs (1996 data) did not include diesel exhaust in the risk estimates.[3] The health risks may also be underestimated, because there is limited information on toxicity values for many of the HAPs,[87] and the risk models did not consider the potential for increased risk in children. These findings underscore the need for better ways to decrease toxic air emissions and assess exposures and risks.

Air-pollution episodes created by disasters (eg, accidents, volcanoes, forest fires, and acts of terrorism) can also create hazards for children. A discussion of these events and of bioaerosols in ambient air (eg, fungal spores and pollen) is beyond the scope of this

policy statement. Additionally, this statement does not address the hazards of indoor air pollution.

PREVENTION

Public health interventions to improve air quality can improve health at the population level. A decrease in levels of air pollution in former East Germany after reunification was associated with a decrease in parent-reported bronchitis[88] and improved lung function.[89] During the 1996 Summer Olympics in Atlanta, Georgia, extensive programs were implemented to improve mass transportation and decrease anticipated downtown traffic congestion. These programs were successful and were associated with a prolonged decrease in ozone pollution and significantly lower rates of childhood asthma visits during this period.[90] Closure of a steel mill in Utah Valley and resultant reductions in particulate matter were associated with a twofold decrease in hospitalizations for asthma in preschool children.[91,92] Finally, lung function improved in children who moved away from communities with high particulate air pollution, compared with those who remained or moved to communities with comparable particulate air pollution.[93] These studies provide support for continued efforts to decrease air pollution and improve health via decreases in motor vehicle traffic and industrial emissions. Dietary factors may play a role in modulating the effects of air pollution in children. A recent study in Mexico City, Mexico, found that children with asthma given antioxidant supplements were less affected by ozone compared with a control group that did not receive supplementation.[94] Additional studies are needed to explore this issue further.

Air Pollution and the Regulatory Process

The Clean Air Act of 1970 mandated the EPA to establish the National Ambient Air Quality Standards (Table 1). Standards were set for criteria air pollutants because they are common, widespread, and known to be harmful to public health and the environment.[11,12,83,95] The standards are reviewed every 5 years and set to protect public health, including the health of "sensitive" populations such as people with asthma, children, and the elderly. These standards are set without considering the costs of attaining these levels.

The standards for ozone and particulate matter were revised in 1997 on the basis of numerous scientific studies showing that the previous standards were not adequate to ensure health protection. Legal challenges were made by the American Trucking Associations, the US Chamber of Commerce, and other state and local business groups. However, the Supreme Court ultimately supported the EPA and ordered implementation of the standards.[2] Establishing implementation plans will be a lengthy process that will require the coordinated efforts of the EPA, state and local governments, and industry and environmental organizations.

Population exposures to toxic air contaminants may be of substantial public health concern.[84,86] In contrast to criteria pollutants, monitoring of toxic air contaminants is more limited. Exposures are estimated on the basis of reported emissions and may underestimate actual exposures.[87] The EPA is mandated to develop regulations through a lengthy process that first sets standards to control emissions on the basis of best-available technology. After maximum available control technology emission standards are established, the EPA must assess the risk remaining after emission decreases for the source take effect (residual risk).

To date, the EPA has focused primarily on establishing technology-based emission standards,[3] and this has been a slow process for some sources (eg, mobile toxic air contaminants and mercury emissions). Nationwide, emissions of toxic air contaminants have dropped approximately 24% from baseline (1990–1993) because of regulation and voluntary decreases by industry. With the current plans for gradual fleet turnover and implementation of controls for motor vehicles and fuels, the EPA projects that toxic air-contaminant emissions from gasoline-powered and diesel mobile sources will not be decreased to 75% and 90% of baseline (1990–1993) levels, respectively, until the year 2020.[3] However, major decreases could be more rapidly achieved simply from a prompt, wider application of existing technology.

Protecting populations from exposure to the harmful effects of air pollutants will require effective control measures. Industry (eg, coal-burning power plants, refineries, and chemical plants) and motor vehicles (both gasoline- and diesel-powered) are major sources of criteria pollutants and HAPs.[11,12] For example, coal-fired power plants are important sources of nitrogen oxides (precursors of ozone), particulates, and sulfur dioxide and are the largest sources of mercury emission in the United States. Smaller sources such as dry cleaners, auto body shops, and wood-burning fireplaces can also affect air quality locally. Municipal and hospital waste incinerators release toxic air pollutants including mercury, lead, cadmium, and dioxin emissions. Depending on weather conditions and individual physicochemical properties, some pollutants can be carried by air currents to areas many miles from the source.

In numerous cities in the United States, the personal automobile is the single greatest polluter, because emissions from millions of vehicles on the road add up. Despite significant technologic advances that have led to tighter pollution control from vehicles, emissions vary substantially between vehicles, particularly between classes of vehicles, because of differences in fuel-economy standards set by regulatory agencies. For instance, the corporate average fuel-economy standards have less stringent fuel-economy requirements (average: 20.7 miles per gallon) for light-duty trucks, sport utility vehicles, and minivans, compared with passenger cars (average: 27.5 miles per gallon). The former group of vehicles tends to have higher emissions of air pollutants, higher fuel consumption, and higher emissions of greenhouse gases.[96,97] Information on emissions and fuel-economy ratings for recent models and a

guide for choosing clean, fuel-efficient vehicles are available from the EPA Web site (www.epa.gov/greenvehicles/index.htm). The high levels of particulate emissions from diesel-powered buses and trucks must also be addressed. More than 70% of fine particle emissions from traffic are attributable to diesel-powered buses and trucks.

Driving a private car is probably a typical citizen's most "polluting" daily activity, yet in many cases, individuals have few alternative forms of transportation. Thus, urban planning and smart growth are imperative. Urban sprawl affects land use, transportation, and social and economic development and ultimately has important implications for public health.[98] Ways in which individuals can help to decrease air pollution are available at www.epa.gov/air/actions and www.arb.ca.gov/html/brochure/50things.htm.

Air Quality Index

The air quality index (AQI) provides local information on air quality and potential health concerns at the observed (or forecasted) levels of air pollution and can be a useful tool for educating families about local air quality and health.[99] The AQI is reported daily in metropolitan areas, often as part of local weather forecasts on television or radio or in newspapers. The AQI divides air-pollution levels into 6 categories of risk for 5 common pollutants (ozone, PM_{10}, nitrogen dioxide, carbon monoxide, and sulfur dioxide). Each category has a descriptive name reflecting levels of health concern (ranging from good through very hazardous), an associated color, and an advisory statement. Information about air quality in a specific area can be obtained from www.epa.gov/air/urbanair/index.html, www.scorecard.org, or www.weather.com. Although many states and local air districts actively forecast and disseminate health warnings, the challenge is to have people take actions to protect themselves and decrease activities that cause air pollution.

Pediatric Environmental Health[100] from the AAP provides additional information about the outdoor air pollutants and the use of the AQI.

CONCLUSIONS

Ambient air pollution has important and diverse health effects, and infants and children are among the most susceptible. Currently, levels of ozone and particulates remain unhealthful in many parts of the United States, and the current National Ambient Air Quality Standards may not protect the public adequately. There is a compelling need to move forward on efforts to ensure clean air for all.

The assurance of healthy air for children to breathe is beyond the control of an individual pediatrician, and there are no easy solutions. State chapters of the AAP, as well as individual members, can play an important role as advocates for children's environmental health. Areas of involvement might include working with community coalitions in support of strong pollution-control measures and informing local and national representatives and policy makers about the harmful effects of the environment on children's health. Advocates for children's health are needed in discussions about land use and transportation issues. Pediatricians can also advocate for energy-saving (and pollution-minimizing) lifestyles to their patients' families, especially regarding vehicles driven.

In communities with poor air quality, pediatricians can play a role in educating children with asthma or other chronic respiratory tract disease and their families about the harmful effects of air pollution. Patients and families can be counseled on following the AQI to determine when local air-pollution levels pose a health concern. Ozone levels tend to be highest in the afternoon, and it may be possible to decrease children's exposure by scheduling strenuous outdoor activity earlier in the day.

As pediatricians become better informed about local air quality issues in their communities (eg, ozone, nearby industrial facilities, traffic, diesel buses, wood burning, etc), these local concerns can provide a starting point for discussion and education.

Pediatricians who serve as physicians for schools or for team sports should be aware of the health implications of pollution alerts to provide appropriate guidance to school and sports officials, particularly in communities with high levels of ozone.

RECOMMENDATIONS

1. The National Ambient Air Quality Standards are designed to protect the public. To achieve this, the following points should be addressed:
   - The revised standards for ozone and particulate matter adopted by the EPA in 1997 should be promptly implemented.
   - During implementation, the standards should not be weakened in any way that decreases the protection of children's health.
   - Because recent studies suggest that current standards for PM_{10}, $PM_{2.5}$, ozone, and nitrogen dioxide may not be protecting children, the standards should be promptly reviewed and revised.
   - Because the law requires that the most vulnerable groups be protected when setting or revising the air quality standards, the potential effects of air pollution on the fetus, infant, and child should be evaluated, and all standards should include a margin of safety for protection of children.
2. The current measures to protect children from exposures to HAPs are not effective and should be critically reevaluated. The EPA should focus on prompt implementation of the Clean Air Act Amendments of 1990 (Pub L No. 101–549) to decrease HAPs. Additional monitoring for HAPs should be undertaken to allow more accurate characterization of children's exposures to these compounds. Risk assessments for HAPs should be reviewed to ensure that goals are protective of children. Control measures that specifically protect children's health should be implemented.
3. States and local air districts with air quality concerns should actively implement forecasting and

dissemination of health warnings in ways that help people take actions to protect themselves and decrease activities that cause air pollution.
4. Children's exposure to diesel exhaust particles should be decreased. Idling of diesel vehicles in places where children live and congregate should be minimized. Ongoing programs to fund conversion of diesel school bus fleets to cleaner alternative fuels and technologies should be pursued.
5. Industrial emissions of mercury should be decreased.
6. Federal and state governments' policies should encourage reductions in mobile and stationary sources of air pollution, including increased support for mass transit, carpooling, retiring or retrofitting old power plants that do not meet current pollution-control standards, and programs that support marked improvements in fuel emissions of gasoline- and diesel-powered vehicles. Additionally, the development of alternative fuel fleets, low-sulfur diesel, and other "low-emission" strategies (eg, retrofit of existing diesel engines) should be promoted. Before promoting new alternative fuels, these alternative fuel sources should be critically evaluated and determined by governmental authorities to have a good safety profile.
7. The same overall fuel-economy standard should apply to all passenger vehicles. Programs that allow certain passenger vehicles to be exempt from the usual fuel-economy standards should be abolished.
8. City and land-use planning should encourage the design and redevelopment of communities to promote mass transit, carpooling, pedestrian walkways, and bicycle use.
9. Siting of school and child care facilities should include consideration of proximity to roads with heavy traffic and other sources of air pollution. New schools should be located to avoid "hot spots" of localized pollution.

Clinical Report—Antenatal Counseling Regarding Resuscitation at an Extremely Low Gestational Age

abstract

The anticipated delivery of an extremely low gestational age infant raises difficult questions for all involved, including whether to initiate resuscitation after delivery. Each institution caring for women at risk of delivering extremely preterm infants should provide comprehensive and consistent guidelines for antenatal counseling. Parents should be provided the most accurate prognosis possible on the basis of all the factors known to affect outcome for a particular case. Although it is not feasible to have specific criteria for when the initiation of resuscitation should or should not be offered, the following general guidelines are suggested. If the physicians involved believe there is no chance for survival, resuscitation is not indicated and should not be initiated. When a good outcome is considered very unlikely, the parents should be given the choice of whether resuscitation should be initiated, and clinicians should respect their preference. Finally, if a good outcome is considered reasonably likely, clinicians should initiate resuscitation and, together with the parents, continually reevaluate whether intensive care should be continued. Whenever resuscitation is considered an option, a qualified individual, preferably a neonatologist, should be involved and should be present in the delivery room to manage this complex situation. Comfort care should be provided for all infants for whom resuscitation is not initiated or is not successful. *Pediatrics* 2009;124:422–427

INTRODUCTION

The anticipated delivery of an extremely low gestational age infant presents difficult ethical issues for caregivers and parents. Despite previously published guidelines,[1–4] no consensus exists on this subject, and it remains one of the most controversial and emotionally charged areas in perinatology. Antenatal treatment decisions at an extremely low gestational age are complex, because they affect both the mother and the fetus, and the balance between risk and benefit may be quite different for each. For example, a cesarean delivery performed for fetal indications increases morbidity to the mother but may or may not benefit the infant. Uncertainty also exists regarding the timing of antenatal interventions, such as corticosteroid administration and fetal monitoring. These difficult decisions should optimally be made by the parents and their obstetrician, in collaboration with a neonatologist, after a thorough discussion of all currently available information.[2]

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

In addition to decisions about antepartum care and mode of delivery, parents and their physicians also must decide whether to initiate resuscitation for an infant born at an extremely low gestational age. The approach to counseling parents about decision-making regarding resuscitation of these infants should be comprehensive and consistent. The purpose of this revised clinical report (previously titled "Perinatal Care at the Threshold of Viability"[1]) is to offer guidance for clinicians providing antenatal counseling to parents in this situation.

BACKGROUND

Most clinicians agree that some infants are so immature that initiating resuscitation is futile, whereas others are sufficiently mature such that not initiating resuscitation is unacceptable.[5] Uncertainty exists, however, for infants between these 2 extremes, when it is unclear whether resuscitation is in the infant's best interest.[5] For these infants, selective resuscitation on the basis of parental preference is often considered to be an appropriate option, and general guidelines for decision-making are commonly based on estimated gestational age.[1–5] The Nuffield Council on Bioethics suggests that infants born from 22⁰⁄₇ through 23⁶⁄₇ weeks' gestation should be considered candidates for selective resuscitation.[4] They also state that from 24⁰⁄₇ through 24⁶⁄₇ weeks' gestation, the "normal practice should be that a baby will be offered full invasive intensive care and support from birth and admitted to a neonatal intensive care unit unless the parents and the clinicians are agreed that in light of the baby's condition it is not in his or her best interests to start intensive care." The Neonatal Resuscitation Program (NRP) considers the group appropriate for selective resuscitation on parental request may include an infant born at 23 to 24 weeks' gestation.[3] The International Liaison Committee on Resuscitation suggests that resuscitation is not indicated for an infant born at <23 weeks' gestation or with a birth weight less than 400 g but also recommends, "In conditions associated with uncertain prognosis, when there is borderline survival and a relatively high rate of morbidity, and where the burden to the child is high, the parent's views on starting resuscitation should be supported."[6] A recent summary of international guidelines concluded that an individual approach consistent with parents' wishes should be considered for infants born at 23 to 24 weeks' gestation.[7]

However, caution has also been expressed against using these general guidelines for managing specific cases, and individualized decision-making is encouraged. The NRP states that "these uncertainties (regarding the accuracy of antenatal gestational age and birth weight estimates) underscore the importance of not making firm commitments about withholding resuscitation until you have the opportunity to examine the baby after birth."[3] The importance of individualized decision-making is also emphasized by a statement from the summary of international guidelines: ". . . because of the uniqueness of every pregnancy and neonate, to protect mothers and infants from futile treatment, as well as incorrect withholding of life-sustaining treatment, the specific circumstances of every individual situation must always be kept in mind."[7] It is clear that individualized decision-making is required for this complex issue, and many factors have to be considered when providing antenatal counseling to parents.

FACTORS TO CONSIDER WHEN COUNSELING PARENTS

Infants born at an extremely low gestational age have a high mortality rate, and a substantial percentage of survivors have serious neurodevelopmental disabilities.[8–18] Estimated gestational age has served as the basis for estimating these risks for parents because of its strong association with outcome.[1–19] However, there are limitations of using estimated gestational age alone for antenatal counseling purposes. One limitation is that the length of gestation is rarely certain to the precise day, except when conception occurred via in vitro fertilization.[3,20,21] Another limitation is that many other factors influence the outcome of infants besides gestational age.[19,22–28] Data from the National Institute of Child Health and Development Neonatal Research Network have been used to create an algorithm predicting outcome that considers birth weight, gender, use of prenatal steroids, and singleton pregnancy in addition to estimated gestational age.[19] Each of these factors individually improves outcome for infants by as much as 1 additional week of gestation from 22 through 25 weeks' gestation. These data were averaged from multiple centers with a wide variety of outcomes, and the healthiest infants (those not requiring mechanical ventilation) were excluded from the analysis. Nevertheless, these data indicate that a decision regarding resuscitation should not be made on the basis of gestational age alone. Because this study included only infants born at a perinatal center, the impact of delivery outside a perinatal center was not evaluated. Because preterm infants born at a perinatal center have better outcomes than those transported after delivery, this should be considered when providing parents of infants born outside a perinatal center with estimates of morbidity and mortality risks.

Studies show that clinicians who provide perinatal care, patients (later in life), and parents differ in their

interpretation of outcomes of extremely preterm birth. Obstetricians and neonatologists tend to overestimate morbidity and mortality rates for extremely preterm infants,[29] which leads to underutilization of proven therapies, creating a self-fulfilling prophecy.[30,31] In addition, neonatal nurses and neonatologists generally view disabilities in surviving infants more negatively than do parents of surviving infants or the children themselves as adolescents.[32] Most families who have a surviving preterm infant with a disability do not believe that there has been a negative impact on the family, although this is not the case for all families.[33,34] Finally, adolescents who themselves were surviving extremely preterm infants generally have the same self-perceived quality of life as their control peers who were of normal birth weight, despite having more physical disabilities.[35–37] These observations highlight some of the challenges in providing guidance to parents in this complex situation.

In the United States, many neonatologists are concerned about the impact of the Born-Alive Infants Protection Act of 2001[38] on antenatal counseling, because this federal legislation specifies that a born-alive infant's legal status does not depend on gestational age, birth circumstances, or "whether anyone happens to want him or her." However, this legislation does not specify when resuscitation efforts must be initiated in the delivery room and recognizes that perceived medical futility is a justification for noninitiation of resuscitation. Although a universal definition of medical futility does not exist, a therapy is generally considered futile if it is very unlikely to benefit the patient.[39]

The antenatal consideration of noninitiation of resuscitation for an extremely low gestational age infant is a unique ethical dilemma in that the patient has not yet been seen or examined. This fact distinguishes this decision-making process from essentially all others in medicine that involve the noninitiation of life support. Therefore, whenever resuscitation is considered an option, a qualified individual should be involved and present in the delivery room to manage this complex situation. Whenever possible, this individual should be a neonatologist.

COMMUNICATIONS WITH THE PARENTS

The purpose of antenatal counseling is to inform parents and assist with decision-making. These discussions should be sensitive to the culture of the family and appropriate for the family's level of understanding of complex issues. Translation services should be used if the family is not proficient in English. Parents should be given the most accurate prognostic morbidity and mortality data available for their infant. In some situations, these may be hospital-specific data,[40,41] and in other situations, regional or national data may be more appropriate.[19] Parents need to be informed that despite the best efforts, the ability to give an accurate prognosis for a specific infant either antenatally or immediately after delivery remains limited.[40–45] Parents should be told that even with resuscitation and intensive care, many infants born at an extremely low gestational age die within the first few days after delivery.[41] Parents also need to recognize that infants who survive the first few days are likely to survive until hospital discharge, but prediction of long-term neurologic outcome remains limited.[42] It should be made clear to parents that if resuscitation is attempted and successful, situations may occur later in which it is reasonable to consider withdrawing treatment.[46] If the parents' preferences regarding resuscitation are either unknown or uncertain, both the Nuffield Council on Bioethics and the NRP suggest that resuscitation should be initiated pending further discussions.[3,4] Two surveys of parents have indicated that the vast majority of parents prefer resuscitation to be initiated even when there is great uncertainty about the outcome.[47,48] Parents should also be told that if the decision is not to initiate resuscitation or if resuscitation is unsuccessful, their infant will be provided comfort care and they will have the opportunity to hold their infant after delivery.

The most effective method of communicating complex information to parents is unknown.[41,49] Some have suggested providing written information, because parents often forget what they have been told.[50] When considering noninitiation of resuscitation for an infant, established ethical principles require that the parents be fully informed about their infant's prognosis and care options.[46,51] Whenever possible, these conversations should involve both parents at the same time, and parents must have adequate time to ask questions and consider the content of the discussions. Ideally, the neonatologist and the obstetrician should speak with the parents together and present a consistent approach. More than 1 conversation may be necessary and decisions may need to be altered if the pregnancy continues. It is important to realize that what physicians think parents hear and understand during these discussions may not reflect what the parents later report being told.[52,53]

Opinions differ on whether counseling of parents should be directive.[41] The traditional approach has been to give parents outcome data in a nondirective manner and ask them to decide whether they want their infant resuscitated. Others have argued that this places an unfair burden on parents, who may later regret their decision,

regardless of what it was, and experience feelings of guilt. In addition, parents can rarely be as informed as physicians about the complexities of prolonged hospitalization and the long-term outcome for these infants. Still others have suggested the degree to which counseling should be directive is in part related to the characteristics of individual parents. Although no consensus exists on this point, antenatal counseling may be of little value unless some degree of direction is provided to parents. After appropriate discussions, conflicts may still exist between parents and physicians regarding whether to initiate resuscitation. Further discussions will usually resolve these conflicts, but for unusual cases, referral to an ethics committee may be necessary.

CLINICAL IMPLICATIONS

1. Whether to initiate resuscitation of an infant born at an extremely low gestational age is a difficult decision, because the consequences of this decision are either the inevitable death of the infant or the uncertainties of providing intensive care for an unknown length of time with an uncertain outcome.
2. Each hospital that provides obstetric care should have a comprehensive and consistent approach to counseling parents and decision-making.
3. Parents should be provided the most accurate prognostic data available to help them make decisions. These predictions should not be based on gestational age alone but should include all relevant information affecting the prognosis.
4. It is not possible to develop specific criteria for when the initiation of resuscitation should or should not be offered. Rather, the following general guidelines are suggested when discussing this situation with parents.
   a. If the physicians involved believe that there is no chance of survival, resuscitation is not indicated and should not be initiated.
   b. If the physicians consider a good outcome to be very unlikely, then parents should be given the choice of whether resuscitation should be initiated, and clinicians should respect their preference.
   c. When the physicians' judgment is that a good outcome is reasonably likely, clinicians should initiate resuscitation and, together with the parents, continually re-evaluate whether intensive care should be continued.
5. Whenever resuscitation is considered an option, a qualified individual should be involved and present in the delivery room to manage this complex situation. Whenever possible, this individual should be a neonatologist.
6. Comfort care should be provided for all infants for whom resuscitation is not initiated or is not successful.

CLINICAL REPORT

Antiviral Therapy and Prophylaxis for Influenza in Children

Guidance for the Clinician in Rendering Pediatric Care

Committee on Infectious Diseases

ABSTRACT

Antiviral agents are available that are safe and effective for the treatment and prophylaxis of influenza virus infections in children. The neuraminidase inhibitors (oseltamivir [Tamiflu] and zanamivir [Relenza]) are preferred agents because of current widespread resistance to the adamantanes (amantadine [Symmetrel] and rimantadine [Flumadine]). Therapy should be provided to children with influenza infection who are at high risk of severe infection and to children with moderate-to-severe influenza infection who may benefit from a decrease in the duration of symptoms. Prophylaxis should be provided (1) to high-risk children who have not yet received immunization and during the 2 weeks after immunization, (2) to unimmunized family members and health care professionals with close contact with high-risk unimmunized children or infants who are younger than 6 months, and (3) for control of influenza outbreaks in unimmunized staff and children in an institutional setting. Testing of current H5N1 avian influenza virus isolates, the potential agents of pandemic influenza, suggests susceptibility to oseltamivir and zanamivir. Because no prospective data exist on the efficacy of these agents in humans for H5N1 strains, the dosage and duration of therapy in adults and children may differ from those documented to be effective for epidemic influenza strains.

INTRODUCTION

Antiviral agents for treatment and prophylaxis of influenza are safe and effective in children. Annual immunization against influenza is the preferred strategy for prevention of infection, but certain situations exist in which the use of antiviral agents is beneficial.

The morbidity and mortality of epidemic influenza in unimmunized children is substantial, particularly in those younger than 2 years.[1–5] The purpose of this report is to offer guidance regarding antiviral treatment and prophylaxis to clinicians caring for children during yearly influenza epidemics and to provide resources for information on antiviral treatment in the event of an influenza pandemic, because no prospective human data currently exist on which to base recommendations for treatment of infections caused by potential H5N1 pandemic influenza virus strains.

ANTIVIRAL DRUGS FOR EPIDEMIC AND PANDEMIC INFLUENZA

Two classes of antiviral medications are currently available for treatment or prophylaxis of influenza infections: neuraminidase inhibitors (NAIs) (oseltamivir [Tamiflu; Roche Laboratories, Nutley, NJ] and zanamivir [Relenza; GlaxoSmith-Kline, Research Triangle Park, NC]) and the adamantanes (amantadine [Symme-

TABLE 1 Dosing Recommendations for Antiviral Agents for Treatment and Prophylaxis of Influenza

Drug	Formulations	Dosing Recommendations									
		Treatment					Prophylaxis				
		Children				Adults	Children				Adults
Oseltamivir (Tamiflu)	75-mg capsule; 60 mg/5 mL suspension	For treatment, children ≥12 mo should receive ~4 mg/kg per d divided into 2 doses for a 5-d treatment course				150 mg/d divided into 2 doses for 5 d	≤15 kg	>15–23 kg	>23–40 kg	>40 kg	75 mg once daily
		≤15 kg: 60 mg/d divided into 2 doses	>15–23 kg: 90 mg/d divided into 2 doses	>23–40 kg: 120 mg/d divided into 2 doses	>40 kg: 150 mg/d divided into 2 doses		30 mg once daily	45 mg once daily	60 mg once daily	75 mg once daily	
		Children ≥7 y and Adults					Children ≥5 y and Adults				
Zanamivir (Relenza)	5 mg per inhalation (Diskhaler)	2 inhalations (10 mg total per dose), twice daily for 5 d					2 inhalations (10 mg total per dose), once daily for 10 d				
		1–9 y		9–12 y		Adults	1–9 y		9–12 y		Adults
Amantadine (Symmetrel)	100-mg tablet; 50 mg/5 mL suspension	5–8 mg/kg per d as a single daily dose or divided into 2 doses but not to exceed 150 mg/d[a,b]; treat for 24–48 h after the disappearance of signs and symptoms		200 mg/d divided into 2 doses (not studied as a single daily dose)[a,b]; treat for 24–48 h after the disappearance of signs and symptoms		200 mg/d, either as a single daily dose or divided into 2 doses[a,b]; treat for 24–48 h after the disappearance of signs and symptoms	Same as treatment dose[a,b]		Same as treatment dose[a,b]		Same as treatment dose[a,b]
		1–9 y		≥10 y		Adults	1–9 y		≥10 y		Adults
Rimantadine (Flumadine)	100-mg tablet; 50 mg/5 mL suspension	Not FDA approved for treatment in children, but published data exist on safety and efficacy[45]				200 mg/d, either as a single daily dose or divided into 2 doses[a]	5 mg/kg per d once daily, not to exceed 150 mg[a,b]		200 mg/d, either as a single daily dose or divided into 2 doses[a,b]		200 mg/d, either as a single daily dose or divided into 2 doses[a,b]
		6.6 mg/kg per d (maximum 150 mg/kg per d) divided into 2 doses		200 mg/d, either as a single daily dose or divided into 2 doses[a]							

[a] Amantadine and rimantadine should only be used for prophylaxis in winter seasons during which a majority of influenza A virus strains isolated are adamantane-susceptible; the adamantanes should not be used for primary therapy because of the rapid emergence of resistance. However, for those requiring adamantane therapy, a treatment course of approximately 7 days is suggested, or 24 to 48 hours after the disappearance of signs and symptoms.

[b] For prophylaxis, antiviral drugs should be continued for the duration of known influenza A in the community because of the potential for repeated and unknown exposures or until immunity can be achieved after immunization.

trel; Endo Pharmaceuticals, Chads Ford, PA] and rimantadine [Flumadine; Forest Pharmaceuticals, St Louis, MO]). Guidelines for the use of these 4 antiviral agents are summarized in Table 1. Little is currently known about the efficacy of antiviral agents against H5N1 strains of influenza A virus that may ultimately cause an influenza pandemic. Current concerns about widespread resistance to the adamantanes limit the usefulness of this class of agents for both epidemic strains and H5N1 strains of influenza A virus.

The NAIs block the action of influenza neuraminidase, an enzyme present on the viral envelope that provides for the efficient release of progeny virion particles from the surface of an infected cell. The target of the adamantanes is the viral M2 matrix protein, an ion-channel protein that spans the viral envelope's lipid bilayer and is required for viral uncoating. Detailed reviews of antiviral therapy have been published recently.[6–12]

With all antiviral medications, treatment earlier in the course of infection is likely to offer maximum benefit. Treatment starting as early as 12 hours after onset of symptoms has the greatest impact on disease resolution.[13] Most studies have been performed in otherwise healthy children who had symptoms for less than 48 hours, with the reported improvement in outcomes being most profound in those children who were provided early therapy. Although study populations may not accurately reflect the diverse patient population seen by health care professionals, the longer symptoms extend beyond 48 hours before starting treatment, the less likely the child will benefit from antiviral therapy.

The antiviral agents discussed below that are approved for treatment and/or prophylaxis of influenza are active only against influenza viruses. Exposing children to antiviral therapy for noninfluenza infections results in unnecessary toxicity and cost and may deplete the supply of antiviral agents. Testing for influenza is encouraged if available and expected to influence clinical management, particularly at the onset of the influenza season.[5] The sensitivity and specificity of rapid diagnostic tests for influenza have been reviewed recently.[9]

NAIs

Background

There are 2 NAIs approved by the US Food and Drug Administration (FDA): oseltamivir and zanamivir. Oseltamivir is available in tablet and liquid forms, but zanamivir is only available in an aerosol formulation.

Infection of the cell by influenza virus is initiated when viral hemagglutinin binds to sialic acid–containing glycoproteins on the cell surface. After the virus enters the cell and viral proteins and nucleic acid subsequently are produced, new viral particles assemble at the cell surface. The viral neuraminidase cleaves the virus from the host cell membrane attachment site, thus freeing the virus to infect other cells. The NAI antiviral agents inhibit productive infection by preventing release of infectious virus from host cell membranes and promote clumping of viral particles via binding to glycoproteins that are present in respiratory mucus.[10,12]

Oseltamivir Treatment

Oseltamivir has been investigated in a prospective, randomized, blinded, placebo-controlled study in children 1 to 12 years of age.[14] A 5-day treatment course was associated with a median reduction in overall clinical illness of 36 hours and a reduction in fever of 25 hours in oseltamivir-treated children compared with placebo recipients. Furthermore, the incidence of acute otitis media (assessed by tympanometry and physician-prescribed antimicrobial therapy) was reduced by 44% compared with placebo recipients. A significant decrease in viral shedding was also noted in treated children, with few children still shedding virus on day 4 of therapy. The most common adverse drug effects noted were gastrointestinal tract disturbances, with vomiting in 14% of oseltamivir-treated children compared with 8% of children who were given placebo.

In studies of unimmunized children with asthma 6 to 12 years of age who received oseltamivir or placebo, no difference in the median time to freedom from illness was demonstrated, but a significant improvement in pulmonary function was noted on day 6 after treatment.[15] For oseltamivir-treated children whose therapy was started within 24 hours of onset, a more dramatic difference in alleviation of all symptoms was noted, compared with those who were started on therapy after 24 to 48 hours of symptoms.

Although earlier therapy may lead to a more profound treatment effect, it is also possible that earlier treatment may impair the host immunologic response to influenza infection. An impaired immune response could leave the host susceptible on reexposure to the virus, as has been reported in 2 children with influenza B virus infections.[16]

Oseltamivir is not approved for therapy in children younger than 12 months because of concerns of central nervous system (CNS) toxicity seen in infant rats.[17] Limited data on safety and efficacy of oseltamivir exist in this young age group, although no specific drug-attributable toxicities have been observed to date.[18,19]

Oseltamivir may be taken with or without food and is eliminated entirely by glomerular filtration and tubular secretion. The dose of oseltamivir should be decreased by 50% for children with decreased renal function associated with a creatinine clearance of between 10 and 30 mL/minute.

Unpublished safety data on oseltamivir were recently reviewed by the FDA on the basis of reports of neuropsychiatric events associated with patients treated for influ-

enza with oseltamivir (www.fda.gov/ohrms/dockets/ac/06/briefing/2006-4254b_09_01_Tamiflu%20AE%20Review%202006%20Redacted_D060309_092.pdf). Although 92% of the most recent cases were reported from Japan, a country with approximately 4 times more courses of oseltamivir prescribed than in the United States, package labeling was changed in the United States in 2006 to alert physicians to the possibility of these rare and unusual clinical findings. Accurate data on the incidence of these events are not available, but they seem to be in the range of 1 in 10 000 to 100 000 treatment courses. On the basis of the FDA review, it is not known whether the spontaneous reports of neuropsychiatric behavior reflect a true adverse event caused by oseltamivir, perhaps with a greater incidence in populations with a certain genetic background; a result of CNS infection caused by influenza virus; or a combination of both drug and virus in the CNS. There are no reports of neuropsychiatric events in adults or children receiving oseltamivir prophylaxis for influenza infection.

Zanamivir Treatment

Zanamivir is administered by aerosol twice daily for 5 days. In a study of children 4 to 12 years of age, the mean duration of symptomatic illness was reduced by 1.25 days in children who received zanamivir, compared with those who received placebo.[20] In 3 trials in subjects 12 years and older, zanamivir treatment decreased symptoms by 1 to 2.5 days in influenza-positive subjects.[21–24] In a multicenter prospective study of subjects whose therapy was started within 30 hours of the onset of symptoms, resolution of major symptoms occurred 3 days earlier in the treatment group compared with that in controls.[24]

Reported adverse effects in otherwise healthy children and adults were similar between those treated with zanamivir and those given placebo. However, concerns by the FDA regarding bronchospasm and decreased pulmonary function after inhalation of zanamivir in patients with underlying reactive airways disease, including asthma and chronic obstructive pulmonary disease, prompted warnings about use of zanamivir in this population. Potential risks and benefits should be carefully weighed before treatment of these children. Monitoring of respiratory function should be considered if treatment is given.[25]

Zanamivir is minimally absorbed from the respiratory tract mucosa. No dosing changes are required for renal failure.

Prophylaxis With Oseltamivir and Zanamivir

Postexposure prophylaxis with oseltamivir has been reported in a multicenter study in North America and Europe for family contacts who were at least 1 year of age after identification of a documented index case within the family.[26] In this setting, in which the index case was also treated with oseltamivir, the protective efficacy against proven influenza for individual contacts was 68%.[26] In a similar multicenter study for household contacts 12 years and older, oseltamivir was 89% effective in the prevention of laboratory-confirmed symptomatic influenza infection when used within 48 hours of contact with an index case who had not been treated.[27] Adverse events reported in treated subjects in this study, including gastrointestinal tract symptoms, were not different from those in controls.[27]

Zanamivir was investigated as postexposure prophylaxis for family members 5 years and older, at a dosage of 10 mg, inhaled once daily for 10 days, with the index case also receiving treatment. After exposure to a virus-positive index case, the number of families with a clinically symptomatic member decreased 72%.[28]

Antiviral Resistance

Development of resistance to NAIs while on therapy occurs less often than resistance to adamantanes.[29] In a multicenter study in the United States, only 5% of children who received oseltamivir therapy developed in vitro resistance in influenza isolates cultured during therapy.[14] In contrast, a study from Japan documented resistance of 18% in isolates cultured from 50 oseltamivir-treated children.[12,30] Fortunately, oseltamivir-resistant isolates from children do not seem to be as capable of sustaining infection as wild-type strains as assessed in animal models of influenza infection.[31,32] However, when generated entirely in vitro, some mutants are just as capable of infectivity as the parent strain,[33] which indicates that the possibility still exists for the development and spread of oseltamivir-resistant strains among children. Zanamivir resistance was not reported in the published large-scale clinical trials.

Adamantanes

Background

Amantadine and rimantadine are approved for children 12 months and older. Amantadine, the first antiviral agent available against influenza, was approved by the FDA in 1966; rimantadine was approved in 1993. Antiviral activity is mediated by binding these agents to the M2 protein ion channels on the viral envelope, preventing acidic conditions within the virus that are required for uncoating and subsequent release of viral nucleic acid into the host cell.[34] Only influenza A virus contains the M2 protein. A different envelope protein that does not bind to the adamantanes provides a similar function in influenza B virus; amantadine and rimantadine are not active against influenza B. The effectiveness of adamantanes has been limited by the emergence of widespread resistance in H3N2 strains isolated in the 2005–2006 influenza season.[35] Recommendations for adamantane antiviral use in subsequent years will be based on the resistance patterns docu-

mented in strains circulating during those influenza seasons.

Amantadine Treatment

Placebo-controlled, randomized clinical trials have documented that amantadine treatment decreases the duration of fever and other influenza-attributable symptoms in influenza caused by adamantane-susceptible strains by approximately 1 day in children 1 year and older.[36–40] However, many of the earlier placebo-controlled studies that included children did not report age-specific response or adverse-event rates. Adverse events have been most accurately assessed and reported in adults. The most commonly occurring (5%–10%) adverse events are nausea, lightheadedness, and insomnia. Those that occur infrequently (1%–5%) include anxiety, nervousness, irritability, dry mouth, headache, fatigue, and diarrhea.[41] The incidence of CNS adverse effects noted above is twofold higher in those taking amantadine than in those taking rimantadine. Gastrointestinal adverse effects are equivalent between the 2 agents. These effects are dosage related and are usually mild, resolving when the agent is discontinued. Serious adverse effects have been reported in adults and are often associated with either high plasma drug concentrations in patients with renal insufficiency or in those with an underlying psychiatric or seizure disorder.[42]

Although no prospective studies have been published on the treatment of children with encephalitis as a complication of influenza, data on cerebrospinal fluid concentrations of amantadine suggest a high degree of cerebrospinal fluid penetration, with concentrations that may provide antiviral activity.[43]

Amantadine is well absorbed orally and is excreted almost entirely by the kidneys with variable metabolism before elimination. The dose should be decreased 50% in children with creatinine clearance between 30 and 50 mL/minute per 1.73 m^2. Additional reductions are required for more profound renal failure.

Rimantadine Treatment

Rimantadine was evaluated in prospective studies of children using acetaminophen-treated controls between 1 and 12 years of age[44] and 1 and 15 years of age.[45] In a study by Thompson et al,[44] no differences were recorded in the reduction of symptoms between the 2 groups, although the amount of virus shed was less during the first 2 days of therapy for the treatment group. Of concern, the virus shed by those who continued to have positive culture results on the fourth day of treatment was often resistant to rimantadine. Hall and colleagues[45] noted a significant reduction in severity of disease, including fever. However, a high rate of rimantadine resistance occurred in treated children, with almost half of the strains noted to be resistant when isolated from children who were still shedding virus at the end of the 7-day treatment course. In addition, it is concerning that rimantadine-treated children were more likely to be shedding virus at the end of therapy than were controls. No differences in adverse-event rates were noted between children treated with rimantadine and those treated with acetaminophen. In controlled studies in adults, no drug-attributable adverse effects occurred in more than 5% of the study subjects, with the most commonly reported events being insomnia and dizziness.[46]

Rimantadine is also well absorbed orally but, unlike amantadine, undergoes extensive hepatic metabolism with subsequent renal elimination. Dose adjustment should be made for severe hepatic dysfunction or renal failure.

Prophylaxis With Amantadine and Rimantadine

Early studies on the prevention of influenza with amantadine were conducted in home or institutional settings during the influenza season using prospective, double-blind trial designs and documented a statistically significant benefit by reducing the attack rate of influenza A.[47–50] However, as with the early amantadine treatment studies, age-specific data are lacking.

Studies on the use of rimantadine as prophylaxis for children within families were conducted during influenza seasons in which the predominant circulating strains were H1N1[51] and H3N2.[52] In both studies, prophylaxis reduced the number of symptomatic influenza cases in children relative to an attack rate of 15% to 20% among placebo recipients. Prophylaxis in children also reduced the number of cases of symptomatic influenza in adult family members. Of note, cases of asymptomatic influenza infection as documented by throat culture or fourfold increase in influenza antibody titers did occur in a small number of children who received rimantadine prophylaxis.

Antiviral Resistance

Amantadine or rimantadine resistance develops in approximately one third of patients who receive antiviral therapy.[53] The development of resistance has implications for therapeutic failure for (1) the child, if resistance develops early in therapy, (2) household or close contacts, because resistance in the index case determines which therapy is likely to be effective in those exposed to the index case, and (3) communities, in which resistance may be so widespread to a particular agent that empiric therapy with that agent may no longer be recommended.

Resistance to adamantanes occurs rapidly, often within the first 3 days of therapy. Mutations lead to structural changes at predictable, specific sites on the M2 protein. These changes are relatively stable, with little reversion to wild-type susceptible virus after stopping the adamantane. Appreciable differences in virulence or

transmissibility between resistant and susceptible viruses have not been noted.

In a recent study, nasal swabs, nasal aspirates, or throat cultures were obtained from hospitalized children before, during, and after a 3- to 5-day course of amantadine, and 80% of isolates from treated children demonstrated amantadine resistance.[54] Shedding of resistant strains was not associated with persistent or relapsing clinical disease, which is felt to reflect an adequate host immunologic response that develops as resistant strains are emerging. For the high-risk child with a poor immunologic response to infection, persistent disease or relapse is a concern.

Close contacts of an amantadine- or rimantadine-treated child who subsequently develop influenza infection are at high risk of infection caused by an adamantane-resistant influenza virus. If such patients require treatment or prophylaxis, an NAI should be used. During the 2005–2006 influenza season, data collected on widespread resistance to adamantanes in circulating influenza A strains in the United States led the Centers for Disease Control and Prevention to recommend against the use of these agents for either treatment or prophylaxis of influenza A infections.[55]

Ribavirin

Ribavirin has in vitro activity against influenza virus but is not currently approved for treatment of influenza infection. Limited studies have been performed with aerosolized ribavirin in the treatment of influenza in children.[56] For life-threatening influenza infection requiring parenteral therapy, intravenous ribavirin may be obtained as an investigational product through the FDA, as supplied by the manufacturer. No prospective, controlled data currently exist on the safety or efficacy of parenteral ribavirin for severe, invasive influenza infection, although limited data on pharmacokinetics of parenteral ribavirin exist for adults.[57]

INDICATIONS FOR THERAPY AND PROPHYLAXIS

Therapy

- Influenza infection of any severity in high-risk children (see Appendix) regardless of immunization status
- Any otherwise healthy child with moderate-to-severe influenza infection who may benefit from the decrease in duration of clinical symptoms documented to occur with therapy

Prophylaxis

- High-risk children during the 2 weeks after influenza immunization, if influenza is active in the community
- High-risk children for whom influenza vaccine is contraindicated
- Family members or health care providers who are unimmunized and are likely to have ongoing, close exposure to (1) high-risk, unimmunized children or (2) infants who are younger than 6 months
- Control of influenza outbreaks for unimmunized staff and children in a closed institutional setting with high-risk pediatric residents (eg, extended-care facilities)
- As a supplement to immunization among high-risk children
- Postexposure prophylaxis in a family setting
- High-risk children and their family members and close contacts, as well as health care workers, when circulating strains of influenza virus in the community are not matched with vaccine strains

ANTIVIRAL THERAPY IN PANDEMIC INFLUENZA

Antiviral therapy may play a major role in both treatment and prophylaxis during a pandemic.[58,59] Pandemic influenza is likely to occur sometime within the next decade. Recent observations document the spread of an epidemic of H5N1 strain of avian influenza A virus in both wild and domestic bird species from southeast Asia to Indonesia, Europe, and Africa, with further spread felt likely to occur. As of October 16, 2006, 256 adult and pediatric cases of H5N1 influenza infection have been documented worldwide, associated with a mortality rate of 59%.[60] These infections have occurred most often in those with close, direct contact with poultry. Efficient transmission of the virus between humans, an event that is required before a human pandemic can occur, has not been documented to date with any of the currently identified H5N1 strains.

Intense planning for the possibility of an influenza pandemic with a virulent strain of H5N1 or another influenza virus subtype is ongoing at international, national, state, and local levels. The American Academy of Pediatrics and other professional organizations and stakeholders have had important input into the Pandemic Influenza Strategic Plan of the US Department of Health and Human Services, which was released in late 2005.[61] Interim priorities for antiviral therapy and vaccine are included as part of the plan and reflect a need to treat and protect those most at risk of severe and fatal influenza and to preserve critical societal infrastructure (eg, law enforcement, medical facilities, government). Efforts are currently underway to stockpile adequate supplies of antiviral drugs to address both health care and societal requirements. The Strategic National Stockpile currently includes oseltamivir and rimantadine. Although most strains of H5N1 are susceptible only to the NAIs, some are susceptible to the adamantanes. The dose

and duration of therapy for H5N1 infections may be different from those for currently circulating H3N2 or H1N1 infections. In the case of a pandemic, the Centers for Disease Control and Prevention, the American Academy of Pediatrics, and state and local health departments will provide current recommendations for therapy and prophylaxis.

APPENDIX: INFANTS AND CHILDREN AT HIGH RISK OF COMPLICATIONS FROM INFLUENZA INCLUDE THOSE WITH:

- Ages between 6 and 24 months (no antiviral agent is currently approved for infants younger than 12 months)
- Asthma or other chronic pulmonary diseases such as cystic fibrosis
- Hemodynamically significant cardiac disease
- Immunosuppressive disorders or therapy
- HIV infection
- Sickle cell anemia and other hemoglobinopathies
- Diseases requiring long-term aspirin therapy, such as rheumatoid arthritis or Kawasaki disease
- Chronic renal dysfunction
- Chronic metabolic disease such as diabetes mellitus
- Neuromuscular disorders, seizure disorders, or cognitive dysfunction that may compromise the handling of respiratory secretions

POLICY STATEMENT

The Apgar Score

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

American Academy of Pediatrics
Committee on Fetus and Newborn
American College of Obstetricians and Gynecologists
Committee on Obstetric Practice

ABSTRACT

The Apgar score provides a convenient shorthand for reporting the status of the newborn infant and the response to resuscitation. The Apgar score has been used inappropriately to predict specific neurologic outcome in the term infant. There are no consistent data on the significance of the Apgar score in preterm infants. The Apgar score has limitations, and it is inappropriate to use it alone to establish the diagnosis of asphyxia. An Apgar score assigned during resuscitation is not equivalent to a score assigned to a spontaneously breathing infant. An expanded Apgar score reporting form will account for concurrent resuscitative interventions and provide information to improve systems of perinatal and neonatal care.

INTRODUCTION

In 1952, Dr Virginia Apgar devised a scoring system that was a rapid method of assessing the clinical status of the newborn infant at 1 minute of age and the need for prompt intervention to establish breathing.[1] A second report evaluating a larger number of patients was published in 1958.[2] This scoring system provided a standardized assessment for infants after delivery. The Apgar score comprises 5 components: heart rate, respiratory effort, muscle tone, reflex irritability, and color, each of which is given a score of 0, 1, or 2. The score is now reported at 1 and 5 minutes after birth. The Apgar score continues to provide a convenient shorthand for reporting the status of the newborn infant and the response to resuscitation. The Apgar score has been used inappropriately in term infants to predict specific neurologic outcome. Because there are no consistent data on the significance of the Apgar score in preterm infants, in this population the score should not be used for any purpose other than ongoing assessment in the delivery room. The purpose of this statement is to place the Apgar score in its proper perspective.

The neonatal resuscitation program (NRP) guidelines[3] state that "Apgar scores should not be used to dictate appropriate resuscitative actions, nor should interventions for depressed infants be delayed until the 1-minute assessment." However, an Apgar score that remains 0 beyond 10 minutes of age may be useful in determining whether additional resuscitative efforts are indicated.[4] The current NRP guidelines[3] state that "if there is no heart rate after 10 minutes of complete and adequate resuscitation efforts, and there is no evidence of other causes of newborn compromise, discontinuation of resuscitation efforts may be appropriate. Current data indicate that, after 10 minutes of asystole, newborns are very unlikely to survive, or the rare survivor is likely to survive with severe disability."

Key Words
Apgar score, asphyxia, neurologic outcome, resuscitation, cerebral palsy

Abbreviation
NRP—neonatal resuscitation program

Previously, an Apgar score of 3 or less at 5 minutes was considered an essential requirement for the diagnosis of perinatal asphyxia. *Neonatal Encephalopathy and Cerebral Palsy: Defining the Pathogenesis and Pathophysiology*,[5] produced in 2003 by the American College of Obstetricians and Gynecologists in collaboration with the American Academy of Pediatrics, lists an Apgar score of 0 to 3 beyond 5 minutes as one suggestive criterion for an intrapartum asphyxial insult. However, a persistently low Apgar score alone is not a specific indicator for intrapartum compromise. Further, although the score is used widely in outcome studies, its inappropriate use has led to an erroneous definition of asphyxia. Intrapartum asphyxia implies fetal hypercarbia and hypoxemia, which, if prolonged, will result in metabolic acidemia. Because the intrapartum disruption of uterine or fetal blood flow is rarely, if ever, absolute, asphyxia is an imprecise, general term. Descriptions such as hypercarbia, hypoxia, and metabolic, respiratory, or lactic acidemia are more precise for immediate assessment of the newborn infant and retrospective assessment of intrapartum management.

LIMITATIONS OF THE APGAR SCORE

It is important to recognize the limitations of the Apgar score. The Apgar score is an expression of the infant's physiologic condition, has a limited time frame, and includes subjective components. In addition, the biochemical disturbance must be significant before the score is affected. Elements of the score such as tone, color, and reflex irritability partially depend on the physiologic maturity of the infant. The healthy preterm infant with no evidence of asphyxia may receive a low score only because of immaturity.[6] A number of factors may influence an Apgar score, including but not limited to drugs, trauma, congenital anomalies, infections, hypoxia, hypovolemia, and preterm birth.[7] The incidence of low Apgar scores is inversely related to birth weight, and a low score is limited in predicting morbidity or mortality.[8] Accordingly, it is inappropriate to use an Apgar score alone to establish the diagnosis of asphyxia.

APGAR SCORE AND RESUSCITATION

The 5-minute Apgar score, and particularly a change in the score between 1 and 5 minutes, is a useful index of the response to resuscitation. If the Apgar score is less than 7 at 5 minutes, the NRP guidelines state that the assessment should be repeated every 5 minutes up to 20 minutes.[3] However, an Apgar score assigned during a resuscitation is not equivalent to a score assigned to a spontaneously breathing infant.[9] There is no accepted standard for reporting an Apgar score in infants undergoing resuscitation after birth, because many of the elements contributing to the score are altered by resuscitation. The concept of an "assisted" score that accounts for resuscitative interventions has been suggested, but the predictive reliability has not been studied. To describe such infants correctly and provide accurate documentation and data collection, an expanded Apgar score report form is proposed (Fig 1).

PREDICTION OF OUTCOME

A low 1-minute Apgar score alone does not correlate with the infant's future outcome. A retrospective analysis concluded that the 5-minute Apgar score remained a valid predictor of neonatal mortality, but using it to predict long-term outcome was inappropriate.[10] On the other hand, another study[11] stated that low Apgar scores at 5 minutes are associated with death or cerebral palsy, and this association increased if both 1- and 5-minute scores were low.

An Apgar score at 5 minutes in term infants correlates poorly with future neurologic outcomes. For example, a score of 0 to 3 at 5 minutes was associated with a slightly increased risk of cerebral palsy compared with higher scores.[12] Conversely, 75% of children with cerebral palsy had normal scores at 5 minutes.[12] In addition, a low 5-minute score in combination with other markers of asphyxia may identify infants at risk of developing seizures (odds ratio: 39; 95% confidence interval: 3.9–392.5).[13] The risk of poor neurologic outcomes increases when the Apgar score is 3 or less at 10, 15, and 20 minutes.[7]

A 5-minute Apgar score of 7 to 10 is considered normal. Scores of 4, 5, and 6 are intermediate and are not markers of increased risk of neurologic dysfunction. Such scores may be the result of physiologic immaturity, maternal medications, the presence of congenital malformations, and other factors. Because of these other conditions, the Apgar score alone cannot be considered evidence or a consequence of asphyxia. Other factors including nonreassuring fetal heart rate monitoring patterns and abnormalities in umbilical arterial blood gases, clinical cerebral function, neuroimaging studies, neonatal electroencephalography, placental pathology, hematologic studies, and multisystem organ dysfunction need to be considered when defining an intrapartum hypoxic-ischemic event as a cause of cerebral palsy.[5]

OTHER APPLICATIONS

Monitoring of low Apgar scores from a delivery service can be useful. Individual case reviews can identify needs for focused educational programs and improvement in systems of perinatal care. Analyzing trends allows assessment of the impact of quality improvement interventions.

CONCLUSION

The Apgar score describes the condition of the newborn infant immediately after birth[14] and, when properly ap-

APGAR SCORE

Gestational Age _____ weeks

Expanded Apgar score form. Record the score in the appropriate place at specific time intervals. The additional resuscitative measures (if appropriate) are recorded at the same time that the score is reported using a check mark in the appropriate box. Use the comment box to list other factors including maternal medications and/or the response to resuscitation between the recorded times of scoring. PPV/NCPAP indicates positive-pressure ventilation/nasal continuous positive airway pressure; ETT, endotracheal tube.

plied, is a tool for standardized assessment. It also provides a mechanism to record fetal-to-neonatal transition. An Apgar score of 0 to 3 at 5 minutes may correlate with neonatal mortality but alone does not predict later neurologic dysfunction. The Apgar score is affected by gestational age, maternal medications, resuscitation, and cardiorespiratory and neurologic conditions. Low 1- and 5-minute Apgar scores alone are not conclusive markers of an acute intrapartum hypoxic event. Resuscitative interventions modify the components of the Apgar score. There is a need for perinatal health care professionals to be consistent in assigning an Apgar score during a resuscitation. The American Academy of Pediatrics and the American College of Obstetricians and Gynecologists propose use of an expanded Apgar score reporting form that accounts for concurrent resuscitative interventions.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Application of the Resource-Based Relative Value Scale System to Pediatrics

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Coding and Nomenclature

ABSTRACT

With an increased focus on payment and productivity measurement in health care, it is essential to understand the genesis and principles behind the Medicare Resource-Based Relative Value Scale (RBRVS) physician fee schedule. The majority of third-party payers, including a growing number of Medicaid programs and commercial payers, use variations of the Medicare RBRVS as their basis for physician payment. Many group practices have also adopted this system to benchmark physician productivity and determine variable compensation and bonus payments. Because pediatric care is underrepresented in any Medicare-based payment system analysis, unique aspects of physician work and practice expense may not be accurately reflected in the total relative value units (RVUs) for certain pediatric services. Despite this potential limitation, the American Academy of Pediatrics supports the use of *Current Procedural Terminology* (CPT) codes to report unique physician work and the RBRVS physician fee schedule as a uniform payment system. The American Academy of Pediatrics will continue to work to rectify perceived inequities of the RBRVS system as they pertain to pediatrics. *Pediatrics* 2008;122:1395–1400

PLI—professional liability insurance
GPCIs—geographic practice cost indices
HCPCS—Healthcare Common Procedural Coding System

BACKGROUND

Creation of Resource-Based Relative Value Scale Payment System

The Medicare Resource-Based Relative Value Scale (RBRVS), which reformed physician payments for Medicare recipients, was enacted by Congress and signed into law as part of the Omnibus Budget Reconciliation Act of 1989 (OBRA 89). The OBRA 89 created a uniform RBRVS physician payment system based on objective measures of physician work (work relative value units [wRVUs]), accurate assessments of the practice expense (PE) in providing professional services to patients, and an additional payment factor representing the professional liability cost (malpractice expense) inherent in each specific service. Together, these 3 components make up the total relative value units (RVUs) for the service. The 5-year transition plan to this payment methodology began on January 1, 1992. Because these RVUs are uniformly applied across all medical specialties providing services, the RBRVS system promotes equity in physician payment. The RBRVS system eliminated many of the dramatic disparities when payments were specialty and practice specific and based on the customary, prevailing, and reasonable (CPR) or usual, customary, and reasonable (UCR) fees for the service provided.

Conversion Factor

Congress also established a budget-neutral conversion factor (CF) that would not increase Medicare payments above that seen under the CPR system. This CF (or dollars per RVU) is an annual legislatively set national dollar value that converts the total RVUs for any service into a physician payment amount (RVU × CF = payment) for the Medicare service provided. Congress recognized that increases in Part B (physician payments) Medicare expenditures attributable to increased enrollment, changes in medical practice, new technology, new *Current Procedural Terminology* (CPT) codes, and additional screening recommendations would occur but decided in toto that they must not exceed $20 million dollars annually. However, every year the projected increases have

exceeded that amount. In response to this conundrum, Congress agreed to a yearly update to the CF that was based on the percentage increase in the Medicare Economic Index (MEI). This index is a comparison of the projected increases in utilization, described as the Medicare Volume Performance Standard (MVPS), to the actual increase in spending and other Medicare funding factors. This link between payment and utilization was anticipated to provide physicians an incentive to control the type and number of services offered to Medicare recipients instead of merely linking the CF only to expenditure targets. Subsequently, the Balanced Budget Act of 1997 replaced the MVPS with a new sustainable growth rate system to control Medicare expenditures.

Sustainable Growth Rate

The sustainable growth rate is a formula for determining the annual CF on the basis of the projected growth in gross domestic product per capita instead of historical patterns of volume growth. The Centers for Medicare and Medicaid Services (CMS) have maintained budget neutrality by a variety of measures but primarily by lowering the CF or rescaling Medicare RVUs. If utilization increases, updates that result in lower Medicare CF updates in subsequent years can lead to annual declines in payments to physicians providing services to Medicare recipients. Medicare RVU reductions have sometimes also been adopted by private payers. Historically, the American Academy of Pediatrics (AAP) has advocated that adjustments must only be made by alterations to the CF to maintain the integrity of the RVU-based payment system. This integrity is best preserved by maintaining the American Medical Association (AMA)/Specialty Society Relative Value Scale Update Committee (RUC)-recommended and CMS-published RVUs for each code.

Five-Year Review Process

The congressionally mandated 5-year review of RVU values is an opportunity to review changes in medical practice that may increase or decrease the cost of providing a specific service. During the 5-year review in 2005, the evaluation and management (E/M) codes, which make up the bulk of primary care billing (office, consultation, and hospital visit codes), were resurveyed. The surveys recognized the increase in average severity of illness as well as the increase in PEs associated with insurance processing and compliance monitoring. The CMS agreed with the 5-year review code revaluations, increasing RVU work values for the higher-level office, consultation, and hospital E/M services.

Payers must be encouraged to embrace the CMS 5-year review of relative work values and the recent efforts to implement an accurate, resource-based approach to the PE portion of total RVUs. The AAP recognizes that the CMS annual budget neutrality adjustments to the CF is a legislative mandate; however, the AAP strongly opposes arbitrary adjustments to the wRVUs as a method of controlling increasing Medicare costs. Private payers and Medicaid programs must recognize that these Medicare adjustments are the result of budgetary constraints imposed by Congress (budget neutrality) and do not reflect changes in the provision of care or the relative value of work expended in providing a specific physician service.

Pediatric CPT Codes

The AAP, through its Committee on Coding and Nomenclature (COCN), continues to develop new/revised CPT codes appropriate for pediatrics. Once new codes are accepted by the CPT Editorial Panel of the AMA, the COCN works within the RUC process to provide the CMS with RVU recommendations that accurately reflect the work and direct PEs involved in providing services to children. The AAP has had significant successes in this process, as evidenced by the expanded list of neonatal and pediatric critical care, continuing intensive care, cardiac catheterization, care plan oversight, immunization administration, and non–face-to-face services codes. However, acceptance of a new code and its RUC valuation does not guarantee payment. As a first step toward appropriate payment, payers are expected to accept new codes as soon as they become effective.

Non-Medicare Use of the RBRVS

Pediatricians care for few patients covered by Medicare (with the exception of children with chronic renal failure). However, because the majority of non-Medicare payers, including Medicaid, have converted to the Medicare RBRVS payment system, changes in Medicare RVUs affect payments for children's services.

Non-Medicare payers are not legally bound to utilize the Medicare RBRVS or its CF and can establish their own payment methodologies. However, most, if not all, non-Medicare payers have adopted the RBRVS system. Although the RBRVS physician fee schedule was initially implemented by the CMS (formerly the Health Care Financing Administration [HCFA]) as a mechanism for the payment of physician services provided to Medicare recipients, the schedule has now been applied to all patient populations, including those commonly covered by Medicaid programs and commercial insurers. A recent report by the AMA revealed that 77% of the private plans surveyed in 2006 reported some use of an RBRVS payment system, compared with 74% in 2001 and 63% in 1998.[1] The AAP has dedicated itself to advocating for non-Medicare payers' CFs to at least be in parity with, if not above, the Medicare CF and for utilization of the most current Medicare RBRVS RVUs to be the basis of their payment methodologies.

APPLICABILITY TO PEDIATRICS

The work estimates driving the RBRVS Medicare physician fee schedule were developed primarily to reflect the services rendered to the typical Medicare patient and, as such, may not accurately reflect the breadth and scope of work expended to provide care to neonates, infants, children, and adolescents. A few Medicaid agencies have established a higher pediatric CF or established auxiliary fee schedules or case management fees to augment physician payment for children's care, recognizing that some pediatric services

are undervalued. These increases have been useful in some states to stimulate participation by physicians to expand access to prenatal care, obstetric care, and well-infant services.

Despite aforementioned reservations, the AAP advocates for the use of the RBRVS physician fee schedule as an appropriate and fundamentally fair system for valuing and establishing payment for pediatric services. The AAP believes that, in principle, an RBRVS-based fee schedule, supported by objective assessments of physician work, is more consistent and equitable than the previous CPR payment system under which physicians historically had been paid for their services. However, if appropriate access to health care for all children is to be ensured, Medicaid and other payers must recognize all of the CPT codes and their values; thus, the CMS must publish values for codes including those that are not applicable to the Medicare population. In addition, all payers, including Medicaid, must update their payment schedules in a timely fashion to include new codes and incorporate annual updates and revisions. Finally, with the advent of the Health Insurance Portability and Accountability Act (HIPAA [Pub L No. 104-191, 1996]), payers should no longer be allowed to utilize their own payment methodologies independent of the RBRVS.

The CMS has recognized that a Medicare-driven payment system may underrepresent or undervalue some components of pediatric work. The original Hsiao et al study[2] that led to the creation of the RBRVS was based on the AMA Master File list of physicians; because few pediatricians maintain membership in the AMA, few pediatricians were surveyed. It is inappropriate and not in the best interest of pediatricians to simply extrapolate work values assigned for services to children from those values determined by surveyed physicians who provide services primarily to adults.

In addition, the assumption that there is equivalency of work of pediatricians and pediatric medical subspecialists to that of internists and adult medical subspecialists has not been rigorously studied. In some pediatric medical subspecialties (eg, pediatric cardiology and pediatric nephrology) in which valid survey data have been collected, there is quantifiable evidence of underestimation of total pediatric physician work, particularly for situations in which major physiologic and developmental differences exist.[3,4]

The AAP appreciates the efforts of the AMA to incorporate most of the unique characteristics of children's health care services into the CPT nomenclature. The AAP supports the continued efforts of the AMA and the CMS through the CPT and RUC processes to ensure that all pediatric services are represented by HIPAA code sets and that all RUC-surveyed codes have their RVU values published in the RBRVS via the *Federal Register*, even in cases in which the service is not paid under the Medicare program. Presently, the AAP is well represented on the CPT Advisory Committee, the RUC, and the *International Classification of Diseases, Ninth Revision, Clinical Modification* (ICD-9-CM) Editorial Advisory Board. This representation provides the AAP a voice that is being more consistently heard and positively received by our adult colleagues and national payers. This representation must continue if children's unique coding challenges and the additional physician work and PE involved in many pediatric services is to be reflected in nationally assigned RVUs. However, given that payment policies vary dramatically across many Medicaid agencies, these published values are not always used for payment. This continues to lead to underpayment for many children's preventive health services, including screening services and immunization delivery. This will continue to threaten the health of children until Medicaid programs assume the same national regulatory requirements for payment that the Medicare program has established.

The connection between payment policy and health policy can be demonstrated in the Medicare system, in which a single national database (Medicare Part B Database) tracks Medicare utilization of CPT codes annually and over time. If Medicare payment levels fall, it is possible to see the immediate effect on health outcomes and higher future costs for Medicare recipients. Although this same premise certainly holds for pediatric patients, the absence of a single national database for Medicaid makes the demonstration of this association challenging. A single national Medicaid database would allow the AAP to demonstrate the strong correlation between access to preventive services and payment policies that fairly compensate the pediatrician for resources expended in the provision of those services.

COMPONENTS OF THE RBRVS PAYMENT SYSTEM

The RBRVS system assigns value to each procedure on the basis of 3 components:

- physician work;
- PE; and
- professional liability insurance (PLI).

Physician Work

The physician work involved in actually providing a service or performing a procedure is called "intraservice work." In the office setting, the intraservice period is defined as face-to-face patient encounter time; in the hospital setting, it is the time spent on the patient's unit or floor; and for surgical procedures, it is the period from initial incision to the closure of the incision. Work performed before and after provision of a service is referred to as "preservice" and "postservice" work, respectively. When preservice, intraservice, and postservice work are combined, they create the "total work" involved in the provision of a service.

Because children are less cooperative and more anxious, many services and procedures for children, even when the more frequent need for procedural sedation is accounted for, require more face-to-face time compared with similar services provided to the typical adult. These differences are not represented in existing CPT codes for children's services. Children also require constant adaptations to the physical examination, in response to their constantly changing behavior and level of cooperation. CPT modifier 63 (procedure performed on infants <4

kg) was developed to recognize the increased intraservice time for and complexity of the smallest patients. For larger infants and children, modifier 25 is available to recognize situations in which a significant and separately identifiable evaluation and management service is provided. Follow-up communication with child-care facilities, schools, absent parents, or extended family (eg, grandparents) can also lead to a significant increase in surveyed postservice times.

Practice Expense

The PE component of the RBRVS includes clinical staff time, medical supplies, and medical equipment and accounts for 44% of a code's total RVUs, on average. Increased paperwork, reporting regulations (eg, immunization registries), and expenses involved in a movement to computerized practices are common to all practitioners. However, pediatric practices are more readily affected by factors such as prevalence of low-intensity office visits, larger volume of telephone calls, and increased case management requirements. High patient volume in pediatric practices requires more examination rooms per provider to maintain physician efficiency when compared with specialties that see only 1 to 3 patients per hour. Higher patient volumes require more administrative staff, more supplies, and more telephone calls. Recognizing that 40% to 50% of most pediatric office visits are scheduled within 24 hours of the encounter, pediatric staff members are often required to perform insurance verification at the time of patient arrival, which adversely affects their ability to process patients efficiently. Providing care to young children also requires more direct hands-on clinical staff time, resulting in less-efficient room use because of difficulties dressing and undressing patients, and is marked by increased complexity and time in collecting laboratory specimens or performing screening examinations. Furthermore, routine services, such as venipuncture, are typically more time and staff intensive for pediatric patients. These factors need to be accounted for in any resource-based PE study and in the resulting PE calculations for pediatric services.

The PE is quite different when the service is reported in the office (nonfacility) versus in a hospital or other facility. The facility PE is much lower, resulting from Medicare's separate payments for hospital services under Part A and physician services under Part B. Therefore, total RVUs to physicians for the same service provided in the office setting exceed the total RVUs for a similar service provided in the hospital or other facility setting.

When the RBRVS system was created, the CMS used the Socioeconomic Monitoring System (SMS) of the AMA to assign PE. The socioeconomic monitoring system was developed through a nationally representative sample of 4000 physicians in 34 specialties (low pediatrician membership in the AMA led to underrepresentation in this sample). PE was higher in the more "boutique" practices of the well-compensated specialties. These differences were retained in the original payment formulas. In 1998, the CMS changed to a new formula for calculating PEs. They chose a so-called top-down approach using actual practice cost data that are allocated to services and procedures by using expert panels to decide what a typical patient encounter required. PE was then broken into 6 categories: clinical labor, medical supplies, medical equipment, office expense, administrative labor, and all other expenses. This new approach has led to significant readjustments in the PE component, which generally have been beneficial to primary care physicians.

Professional Liability Insurance

The RBRVS system assigns RVUs to cover the malpractice risk incurred by physicians in providing each cognitive or procedural service. These malpractice RVUs (PLI), originally calculated for office-based pediatricians, may systematically undervalue the practice liability costs for many pediatric specialties. The prolonged statute of limitation on child-related medicolegal actions, as compared with adult care, results in increased malpractice risk exposure (malpractice insurance tail) for physicians providing services for children, compared with adults. In many states, that exposure risk is measured in decades rather than years. As such, physicians treating minors are required to purchase an "extended reporting endorsement" to cover the liability risk until the patient achieves at least the age of majority. This imposes additional PEs in retaining medical charts and the attendant security protections for that protracted period. This difference in exposure is not calculated into the RBRVS PLI and was not included in the initial Hsiao et al study.[2] Pediatric-specific survey data for malpractice expense should be used for this component when assigning final RVU valuations. Without pediatric-specific CPT codes, however, there is no way to do this without having different CFs for pediatric patients.

Geographic Practice Cost Indices

The OBRA 89 also introduced the concept of geographic practice cost indices (GPCIs), initially to address the disparity in CPR charges seen in urban (37% higher) versus rural practices. This was implemented despite the difficulty that rural communities faced in recruiting and retaining sufficient medical providers. Both the PE and the medical liability costs (PLI) are known to be higher in the urban setting. Physician earning calculations also include inherent cost-of-living expenses, most usually higher in more urban settings. Higher PE and medical liability costs in the urban setting were built into these RVU values. However, only one quarter of the cost-of-living difference was built into the RVU values. Each component of the total RVU (physician work, PE, and PLI) are subjected to different correction values, with states varying in the number of regions that are assigned different GPCIs. For example, Alabama has only a single correction value for each component, whereas California has 10 regions with different GPCIs, and Texas has 8 such regions.

RBRVS CONVERSION

Conversion from RVUs to dollar payments is a multistep process that is covered in detail in the AAP RBRVS

brochure (www.aap.org/visit/rbrvsbrochure.pdf) and RBRVS conversion spreadsheet (www.aap.org/visit/RBRVSConversionSpreadsheet.xls).

HIPAA CODE SETS

The HIPAA established standard transaction codes for medical claims submission. The primary codes for reporting physician encounters include the Healthcare Common Procedure Coding System (HCPCS) level I and level II codes for procedural reporting and the ICD-9-CM[5] codes for diagnosis reporting.

HCPCS Level I Codes: CPT

HCPCS level I codes are also called CPT codes. CPT is a listing of descriptive terms and identifying codes for reporting medical services and procedures developed and maintained by the AMA. The CPT nomenclature comprises 3 categories of codes: category I CPT codes, category II CPT codes, and category III CPT codes.

Category I CPT Codes

Category I CPT codes describe a procedure or service identified with a 5-digit CPT code and descriptor nomenclature. Category I CPT codes must represent services/procedures that are:

- approved by the US Food and Drug Administration;
- performed across the country in multiple locations;
- performed by many providers; and
- clinically efficacious.

Category II CPT Codes

Category II CPT codes are supplemental tracking codes used to measure performance. The purpose of these codes is to decrease the need for record abstraction and chart review associated with performance-improvement initiatives, thereby minimizing administrative burdens and associated costs to providers when measuring the quality of patient care. Category II CPT codes are intended to facilitate data collection about the quality of care rendered by allowing providers to code certain services and test results that support nationally established performance measures, presumably having an evidence base contributing to quality patient care. Category II codes are optional and are not required for correct coding and may not be used as a substitute for category I codes. As physician payment begins to be tied more closely to patient outcomes through pay-for-performance programs, the reporting of category II codes will be necessary to qualify for supplemental payments. Pediatric practices must also be prepared for rapidly expanding quality and disease management measures. To qualify for payer pay-for-performance (P4P) incentives, pediatricians must be able to easily code for the services being measured or explain why services were not indicated or refused by patients. Although this need has led to a rapidly expanding set of codes that describe these expected/refused services, the number of applicable pediatric measures has not kept pace with adult measures. There must be appropriate codes and modifiers in place to accurately report pediatric patient encounters.

Category III CPT Codes

Category III CPT codes are temporary codes for emerging technology, services, and procedures. If a category III CPT code is available, it must be reported in lieu of an unlisted category I CPT code, because the latter does not allow the opportunity for the collection of specific data.

HCPCS Level II Codes

HCPCS level II codes (commonly referred to as "hick-picks" codes) are Medicare national level II codes used to identify services not included in the CPT nomenclature (eg, ambulance services, durable medical equipment, prosthetics, orthotics, and supplies). HCPCS level II codes are alphanumeric codes that consist of a single letter followed by 4 digits. Pediatricians most commonly utilize HCPCS level II codes that start with the letter "J" for reporting things such as injectable drugs that ordinarily cannot be self-administered, chemotherapeutic and immunosuppressive drugs, and inhalation solutions, as well as some orally administered drugs. HCPCS level II codes also include American Dental Association *Current Dental Terminology* (CDT) codes ("D" codes) used to record and report dental procedures.

ICD-9-CM Codes

The *International Classification of Diseases, Ninth Edition* (ICD-9)[6] was published by the World Health Organization (WHO) in 1975. The current edition in the United States for morbidity classification, ICD-9-CM,[5] has been in use since 1979. The original intent of ICD codes was for epidemiologic reporting and not billing for services, albeit in the United States third-party payers tend to use it for that purpose. The ICD-9-CM consists of 3 volumes. Volumes 1 and 2 (a tabular list containing a numerical list of the disease code numbers and an alphabetical index to the disease entries) are used to assign diagnosis codes. Volume 3 is a classification system only used by hospitals for tracking inpatients for surgical, diagnostic, and therapeutic procedures. The rules and guidance for ICD-9-CM are published in the *ICD-9-CM Official Guidelines for Coding and Reporting*[7] and the American Hospital Association *Coding Clinic for ICD-9-CM*.[8]

In 1989, the World Health Organization released ICD-10. It has replaced ICD-9 throughout the world for both morbidity and mortality statistics since 1994 and has been used in mortality statistics in the United States since 1999. The AAP has been a supporter of implementing ICD-10-CM for morbidity diagnosis coding because of its greater specificity. In addition to allowing for better epidemiologic tracking of injuries and diseases, it would also allow providers to better identify certain patients with specific conditions that might benefit from tailored disease management programs.

HIPAA Standard

Because HIPAA code sets are the national standard for coding physician services and communicating with

third-party payers, regulations require their use for electronic data exchange. Third-party payers, however, do not necessarily recognize or pay for the full spectrum of health care services or follow the diagnosis coding rules represented by these codes. The HIPAA does not require insurers to pay for all HIPAA-mandated codes; it merely requires them to follow the respective code-set coding rules and accept transactions electronically that utilize these codes. The AAP strongly advocates for the acceptance and payment for all HIPAA-mandated CPT codes by all payers and encourages AAP members to work to that end in negotiating contracts with individual payers.

RECOMMENDATIONS

1. The principles of the Medicare RBRVS system should be supported by pediatricians as an intrinsically more reasoned and equitable payment methodology than alternative systems.
2. The AAP and its members should continue, through the involvement of the COCN on the AMA/Specialty Society Relative Value Scale Update Committee, to correct RBRVS system inequities and ensure that the RBRVS system appropriately accounts for the work, PE, and professional liability expense in caring for neonates, infants, children, and adolescents.
3. Pediatric health care providers should advocate for recognition by all payers, including Medicaid, of the full spectrum of CPT codes and their guidelines.
4. The AAP and its members should continue to advocate that RBRVS adjustments only be made by the CMS exclusively through changes to the annual CF and not through changes to wRVUs to maintain the integrity of the RVU-based payment system that is used by most payers.
5. Pediatric health care providers should insist that the CMS publish values for all RUC-valued CPT codes, not just those that are applicable to the Medicare population.
6. The AAP and its members should continue to advocate for a national Medicaid pediatric database analogous to the Part B Medicare Data Files database that is legislated and published annually. A national Medicaid database for health care services for children is critical for making the Office of the Inspector General, Medicare, and Medicaid compliance programs applicable to pediatricians. The current use of Medicare-based utilization patterns inappropriately labels pediatricians as "outliers" and potential targets for health care fraud investigations. Only by understanding the frequency with which codes for pediatric services are reported will there be an ability to analyze utilization patterns and the effects of new codes on total health care costs. Such a database will also provide an improved ability to determine the effects of coding and payment on access to children's health care services.

Appropriate Medical Care for the Secondary School-Age Athlete

Objective: To provide evidence-based support for the recommendations made by the Appropriate Medical Care for Secondary Schoolï Age Athletes (AMCSSAA) Task Force consensus statement.

Data Sources: MEDLINE, CINAHL, and Sport Discus databases were searched for relevant literature regarding secondary school-age athletes, health care administration, pre-participation physical examination, facilities, athletic equipment, emergency action planning, environmental conditions, recognition, evaluation, and treatment of injuries, rehabilitation and reconditioning, psychosocial consultation, nutrition, and prevention strategies.

Conclusions & Recommendations: There is adequate evidence-based support for all eleven of the AMCSSAA Task Forceôs consensus points. Organizations that sponsor athletic programs for secondary school-age athletes should establish an athletic health care team (AHCT) to ensure appropriate medical care is provided to all participants.

TABLE OF CONTENTS

DOCUMENT BACKGROUND

In 2002, the National Athletic Trainers' Association developed an inter-association task force to develop recommendations and guidelines for adolescents competing in school and club-level sports. The Appropriate Medical Care for Secondary Schoolï Age Athletes Task Force (AMCSSAA) comprised experts from 17 school, health care, and medical associations who all shared the same goal ð ensuring young athletes receive consistent and adequate medical care while participating in practices and games.

The group developed a consensus statement (Appendix A) stating minimum standards of health care for adolescent athletes. After unanimously approving the document, the task force decided to take the project one step further and put together this scientifically based document that augments the recommendations set forth in the consensus statement.

This communication will help organizations sponsoring athletic programs for this age group justify the importance of providing appropriate medical care and establishing an athletic health care team to identify the resources they should make available to adolescents participating in organized athletic programs. The article can also be used as an evaluation tool to assess current athletic health care delivery programs.

Disclaimer: This communication provides general practice recommendations and guidelines for medical care provided by organizations sponsoring athletic programs for secondary school-age individuals. Actual medical care provided should not be based solely on the information contained in this manuscript, but should be tailored to specific facts and circumstances unique to each entity and location.

PARTICIPATING IN THE DEVELOPMENT AND IMPLEMENTATION OF A COMPREHENSIVE ATHLETIC HEALTH CARE ADMINISTRATIVE SYSTEM

Organizations sponsoring athletic programs for secondary schoolï age individuals should establish an athletic health care team (AHCT) that functions to ensure appropriate medical care is provided for all participants. To provide appropriate medical care, the AHCT must function in a coherent, coordinated, and efficient manner with coaches and administrators of sponsoring organizations and adhere to commonly accepted standards of good clinical practice.

Medical and allied health professionals representing various disciplines are involved in the provision of athletic health care to adolescents. This communication summarizes the evidence base for points addressed in the consensus statement, which was was prepared and ratified by professional organizations representing numerous disciplines but does not mandate which specific individuals are essential to the AHCT. Nonetheless, the American Medical Association (AMA), at the request of the American Academy of Pediatrics (AAP), has recommended that athletic medical units (AMUs) include a physician director and an athletic health coordinator, with preference given to NATABOC-certified athletic trainers (ATCs) in this role (AMA Resolution H-470.995 Athletic [Sports] Medicine, 1998).[1] Furthermore, many jurisdictions require that ATCs be supervised by licensed physicians, just as school nurses are supervised by school physicians and emergency medical technicians (EMTs) are supervised by emergency medical services (EMS) physicians. Therefore, the ATC and team physician form the core of the AHCT, with the ATC being the most appropriate on-site member of the AHCT and the official team physician, if one has been designated, being ultimately responsible for medical decisions made by the AHCT (Figure 1). A designated school official or member of the sponsoring organization should be a liaison to the AHCT when having a member of the AHCT on-site is not possible. Other members of the team, along with the relationships among them, should be dictated by local needs and statutes.

A comprehensive athletic health care system should enhance the care of the athlete by allowing the strengths of individual members to complement each other and by preventing the unnecessary duplication of efforts. The roles and responsibilities of all team members should be clearly defined and available to all. Regardless of the specifics of a given situation (i.e., local and state qualifications and regulations) or the personnel involved in the AHCT, the extent to which the ATC is responsible for medical decisions must be explicitly understood between the team physician and ATC, with administrative members of the AHCT (e.g., athletic directors) being wholly supportive of the guidelines for decision-making established between the team physician and ATC.

At the request of the AAP, in 1998 the AMA passed Resolution H-470.995, which called for the establishment of athletic medical units (AMUs) by all organizations that sponsor athletic programs, school boards, and local boards of health. The scientific rationale for this resolution was thoroughly reviewed and published by the AMA and NATA in 1999.[1]

Expert panels[2] and peer-reviewed journal articles[3] have recommended standardization of sports injury surveillance systems to help improve athletic health care, but little to no primary research has been conducted to demonstrate that AMUs either decrease injury rates or improve athletic health care. The AHCT proposed in this document is similar to the AMU with respect to the allied health care professionals recommended to comprise the team and the roles and responsibilities of the team.

Nonetheless, case law over the past three decades[4, 5] has established the precedent that school districts and other agencies sponsoring athletic programs have a legal responsibility to provide medical care for participants. In *O'Brien v. Township High School District* (1979),[6] the court held that a school district has a responsibility to provide proper medical treatment. Care provided by a minor student was not found improper or negligent at the time, but in the interim many states have enacted licensure statutes for athletic training. Therefore, organizations that do not provide appropriate medical care for athletes, defined as that administered by trained and certified professionals, could risk significant liability exposure.

Components of recommendation

To properly develop and implement a comprehensive athletic health care administrative system, the sponsoring organization must create the AHCT, identify their roles and responsibilities, create the appropriate policies and procedures to ensure all on-site athletic staff adhere to safe clinical practice parameters for adequate medical care, designate appropriate physical space and equipment, document the activities of the AHCT, take part in injury surveillance, and commit to cycles of quality improvement so that appropriate medical care is available for all secondary schoolï age athletes.

Members of the Athletic Health Care Team

Local availability, needs, and statutes should guide organizations that sponsor athletic programs (e.g., schools, school districts, clubs, youth leagues) to establish desirable team members. Also, organizations should be aware of recommendations made in AMA Resolution H-470.995, the American College of Sports Medicine (ACSM)/American Orthopaedic Society for Sports Medicine (AOSSM) *Team Physician Consensus Statement*, the National Federation of State High School Associations (NFHS) *Sports Medicine Handbook*, and the National Collegiate Athletic Association (NCAA) *Sports Medicine Handbook*. The AHCT should include medical professionals from various organizations, including those listed in Table 1. When appropriate, the AHCT should consult with and develop an on-going coordination of efforts with the athlete, the athlete's parents, coaches, administrators, and other school or organization officials.

Individuals interested in improving the care provided to athletes should generate a needs assessment for their program based on injury risk data collected locally as well as that found in national databases, including the NATA surveillance studies, National Electronic Injury Surveillance System (NEISS), NCAA Injury Surveillance System, and National Center for Catastrophic Sports Injury Research.

Local professionals and groups should be identified and approached to join the AHCT. These may include sports medicine and other physician groups, medical schools, athletic training curriculum programs at local universities, physical therapy groups, physical therapy schools, and nursing schools.

Guidelines such as the NATA *Position Proposal Guide* (PPG) for the creation of new programs or the NATA *Position Improvement Guide* (PIG) for the improvement of existing athletic health care programs are available to the sponsoring organization as resources. Funding issues may need to be addressed by demonstrating savings in liability/health insurance premiums through the establishment of an AHCT and athletic health care delivery program, although such national data are not available.

Roles and responsibilities

The roles and responsibilities of each team member should be clearly defined and established, especially with each of the areas addressed in the following sections of this document. It is recommended that an "exclusion policy" be instituted whereby any single member of the AHCT, including but not limited to the ATC, team physician, consulting physician, or primary physician, may, based on the member's particular expertise, render an athlete ineligible for participation due to concerns for the health or welfare of the athlete. This exclusion policy should also allow the athlete, his/her parents, coaches, and sponsoring organization to limit participation for reasons justified by their role.

Policies and procedures

Written policies and procedures for the AHCT should be established and kept in a manual easily referenced by team members as well as outside constituencies (e.g., parent-teacher associations) and governing bodies (e.g., school boards, local boards of health). Specific policies should be established and approved in advance of the athletic season relating to the following: 1) Readiness to participate and return-to-play decisions, 2) Facilities inspection and maintenance, 3) Proper fit, inspection, and maintenance of athletic equipment, 4) Emergency responseð the written emergency action plan, 5) Environmental conditions protocols, 7) Sideline preparedness for practice and competition sessions, 8) Nutritional and weight requirements for different activities, such as wrestling, 9) Coordination of referrals to consultants, 10) Channels of communication, 11) Chain of command, 12) Documentation and record-keeping, and 13) Injury surveillance and quality improvement

This communication has been devoted to outlining the recommended roles, responsibilities, policies, and procedures of the AHCT. Several other professional organizations in medicine, sports medicine, and athletic health have also published policies and procedures that may serve as useful templates for local AHCTs.

Physical space and equipment

The physical space and equipment necessary for the AHCT must be established and maintained. To obtain and maintain this equipment, the athletic health care annual budgeting process should include input from a member of the AHCT. Recommended

standard athletic health care equipment and supplies are detailed later in this communication. In addition, other resources[7] have extensive sections devoted to planning, constructing, equipping, and maintaining facilities for appropriate medical care of the adolescent athlete.

Documentation

Issues relating to the safety of equipment and facilities, as well as athlete injuries, treatment, and reconditioning, should be well documented in accordance with generally accepted standards of their respective state practice acts. To facilitate communication among members of the AHCT as well as with outside consultants and primary treating clinicians, all patient encounters should be documented in adherence with federal, state, and local regulations while keeping within the recommendations set forth by the Health Insurance Portability and Accountability Act of 1996 (HIPAA)[8] and Federal Education Records Protection Act (FERPA)[9] when applicable. Patient records (i.e., personal medical information) should be maintained in such as manner as to ensure privacy and confidentiality in all circumstances.

Injury surveillance

As detailed later in of this document, surveillance is the first step in the cycle of developing effective public health injury control strategies. Anonymous, high-quality injury surveillance and outcomes data should be collected regularly and shared not only with public health officials and other supervisory and regulatory agencies but also with professional health care societies committed to the advancement of their respective fields.

Injury surveillance can be defined on a continuum from action at the local level to the national level. At the local level, injury surveillance can be as simple as a coach removing a field hazard following injury to an athlete so as to not cause additional injuries to other athletes or a coach altering the bullpen throwing schedule if a rash of shoulder injuries occurs to the pitching staff. Injury surveillance at the national level could mean establishing a national secondary schoolï age sports injury and illness database to begin to collect data regarding the incidence of various injuries and illnesses in this population.

To more easily compare and share such information, it would be ideal to establish uniform sports injury surveillance system standards on the local, state, and national levels. Important elements of sports injury surveillance data may include a clearly defined and standardized definition of injury, type of sports event, position played, and particular activity and moment of injury, level of competition, place where the injury occurred, injury mechanism, level of supervision, nature of the injury, injured body region, severity of the injury (e.g., activity lost, working time lost, need for treatment, cost of treatment, permanent damage, impairment, and disability), characteristics of the injured person, duration and nature of the treatments needed, use of protective equipment, follow-up of game rules, cost of the injury, and well-defined exposure data (population at risk and exposure time), which are critical in determining and comparing incidence rates.[10] However, staffing, time, and cost constraints may limit the feasibility of such extensive injury surveillance. A cooperative effort between the primary members of the AHCT along with the administrators of sponsoring organizations, coaches, and

parents provides the best opportunity to establish an injury surveillance system for each specific group. Analysis of the results of this surveillance system can provide vital information regarding recommendations to improve the overall safety of the athletic activity.

Just as injury surveillance is but the first step in the public health model of prevention, AHCTs and members of the sponsoring organization, including administrators, coaches, and parents, should be committed to ongoing, continuous cycles of quality improvement, whereby local surveillance and outcome data are used to suggest changes in its own members' roles, responsibilities, policies, and procedures. Practices involving quality improvement and injury surveillance need to start locally and move toward a national level.
Ideally, such information would be shared regionally and nationally to contribute to the medical literature and to provide a basis for evidence-based practice of clinical medicine.

Strategies for implementation
Potential strategies for the prevention of injury and illness as they relate to athletic participation by secondary schoolï age individuals are described in detail in the following sections of this communication. A brief overview of each consensus statement point is listed.

Consensus Statement Point 1: Develop and implement a comprehensive athletic health care administrative system
The demands of athletic health care require a team with diverse skills and a comprehensive administrative system. The AHCT should coordinate the various aspects of the athletesôhealth in a coherent, effective, and professional manner.

Consensus Statement Point 2: Determine the individualôs readiness to participate
To promote safe participation of the student athlete, the preparticipation physical examination (PPE) is used to identify individuals who may be at risk for the development of injuries related to their activity and those who may be at risk for sudden death due to an underlying medical problem.

Consensus Statement Point 3: Promote safe and appropriate practice, competition, and treatment facilities
Sports organizations are expected to provide a safe environment for all athletes, including keeping the premises in safe repair, inspecting the premises for obvious and hidden hazards, removing the hazards if possible or warning of their presence, protecting invitees from foreseeable dangers, and conducting operations on the premises with reasonable care for the invitees. It is recommended that a specific treatment facility be set-up by the organization.

Consensus Statement Point 4: Advise on the selection, fit, function, and maintenance of athletic equipment
Sports organizations should, to the greatest degree possible, ensure that athletes have access to appropriate equipment for the sport and that such equipment is properly fit in accordance with manufacturer recommendations and maintained by qualified

personnel.

Consensus Statement Point 5: Develop and implement a comprehensive emergency action plan
Based on the activity, skills of participants, and geographic characteristics, various types of emergency incidents are likely to occur. An emergency action plan (EAP) is essential to ensure that all incidents are responded to in an appropriate manner and that the roles of the AHCT members are well defined and communicated in advance.

Consensus Statement Point 6: Establish protocols regarding environmental conditions
Environmental conditions pose potential threats to the safety and welfare of athletic participants. It is crucial that organizations responsible for athletic events develop policies and protocols to address the safety of play in hazardous environmental conditions.

Consensus Statement Point 7: Provide for on-site recognition, evaluation, and immediate treatment of injury and illness, with appropriate referrals
Injured athletes who do not receive timely evaluation or treatment are at greater risk for improper healing, reinjury, extended time loss from athletic participation and school, and potentially life-threatening consequences. Having a qualified individual on-site and ready to care for the ill or injured person is critical to the safety of the participants and for decision making regarding when an athlete can safely return to play.

Consensus Statement Point 8: Facilitate rehabilitation and reconditioning
Although the evaluation and treatment provided immediately after an injury are critical, a rehabilitation and reconditioning program designed to return the individual to their pre-injury level of function is just as important. The process of rehabilitation and reconditioning is fundamental for the safe return of injured athletes to their prior level of competition as quickly as possible and prevention of further injuries.

Consensus Statement Point 9: Provide for psychosocial consultation and referral
The AHCT should be able to identify potential psychosocial pathologies (e.g., disordered eating) frequently associated with secondary schoolï age athletes and refer them for appropriate diagnosis and management. Sponsoring organizations must identify local experts in these medical fields and facilitate the referral of athletes to these consultants.

Consensus Statement Point 10: Provide scientifically sound nutritional counseling and education
Nutrition is a key factor for an athleteûs health, growth, and performance. It is essential that valid and understandable information regarding nutrition be provided to secondary schoolï age athletes, parents, and coaches. Even more essential is the ability to refer athletes to appropriate medical personnel for treatment when necessary.

Consensus Statement Point 11: Develop injury and illness prevention strategies
Injury and illness can be a heavy burden on the well-being of the secondary schoolï age athlete. A public health framework can be used to develop effective interventions to reduce the affliction of injuries and illnesses to these young persons.

DETERMINING AN INDIVIDUALÕS READINESS TO PLAY: THE PREPARTICIPATION PHYSICAL EXAMINATION

The number of individuals participating in organized sports has increased dramatically, with various sources estimating close to 6.5 million student participants in high school athletics each year.[11] The National Center for Catastrophic Sports Injury Research (NCCSIR) noted that between fall 1982 and spring 2001, close to 72 million males and 35 million females had participated in high school athletics.[12] These numbers unfortunately do not reflect the number of people participating in non–school-sanctioned programs such as community- or religious group–based leagues and recreational and developmental programs.

The Preparticipation Physical Examination (PPE) is essential to identify athletes at risk for injury and implement corrective actions before injuries occur. Yearly screening of these athletes is imperative because health conditions may change from year to year and the development of subtle problems may be overlooked. The PPE is an important requirement for all participants in any organized program and should be performed by the athleteÕs primary care physician, school physician, or team physician.

The purpose of the PPE is not to exclude an individual from activity but instead to recognize individuals who may be at risk for developing injuries related to their activity and those who may be at risk for sudden death due to underlying medical problems. The goal is to promote safe participation of the secondary schoolï age athlete. There is an inherent risk of injury in secondary schoolï age athletes through participation in sports and recreational activities. Krowchuk[13] noted that 22% to 39% of high school athletes sustain a significant injury and that as many as 20% of such injuries may be preventable. The value of identifying those at risk therefore is paramount to prevention.

In 1997, Beachy et al.[14] noted that over an 8-year time span, 14,318 athletes participating in more than 32 different sports reported a total of 11,184 injuries that required medical help. The male injury rate was 0.90 injury per athlete with 0.33 day-lost injury per athlete; the female injury rate was 0.64 injury per athlete with 0.21 day-lost injury. The overall injury rate for day-lost injuries was 28%. Almost all of the injuries reported in this study were musculoskeletal in nature.

Fortunately, the risk of sudden death is not as common as is that of musculoskeletal injuries. Between 1983 and 1993, 126 nontraumatic deaths among high school athletes were identified by the NCCSIR (overall annual death rate, 4.68:1 million athletes).[13] The impact of an unexpected death in a perceived healthy young person is remarkable and warrants screening measures and education for recognizing those at risk. Unfortunately, not all injuries and sudden deaths can be prevented, but strategies to minimize the risk are paramount. Periodic assessment of an athleteÕs medical history and a comprehensive physical examination provide one such prevention strategy. The AAP noted in a 2001 policy statement that although PPEs are typically not mandated until junior high school and high school, annual examinations for younger children afford the opportunity to promote physical activity and to address issues of readiness as they apply to organized sports.[15]

In July 2002, the NFHS released the second edition of their *Sports Medicine Handbook,* which clearly states that the PPE is ña necessary and desirable pre-condition to participation.ò[16] It is our objective to have the PPE be required for all participants in all organized programs, including those that are school, community, and religious group based.

Components of recommendation

In 1992, five organizations (American Academy of Family Physicians, American Academy of Pediatrics, American Medical Society for Sports Medicine, American Orthopaedic Society for Sports Medicine, and American Osteopathic Academy of Sports Medicine) published a consensus report regarding the PPE. This document, herein referred to as the PPE Monograph,[17] clearly outlines the stated goals of the PPE along with guidelines for the organization and administration of the examination. Along with the 1998 American Heart Association guidelines for cardiovascular screening of competitive athletes,[18] these documents set the standard for the PPE.

The PPE should be incorporated to detect conditions that may predispose injury or preclude participation in specific sports; prevent further injuries by identifying and treating musculoskeletal abnormalities; detect medical conditions that may be life threatening or disabling; determine the athleteôs general health; assess fitness level for specific sports; advise the athlete in which sports he or she can participate if a condition exists that precludes participation in some sports; develop treatment and rehabilitation plans for problems; counsel the athlete on health-related issues such as nutrition, alcohol, drugs, and other psychosocial issues,;and meet legal and insurance requirements. [16-20]

Discovery of limiting or disqualifying conditions

Conditions such as acute, recurrent, chronic, or untreated injuries or illnesses may compromise the performance of the athlete and place him or her at greater risk for the development of other injuries. For example, examination of foot pain in a young gymnast may uncover a chronic stress fracture that may be due in part to an underlying eating disorder and, if left unrecognized, may lead to further disability and injury.

The discovery of a new medical condition during the PPE is very rare. Recently, the Mayo Clinic[21] reported that of 2,739 students screened over a 3-year period, 13.9% were given dispositions other than being cleared for sports. In this group, 1.9% (53 students) were not cleared for sports due to underlying medical concerns.

Musculoskeletal abnormalities accounted for the largest proportion of those not cleared (43.4%). Cardiac abnormalities, which included exertional presyncope or syncope and palpitations, were the second leading cause of a ñnot clearedò disposition.

If medical conditions are identified during the PPE, recommendations for handling these problems should be dealt with on an individual basis and follow guidelines set forth by the AAP[22] and the 26th Bethesda Conference.[23] A summary of these guidelines can be found in various sources, including the PPE Monograph.[17]

Sudden death
The incidence of sudden death in school-age athletes is low compared with the number of musculoskeletal injuries incurred during participation. However, sudden death in a young competitive athlete is usually a devastating and tragic event that affects the community. Most cases of sudden death are related to underlying cardiac abnormalities. Maron et al.[24] evaluated a total of 158 sudden deaths that occurred in trained athletes between 1985 and 1995. A total of 124 deaths were cardiac: 48 (36%) were due to hypertrophic cardiomyopathy and 17 (13%) were due to congenital malformations of the coronary arteries. In 3 individuals (2%), a ñormalò heart was found on autopsy with no other apparent cause of death. In the same study, Maron et al.[24] noted that PPEs were performed before competition in 115 of the 158 cases reviewed. Of these 115, only 4 (3%) were suspected of having cardiovascular disease and the cardiovascular abnormality responsible for sudden death was correctly identified in only 1 athlete (0.9%).

Given this information, it has been argued that the PPE may not be an adequate tool in assessing risk for sudden death in young athletes. Many articles have been written about using other noninvasive means for screening this population such as the use of echocardiograms, electrocardiograms, and stress tests to identify those at risk. This testing is cost prohibitive and the yield is too low to have a dramatic impact on the overall screening process and therefore is still not required as part of the PPE.[23, 25-28] However, there remains a critical need for effective, low-cost screening methods. The American Heart Associationôs[29] history module that consists of five questions has been adopted by some states for use on the PPE and may be a reasonable alternative.

Assessing general health of the athlete
The PPE should be considered as part of an overall health care plan for the secondary schoolï age athlete and should not be a substitute for the student-athleteôs routine medical care. It can be incorporated into a regular examination with the student-athleteôs primary care physician and should not replace regular scheduled visits and/or checkups. Unfortunately, approximately 80% to 90% of adolescents report that the PPE substitutes for a routine examination.[30]

It is important to recognize that the PPE may be the only contact that some student-athletes have with a physician on a regular basis and that attention should be given to issues of routine health maintenance. A standardized form, like that printed in the PPE Monograph,[16, 17] helps address some of these issues and can aid in further screening of potential problems and/or deficiencies.

Assessing fitness level for specific sports
The fitness assessment should include body composition, flexibility, strength, and endurance.[16] Not all of these components can be routinely assessed as part of the PPE, but a review of some of these components and a discussion of the sports in which they want to participate can help establish a baseline for training. For example, an obese male who wants to participate in his high school football program should be counseled on the effects his weight may have on his play. The excess weight may also make him more prone to heat injuries and this should be discussed, by a member of the AHCT, with the athlete, his parents/guardians, and the coaching staff. The athlete should be

encouraged to participate because the physical activity is important, but it should also be recommended that he be counseled on proper nutrition, weight training, and aerobic conditioning prior to and during the season to help improve his performance and to avoid injury and illness.

Counseling athletes on health-related topics
The PPE affords an opportunity for the physician to counsel athletes on potentially risky behaviors such as drug, alcohol, and supplement use and nutritional concerns. As previously noted, the PPE may be the only contact a student has with a health care provider during the school year and this opportunity should not be lost.

The use of a standardized PPE form that includes questions about drug, alcohol, and supplement use and concerns about weight can provide a useful screening tool for the physician and coaching staff; any ñyesòresponse should prompt discussions with the athlete at the time of the PPE. Further recommendations for counseling and/or follow-up with the athlete's primary care provider can be made on an individual basis. In female athletes, a review of menstrual history is paramount because many young female athletes have menstrual irregularities that may be related to their training.

Screening for amenorrhea, alterations in body image, and eating disorders can be accomplished by review of the medical history and discussion with the student-athlete at the time of the PPE.

Implement rehabilitation programs
If a chronic condition is uncovered during the PPE or if the athlete has not completely recovered from a prior injury, the examiner should address the potential for reinjury or the risk for other injuries. The medical team should perform a thorough evaluation. Any problems noted during this evaluation should be addressed, treated, or referred to an appropriate medical professional to prevent further injury

McCoy et al.[31] noted that primary care physicians now carry a major responsibility to become familiar with general rehabilitation principles for all types of sports-related injuries and that the reinforcement of a sophisticated plan of applying ice and elevation as treatment for acute injury and range of motion (ROM) exercises followed by strengthening exercises and functional evaluation is critical in the return-to-play decision process. It is no longer acceptable to keep an athlete away from the sport for an indefinite period of time. Short- and long-term goals of treatment need to be established and monitored. In schools or organizations with access to ATCs, this process can usually be accomplished more quickly and efficiently. If ATCs are not available, the responsibility rests with the primary care physician, team physician, school nurse, coaching staff, parents/guardians, and the athlete to ensure proper referrals to appropriate resources for an efficient and safe return to play.

Meeting legal needs
In 1988, Feinstein et al,[32] found that 35 states require yearly physical examinations, 3 states require a physical examination every 3 years, 1 state required only 1 physical examination, and 6 states did not specify their requirements. Many local school districts and organizations have their own policies in place with regard to the medical eligibility of

secondary schoolï age athletes, with the PPE, generally the cornerstone of this requirement.

Strategies for implementation

Implement an optimal time frame for the PPE

While no time frame exists for performing the PPE, it has been suggested that the PPE be performed in advance of the sports season to allow optimum time to address any issues that may arise during the examination ï 4 to 6 weeks before the start of a season seems to be most appropriate. In scholastic sports played in the fall season, the PPE should be performed before the end of the preceding school year so that any chronic injuries can be addressed and a treatment plan can be laid out for the student-athlete for the summer months.

Many schools and states require yearly evaluations as a prerequisite to participation. The American Heart Association[18] recommends that both a history and physical examination be performed before participation in organized high school sports, with repeat screening every 2 years. An interim history should be performed in intervening years or sooner if there have been any changes in the student-athleteôs health.

The AMA Group on Science and Technology endorses the work of Risser et al.[33] and McKeag,[34] who recommend that a PPE be performed at the beginning of any new level of competition with an intercurrent review before the start of each new season.[35] Regardless of the time frames adapted, it is important to realize the importance of routine screening for injury and illness recognition and prevention.

Methods of performing the PPE

The PPE can be performed in three different ways: (1) by the athleteôs private physician in the office setting; (2) by multiple examiners as part of a station examination; or (3) by a physician as part of a mass ñassembly-lineò examination.[16, 19, 32]

Examination by the athleteôs *private physician* would be the most ideal situation because this offers the most continuity of care with the most comprehensive medical history. The physician is likely to have an established relationship with the athlete, and the components of the PPE can be incorporated into a comprehensive health evaluation. Unfortunately, not all physicians are familiar with sports medicine issues, and they may be limited in their ability to detect musculoskeletal abnormalities. Also, many student-athletes do not have a physician whom they see on a regular basis.[13] Communication issues may arise because the private physician is not usually the school or team physician. Confusion regarding abnormalities, treatment plans and clearance can ensue if concerns are not directly forwarded to the ATC, coaching staff, and/or athletic director by the private physician. Comments from the primary physician should be forwarded to on-site personnel through the AHCT to alleviate any possible problems.

The *station* method, in which components of the PPE are broken down and delegated to adequately trained support staff, has been more widely accepted as the best model for efficiently performing large numbers of examinations.[16, 18, 19, 33]

These stations are often staffed by personnel who are educated in sports medicine and can provide better evaluation of potential problems. The final station is manned by the supervising school or team physician, who reviews each athleteôs history and physical examination and makes final recommendations with regard to clearance. This method is very helpful in providing adequate communication with the other members of the AHCT and the coaching staff, as most will be actively involved in the PPE process. A potential drawback to the multistation PPE is lack of sufficient qualified medical personnel to man the stations. In addition, any abnormal findings identified through use of this method should be reported back to the athleteôs family physician for follow-up care.

The ñ*assembly line*ò method or traditional ñ*locker room*ò examination, in which one physician examines a large number of athletes with little or no support staff, is very inefficient and not recommended.[18]

Identify and use a standard form for all PPEs
The history portion of the PPE is vital in obtaining accurate and up-to-date information regarding the student-athleteôs past medical problems, injuries, and current medications. Rifat et al.[35] reviewed 2,574 PPEs and showed that the history accounted for 88% of the abnormal findings and 57% of the reasons cited for restriction from a particular sport. Many sources advocate the development of a standardized form to help ensure uniformity; these forms can be given to the student-athlete before the PPE for completion of the history section with their parents/guardians. The **history** section should include questions that assess for the following[13, 16, 17, 19]:

1. *Past injuries causing the athlete to miss a game or practice.* Specific questions should be posed regarding a prior history of fractures, operations, or use of casts or braces.

2. *A loss of consciousness or memory after a head injury.* Repeated concussions may be criteria for exclusion from contact sports and/or prompt or warrant a comprehensive assessment.

3. *Previous exclusion from sports for any reason*

4. *Syncope, near syncope, chest pains, or palpitations during exercise.* Specific questions regarding passing out, nearly passing out, chest pains, or irregular heartbeats during exercise must be asked because these may be the only clue to an underlying cardiac condition.

5. *Past medical history.* This includes conditions currently being treated, history of asthma or exercise-induced bronchospasm, history of one paired organ, and history of sickle cell disease or trait.

6. *Prior surgical procedures and complications*

7. *Current medications and dosage*

8. *Allergies to medication, stinging insects, foods, and other environmental triggers*

9. *Immunization records, including tetanus*

10. *Family history of sudden death*

11. *Menstrual history with age of menarche and frequency of menses for all female athletes*

12. *History of significant weight gain or loss and the athleteôs perception of his or her current body weight*

13. *History of over-the-counter supplement use*

The **physical examination** portion of the PPE form should include the following[13, 16, 17, 19].

1. *Vital signs, including height, weight, blood pressure, and resting and postexercise pulse*

2. *Vision screening with the use of a traditional Snellen chart.* If corrected acuity in either eye is 20/40 or greater, the athlete should be referred to a specialist for follow-up.

3. *Tanner staging*

4. *Assessment of the head, eyes, ears, nose, mouth, and throat for any abnormalities*

5. *Cardiovascular and lung examination*

6. *Abdominal examination with evaluation for hernia in males.* Pelvic examinations in females should be referred to appropriate specialists if the history warrants concerns because these are usually not required as part of the PPE.

7. *Muscle strength testing and brief neurological assessment*

8. *Examination of the skin for any rashes, chronic skin condition, or abnormal moles*

9. *Musculoskeletal evaluation.* This should include ROM testing in the upper and lower extremities; assessment of laxity or instability in the shoulders, elbows, wrists, hips, knees, and ankles; and assessment of the spine for scoliosis and/or abnormalities of the thorax, such as pectus excavatum.

10. *Section to list abnormalities and recommendations for clearance and, if necessary, treatment plans*

11. *Determine Body Mass Index (BMI)*

Preprinted forms that encompass all of the above points can be found in several sources, including the NFHS *Sports Medicine Handbook*[16] and the PPE Monograph.[17]

These forms can be copied and adapted to the needs of the school district or organization.

Communication system

A good communication system should be in place between the medical staff, athlete, parents/guardians, coaches, and athletic director. It is recommended in HIPAA that this communication begin with a formal letter to parents/guardians advising them of the purpose and nature of the PPE. Consent forms and a copy of the PPE history can be mailed separately or along with the introductory letter with instructions for completion before the PPE. A cover letter should also accompany the PPE to the family physician as a mechanism to avoid any communication problems that could arise. This cover letter should specifically ask for any physician comments on any specific concerns that might affect athletic performance as well as suggested rehabilitation or treatment options for current problems. Once the data have been collected, it must be kept on file for reference purposes; this should be the responsibility of the school nurse or ATC. If the athlete is participating in a non–school-sponsored program, the sponsoring organization should keep these records up to date. Any abnormalities need to be communicated to the student-athlete, his/her parents/guardians, the ATC, and the athletic department. If the student opts to have the PPE performed by his or her primary care physician, the use of the standardized PPE form is imperative to maintain uniformity and to ensure that all components of the examination have been addressed. New regulations instituted by HIPAA may require other specifications with regard to the privacy of these records; this should be part of the organizationôs overall compliance plan. School-based groups should adhere to FERPA regulations.

PROMOTING SAFE AND APPROPRIATE PRACTICE, COMPETITION, AND TREATMENT FACILITIES

Secondary schoolï age athletes have a right to play in facilities that are safe and without the potential for unnecessary harm. When injuries do occur, these participants also have a right to be treated in a clean and appropriate environment that is dedicated to this purpose. While the benefits young athletes gain from sports participation are immeasurable, the impact of accidental injuries and deaths to this age group cannot be ignored. Although very few youth sports injuries are fatal, or even catastrophic, their frequency and financial impact warrant our attention. The U.S. Consumer Products Safety Commission has estimated that up to 22% of girls and 39% of boys in organized sports are injured per season.[36] According to the National Youth Sports Safety Council,[37] sports-related injuries to youths up to 14 years of age cost society more than $49 billion in 1997.

These statistics, coupled with a desire to make sports participation a positive experience for children, underscore the need to prevent injuries whenever possible. Making sports facilities safe for young athletes is of paramount importance.

Providing safe facilities is an integral component of effective sports management and is governed by ethical, legal, and other administrative considerations. Safe facilities provide the opportunities for safe participation and a positive experience for the young athlete. The right to participate in safe and healthy environments is contained in *The Bill of Rights for Young Athletes*.[38] Well-maintained facilities ensure that safety is a priority, and that priority is then carried to the public.

A review of case law shows that sponsoring organizations that do not provide a safe environment expose themselves to unnecessary legal action and the athletes they are supposed to help to undue preventable injury. Facilities that are not maintained routinely also provide opportunity for undue accidental injury.

Countless lawsuits have been filed, and frequently won, by parties who have sustained injuries due to improper inspection and maintenance of facilities,[39-41] hazards in and around facilities,[42-45] unsafe grounds and external walkways,[46-48] and improper facility signage.[49-51] Such litigation depletes the financial resources of sponsoring institutions and reflects a negative image to the public about the specific institution and about sports in general.

Federal, state, local, and professional guidelines regulate certain aspects of most sports facilities. Parties who administer youth sports programs can avoid potential professional censure or criminal proceedings through diligent compliance with regulations pertaining to health and safety.

Components of recommendation

Athletic facilities can vary greatly in size and complexity. Regardless of the size and purpose of a facility or the resources of its caretakers, entities that sponsor sports opportunities for secondary schoolï age athletes should ensure that all facilities are

safe. The AHCT can play a vital role in sports facility safety issues, specifically maintenance and sanitation, use, and supervision.

Maintenance and Sanitation

A regular maintenance program should be developed for all said facilities and capital equipment. Organizations sponsoring athletic events for the secondary schoolï age athletes, as well as members of the AHCT, should be aware of maintenance issues in and around the athletic facility. In addition, it is imperative for AHCT members to incorporate proper sanitary procedures when treating the secondary schoolï age athlete and to provide guidance and recommendations for coaches to comply with proper sanitary, maintenance, and repair procedures.

Maintenance schedules should follow industry or regulatory standards. Individuals who will perform specific maintenance tasks must be familiar with the prerequisite techniques (e.g., pool sanitation, field maintenance) and ensure that these techniques are used. With indoor facilities, appropriate circulation, temperature, and humidity must be maintained. Other health and safety considerations pertaining to sports facilities may include electrical, lighting, signage, and slip control areas of floors.

Locker rooms, bathrooms, and shower areas can present special problems in maintaining a safe environment for young athletes. According to Seidler,[52] ñConcrete floors and walls, steel lockers with sharp corners, and standing water, all make locker rooms perhaps the single most dangerous facility in sports and recreation.òBecause of the potential for injury and infection that these areas pose, they should be checked frequently for hazards, sanitized regularly, and supervised closely to prevent horseplay.

When dealing with outdoor facilities, the sponsoring organization should be concerned with the ground and surface conditions, spacing around fields, and vehicular traffic around the facility. Hazards in any of these areas could pose a risk to participating secondary schoolï age athletes. Ground hazards requiring immediate attention include holes and depressions in fields, excess moisture, erosion, rocks, broken glass, and playing surfaces or access ways that are abnormally uneven. Prior to athletic competitions, the grounds and/or playing fields should be inspected by the coach or an on-site member of the AHCT as a means of injury prevention. Structures that encroach upon playing areas should be moved. If this is not feasible, then the activity should be repositioned or modified to eliminate potential player impact with the structure. Other hazards include low hanging power lines over playing areas and exposing young athletes to vehicular traffic, either as they play or as they enter and leave the facility.

When a facility hazard is discovered, it is appropriate to either avoid using the facility or modify the sports activity to avoid exposing the young athletes to the hazard. If the problem cannot be corrected on the spot, written reports and requests for repairs should be submitted at the earliest opportunity.

Treatment facilities where athletes would be provided injury treatment and rehabilitation should be maintained in a manner consistent with medical facilities.

Use and Supervision

Before activity begins, venue-specific Emergency Action Plans (EAPs) must be formulated, reviewed, and posted within the facility (Section 5 of this document addresses EAPs in detail). Adult sponsors must ensure that first aid/emergency equipment is readily available, that some form of communication is available to contact EMS personnel, and that the facilities are accessible to EMS vehicles. This designation should be clearly marked so all know where help can be obtained. In addition, an area of the facility should be dedicated to sports medicine, with an AHCT member available to provide appropriate treatment and care for injuries sustained through the course of participation in sport.

To minimize injury potential, the activities of young athletes must be supervised. Athletes must also be instructed to use facilities safely. This is particularly true in higher-risk venues, such as aquatic facilities. The use of appropriate signage can help instruct the secondary schoolï age athlete on safe facility use, but should be used in conjunction with appropriate adult supervision. Some signage, such as those marking emergency exit routes, may be required and/or regulated by local fire codes. Signage should comply with the American National Standards Institute (ANSI) and other professional standards for readability, color, and size. Although specific needs will be unique to a particular facility, safety-oriented signage within sports facilities can include general regulations for facility use, instructions for use of specific equipment (e.g., weight equipment, whirlpools, saunas), the EAP, the location of emergency/first aid equipment, the location of automated external defibrillators (AEDs) if available, warning signs identifying known or potential hazards, and markers to delineate play/activity areas, as well as those used to designate buffer areas around equipment.

Facilities specifically designated for injury treatment and rehabilitation should be used in a manner that promotes a safe environment for all participants and allow direct supervision of all athletes and equipment at all times by a qualified member of the AHCT.

Construction and Design

The opportunities to be involved in the design and construction of sports facilities are limited, but there is little doubt that a well-designed facility can make the job of injury prevention easier. In addressing the significance of design and construction on sports facility safety, it has been noted that poorly planned, designed, or constructed sports and recreation facilities often lead to an increase in the exposure to hazardous conditions for the participants.[52] In addition, these hazardous conditions may make facility maintenance and daily operation more difficult and can increase liability.

Problems commonly encountered in the design and construction of sports facilities include the use of improper building materials, poor access control and security, poorly planned pedestrian traffic flow through activity areas, a lack of proper storage space, inadequate lighting, and inadequate safety zones around courts and fields. It should be noted that once construction on a sports facility has been completed, these problems can be difficult to correct.

Strategies for implementation
The best implementation strategy begins during the design and construction of new athletic facilities to ensure that all of the safety features listed above are present. However, because most secondary schoolï age athletes practice and compete in existing facilities, individuals and organizations involved with these athletes should implement strategies to establish procedures, inspect facilities, and record and repair potential hazards.

All parties involved with youth sports activities should regularly and thoroughly inspect their facilities: coaches, administrators, grounds/facilities staff, and members of the AHCT. Some areas, such as fixed building structures, will require less frequent inspections, whereas other areas, such as fields and floors, must be constantly inspected. Young athletes should be encourage to be a part of this ñinjury prevention teamò by immediately reporting any unsafe conditions to their adult sponsor.

The methods to be used for evaluating the safety of facilities and locations to be inspected should be established and recorded (Table 2). In general, sports safety inspections should include all structures and surfaces used by the athletes. A form or other instrument onto which findings are recorded can be helpful. The individual performing the inspections should sign the tool. As Hossler[53] points out, ñIt is better to prepare than to repair.òThis statement underscores the importance of aggressive injury prevention in youth sports. Many strategies for providing safer sports facilities have been previously mentioned in this document. The success of any sports facility safety program depends on the cooperation of many individuals, from players to parents to coaches to administrators. Therefore, it is of paramount importance to involve these persons as the program is planned and then implemented.

In addition, Clover[54] suggests professional staff use the mental cue ñS.A.F.E.òto ensure safety in the performance of their duties and responsibilities: **Supervision** from the locker room to the practice field. **Aid** the athletes when needed. This includes creating and practicing the EAP; keeping proper records of physical examinations, injuries, treatments, insurance, parental releases, and equipment; ensuring first aid kits are available and well stocked; and checking to ensure that water and injury ice are available for the athletes. **Facilities** must be checked daily for possible hazards. If there is a hazard, the area must be clearly marked or precluded from use. A written work order must be filled out and a time frame for completion of work must be established in writing on the work order. A copy of the work order should be kept on file. **Equipment** in facilities should be checked daily. From the pitching machine to the modalities used in the athletic training room, all equipment should be well maintained. This ensures the equipment lasts longer and stays in proper working condition.

ADVISING ON THE SELECTION, FIT, FUNCTION, AND MAINTENANCE OF ATHLETIC EQUIPMENT

Participation without proper equipment, or with equipment that is inappropriate or improperly fitted, subjects the participant to an increased risk of injury, illness, and even death. A great number of secondary schoolï age children want to participate in sports, and most parents allow and encourage their participation. Equipment essential to some sports (helmets, shoulder pads for football, sticks for field hockey) may be supplied by the sponsoring organization or the individual participant. If a sponsoring organization requires the participant to provide such equipment, it is incumbent upon the sponsoring entity to ensure that all equipment worn and used is appropriate and properly fitted. In addition, equipment specific to the purpose of caring for injuries and illnesses of athletes on-site will be addressed. Proper supervision is also essential when using equipment, including frequent inspections to ensure proper fit and function. Safe, effective, and appropriate equipment should be maintained and provided to the participant. Sponsoring organizations that require the participant to provide their own equipment must ensure that personal equipment complies with requirements outlined by a sports regulatory agency.

Entities that provide guidelines for approval of athletic equipment are the National Operating Committee on Standards in Athletic Equipment (NOCSAE) and the American Society for Testing and Materials (ASTM). Equipment that has not been approved by certifying bodies ï that is, inappropriate equipment or appropriate equipment that is improperly fitted or in poor repair or not maintained on a regular schedule ï could introduce the athlete to injury that is needless and preventable.

Equipment that is properly fitted and appropriate for the sport or activity is essential for the secondary schoolï age athlete to be able to enjoy athletic participation in a safe and orderly environment. ATCs and educated coaches of the particular sport are the persons most likely to have the education and qualifications to select, fit, maintain, inspect, and supervise athletic equipment use. An on-site member of the AHCT may be recommended as responsible to perform this activity and a member of the AHCT can be responsible to oversee this in the absence of an on-site AHCT member. A review of case law shows that equipment that is not well maintained or improperly fitted can contribute to, if not cause, injury to participants. In addition, the use of equipment that has not been approved by the appropriate certifying body exposes the athlete to injury as well as liability and negligence to the sponsoring entity.[4-6, 55-65]

<u>Fitting Protective Equipment</u>

Ensuring that all athletes have properly fitting equipment is important to maintaining a safe athletic environment. Sponsoring agencies should ensure that qualified personnel (coach, ATC, equipment manager) fit equipment and that the participant has appropriate equipment for participation. Schutt Inc., a helmet manufacturer, as well as other manufacturers, provide detailed instructions on the fitting of their equipment.[66-68] Use of these instructions should be followed when fitting participants or the sponsoring agency could be found liable. In the case of *Gerritty v. Beatty,*[63] the school was found liable when an athlete reported poorly fitting equipment and the school had done nothing about it.

Maintenance and Reconditioning

Once equipment is properly fit to the athlete, sponsoring agencies and members of the AHCT must make sure the equipment is properly maintained and reconditioned. All athletic equipment should be examined periodically during the season and the fit maintained throughout the season (i.e., if an athlete shaves his head, the helmet should be refit).[69] In addition, school and team officials should closely inspect any equipment used by or around participants and know the risks involved in the use of such equipment. Case law has judged in favor of the plaintiffs in cases where a latent defect in a pitching machine caused injury to the face of an athlete while the machine was unplugged[58] and where a vaulting horse was altered and the holes for the pommels were exposed.[65]

Many manufacturers now recommend that equipment be reconditioned on a regular basis, checking for flaws and defects in the product. Most manufacturers state that they will not stand behind the product if the proper reconditioning and checks have not been made.[70] In the case of *Gerritty v. Beatty*,[63] the school district was found negligent for refusing to furnish well-maintained equipment. Therefore, school districts should ensure that qualified personnel purchase, fit, and maintain appropriate athletic equipment and recondition existing equipment according to manufacturer recommendations. In addition, the sponsoring organization should be cautioned not to accept used equipment passed down from higher level organizations unless the equipment has been properly maintained and reconditioned.

Supervision During Use of Equipment

Finally, all participants in physical education, sports, and recreational teams and events have the right to be supervised by qualified and competent coaches and provided with competent health care.[71] *Competent* may be defined as being proficient in the skills required by the job description and training. Sponsoring entities and governing bodies should ensure that competent, trained individuals always supervise participants. State or local regulations may influence the parameters of what is required for appropriate supervision. Training should focus on the sport(s) to be supervised, as well as proper fit and use of equipment. In addition, the sponsoring entity or school should provide adequate and appropriate health care as described throughout this monograph.[71, 72]

Lack of appropriate supervision when using equipment in sport can also expose the athlete to undue risk. Two cases, *Grant v. Lake Oswego School District Number 7*[59] and *Tiemann v. Independent School District #740,*[65] provide emphasis that not only should participants be supervised while using equipment but also that the supervisors or coaches should be trained in how to adequately supervise individuals. In both cases, equipment was used that either was set up incorrectly or dangerously (*Grant*) or was faulty (*Tiemann*).

Components of recommendation

The sponsoring organization should identify personnel to educate in the necessary procedures to appropriately select, fit, and maintain all equipment specific to individual sports; protective equipment consistent with specific sports; and protective equipment general to all sports. The person who issues equipment should be trained in the proper fit, function, and use of athletic equipment specific to his/her sport. Members of the

AHCT should be educated on the proper selection, fit, and maintenance of athletic equipment and take an active role in reviewing quality and selection of safety equipment provided by a sponsoring organization. Equipment should be chosen based on the appropriateness to the sport, level of competition, age of participants, and overall quality. Maintenance of such equipment should be subject to a predetermined schedule and follow all of the manufacturer's recommendations and rules of the governing sporting association.

Rule changes should be investigated by governing bodies of contact and collision sports and of small ball sports to protect the face and eye from injury. Rules should include requiring the use of eye protection in practice and games.[73, 74] Investigation by a governing body provides the basis for rules changes to be implemented by that governing body. These changes should be based on scientific data. Governing bodies should use such scientific data to amend rules to best protect the participant.
Many times, professional athletes do not wear a complete set of *pads*, making it enticing for younger athletes to emulate the actions of the professionals. Secondary school leagues and officials should be encouraged to enforce the rules designed to protect these players.

Strategies for implementation
Coaches, parents, athletes, and members of the AHCT should be aware of the limitations of each piece of equipment and be able to instruct the athlete in its proper use, as well as potential hazards with its misuse. Sponsoring entities should mandate general training as well as sport-specific training for all coaches and individuals dealing with participants, including but not limited to equipment fit, function, and maintenance.[71, 72] In addition, sponsoring organizations should require appropriately trained personnel to maintain adequate supervision (i.e., within a close proximity as to prevent an inappropriate or dangerous action) of participants at all times.

With respect to equipment, braces should be used to treat or prophylactically prevent injury as directed by, or under the supervision of, a physician.[75] A qualified member of the AHCT should be the designated person to determine and fit appropriate braces, tape, or safety equipment. *Shoulder harnesses; braces* for the wrist, elbow, ankle, and knee; and custom-made braces should all conform to the rules of the sport and be used under the direction of a physician or other health care provider.[75] No equipment should be modified from manufacturers' standards. Equipment should be used only for the intent it was manufactured.

Mouthguard use is recommended for all sports with a risk for mouth and dental injuries. The use of a *mouthguard* is required by some organizations in football, lacrosse, ice hockey, and boxing for both practices and games.[76-78] Organizations that sponsor sports in which mouthguards are required should provide education to the participants and parents on the appropriate fit and care of mouthguards.[79]

Helmets for all sports should always comply with the appropriate standards. They should be periodically inspected and reconditioned in accordance to the manufacturers' recommendations. Helmets should be used only as directed and should never be used as a weapon or be the point of attack.[16, 69, 80, 81]

Facial protection or *facemasks* should be worn in sports where such rules apply or the possibility for injury to the face is high, such as football, ice hockey, menôs lacrosse, baseball, and softball. In baseball and softball, it is recommended that children between 5 and 14 years of age wear a batting helmet with a polycarbonate face shield.[82-84]

Eyewear is recommended as a wise precaution in limited-contact sports[85] such as racquetball and high school girls' lacrosse.[74] Extra eye protection should be required for any athlete with corrected vision poorer than 20/40 in either eye or with a history of eye injury or surgery.[69, 74]

Footwear that fit and is appropriate for the sport and playing surface should be used. The footwear should be replaced when worn out.[69]

Athletic mats, such as those used in wrestling, should be cleaned at least once daily and on a regular schedule with a tuberculocidal cleaner. Further study is recommended to determine the effectiveness of mat-cleaning programs to prevent the spread of skin disorders in wrestling.[86]

Maintenance and reconditioning are essential in providing appropriate safe equipment. A member of the AHCT should document that a designated employee of the sponsoring organization has been trained in the proper fit and care of athletic equipment in the absence of an on-site AHCT member. Sponsoring entities should schedule regular maintenance before equipment is issued to or used by participants. Inspections should be performed on a regular basis throughout the course of the season. In addition, season-end equipment inspections are also recommended to ensure that equipment is repaired or replaced before the start of the next season.

In some sports, forms stating ñassumption of riskò for equipment fitting and appropriate use should be used to ensure that there is proper documentation that the participants, and their parents, understand these concepts. If rule changes are to be used to implement improved equipment to protect the participant, care must be used to address public education, the cost of implementation, liability, manpower to implement the rule changes, and the timing of the program. [87]

Additional research has been identified in a number of recommendations. This research is vital in determining how best to protect the participant in any sports program. Every effort or consideration should be made to fund research when it is proposed.

DEVELOPING AND IMPLEMENTING AN EMERGENCY ACTION PLAN

Sports-related injuries and illnesses are common in athletics involving secondary schoolï age athletes. Members of the AHCT, along with coaches and administrators, need to be prepared for possible emergency situations through the development and implementation of a comprehensive Emergency Action Plan (EAP).

An understood principle within athletics is the possibility that a serious or life-threatening injury and/or illness may occur. There are both intrinsic and extrinsic risks involved with participation in athletics, and it is essential for the sponsoring organization to have a well-developed EAP for such instances to ensure that the appropriate care can be provided in a timely manner. In addition, the EAP should include planning for events that are not athletic related such as natural disasters and crowd control problems that may occur when large groups of people are gathered for athletic events.

In 2002, NATA issued a position statement regarding the need for established emergency plans in all athletic venues and suggested guidelines for developing and implementing the plans.[88] The need for an EAP has been well documented in literature and injury/illness statistics[15, 88-94] and supported in case law.[95] In *Kleinknecht v. Gettysburg College* in 1993,[96] it was decided that an institution owes a duty to each athlete to provide an emergency plan that is adequate for the risks involved in sport participation. This extends beyond the collegiate level and interscholastic athletic events, as seen in *Barth by Barth v. Board of Education* in 1986,[97] which showed the need for obtaining prompt medical treatment for students injured in physical education activities. In the case of *Jarreau v. Orleans Parish School Board* in 1992,[98] a school board was found to be vicariously liable for the failure to promptly seek medical attention for an injured athlete. The implementation of an EAP addresses these needs and provides the most efficient opportunity for treatment for injury and/or illness.

Components of recommendation

The AHCT is an important component of establishing a good EAP. The medical personnel who make up the AHCT often have experience in various areas of emergency athletic care and can contribute to the plan to ensure it is comprehensive and appropriate for school-age athletic events. The development of an EAP requires the input of all members of the AHCT in addition to the administrators of the sponsoring organization, coaches, and facility managers, along with parents and official groups. This allows for the writing of a comprehensive EAP that fully covers all aspects of emergency situations and environmental conditions and involves the expertise and cooperation of all team members. Examples of individuals to participate in EAP development include the members of the AHCT, coaches, administrators, venue managers, officials, and organizations.

If the event will take place in areas such as city parks, recreation departments, or golf courses, then the governing bodies of these organizations should also be involved or consulted in the development of the EAP. This multiorganization committee would be responsible for developing protocols to manage emergency situations, including establishing the chain of command for emergencies, the specific responsibilities for each team member, emergency situations specific to each sport, emergency situations

specific to a particular venue, the necessary emergency equipment and use of said equipment and the training of athletes to help the coach in an isolated situation.

Once the EAP has been developed and implemented, it is essential that all personnel be fully trained in the steps of emergency management, that these training procedures are documented and that there is communication with EMS personnel before the event to ensure cooperation and quicker response to emergency situations. Game and event personnel should also be trained in the necessary skills for emergencies, such as first aid, CPR and AED use, and the prevention of disease transmission.

Minimum athletic emergency equipment should include vacuum splints (or suitable alternative), a long spine board (or scoop stretcher), hard neck (Philadelphia) collars, facemask removal equipment, resuscitation masks, shoulder immobilizers, blankets, crutches, blood pressure cuff, gloves for universal precautions, and a first aid kit. [99] It is also advisable to have access to an AED during practice and/or competition. This emergency equipment must be readily accessible during all practices and games to all staff responsible for first aid or medical care of the injured athlete.[72]

Steps should also be in place for the documentation of all injury and/or illness situations that occur during the event. A review of the established procedures and all incidences of emergency situations should occur at the conclusion of each event, and a comprehensive review of the entire EAP should occur on an annual basis.

Strategies for implementation

One of the most important immediate steps is to identify the appropriate personnel to write the EAP. The AHCT should be led by a medical director, preferably the team physician, and include the other members of the team. The members of this team must take into consideration all possible emergency situations that might arise during practice and/or competition. Categories of incidences to consider would be life-threatening injuries, life-threatening illness, and environmental threats. There should be specific thought given to the types of possible incidents based on the type of activity as well as the specific venue in which it is being held. It is also imperative to ensure that emergency medications, such as an individual athleteôs asthma inhaler, EpiPen, Glucagon, or insulin, are available and that the correct protocols for use are followed. Although it is not anticipated that all contingencies will be thought of, a well-developed plan can cover most emergencies and leave a protocol in place to address other issues that arise. The development team should carefully document the emergency treatments and procedures for incidences based on the input and advice of physicians, ATCs, EMS personnel, and other qualified AHCT members. Careful consideration should be given to establishing and documenting specific responsibilities for each member of the AHCT before and during the event.

Written documentation should also include the types and locations of emergency equipment present, methods of communication (e.g., walkie-talkie, cellphone, land line telephone), venue-specific maps, and the location of the hospital or other health care facility for transportation and a list of emergency telephone numbers.

Once the EAP has been written, it is essential to review, practice, and revise the EAP

so that all duties and responsibilities are clearly outlined and understood. Placing the responsible individuals in mock scenarios is an effective way of testing the EAP for validity. Documentation of all emergency situations during an event is key for liability issues and for revision of the existing EAP. At a minimum, the EAP should be reviewed and practiced on an annual basis and subsequent retraining should take place to refamiliarize the necessary personnel with their duties and responsibilities.

There are several existing documents from supporting organizations that can assist in the development and implementation of an EAP for various venues and athletic settings, including those published by the NATA [88], NFHS[16], NCAA[94, 100], American Academy of Pediatrics [15, 91, 92, 94, 100], AOSSM[101], and The Inter-Association Task Force for Appropriate Care of the Spine-Injured Athlete.[102]

ESTABLISHING PROTOCOLS REGARDING ENVIRONMENTAL CONDITIONS

Secondary schoolï age individuals participating in athletics are subject to injury due to adverse environmental conditions. Each organization that sponsors an athletics program should establish protocols related to adverse environmental conditions specific to their region. The organizations should identify individuals responsible for ensuring the implementation of the protocols.

Adverse environmental conditions pose varying challenges to athletic events based on geographic regions and the influencing factors specific to those regions. The sponsoring organizationôs AHCT should be responsible for the development and implementation of policies regarding adverse environmental conditions. Threats can include heat stress, cold stress, lightning, severe weather, air quality, insects, rodents, reptiles, fire, and possible allergic reaction–inducing conditions. Other factors as indicated by geography and climate should be taken into consideration.

It is an understood principle that adverse environmental conditions can pose potential threats to the safety and welfare of athletic participants. Therefore, it is essential that institutions and organizations associated with athletic events have policies and protocols in place to regulate athletic participation.[101] These protocols should be specific to each athletic venue and should take individual geographic effects into consideration. Some environmental conditions can pose greater threats to athletes in particular regions of the country.

There are several environmental considerations and threats that can be included in an individual protocol depending on the venue and geographic region, as given earlier. Several established policies regarding heat stress,[103-107] cold stress,[107, 108] and lightning[109, 110] can be used as models for development. Other environmental condition protocols should be established with the members of the AHCT to ensure that all contingencies have been discussed in detail.

Heat Stress

Exercising in hot temperatures has been shown to have a variety of physiological effects on the human body and can compromise the health of the athlete if not closely monitored.[111, 112] *Heat acclimatization* is a process through which athletes improve from a physiological standpoint when exposed to exercise in the heat through careful monitoring.[113] Athletes often become acclimatized and adjust to the demands placed on the body by exercise in heat. Throughout this acclimatization period, they should be closely monitored by qualified personnel, most preferably an on-site member of the AHCT.[114] The responsibility of the members of the AHCT should be to allow athletes to acclimatize to heat conditions within certain limits.

There are several position statements and supporting documents that outline safe methods of participation in heat stress conditions and when practice and competition should be suspended.[103, 105, 106, 115] In 2000, the NATA position statement on fluid replacement for athletes outlined the practices that would encourage the optimum fluid replacement for athletes, decreasing the chances for occurrence of heat stress syndromes.[115] In 2002, the NATA position statement on exertional heat illness

established recommendations for preventing, recognizing, and treating illnesses that occur from athletic participation. This position statement,[103] as well as the Inter-Association Task Force on Exertional Heat Illnesses Consensus Statement,[105] contains many details concerning the methods of preventing heat stress syndromes as well as the necessary accommodations that should be made for practices and competitions under given conditions.[103] The NFHS also addresses heat illnesses in detail in their *Sports Medicine Handbook*.[16] The handbook describes the signs and symptoms of heat stress syndromes, as well as treatments and prevention techniques, and provides information on when practices and competitions should be limited based on the ratio of heat to relative humidity.[16] Other organizations that have issued policy statements, position stands, and/or guidelines for heat illnesses include the ACSM,[107] the NCAA,[106] and the AOSSM.[101]

Cold Stress

Cold stress is often an overlooked cause of injury and illness, as heat stress syndromes tend to receive the most attention. However, exposure to cold is obviously more of a concern in certain geographic regions than in others.[116] Extensive research has been done concerning the effects of and possible damage caused by cold on the body during exercise. Exercise and athletic activity in a cold environment can have deleterious effects on performance and human health, which may not be realized by the participant until damage has occurred.[117] Therefore, it is essential to carefully establish a protocol regarding participation in cold environments.

Lightning

Lightning is the second most common environmental cause of death in the United States after floods.[118] It is particularly abundant in early afternoon storms, during which many outside athletic practices and competitions occur.[109] Because there is no absolute protection against the effects of lightning while outside, proper education and a well-established protocol can prevent many deaths and injuries.[119, 120]

The NATA published a position statement on lighting safety for athletics and recreation in 2000 to educate those involved in athletics about the risks involved with participation in a lightning environment and to provide guidelines for safe behaviors during lightning and to advocate appropriate care for lightning strike victims.[109] The NCAA guidelines for lightning safety emphasize many of the same points, including details on an established chain of command and on obtaining weather reports and monitoring of weather systems to provide the most accurate and up-to-date data.[110] The NATA and the NCAA advocate evacuating outside areas as soon as lightning is seen or thunder is heard and seeking shelter in safe buildings. This is the protocol encouraged by the NFHS.[16] The key to lightning injury prevention is to carefully monitor the weather conditions and to allow those individuals in the chain of command to perform their duties in protecting the athletes and participants.

The established environmental protocols should be carefully documented and distributed to all members of the AHCT, coaches and administrators. Opportunities for rehearsing scenarios and revising policies should also be made. It is imperative to ensure that all involved individuals must be aware of the protocols and understand their role in the event of an environmental emergency. An annual revision (similar to that of

the EAP) should take place to retrain AHCT members and to address any inaccuracies and inadequacies in the plan.

Components of recommendation

Before an athletic event or contest takes place, it is essential for the necessary members of the AHCT to meet to develop policies regarding adverse environmental conditions, including lightning, heat stress, and cold stress. The details of this vary as each individual venue and geographic region have concerns that are inherent to that area. The AHCT will begin to develop methods for assessing the site-specific concerns that have been identified. There is a great deal of information available concerning the various environmental conditions and the appropriate planning for prevention and treatment that can be used in identifying the steps to take in each circumstance.[103, 109, 115] Each AHCT will have to decide what is best for each geographic region based on normal environmental conditions for that area.

Taking into account the given possible adverse environmental concerns, written detailed plans that provide for the safety and welfare of all participants will assist the AHCT and event management personnel with decisions regarding participation. In writing these environmental policies, it is also important to carefully delegate responsibility to the appropriate decision makers. Factors to take into consideration include who is responsible for monitoring conditions, what methods will be used to monitor the environment, the time frame parameters for decision making, detailed alternative plans for participants and spectators, and who communicates plans to all relevant individuals.

Strategies for implementation

There are many members of the AHCT who may be capable of providing input into the development of environmental conditions policies, but it is essential that there is effective communication between the medical director, the ATC, and the administrators of the sponsoring agency. These individuals have the greatest opportunity to effectively design and provide input for the development of these policies. The involvement of all members of the team not only increases the effectiveness of the document but also ensures that all individuals are aware of the policies for safeguarding athletes. It is also essential that communication from the AHCT during contest continues to include the administration and officials.

The use of existing position statements and policies will ease the process of developing individual policies. It is essential that these policies be put into writing so that they may be adequately enforced. Responsibilities for each member of the AHCT should also be put in writing to ensure compliance and to ensure that all members are clear as to what they are to do in given situations. The methods of communication between AHCT members and for the acquisition of necessary environmental information need to be clearly outlined as well (e.g., walkie-talkie, cellphone, CB radio, weather radio).

Heat Stress

Members of the AHCT should be involved with the written guidelines regarding when it is potentially hazardous to participate in athletic events during times of heat and humidity. These guidelines should be implemented by the sponsoring organization and AHCT to determine when it is unsafe for the secondary schoolï age athlete to participate

in sporting events. Several position statements have been written regarding heat illness, and they recommend that an individual be responsible for evaluating the temperature and humidity. Established local guidelines (limiting personal equipment, increasing fluid replacement breaks, limiting practice intensity and duration, avoiding the heat of the day when possible, etc.) can be followed. Inexpensive sling psychrometers can be used to evaluate wet-bulb and dry-bulb temperatures and humidity, and heat stress.[103, 105, 106, 115]

Cold Stress

Sponsoring agencies and the AHCT also need to create guidelines for determining when it is unsafe to participate in athletics due to the cold and/or wind chill. The implementation of these protocols should fall to a designated individual who determines the outdoor temperature with the wind chill and advises whether it is safe for the secondary schoolï age athlete to participate without the added risk of frostbite or hypothermia. The NCAA has written a guideline for member institutions that reflects the effects of exposure to cold temperature and wind over a period of time and the increased risk for frostbite. These guidelines also include methods of preventing cold illness, such as appropriate clothing, maintenance of energy/hydration levels, and use of a proper warm-up.[108] The NFHS also addresses cold illness in their *Sports Medicine Handbook* and includes greater details on the effects of temperature and wind on the body as well as recognition and treatment of frostbite, hypothermia, and related syndromes.[16] Both organizations provide a solid foundation that can be used to develop an individual cold stress protocol to protect athletic populations.

Lightning

A written lightning policy, such as that published by the NATA,[109] should be put into place by the sponsoring agency. It should include the name of a person(s) responsible for monitoring the weather, the criteria for suspension and resumption of activity during lightning, and the safe areas to which the participants and spectators should retreat during inclement weather. Often, the criterion used to determine when activities should cease and resume during lightning is the 30-30 rule, which dictates suspension of activities when the flash-to-bang count nears 30 seconds and resumption of activities after a 30-minute wait following the last lightning flash thunder or after lightning has been seen or heard.[121] In addition, there are other methods of detection, including the weather service radio, lightning detection equipment, and lightning detection services.

There should be a designated person responsible for determining the flash-to-bang count at each outside venue, practice, and competition when severe storms are forecast. It is recommended that this designee be someone other than a game official or coach due to the attention they must pay to the game. This count is determined by beginning to count the seconds from the time the lightning is seen to the time the thunder is heard. The time in seconds between the flash of the lightning and the bang of the thunder is divided by 5 to determine the how far the storm is from the individual who is counting.[119, 121] It is recommended that as the flash-to-bang count nears 30 seconds (means that lightning strike was 6 miles away), all participants and spectators should immediately seek a safe shelter.[109]

Other Environmental Conditions

Special consideration should be given to the incidence of environmental allergens and potential bites from insects, rodents, and reptiles. The on-site member of the AHCT, or the coach when there is no on-site AHCT member, should be aware of those athletes with allergies who might be at increased risk for respiratory ailments or anaphylaxis. The AHCT should monitor the exposure of those athletes and plan ahead for proper treatment (e.g., have an athleteôs EpiPen available) should it occur. Specific information can be gathered from the American Academy of Asthma, Allergy and Immunology (AAAAI) and from organizations such as the National Outdoor Leader School (NOLS) and their Wilderness Medicine School.

PROVIDING ON-SITE RECOGNITION, EVALUATION, AND IMMEDIATE TREATMENT OF INJURIES AND ILLNESSES

Secondary schoolï age individuals participating in athletics are subject to injury, including certain injuries and medical conditions unique to this population.[3] Each organization that sponsors an athletics program should develop an EAP that highlights mechanisms for evaluating and treating adolescents sustaining an injury. As part of the EAP, the organization should identify individuals responsible for providing these services and ensure they are educated, trained, and appropriately certified and licensed (if required by state law) to provide these services during every practice and competition. The ATC offers the best option, offering advanced first aid knowledge, CPR/AED use, and the ability to make return-to-play decisions. The AMA recommends that ATCs provide these services, although the AMA recognizes that EMTs, paramedics, and physicians are viable options in the absence of an ATC.[1, 122] In some cases, the coach is the only person available on-site during practices and games and should be trained in first aid and CPR; however, the coach cannot practice outside of his/ her scope of practice, which would include making decisions regarding when it is appropriate for an athlete to return to play following an injury or illness.

Early injury evaluation and treatment encourages proper healing and decreases the risk of reinjury,[1, 3, 123-125] and the initiation of prompt treatment is critical in the management of life- or limb-threatening injuries or conditions. These services should be available to injured athletes at each and every athletic activity.

The amount of epidemiological data concerning the incidence of injury in youth sports participation is increasing.[1, 3, 14, 85, 91, 125-144] The injuries sustained by the participants vary in severity, from relatively minor to catastrophic.[3, 14, 135, 139] It is important to remember that secondary schoolï age athletes are not miniature adults[124] and are susceptible to injuries that are specific to their age and level of physical maturity, presenting special challenges with respect to their participation in athletic activities.[85] A thorough, on-site initial evaluation is important in recognizing the nature and severity of the injury, determining if more advanced treatment and care are required, and limiting participation to protect the initial injury and prevent further harm.

One of the primary concerns regarding adolescent injuries is the child's developing musculoskeletal system.[124, 135, 136, 139, 145] The fact that the epiphysis, or growth plates, remain open is the reason physically immature youngsters are at greater risk, especially if they compete against more mature youngsters who have completed puberty and have closed growth plates and more mature muscular support for joints.[124, 145] An adolescentôs bones and articular surfaces may not be sufficiently developed to handle the stresses associated with athletic activity. Therefore, adolescents may develop a number of characteristic injuries, including osteochondritis dessicans, spondylolysis, stress fractures, and Salter-Harris fractures, many of which may have long-term consequences.[135, 136, 139, 144, 145]

Adolescents who have sustained an injury should be evaluated immediately to determine the nature and extent of the injury, because its signs and symptoms may change relatively quickly.[1, 3, 123-125] For example, the signs and symptoms of a head

injury may resolve soon after the injury, even though a significant, possibly life-threatening, head injury has occurred.[132] This individual may return to play because of resolution of their symptoms; however, Guskiewicz et al.[132] report that football players sustaining one concussion were three times more likely to sustain a second concussion during the same season than were athletes who have not had a concussion. Identifying the head injury through a thorough initial injury evaluation is essential to limiting the õserious sequelaeò associated with repeated head injury.[132] An example of this sequelae is second impact syndrome (SIS), which occurs when an individual with a head injury receives a second blow to the head before the brain has recovered from the first injury and can lead to death.[127, 134] Immediate recognition of the initial concussion by members of the AHCT, as well as team members and coach, is important in the prevention of SIS and can be made through a proper initial evaluation.

An immediate injury evaluation also permits the quick initiation of appropriate medical treatment, which is associated with proper healing and a reduced risk of reinjury.[1, 124] Immediate treatment can mean the difference between life and death. Heat exhaustion, for example, is one condition that can be fatal without prompt recognition and treatment.[103] In addition, improper treatment of a suspected neck or spine injury may lead to secondary injury or a worsening of the original injury.[102]

When identifying the individuals to fulfill these roles, most organizations consider several options: physicians, paramedics or EMTs, coaches, and ATCs. Physicians certainly have the knowledge to complete an injury evaluation. Physicians also possess the medical expertise required to make decisions regarding injury treatment. However, one concern when asking physicians to provide these services is their availability at each practice and competition.

Several studies discuss the medical coverage afforded high schools for athletic activities in a variety of states.[128, 143, 146] In a survey of 240 California high schools, physicians provided medical coverage at football games over 70% of the time.[146] In contrast, a survey of 119 high schools in Alabama reported physician coverage at less than 25% of school-sponsored sporting events and less than 15% of practices.[128] Although practice coverage was not addressed specifically, reports from 301 high schools in Wisconsin indicated that only 35.5% of schools had a designated team physician.[143] Hence, although physicians certainly have the skills and training required to provide immediate medical care, they are often not available or able to satisfy the need for immediate injury evaluation and treatment at all practices and games.[1]

Similar results were found when schools were surveyed regarding the presence of an ambulance during practices and competitions. Vangsness et al.[146] report that less than 38% of schools had an ambulance with an EMT or a paramedic available at home football games. Culpepper[128] found that at least 80% of schools provided an ambulance during varsity football games, although less than 38% provided an ambulance for junior varsity football games. In a survey of 302 high schools, Rutherford, Niedfeldt, and Young[143] found that almost 79% of schools had an ambulance available or on call for practices or scrimmages. Although this percentage is higher than reports from other states,[146] having an ambulance õon callò does not necessarily mean the ambulance is on-site. In cases where an ambulance is available on-site, that ambulance may be

called away at a moment's notice in response to an emergency. An athleteôs medical condition can change dramatically in a few minutes, less time than it may take an ambulance to arrive on the scene. Relying on the presence of an ambulance and personnel to provide medical care may not satisfy the need for immediate injury evaluation or treatment.

Coaches are another viable option for providing immediate injury evaluation and treatment. Coaches certainly are available on-site at each practice and competition and are encouraged to become educated about responding to emergencies, including certification in first aid and CPR.[16, 85, 88, 91, 123, 125, 126] In fact, some states require coaches to obtain these certifications.[141, 146] However, state laws often prohibit coaches from making return-to-play decisions or care beyond first aid such as taping an injured body part. The U.S. Navy defines *first aid* as the emergency care and treatment of a sick or injured person before professional medical services are obtained. First aid measures are not meant to replace proper medical diagnosis and treatment ï they only provide temporary support until professional medical assistance is available. The purposes of first aid are to save life, prevent further injury, and minimize or prevent infection. Therefore, using coaches as health care providers is not always appropriate.

Moreover, a study by Ransone and Dunn-Bennett[141] questions the ability of coaches to provide these services. They surveyed 104 coaches of boys' and girls' sports at 17 high schools in California. The survey consisted of two separate parts: a test of first aid knowledge and a game situation data sheet that asked coaches to make decisions regarding athletic injuries in nine different athletic scenarios. Of the coaches surveyed, 92% were certified in first aid, yet only 36% passed the first aid assessment. The game situation questionnaire asked coaches to indicate whether they would return a starting player to the game after an injury. The authors note that, in general, coaches tended to return players to the game, especially those coaches who passed the first aid assessment. The authors express concern that coaches may not understand the ñramifications of returning an athlete to competitionò and suggest that ñadditional knowledge on the treatment and rehabilitation of athletic injuries should enable coaches to make more objective decisions.ò[141] Of additional concern is that standard first aid courses do not teach the specifics regarding athletic-related injuries so many coaches have not been taught how to make these types of decisions. There is also a conflict of interest in allowing coaches to make return-to-play decisions.

Coaches should not be expected to split their attention between evaluating athletes, making return decisions, and their coaching duties. In addition, they do not possess the education to appropriately make the decision to return an athlete to participation following an injury.

In many cases, coaches are asked to fill the role of injury evaluator and treatment provider. However, during the course of an athletic practice or competition, coaches focus their energy on supervising their athletes and instructing them in the skills of the game. In addition, of the coaches responding to Culpepperôs survey examining medical coverage in Alabama high schools, ñonly about half of them said they felt adequately trained to handle a medical emergency.ò[128] Given the concerns expressed regarding a coachôs ability to handle medical emergencies, their expertise in first aid and CPR, and

their ability to make objective return-to-play decisions, assigning coaches the additional responsibility of providing immediate injury care may not be the best solution. The CDC will soon release a coachôs kit for concussion management that was developed based on input from coaches and an expert task force. The consensus was that coaches should be able to identify a concussion but should make no decisions about return to play based on their preoccupation with all the other players and a limited knowledge. Providing an individual, such as the ATC, to specifically provide injury evaluation and treatment services at all athletic activities has been recommended.

In summary, while physicians are capable of performing injury evaluations and rendering decisions about injury treatment, they generally are not available to perform these duties at all practices and competitions. And although an ambulance complete with EMTs and paramedics is only a telephone call away, rarely is an ambulance available at each and every athletic activity. Immediate injury evaluation and treatment is a critical component in the successful management of many athletic injuries; however, EMTs are trained in only emergency care and cannot fulfill the role of the comprehensive AHCT. Therefore, organizations that sponsor athletic programs must ensure that an individual or individuals capable of performing these tasks are on-site at each and every athletic event.

The AMA recommends that schools sponsoring athletic programs establish an AMU that consists of a physician and an athletic health coordinator.[1, 122] The AMA suggests that athletic organizations place an ATC in the role of the athletic health coordinator.[1, 122, 147] ATCs are appropriate choices for the athletic health coordinator because they have the skills and knowledge required to perform injury evaluations and to provide immediate treatment.[1]

Components of the recommendation

Organizations that sponsor athletic programs should establish an AHCT, identify an athletic health coordinator, and develop a comprehensive EAP[1, 122] that includes mechanisms for providing immediate injury evaluation and treatment. Individuals capable of providing these services should be available for all athletic practices and competitions.

Strategies for implementation

On-site medical professionals such as the team physician or ATC should lead the AHCT. The organization sponsoring the athletics program should identify the individuals responsible for performing injury evaluations and providing injury treatment within applicable state law. The selection of this individual should be based on his/her education and availability to provide these services at each athletic practice and competition. At a minimum, a coach or other individual who is with the team on a regular basis, and is trained in CPR (including AED use) and first aid, should be available to tend to injuries that occur. In addition, protocols should be established, in advance, governing referrals and return-to-play decisions, especially in instances where a sponsoring organization may have multiple events going on at several sites.

Another viable option is the presence of an EMT/paramedic or a registered nurse at practices and games. These individuals would offer a higher level of care than an

individual with first aid and CPR training; however, these individuals may be limited in their ability to render return-to-play decisions and apply protective taping and padding following an injury.

FACILITATING REHABILITATION AND RECONDITIONING

Adolescents who participate in athletics are subject to injury. When injuries occur, the injured individual requires proper treatment and rehabilitation to regain full physical function and safely return to athletic participation. This treatment should include not only the care provided immediately after the injury but also the postinjury rehabilitation and reconditioning. Rehabilitation and reconditioning programs reduce the likelihood of reinjury and promote a safe return to play. Organizations that sponsor athletic programs should establish an on-site member of the AHCT and identify this individual to manage the postinjury treatment plans of the athletes. Coaches should also be taught to follow the AHCTôs recommendations in regard to athlete rehabilitation.

Injuries are a common occurrence in all levels of athletics. For most athletes, a return to activity after the injury is expected. However, when the individual returns to competition, the likelihood of reinjury is directly dependent on the care this individual receives after the injury. Although the evaluation and treatment provided immediately after the injury are critical, a rehabilitation and reconditioning program designed to safely return the individual to play is just as important.

Trauma to the body causes tissue damage and cell death, resulting in swelling, pain, and decreased ROM.[148] Prolonged periods of disuse can further limit ROM and lead to decreases in strength, cardiovascular conditioning, and muscular endurance.[148] Effective postinjury care can limit the long-term consequences of the initial injury by decreasing pain and increasing ROM, muscular strength, and overall function.[149-151]

Programs designed to return an injured individual to a preinjury level of function can be described using a variety of terms, including *injury treatment, rehabilitation programs*, and *therapy.* In general, these programs consist of exercise, therapeutic modalities, and functional activities specific to the individual and his/her injury.[148, 152, 153] The goals of rehabilitation and reconditioning programs include preventing further injury and promoting a safe return to play.[148] Adolescents who are injured during athletic performance should complete a rehabilitation and reconditioning program to promote a safe return to play.

Adolescents who sustain an athletic injury should receive treatment. This, as a whole, consists of two distinct parts or phases. The first component is the treatment received immediate after the injury; the second component is the postinjury rehabilitation and reconditioning. The rehabilitation and reconditioning component should be viewed as a process that lasts days, weeks, or months, with the length dependent on the severity of the injury.

Programs designed to return an injured individual to a preinjury level of function can be described using a variety of terms, including *injury treatment, rehabilitation and reconditioning programs, therapy,* and *physical therapy*. Although these terms are familiar to most, the concepts behind them are less well known. Understanding these concepts is best achieved by describing the characteristics and goals of rehabilitation and reconditioning programs. The first primary goal of every rehabilitation and reconditioning program is injury prevention.[3, 148] The second goal is a safe and timely

return of injured athletes to their preinjury level of competition.[148] Rehabilitation and reconditioning programs consist of individualized therapeutic exercise that is performed in orderly, progressive steps until return to play.[148]

One of the hallmarks of rehabilitation and reconditioning programs is the progression of *therapeutic exercise*. This is enhanced through the setting of both short- and long-term goals. Short-term goals tend to focus on increasing ROM, strength, and flexibility and on restoring proprioception.[130, 148] Long-term goals tend to focus on optimizing the individualõs functional status.[148, 154] Achieving these goals depends on many factors, of which perhaps the most important is *frequent reevaluation* of the athlete to modify the goals and treatments as needed.[148] Therefore, qualified personnel capable of reevaluating and modifying the rehabilitation and reconditioning program as needed should be available.

The benefits of completing rehabilitation and reconditioning programs are also well known. Stylianos[155] notes that individuals participating in ñeffective rehabilitation programs will often surpass expectations for functional recovery.ò Entering into a rehabilitation and reconditioning program after injury permits injured athletes to return to play sooner with fewer long-term disabilities.[136] Individuals have noted decreased pain and disability and increased ROM and functional activity following the completion of rehabilitation programs for patellofemoral pain and neck pain, respectively.[149, 151] Gilbey et al.[150] found that individuals who completed an exercise program before total hip arthroplasty and continued with the program after surgery exhibited an earlier return to functional activity.[150] In a study of injury patterns in select high school sports, Powell and Barber-Foss[3] noted that, as part of an overall injury prevention program, rehabilitation after the initial injury minimized the risk of reinjury.

Adolescents who return to participation before completing a rehabilitation and reconditioning program are risking reinjury and other long-term consequences. There are a number of reasons why an adolescent may not successfully complete a rehabilitation and reconditioning program. An adolescent may lack access to such a program or choose not to participate in the program. Compliance with rehabilitation and reconditioning programs and the length of time an individual receives these services correlates strongly with better treatment outcomes.[156, 157]

The rehabilitation and reconditioning of athletic injuries represents a major component of a comprehensive injury prevention program and should be undertaken by a selected member of the AHCT. The NATABOC-certified athletic trainer (ATC) is the choice of the AMA because they have the appropriate training and educational background to provide appropriate care for injured athletes and to make sound decisions regarding when an athlete can return to play.[1, 122] Although it has been noted that not all organizations have the resources to hire an ATC or implement a sophisticated sports medicine program, they can designate a qualified member of the coaching staff to work with a member of the AHCT to prevent injuries, provide medical care, and rehabilitate injured athletes.[1]

Components of recommendation

Organizations that sponsor athletic programs should identify an individual who is responsible for coordinating rehabilitation and reconditioning programs with physicians

and other health care professionals. This individual should also be responsible for determining return-to-play following rehabilitation.

Strategies for implementation

Organizations that sponsor athletic programs should establish an AHCT consisting of a team physician and an athletic health coordinator.[1, 122] The organization may choose to provide an athletic health coordinator such as an ATC who is qualified to evaluate injured individuals and develop appropriate rehabilitation and reconditioning programs. If the organization cannot provide an ATC, it should identify both (1) an athletic health coordinator to provide rehabilitative care and (2) an athletic health coordinator to work with health care providers outside the organization to ensure their recommendations regarding treatment and participation are being followed.

The on-site member of the AHCT can ensure injured athletes receive appropriate rehabilitation and reconditioning services in several ways. An ATC possesses the education and credentials to design the rehabilitation and reconditioning program, supervising and reevaluating individuals as they progress through it. In cases where the athletic health coordinator does not have the training to provide these services, s/he can coordinate with outside health care providers to ensure that the recommendations of the treating physician, physical therapist, and others are followed. Regardless of the athletic health coordinatorôs qualifications, this individual plays an important role in injury rehabilitation and reconditioning.

PROVIDING FOR PSYCHOSOCIAL CONSULTATION AND REFERRAL

Members of the AHCT may be the health care professionals who most often interact with adolescent athletes. In some cases, a PPE or injury management may be an adolescentôs only interaction with any health care system. Members of the team must therefore be capable of identifying potential psychosocial pathologies and referring the athlete for appropriate diagnosis and management. Organizations that sponsor athletic programs must identify local experts who specialize in these areas.

Adolescents are at significant risk for morbidities associated with substance abuse, sexual activity, depression, eating disorders, suicidal tendencies, weapon use, violence, and vehicular recklessness. Adolescent athletes in particular may have an increased risk of depression associated with injury or athletic ñburn-out.ò Furthermore, although adolescent athletes may have a decreased risk of cigarette smoking, some studies have suggested an increased use of smokeless tobacco, unsafe sexual activity, alcohol abuse, vehicular recklessness, and other risk-taking behaviors among certain adolescent athletes.

The AMA has estimated that the athletic PPE serves as the only routine health maintenance for 80% to 90% of adolescents.[30] Even though the consensus PPE monograph recommends counseling and screening for psychosocial problems,[17] some have called the PPE a ñmissed opportunityò[158] to adequately evaluate the physical, emotional, and psychological well-being of secondary schoolï age athletes.

Studies have shown that not only do secondary schoolï age athletes engage in numerous health risk behaviors,[159] they may also have a higher rate of certain behaviors than their non-athletic peers. Due to the requirement for parental consent, conducting research to estimate the prevalence of health-risk behaviors is difficult in secondary schoolï age athletes. However, if one extrapolates conclusions from data in the collegiate population, to which many secondary schoolï age athletes aspire and will graduate, some conclusions can be made regarding athletes and risky health habits. Nattiv and Puffer[160] found that collegiate athletes have higher proportions of risky behaviors than do their non-athletic peers, including a higher quantity of alcohol consumed, lower use of contraception, higher number of sexual partners and sexually transmitted diseases, greater rates of driving while intoxicated with alcohol or other drugs and riding with an intoxicated driver, and lower use of seatbelts and of helmets when riding a motorcycle or moped. In addition, high school athletes have been found to have a higher rate of accidental non-athletic injuries[161] and to demonstrate earlier sexual contact[162] compared to non-athletes.

The risk-taking behaviors seem to vary by gender, with male athletes disproportionately more likely to engage in them than female athletes.[163] Nattiv et al.[164] confirmed this finding in a follow-up study to their prior work and further identified participants in contact sports as at the highest risk. They also showed that athletes who engage in one high-risk behavior are more likely to engage in multiple high-risk behaviors. There are suggestions that addictive disorders, such as gambling, may often be seen as a comorbid factor with depression among athletes.[165] An excellent review of certain risk-

taking behaviors of athletes and the studies comparing health risk behaviors in athletes and nonathletes was published by Patel and Luckstead.[166]

Of importance is that the same studies also demonstrated important benefits of athletic participation, including lower likelihood to smoke cigarettes or marijuana, greater likelihood to engage in healthy dietary behaviors, and lower likelihood to feel bored or hopeless[161]; a significant decrease in drug and alcohol use and abuse over all 4 years of high school[162]; and less depression, less suicidal ideation, and fewer suicide attempts.[167] Looking more critically at the Nattiv and Puffer[160] data, if certain male contact sports were removed from the sample, the remaining athletes may have demonstrated no greater risk-taking behaviors than the general student body.

In general, then, athletic participation seems to correlate with improved emotional well-being in adolescents.[168] Injured patients in sports medicine clinics may therefore experience significant psychological distress associated with the loss of this participation.[169] Interestingly, among injured adolescent athletes who reported higher athletic self-identity, higher depressive symptom scores were measured.[170]

The health professionals best positioned and suited to address these psychosocial concerns in the athletic setting may be ATCs, because the necessary skills and knowledge are standard to their professional practice and because they are more likely to be consistently available on-site.[171]

Components of recommendation

Members of the AHCT team and coaches often develop close and/or long-term relationships with adolescent athletes and may be well positioned to identify subtle early warning signs of common psychosocial problems. Coaches should work with members of the AHCT to provide for psychosocial consultation and referral of adolescent athletes with the following guidelines:

- Coaches and AHCT members should be aware of the psychosocial problems of adolescence, including disordered eating, substance abuse, sexual activity, athletic ñburn-out,ò depression, suicidal tendencies, weapon use, violence, and vehicular recklessness.
- At least one AHCT member should review the PPE to look for specific warning signs.
- Coaches and AHCT members should be aware that psychosocial problems of adolescent athletes might manifest themselves as overtly as dropping out of participation or as subtly as small decreases in performance.
- AHCT team members should be able to easily refer athletes to identified consultants who can further evaluate and treat these suspected conditions.
- The organizations that sponsor athletic programs must establish systems to facilitate these referrals by identifying local mental health providers, ensuring prompt access to them, and minimizing barriers such as insurability and payment.

- At least one, if not all, of the AHCT members should be aware of the specialized developmental needs and stages of growing adolescents.
- At a minimum, one on-site AHCT or coach should be well versed in the recognition of psychosocial issues and the referral system established by the sponsoring organization

Strategies for implementation

Members of the AHCT may be well positioned but, because of their training, not well suited to identify emerging psychosocial problems. Implementation of this recommendation would therefore require some, if not all, of the following elements: As detailed in the PPE monograph,[17] thorough psychosocial screening should be an important component of the PPE and should be conducted, ideally, by the athleteôs primary care provider. If not conducted by the primary care provider, a thorough psychosocial screening could be conducted by another health care professional who is comfortable with adolescents and familiar with the basic tenets of confidential and sensitive interviewing. The issues that can be addressed in a thorough psychosocial screening can include questions regarding home life and family dynamics, education (school performance and relationships), activities (sports, jobs, and leisure enjoyment), diet, drug use, safety issues (violence, weapon use vehicular recklessness), sexuality (contraception, type, number and frequency of partners), depression, and suicidal tendencies

Texts such as Neinsteinôs *Adolescent Health Care*[172] provide more detailed examples of the content of and techniques for adolescent psychosocial screening. Other tools for screening specific conditions include a screening instrument that can reliably and validly identify disordered eating behaviors in the secondary schoolï age population and ones that evaluate depressive symptoms such as sleep disturbances, irritability, guilt, low energy levels, inability to concentrate, changes in appetite, and suicidal tendencies.

Team members should be provided education and training by local experts in adolescent health such as the multidisciplinary members of the Society for Adolescent Medicine (SAM) (http://www.adolescenthealth.org). Curricular goals could include understanding of the basic cognitive, emotional, physical, and psychosocial developmental stages of adolescence (Table 3) and identifying signs and symptoms of common psychosocial problems, such as disordered eating, substance abuse, sexual activity, athletic ñburn-out,ò depression, suicidality, weapon use, violence, and vehicular recklessness.

While a sports psychologist may be a valuable member of or consultant to the AHCT, ATCs are specifically trained in the components listed and often practice on-site with adolescent athletes and therefore would be extremely valuable members of the AHCT. In addition, the ATC should refer any athletes with identified problems to the school counselors and, if comfortable, discuss the issue with the athlete and/or his or her parents.

PROVIDING SCIENTIFICALLY SOUND NUTRITIONAL COUNSELING AND EDUCATION

Sports nutrition is a key factor in an athleteôs growth, development, and performance. It is well known that adolescents have unique nutritional requirements that are further complicated by sport participation. The massive industry of supplements marketed to enhance sports performance and the lack of regulation as to the effectiveness and safety of such products pose an additional risk to secondary schoolï age athletes. Athletes need guidance to make sound nutritional decisions in an age where fad diets and performance enhancement products are prevalent.

Sponsoring organizations of athletic programs have a responsibility to provide a safe environment including sound, scientifically based information regarding nutrition and supplements. A solid knowledge of nutritional concepts is crucial to any AHCT; especially those caring for secondary schoolï age athletes. In addition to basic growth and development, competition puts an increased demand on daily nutritional requirements. Factors such as ethnicity, social and economic status, family history and environment, peer pressure, and inaccurate diet information can complicate the prescription for good nutrition. In addition, adolescents' tendencies to skip meals, snack on junk food, and feast at fast food restaurants can add to poor eating habits.

A system for reviewing an athleteôs nutritional status is the basis of providing appropriate information to athletes and parents regarding long-term nutritional health. Childhood obesity is on the rise in United States and puts children at risk for heart disease, illness, and injury.[173] A review of an athleteôs nutritional status could alert the child and parents to a problem. If a child is found to have poor nutritional habits, an allied health care professional should help combat the problem by creating a plan to address the issues identified in the nutritional review.

Included within the topic of nutrition is proper hydration, especially during activities conducted in high heat stress environments. The availability of hydration fluids in a clean, noninfectious environment at all sport settings should be ensured. It has been well documented in the NATAôs Heat Illnesses Position Statement[103] that one major preventative measure is to maintain proper hydration. Not only should the athlete be given the opportunity to consume the appropriate amount of fluid, but s/he should also be educated as to how much to consume and why it is important. Athletic performance may decrease due to hypohydration.[115] Education of athletes, coaches, and parents in regard to hydration is crucial in the prevention of unwanted injuries and illness and should be a consideration of any group working with adolescent athletes. In addition, coaches or other personnel should never restrict fluids for exercising athletes.

Pre-event and post-event nutritional needs are important considerations for the secondary schoolï age athlete. For optimal performance, an athlete needs to know what to eat and when to stop eating before a competition. Eating the wrong foods at the wrong time will not give an athlete the appropriate energy for competition and may cause bloating and discomfort.[174]

After exercise, it is important to replenish the nutrients used. Athletes, parents, and coaches should have an avenue to find out the necessary information. Resources reflecting sound scientific material should be used; examples are provided in the Identification of Additional Resources section of this document.

Body weight has a direct influence on some sports such as wrestling and crew and is associated with performance in many other sports such as gymnastics and dance. It has an aesthetic impact in sports such as cheerleading. The pressure to achieve or maintain a low body weight during the secondary school years can lead some to develop disordered eating. There should be a system in place to identify athletes at risk for eating disorders and to treat those who have been identified. It is important that someone close to the athlete knows what to look for. People with eating disorders are very manipulative; so once they have been identified, it is very important to have a plan set in place to provide referral to an appropriate allied health care professional who specializes in this field.

Use of sports supplements and performance-enhancing drugs is fairly common among secondary school students.[175] Young people are taking them to perform better or to build muscle, as well as to look better. The main sources of knowledge regarding supplements and performance-enhancing drugs are friends and advertising. Most athletic governing bodies prohibit the use of supplements and drugs that are designed to enhance performance.[16] Supplements marketed to enhance athletic performance often are touted as ñherbalòor ñnatural,òwhich implies an element of safety. This, coupled with the massive marketing campaigns and use by professional athletes, provides for the ñeasy path to successòfor the secondary schoolï age athlete. Societyôs emphasis on winning and a childôs desire to please parents and coaches make for a potentially deadly combination. While young people may realize that supplements and performance-enhancing drugs are dangerous, few are reported to know the potential side effects.[175]

Dietary supplements are not required to be standardized in the United States. In fact, no legal or regulatory definition exists in the United States for standardization as it applies to dietary supplements.[176] Studies conducted on sports supplements rarely include subjects of adolescent population. Adverse potential side effects of sports supplements may include, but are not limited to, heart failure/cardiac anomalies, organ malfunction, personality disorders, reproductive disorders, headache, and acne.

Members of the AHCT should be well versed in proper sports nutrition for the adolescent and have a basic knowledge of proper nutrition and eating habits. They should also have access to a professional nutritionist or dietician.

Components of recommendation

Sponsoring organizations should establish components of a comprehensive sports nutritional support system, based on current scientific facts, and should include, 1) A system for reviewing an athleteôs nutritional status, 2) Policies to ensure the availability of hydration fluids in a clean, noninfectious environment at all sport settings, 3) Encouragement of appropriate pre-exercise and post-exercise food, 4) A system to identify athletes at risk for disordered eating and a system to treat those who have been

identified, and 5) The use of scientifically supported literature when developing rules that restrict the use of performance-enhancing supplements, drugs and substances, or educational programs to inform coaches, athletes, and parents of the dangers of ergogenic aids

Strategies for Implementation

Reviewing the athleteôs nutritional status

Information sheets with general nutrition goals for an active secondary schoolï age athlete can be provided by the sponsoring organization. Each athlete should have a basic understanding of what nutritional requirements s/he needs to have for normal growth and activities of daily living as well as the additional needs that exist because of the energy expenditure caused by his/her sport. Reference to appropriate print and Web media can also be provided; sources are available later in this document. Coaches, as well as members of the AHCT, should be alert to the athletesônutritional well-being and provide additional information and interaction when circumstances warrant.

Maintaining adequate hydration

The sponsoring organization, via the coaches and members of the AHCT, has a responsibility to provide an environment and information to facilitate or help athletes maintain adequate hydration during physical activity. Several documents are available to assist with the development of a fluid replacement program such as NATAôs Position Statement on Fluid Replacement,[115] as well as educational materials that can be provided to athletes, coaches, and parents, such as NATA's Exertional Heat Illness Consensus Statement.[105] Encouraging fluid replacement adequate to replace fluids lost due to sweating before, during, and after intense physical activity is essential to maintain performance levels and general health.

Pre-exercise and post-exercise nutrition

There should be an encouragement of appropriate preexercise and postexercise food. For optimal performance, an athlete needs to know what to eat and when to stop eating before a competition. Informational handouts with recommendations based on accurate scientifically proven information can be provided to athletes and parents.

Sponsoring organizations that provide opportunities for athletes to travel (e.g., youth travel soccer) can lead by example and provide the teams with nutritionally sound eating opportunities, both before and after exercise. Members of the AHCT should investigate available resources such as community-based wellness centers and hospitals that have registered dietitians and nutritionists on staff to provide appropriate information to the team, coaches, and parents.

Identify athletes at risk for disordered eating

Disordered eating can have a variety of signs and symptoms. Providing information to coaches about the signs and symptoms of disordered eating can encourage early recognition. The complexity of dealing with disordered eating necessitates referral of athletes who exhibit signs and symptoms to an appropriate professional. Appropriate professionals include physicians, psychologists, school nurses, and nutritional counselors. Establishing, in advance, a systematic protocol to follow when an athlete is

suspected of disordered eating is essential to ensure athletes receive the appropriate support.

Performance-enhancing supplements

Supplements marketed to enhance athletic performance come in many different forms. Most athletic governing bodies prohibit the use of supplements and drugs that are designed to enhance performance. Sponsoring organizations should support rules prohibiting supplement use and provide education addressing the potential health risks associated with them. Caution should be taken when researching information on specific supplements and drugs to ensure it is from a reputable source.

DEVELOPING INJURY AND ILLNESS PREVENTION STRATEGIES

Injuries and illnesses are a heavy burden on the well-being of secondary schoolï age athletes and a leading reason why people stop participating in physical activities. There are many interventions that have proved to be effective in reducing the severity of athletic injuries.[177-180] Still, many opportunities for prevention remain. This document establishes recommendations for the prevention, care, and appropriate management of athletic-related injury and illness specific to the secondary schoolï age individual. This overview presents a public health framework for developing effective interventions to reduce the burden of injuries to secondary schoolï age athletes.

Participation by secondary schoolï age children in sports, recreation, and exercise is widespread, with nearly 6.5 million high school students participating in organized athletics.[11] However, many of these activities involve elevated risks of injury. As a result, approximately 715,000 sports- and recreation-related injuries occur in the school setting each year.[181] These injuries may lead to a number of costs, some of which are financial and some of which affect a personõs quality of life.[182] In the short term, costs include medical care expenses and time lost from classes and athletic play. Of U.S. schoolchildren who received medical attention for a sport/recreation injury, 20% had one or more days of lost time from school.[183] Long-term costs may include medical and rehabilitation expenses, restriction of future athletic activities, loss of some amount of physical function, and increases in insurance premiums.

A wide variety of injury control interventions have been accepted in the athletic community over the years, including changes to the environment (e.g., break-away bases),[184] use of protective equipment in contact sports (e.g., helmets),[185] and rule changes (e.g., footballõs prohibition of spearing).[186] Scientific progress has demonstrated that certain sports, certain positions, and certain competitive situations have greater risks of injury than others. By recognizing the greatest risks, we can develop ideas that reduce the chances of a serious injury to a young athlete.

Developing a comprehensive approach to injury control strategies for athletics is difficult. To begin to establish this direction, NATA sponsored the development of recommendations for appropriate medical care of secondary schoolï age athletes. This effort addresses more than basic emergency care during sports participation; it involves virtually all aspects of prevention, and activities of ongoing daily athletic health care. The recommendations are intended for use by the sponsoring organizations of athletic programs, and the AHCT they establish, in consultation with administrators, coaches, parents, and participants. Establishing an AHCT should be one of the sponsoring organizationõs first priorities and should include medical professionals such as ATCs, allopathic or osteopathic physicians, school nurses, and other allied health care providers.[1] By approaching the issue of athletic injuries in a comprehensive way, we develop a better sense of where the problems lie and what can be done to eliminate or reduce them.

This holistic approach involves considering characteristics of the athlete (host), the environment associated with athletic performance (both physical and social-cultural), and the energy that is transferred to the body that causes damage. These elements and

their relationships are represented as a public health framework. This framework has long been used in the study of disease and has recently been applied to the topic of athletic injury. As described by Weaver et al.,[125] ñThe public health framework suggests that multiple types of social environmentsé operate within a physical environment, and provide the context in which an energy vector acts on an athlete to cause an injury. Each of these components and their multiple interactions can be further investigated as a potential target for injury prevention efforts."

Athletics includes a long history of interventions designed to protect players from specific injuries. However, not all of these efforts have been scientifically evaluated to demonstrate their effectiveness. Also, not all interventions have been found to be acceptable to players, and enforcement of protective rules may be rejected by the athletic community, who view the rule change as an offense to the sportôs tradition.[182] Nevertheless, games are constantly evolving with safety concerns often driving the changes. The following outline presents some examples of the best practices for injury control in modern sport using elements of the implementation hierarchy previously described.

Engineering controls
Although safety balls have long been assumed to cause fewer injuries, no epidemiological study had examined their effectiveness before the study of Marshall et al.[84] in a 3-year nationwide study involving more than 6.7 million player-seasons, the use of safety balls was associated with a 23% reduced risk of ball-related injury in Little League Baseball. The effect was more dramatic among younger divisions than among older divisions. The authors also suggest that concerns of poorer performance by the reduced-impact ball, the greatest barrier to wider acceptance, are based on misperception ñof the ballôs play, rather than the actual performance of the ball.ò[84]

Administrative controls
Based on surveillance data of head and neck injuries occurring in tackle football, axial loading was identified in 1975 as the primary cause of serious cervical spine injuries.[187] The incidence of catastrophic head and neck injuries increased in 1976 as a result of the new helmets, which led some athletes to consider themselves indestructible. Subsequent rule changes in high school and college play banned ñspearingò and using the top of the helmet as the initial point of contact in striking an opponent during a tackle or block. Once the actual mechanism of injury was understood, modification of the rules to affect a change in playing technique was very effective. From 1976 to 1984, cervical spine injury rates sharply decreased and injuries that resulted in quadriplegia decreased 85% from 34 to 5 incidences.[186]

Educational intervention
In a prospective controlled intervention study, a prevention program that focused on education and supervision of soccer coaches and players demonstrated 21% fewer injuries in the intervention group among male youth amateur players.[178] The effects were more dramatic for injuries that were mild, resulted from overuse, or occurred during training. Also, the program was more successful with low-skill teams, demonstrating the potential of education strategies for a great number of youth teams.

Personal protective equipment
A good case study of the need for personal protective equipment involves the long-running debate over whether protective eyewear should be required in womenôs lacrosse. Proponents of protective equipment cite a fast-moving sport, the use of sticks and a hard rubber ball, and documented eye injuries as evidence of the need for protective eyewear. Opponents suggest that by requiring protective equipment, players will feel secure enough to increase their aggression and ultimately change the nature of the game from one of incidental contact to one of full contact, similar to the menôs game. Further, it is argued that this increase in aggression will eventually cause more injuries than the original intervention (protective eyewear) prevents.

To assess the true effect of protective eyewear, Webster et al.[188] collected field data from 700 varsity and junior varsity players in central New York over a 2-year transition from sparse to almost complete eyewear use. The findings indicated a 16% reduction in overall head/face injuries among goggle wearers, with an even greater effect in game situations (51% reduction). This and similar studies[189] demonstrated a beneficial use of eyewear and provided the basis for strategic decisions on how best to prevent head and facial injuries in young athletes. One such change is the recent decision by the U.S. Lacrosse Womenôs Division Board of Governors to amend the rules of womenôs lacrosse to highly recommend the use of protective eyewear meeting current ASTM lacrosse standards for 2004 and to mandate use beginning in 2005.[190]

Components of recommendation
There is a well-accepted scientific process for addressing a public health injury problem, and in this case, athletic injury among secondary schoolï age athletes. This public health approach[191-194] includes the following five components, which are then described in greater detail: 1) Determine the existence and size of the problem, 2) identify what may cause the problem, 3) determine strategies and interventions that may prevent the problem, 4) implement prevention strategies, and 5) monitor and evaluate the effectiveness of prevention efforts.

Determine the existence and size of the problem
The success of the first step relies on a complete and accurate collection of relevant data. This includes a good description of the circumstances surrounding the injury, including person, place, and time. Surveillance describes such characteristics as the magnitude of the problem (ñHow many players have been injured?ò), the physical location of the problem (ñWhere on the field do injuries occur?ò), what body parts are at greatest risk of injury (ñAre there more head injuries than shoulder injuries?ò), and who is affected (ñAre more boys injured than girls?ò).[195] Along with the descriptive injury data, it is imperative that injury surveillance also takes into consideration exposure data (athlete-exposures). Additional information should be collected to allow for comparisons to be made within and between positions, sports, and those with and without a previous injury history. Only with a strong surveillance effort can we be sure that the biggest problems are being addressed and our efforts to reduce them are successful.

Identify what may cause the problem
This information suggests why certain people may be at greater risk of injury while others are protected. This type of data requires long-term, expensive longitudinal

studies. However, some risk factors have already been identified in high school athletes and interventions can be developed from these known risk factors (e.g., landing biomechanics and anterior cruciate ligament [ACL] injury in females has led to jump training programs). Understanding which risk factors are involved is often overlooked, yet is crucial to developing effective interventions.

Determine strategies and interventions that may prevent the problem
Developing strategies for injury prevention is usually based on the approach introduced by William Haddon, known as the Haddon Matrix.[196] It is based on Haddon's observation that all injury events come from the uncontrolled release of physical energy.[197] Efforts focused on prevention can occur at one of three times: before the injury (when the energy becomes uncontrolled), during the injury (when the energy transferred to the body is more than can be safely absorbed), or after the injury (when the body attempts to heal the damage). In addition to the time axis, the Haddon Matrix includes an axis of risk factors also found in the public health framework; the host (potentially injured person), the agent (the energy and the way in which it is transferred), and the environment (both physical and social). The resulting 12-cell matrix can be used as a brainstorming tool to devise interventions according to a specific time phase and a specific risk factor. An example of the use of the Haddon Matrix applied to the problem of athletic injuries is found in Table 4. A strong prevention program incorporates interventions that address the different risk factors and span the time axis.

Implement prevention strategies
Once potential strategies are identified, the next step is to assess which strategies should be implemented and how to put them into action. Recently, Runyon[198] added another dimension to the Haddon Matrix to help with this decision. A set of value criteria is included as a starting point for planners to consider. Depending on the nature of the injury problem, some criteria will be weighted more heavily than others; these criteria include

- *Effectiveness:* How well does the intervention work when applied?
- *Cost:* What are the costs of implementing and enforcing the program?
- *Freedom:* Do the freedoms of some groups have to be sacrificed to achieve the goal?
- *Equity:* Are people treated equally or in a universal fashion?
- *Stigmatization:* Does a program result in a person/team being stigmatized?
- *Preferences:* Are preferences recognized to encourage compliance?
- *Feasibility:* Can the intervention actually be produced?

Another strategy for developing effective interventions for athletic injuries is to consider whether players are protected from injury without having to take additional precautions.[125, 199] A passive strategy, such as adding padding to an outfield wall, provides automatic protection without requiring the cooperation of the athlete to be effective. An active strategy, such as a rule change to ban slaps to the side of the helmet, requires an athlete to modify his or her play or cooperate in some other way. Passive strategies are generally considered to be more effective because they do not rely on player compliance each and every time a potential injury situation presents itself.

Different types of interventions can be classified according to the degree of compliance required of athletes. This principle is presented in an intervention implementation hierarchy that includes engineering modification to the athletic environment, administrative changes to a rule, educational efforts to introduce a safer technique or less risky behavior during play, and the use of personal protective equipment. [200] Engineering controls are typically considered to be most effective because they require the least amount of effort/cooperation from the athlete to provide safety, although they also require a greater commitment and resources from the organization with overall responsibility for player safety. Educational controls and personal protective equipment are more active interventions because they require the players to consider the risk of a situation and to act in a safe manner every time the situation presents itself during play.

Monitor and evaluate the effectiveness of prevention efforts

The evaluation step provides answers to the ultimate questions, ñDoes our intervention work?ò or ñHave injuries been reduced?ò[195] We return to our first step of surveillance for data that support or deny the effectiveness of the interventions that have been implemented. Although we are most interested in this primary question, we also must consider whether there may be other reasons, unrelated to the intervention, which might explain why injuries were reduced. Another key issue is whether there are any unintended consequences (good or bad) that are a direct result of the intervention. A bad unintended consequence may ruin any positive effect of the intervention, so it must be determined not only whether fewer injuries occurred, but also whether the intervention had a positive effect on the athletes' overall well-being. Evaluation requires the conduct of well-designed randomized controlled effectiveness studies.

Strategies for implementation

The potential strategies for the prevention of injury and illness in the secondary schoolï age athlete have been presented in the previous 10 sections of this monograph. These interventions address various aspects of the framework previously described, including the athlete, energy transfer, and environment. They also relate to efforts that affect the safety and welfare of athletes before, during, and after the injury or illness.

CONCLUSIONS

Appropriate medical care of the secondary schoolï age individual involves more than basic emergency care during sports participation. It encompasses the provision of many other health care services. While emergency medical care and event coverage are critical, appropriate medical care also includes activities of ongoing daily athletic health care. The athletic health care team (AHCT) comprises appropriate health care professionals in consultation with administrators, coaches, parents, and participants. Appropriate health care professionals could be certified athletic trainers, team physicians, consulting physicians, school nurses, physical therapists, emergency medical services (EMS) personnel, dentists, and other allied health care professionals. Organizations sponsoring athletic programs for secondary schoolï age individuals should establish an AHCT that functions to ensure appropriate medical care is provided for all participants.

TABLE 1. MEDICAL PROFESSIONALS WHO SHOULD BE CONSIDERED MEMBERS OF THE ATHLETIC HEALTH CARE TEAM

Certified athletic trainers
Team physicians
Orthopaedic physicians
School physicians
Primary care providers (pediatricians, family practice, nurse practitioners, etc.)
Consulting and other physicians
School nurses and guidance counselors
Physical therapists
EMS personnel
Physician assistants
Registered dieticians
Public safety personnel
Public health officials
Dentists
Other allied health care professionals
Students and trainees in the above disciplines

TABLE 2. STRATEGIES TO ENSURE SAFE FACILITIES

Develop a written EAP for all venues or facilities
Evaluate your present facilities for safety
Develop appropriate checklists, forms, and other documentation to ensure thorough and consistent standards of facility evaluation
Follow a standardized timeline for when facility evaluations will take place and who will be responsible for completing the forms
Use ñCritical Incident Reportsòto direct corrective actions whenever an accident occurs
Post warning signs where appropriate.
Provide in-services for staff regularly on injury prevention and how to monitor and manage facility safety
Cultivate a safety awareness culture in your program
Ensure facilities are adequately secured to prevent improper use
Ensure athletes are properly supervised during participation
Maintain a regular schedule for cleaning shared equipment shared and encourage athletes to maintain good hygiene
Follow universal precautions for blood and body fluids

TABLE 3. CHARACTERISTICS OF THE DEVELOPMENTAL STAGES OF ADOLESCENCE

Stage	Characteristics
Early ï individuation	During this time, athletes may become confused or question their identity as they encounter the physical and emotional changes of puberty.
Middle ï separation/rebellion	This is the phase during which many of the risk-taking behaviors may be initiated or reach their peak
Late ï abstract thinking, future/goal orientation	This level of maturity is not often reached during the secondary school years

TABLE 4. HADDON MATRIX APPLIED TO THE PROBLEM OF ATHLETIC INJURIES*

Phases/Factor	Host	Agent	Physical environment	Social environment
Before injury	CS #2. Determine the individualûs readiness to participate.	CS #3. Advise on the selection, fit, function, and maintenance of athletic equipment.	CS #3. Promote safe and appropriate practice, competition, and treatment facilities. CS #5. Establish protocols regarding environmental conditions.	CS #10. Provide scientifically sound nutritional counseling and education. CS #1. Develop and implement a comprehensive athletic health care administrative system.
Injury	Protective responses	Player size and speed	Field condition	Rules enforcement
After injury	CS #8. Facilitate rehabilitation and reconditioning.	Exposure to repeat trauma	CS #4. Develop and implement a comprehensive emergency action plan. CS #7. Provide for on-site recognition, evaluation, and immediate treatment of injury and illness, with appropriate referrals.	CS #9. Provide for psychosocial consultation and referral.

APPENDIX A. CONSENSUS STATEMENT

APPROPRIATE MEDICAL CARE FOR SECONDARY SCHOOLï AGE ATHLETES

CONSENSUS STATEMENT

(Revised April 2004)

Mission Statement

Establish recommendations for the prevention, care, and appropriate management of athletic-related injury and illnesses specific to the secondary schoolï age individual.

Athletic Health Care Team

The athletic health care team (AHCT) may be composed of appropriate health care professionals in consultation with administrators, coaches, parents, and participants. Appropriate health care professionals could be certified athletic trainers, team physicians, consulting physicians, school nurses, physical therapists, emergency medical services (EMS) personnel, dentists, and other allied health care professionals.

Recommendations for Appropriate Medical Care

Appropriate medical care of the secondary schoolï age individual involves more than basic emergency care during sports participation. It encompasses the provision of many other health care services. While emergency medical care and event coverage are critical, appropriate medical care also includes activities of ongoing daily athletic health care.

Organizations sponsoring athletic programs for secondary schoolï age individuals should establish an AHCT that functions to ensure appropriate medical care is provided for all participants.

The AHCT should have a designated athletic health care provider(s) who is educated and qualified to

1. Participate in the development and implementation of a comprehensive athletic health care administrative system (e.g., personal health information, policies and procedures, insurance, referrals).
2. Determine the individualôs readiness to participate.
3. Promote safe and appropriate practice, competition, and treatment facilities.
4. Advise on the selection, fit, function, and maintenance of athletic equipment.
5. Develop and implement a comprehensive emergency action plan.

6. Establish protocols regarding environmental conditions.
7. Provide for on-site recognition, evaluation, and immediate treatment of injury and illness, with appropriate referrals.
8. Facilitate rehabilitation and reconditioning.
9. Provide for psychosocial consultation and referral.
10. Provide scientifically sound nutritional counseling and education.
11. Develop injury and illness prevention strategies.

Education

Designated athletic health care providers shall maintain expertise through continuing education and professional development.

All coaches should be trained in first aid, cardiopulmonary resuscitation (CPR), and automated external defibrillator (AED) use; utilization of AHCT professionals; injury prevention; and modification of training in response to injury and illness.

DEFINITIONS

Certified athletic trainer: An allied health care professional who, on graduation from an accredited college or university, and after successfully passing the National Athletic Trainers' Association Board of Certification (NATABOC) examination, is qualified and appropriately credentialed according to state regulations to work with individuals engaged in physical activity in the prevention of injuries and illnesses; the recognition, evaluation, and immediate care of injuries and illnesses; the rehabilitation and reconditioning of injuries and illnesses; and the administration of this health care system. This individual must have current certification in cardiopulmonary resuscitation (CPR) and be qualified in first aid and blood-borne pathogens. Other health care professionals with equivalent certification and/or licensure would also meet this standard.

Team physician: The team physician must have an unrestricted medical license and be an MD or a DO who is responsible for treating and coordinating the medical care of athletic team members. The principal responsibility of the team physician is to provide for the well-being of individual athletes, enabling each to realize his or her full potential. The team physician should possess special proficiency in the care of musculoskeletal injuries and medical conditions encountered in sports. The team physician also must actively integrate medical expertise with that of other health care providers, including medical specialists, athletic trainers, and allied health professionals. The team physician must ultimately assume responsibility within the team structure for making medical decisions that affect the athlete's safe participation.

Committee on Injury and Poison Prevention

Bicycle Helmets

ABSTRACT. Bicycling remains one of the most popular recreational sports among children in America and is the leading cause of recreational sports injuries treated in emergency departments. An estimated 23 000 children younger than 21 years sustained head injuries (excluding the face) while bicycling in 1998. The bicycle helmet is a very effective device that can prevent the occurrence of up to 88% of serious brain injuries. Despite this, most children do not wear a helmet each time they ride a bicycle, and adolescents are particularly resistant to helmet use. Recently, a group of national experts and government agencies renewed the call for all bicyclists to wear helmets. This policy statement describes the role of the pediatrician in helping attain universal helmet use among children and teens for each bicycle ride.

ABBREVIATIONS. ANSI, American National Standards Institute; ASTM, American Society for Testing and Materials; CPSC, Consumer Product Safety Commission.

BACKGROUND

Bicycling continues to be one of the most popular recreational sports in America. An estimated 44.3 million children younger than 21 years ride bicycles in the United States.[1] It is a clean, efficient mode of transportation for children to make short neighborhood trips, and bicycling can be an enjoyable form of aerobic physical activity for children and adolescents.

As with all physical activities, bicycling is not without hazards. Children are at risk of injury from falls resulting from either intrinsic factors, such as exceeding their ability level, or extrinsic factors, such as swerving from or striking a motor vehicle or fixed object. Bicycle-related injuries among children younger than 21 years resulted in approximately 275 deaths[2] and an estimated 430 000 visits to emergency departments in 1998.[3] Among all recreational sports, bicycling injuries are the leading cause of emergency department visits for children and adolescents. Traumatic brain injury accounts for two thirds of all bicycle-related fatalities.[4] An estimated 23 000 children required emergency care after sustaining a traumatic brain injury while bicycling in 1998, accounting for about 5% of all bicycle-related injuries.[3]

Use of a bicycle helmet can prevent or lessen the severity of brain injury during a bicycle crash. Helmets work by absorbing some of the energy and dissipating the sharp energy peak of the blow over a larger area for a slightly longer time. A bicycle helmet typically consists of rigid crushable foam covered with a thin layer of plastic. It is held to the head by a retention system (chin strap) composed of flexible straps and hardware. The skull provides another layer of protection and absorbs additional energy. If forces are not extreme and the helmet is intact and worn correctly, the helmet-skull system should protect the brain from injury in most cases.

Correctly placing and securing a helmet on the head is important to maximize protection. Because 4 helmet sizes exist and models fit slightly differently, a child should try on several sizes and models to find the best fit when purchasing a helmet. Correct fit involves positioning the helmet on the head so it sits low on the forehead and is parallel to the ground when the head is held upright (the wearer should be able to see its lower brim when looking all the way up); installing or removing inside pads to make the helmet snug; and adjusting the chin strap so it is comfortably snug (ie, tight with room for only 2 fingers to be inserted between the strap and the chin). When in place with the chin strap secure, the helmet should not come off or shift over the eyes when the wearer tries to shake it loose.

Even when worn properly, a helmet does not offer an unlimited degree of protection, particularly against high-energy crashes. Even in low-impact falls, the helmet may be damaged by the force delivered, rendering it less effective in subsequent impacts. This damage may not be apparent to the eye. Accordingly, any helmet that has sustained a substantial blow should be discarded and replaced, including any helmet involved in a crash in which the head has hit a hard surface or in which a fall has resulted in marks on the shell. Furthermore, helmet integrity does not persist throughout time. Because some helmet materials deteriorate with age, the Snell Memorial Foundation, a nonprofit organization established to test and certify helmet safety, recommends that a helmet be replaced at least every 5 years, or sooner if the manufacturer recommends it.

Wearing a bicycle helmet is one of the most effective safety measures a child can take to prevent injury. The first study of helmet effectiveness indicated that it could prevent 88% of serious brain injuries.[5] In subsequent studies, helmets prevented 69% of head injuries[6] and 65% of injuries to the mid and upper face.[7] Despite the enormous degree of protection afforded by a bicycle helmet, a 1994 study indicated

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

that only 25% of children 5 to 14 years of age usually or always wore a helmet while bicycling.[8] In 1999, the percentage of children who reported always using helmets varied among states from 13% to 65%.[9] Reasons usually given for not using a helmet are discomfort (especially heat), perceived lack of importance for casual riding (in contrast to sport or race bicycling), lack of style, or peer pressure.[8,10] Cost was seldom cited as an important factor now that helmets are widely available for less than $20.

Two factors are strongly associated with bicycle helmet use by young children—helmet use by an accompanying parent and a state mandatory helmet use law or local ordinance. In one study, a helmet was worn by 90% of children from a low-income neighborhood and 100% of children from a high-income neighborhood when an accompanying parent wore a helmet.[11] After enactment of a helmet law in Georgia, reported helmet use increased from 35% to 53%,[12] and in Oregon, enactment of a helmet law was associated with a doubling of observed helmet use to 49% among children and youth.[13] Presently, 17 states and the District of Columbia have age-specific bicycle helmet laws, usually covering bicyclists younger than 16 years. These laws affect 49% of all US children younger than 15 years. Another 2 states have recently enacted legislation. Such legislation has been shown to be more cost-effective than community-based or school-based interventions[14] and is a *Healthy People 2010* objective.[15]

Recently, a group of national experts from safety organizations and government agencies called for universal helmet use by all bicyclists, regardless of age. This goal has 3 strategies: 1) creating a national bicycle helmet safety campaign; 2) creating tools to promote helmet use; and 3) assisting states and communities wishing to address helmet use through legislation.[16]

Voluntary helmet safety standards have existed for many years, with the American National Standards Institute (ANSI), Snell Memorial Foundation, and American Society for Testing and Materials (ASTM) each establishing their own safety standards based on the ability of a helmet to manage the energy of a drop onto a metal anvil and the strength of the strap system. In 1999, the US Consumer Product Safety Commission (CPSC) issued a mandatory safety standard for bicycle helmets, requiring all helmets manufactured or imported for sale in the United States after March 1999 to comply with this standard.[17] Accordingly, parents should look for a sticker documenting CPSC approval on the inside liner of any new helmet purchased. Older helmets certified by the ASTM and/or the Snell Memorial Foundation may continue to be used, but helmets certified only by the ANSI should be discarded, because they were drop-tested from a height below the current 2 meter standard. Multisport helmets are designed for in-line skating, skateboarding, bicycling, and other sports. If a multisport helmet is intended or marketed (even by implication) to be used while bicycling, it must be certified to meet the CPSC standard for bicycle helmets.

RECOMMENDATIONS

Helmet Use

1. All bicyclists should wear properly fitted bicycle or multisport helmets each time they ride. A bicycle helmet or multisport helmet intended for bicycle use manufactured after March 1999 must have certification that it met the CPSC standard, regardless of whether it met the standards of any other organization. If a bicycle helmet manufactured before March 1999 meets the standards established by the Snell Memorial Foundation or ASTM (but not ANSI alone), it may be used. However, once damaged or outgrown, it should be replaced with a new helmet that has been certified to meet the CPSC standard.
2. Young children who ride as passengers must wear an appropriately sized helmet and be placed securely in a bicycle-mounted child seat or, preferably, a bicycle-towed child trailer. Children should never ride on the handlebars or crossbar.[18] Passengers should be at least 1 year old, by which age most children have sufficient muscle strength to control head movement during a sudden stop, even with the additional weight of a helmet.
3. Pediatricians should emphasize that any helmet involved in a crash or otherwise damaged should be discarded and replaced. Otherwise, all helmets should be replaced at least every 5 years, or sooner if the manufacturer recommends it. Purchase of helmets from yard sales should be discouraged, because the age and integrity of the helmet cannot be assured.
4. Parents and children should learn all essential aspects of bicycle safety. Helmet use is only 1 aspect of bicycle safety and does not substitute for the child's knowledge and practice of the rules of the road, sufficient visibility to drivers, and other safety measures.

Advocacy

1. Pediatricians should encourage parents and other child care providers to require children to wear a bicycle helmet when they begin riding tricycles or other wheeled vehicles or toys. Pediatricians should inform parents and patients of the importance of wearing a bicycle helmet and the dangers of riding without one. This information is especially important for adolescents, because they are particularly resistant to wearing a helmet.
2. Pediatricians should encourage parents to wear a helmet when bicycling to model safe behavior for their children.
3. Pediatricians should serve as community and legislative advocates to encourage state and local governments to enact legislation requiring helmet use by all bicyclists and mandating bicycle rental agencies to include helmets as part of the rental contract. The American Academy of Pediatrics has developed model state legislation titled "Child Bicycle Safety Act."[19]

4. Pediatricians should encourage school districts to make helmet wearing mandatory during bicycle rides to and from school and during school-related bicycle trips.
5. Coalitions of physicians, parents, and community leaders should develop and support community-based and school-based education programs to promote bicycle safety training that emphasizes helmet use. A national initiative to encourage all children to wear a helmet whenever bicycling deserves support.
6. Retail outlets are urged to carry affordable helmets and include them in the purchase of every new bicycle sold.
7. Organizations promoting helmet use are encouraged to provide attractive posters and educational videotapes for retailers and pediatricians to display as well as other materials for parent groups to distribute, emphasizing the safety advantages and attractiveness of protective headgear. All materials should teach how to wear a helmet correctly.
8. When bicyclists are shown in the popular media (including television, advertisements, movies, and promotional materials), those responsible are urged to consistently show them wearing a helmet.

abstract

FREE

Concern for bone fragility in children and adolescents has led to increased interest in bone densitometry. Pediatric patients with genetic and acquired chronic diseases, immobility, and inadequate nutrition may fail to achieve the expected gains in bone size, mass, and strength, which leaves them vulnerable to fracture. In older adults, bone densitometry has been shown to predict fracture risk and reflect response to therapy. The role of densitometry in the management of children at risk of bone fragility is less certain. This clinical report summarizes the current knowledge about bone densitometry in the pediatric population, including indications for its use, interpretation of results, and its risks and costs. This report emphasizes consensus statements generated at the 2007 Pediatric Position Development Conference of the International Society of Clinical Densitometry by an international panel of bone experts. Some of these recommendations are evidence-based, and others reflect expert opinion, because the available data are inadequate. The statements from this and other expert panels have provided general guidance to the pediatrician, but decisions about ordering and interpreting bone densitometry still require clinical judgment. Ongoing studies will help to better define the indications and best methods for assessing bone strength in children and the clinical factors that contribute to fracture risk. *Pediatrics* 2011;127:189–194

INTRODUCTION

The bone health of children and adolescents has become an increasingly important medical concern. There is growing recognition that low bone mass and fractures may complicate several genetic and acquired chronic disorders of childhood.[1] Fractures are common in otherwise healthy youth as well; peak incidence occurs during the peripubertal growth spurt.[2] The documented 35% to 65% increase in common childhood fractures over the past 4 decades has raised concerns that current lifestyles are compromising early bone health.[3] Children with forearm fractures have been shown to have lower bone mass, a greater percentage of body fat, and less calcium intake than their peers without a history of fracture.[4,5] Vitamin D insufficiency and deficiency are widespread, calcium intake often falls below recommended levels, and physical inactivity is common among American youth.[6,7]

These observations have increased the demand for better diagnostic and therapeutic tools to address bone health in children and adolescents. Bone densitometry and pharmacologic therapy for osteoporosis in older adults have been refined in recent years. The efficacy, cost-effectiveness, and safety of these tests and treatments in pediatric

patients have not been adequately determined. This lack of data has left the pediatrician in a quandary about how to best diagnose and manage skeletal fragility in children and teenagers. To address these uncertainties, pediatric bone experts have proposed guidelines for evaluating skeletal health in youth.[8] This report briefly reviews current bone-densitometry methods, indications for ordering densitometry, and the role for densitometry in choosing and monitoring therapy.

BONE-DENSITOMETRY METHODS

The pediatric skeleton can be assessed by using dual-energy x-ray absorptiometry (DXA), quantitative computed tomography, peripheral quantitative computed tomography, quantitative ultrasonography, magnetic resonance imaging, or plain films (radiogrammetry). Each modality offers distinct advantages and disadvantages, which have been reviewed previously.[9] DXA remains the preferred method for clinical measurements of bone density in children because of its availability, reproducibility, speed, low exposure to ionizing radiation, and robust pediatric reference data.[10]

FOR WHOM SHOULD BONE DENSITOMETRY BE PERFORMED?

The general goals of bone densitometry are to identify patients at greatest risk of skeletal fragility fractures, to guide decisions regarding treatment, and to monitor responses to therapy. Skeletal assessments have been recommended for children with recurrent fractures, bone pain, bone deformities, or osteopenia on standard radiographs or to monitor therapy.[11,12] Specific recommendations have been proposed for monitoring bone health in patients with cystic fibrosis[13] and childhood cancer.[14] For example, a baseline DXA is recommended by 18 years of age or 2 years after the end of chemotherapy (for cancer survivors) but earlier in patients with more severe disease, low body weight, chronic glucocorticoid therapy, delayed puberty, gonadal failure, or a history of fracture. For patients receiving drugs that may adversely affect bone, such as anticonvulsants or depot medroxyprogesterone (Depo-Provera), there is insufficient evidence to support routine bone densitometry.[15,16]

The most comprehensive recommendations related to bone densitometry have evolved from the Pediatric Position Development Conference (PDC) of the International Society of Clinical Densitometry after rigorous analysis of the literature.[8] The PDC guidelines identified the primary and secondary disorders that have been associated with evidence of increased fracture risk (Table 1). PDC guidelines recommended that densitometry be performed "at clinical presentation" of these disorders and "before initiation of bone-active treatment," such as bisphosphonates.[17] The authors of the guidelines acknowledged that the recommendations are controversial and that experts will not agree with all the statements,[18] which reflects the lack of sufficient high-quality evidence to support some of the recommendations. Until such evidence is obtained, however, these parameters provide general guidance for the pediatrician and may help to secure reimbursement from insurance providers.

TABLE 1 Diseases That May Affect the Skeleton

Primary bone disorders
Idiopathic juvenile osteoporosis
Osteogenesis imperfecta
Potential secondary bone diseases
Chronic inflammatory disorders
Inflammatory bowel disease
Juvenile idiopathic arthritis
Cystic fibrosis
Chronic immobilization
Cerebral palsy
Myopathic disease
Epidermolysis bullosa
Endocrine disturbance
Turner syndrome
Anorexia nervosa
Cancer and therapies with adverse effects on bone health
Acute lymphoblastic leukemia
Status post chemotherapy for childhood cancer
Status post transplantation (nonrenal)
Hematologic disorders
Thalassemia

Data source: Bishop N, Braillon P, Burnham J, et al. *J Clin Densitom.* 2008;11(1):29–42.[17]

Beyond these guidelines, the decision to order bone densitometry for an individual patient requires clinical judgment. The risk of bone fragility will depend on age of onset and severity of the underlying disorder, if any; the number of associated risk factors (such as poor nutrition or inactivity); and exposure to potentially bone-toxic drugs (eg, glucocorticoids, anticonvulsants) or irradiation. A family history of bone fragility is relevant, because an estimated 60% to 80% of the variability in bone mass between individuals is determined by genetic factors.[6] This history is best assessed by asking about a history of hip fractures in older relatives. The decision to evaluate an otherwise healthy child with a history of fractures will depend on the number of broken bones and the intensity of the trauma that caused the injury. Low-trauma fractures are defined as those that occur from standing height or less. The PDC has defined a clinically significant fracture history as "one long bone fracture of the lower extremity, two or more long bone fractures of the upper extremity or a vertebral fracture."[8] Children with this history sustained after minimal or no trauma should be considered for evaluation with densitometry, whereas children with fractures of digits and toes do not warrant such investigation. Data are insufficient to recommend routine densitometry for infants in these situations. A final consideration before ordering DXA scans should be how the results will influence patient management. For example, it may not be helpful to document that bone mineral

density (BMD) is low for age in a child with cerebral palsy if the child has not had a fracture, because low BMD alone is not considered an indication for bisphosphonate therapy.[8]

ORDERING DXA IN PEDIATRICS

The preferred skeletal sites for DXA measurements in children are the lumbar spine and total body.[10] If possible, the cranium should be excluded from the total-body-scan analysis, because the head constitutes a large portion of the total body bone mass but changes little with growth, activity, or disease; inclusion of the skull potentially masks gains or losses at other skeletal sites.[19] DXA measurements of the hip region (total hip or femoral neck) are not as reliable in younger patients because of difficulties in identifying the bony landmarks for this region of interest. For children with contractures who cannot be positioned properly for spine or whole-body studies, measurements of the lateral distal femur may be a useful alternative but have been less extensively studied than spine or whole-body measurements.[20] Scanning alternative skeletal sites may also be necessary for patients with metal hardware (such as rodding for scoliosis) in the usual regions of interest. Vertebral fractures are best detected by standard lateral radiographs of the thoracolumbar spine,[21] not by DXA.[22]

INTERPRETATION OF DXA RESULTS

Bone mass, as measured by DXA, is reported as bone mineral content (BMC) (g) or areal BMD (g/cm^2). These values are compared with reference values from healthy youth of similar age, gender, and, if possible, race/ethnicity to calculate a *z* score, the number of SDs from the expected mean. Abundant pediatric reference data are now available for children and teenagers but not for infants.[10] It is essential to select norms collected by using equipment from the same manufacturer as that used for the patient because of systematic differences in software.[10] *T* scores (which compare the patient's BMD with that of a healthy young adult) should not be used before 20 years of age, because the person may not have achieved peak bone mass. Unfortunately, some software packages from DXA manufacturers automatically generate a *T* score, even for younger subjects. The ordering physician must be careful to not use *T* scores when interpreting DXA results.

Appropriate interpretation of DXA results may require more than the calculation of *z* scores. Children with chronic illness often have delayed growth and pubertal development, which are factors that contribute to a low bone mass for age or gender. BMD, as measured by DXA, corrects bone mineral for the area (height and width) but not for the volume (height, width, and thickness) of bone. For this reason, if 2 people with identical "true" volumetric bone density are compared, the shorter person will have a lower BMD than the taller one.[9,23] Similarly, a child with delayed puberty will not have had the gains in bone size, geometry, and density that occur with sex-steroid exposure. Controversy persists about the optimal method for adjusting for variations in bone size, body composition, and maturity as well as the criteria by which "best method" is defined; ideally, the adjustment method would prove to be a stronger predictor of fracture.[23] The PDC guidelines recommend that BMD in children with delayed growth or puberty be adjusted for height or height age or compared with reference data with age-, gender-, and height-specific *z* scores.[10]

A BMC or BMD *z* score of more than 2 SDs below expected (less than −2) should be labeled "low for age."[10] The terms "osteopenia" and "osteoporosis," which are used to describe milder or greater deficits in bone mass in older adults, should not be used for pediatric patients. Instead, the PDC guidelines suggested that the diagnosis of osteoporosis in children be made only when both low bone mass (BMC or BMD *z* scores of less than −2) and a clinically significant fracture history (defined previously) are present.[24]

INTERPRETING LONGITUDINAL DATA

Repeat DXA studies are performed to monitor the skeletal response to ongoing illness, the regaining of health, or the response to bone-active therapies. For a change in BMD to be technically meaningful, it must exceed the variability that is observed when DXA measurements are repeated for the same patient. The "least-significant change" refers to the smallest percentage difference in measurements that exceeds the variability or "noise" from repeated measurements.[25] In densitometry centers that provide rigorous attention to precision, a least-significant change of 3% or less can be achieved.[25] Gains or losses of BMD that are less than that cannot be labeled as change with certainty.

Longitudinal changes in bone densitometry must also take into account interval changes in growth and maturity. Assessing whether observed gains in bone mass and size are appropriate for age and pubertal stage requires thoughtful assessment of *z* scores, as described above. The recommended interval between repeat densitometry studies will depend on the progression of disease or the type of intervention being used. The minimal interval between scans should be 6 months,[10] but often 1 year or more may be appropriate to allow for measurable change to occur.

CAN DXA PREDICT FRACTURES?

Low BMD is such a sufficiently powerful predictor of fracture in older

adults that it has been used as a diagnostic criterion for "osteoporosis" in elderly patients.[26] Reduced BMD is associated with increased fracture risk in children and teenagers as well, but data are not sufficient to establish the diagnosis of osteoporosis on the basis of bone-densitometry criteria alone.[10,24] In studies of otherwise healthy youth, children with a history of fracture have been shown to have lower BMC, BMD, and estimated volumetric BMD than their peers without fractures.[4,5] In particular, children with reduced spine or whole-body bone mass or smaller bone area for height had an increased risk of fracture.[5,24]

Less is known about the relationship between low bone mass and fracture risk in children with chronic illness, because the studies in these populations have been limited to smaller cohorts with varying diagnoses and risk factors for poor bone health. The most common site of fractures in these children may not be the forearm; lower-extremity fractures are common in immobilized children,[27] and spine fractures are more common in young patients with childhood leukemia, osteogenesis imperfecta, or exposure to glucocorticoids.[28] In a study that examined only children with acute lymphoblastic leukemia, the odds for fracture increased by 80% for every 1-SD reduction in spine BMD *z* score.

Clinical variables other than bone mass influence the risk that a person will have a fracture. For older adults, age, weight, family history of hip fracture, exposure to glucocorticoids, smoking and alcohol use, and history of a fracture are key predictors of absolute fracture risk.[26] Clinical factors that influence bone fragility in children have not yet been well established. However, it has been recognized that bone densitometry by DXA is only part of a comprehensive skeletal health screening that includes review of nutrition, physical activity, pubertal stage, disease severity, patient and family fracture history, and medication exposure. A child with low bone mass for age or one with a significant fracture history warrants evaluation by a pediatric endocrinologist, nephrologist, geneticist, or rheumatologist (depending on clinical presentation) with expertise in bone.[10]

RISKS AND COSTS OF DENSITOMETRY

Exposure to the very low doses of ionizing radiation with DXA poses no known health risk. The estimated 5 to 6 microsieverts (μSv) of radiation exposure from a spine and whole-body DXA scan is far less than the 80 μSv accumulated during a round-trip transatlantic flight.[29] More concerning is the potential risk of misdiagnosis if DXA data are not interpreted by skilled professionals at pediatric densitometry centers. One study revealed errors in 88% of the scans from children referred for an osteoporosis-intervention study; 62% of the errors involved a misdiagnosis of osteoporosis based on inappropriate use of a *T* score.[30] Errors in interpreting DXA results generate considerable parental concern and can result in costly and unnecessary use of pharmacologic agents and restrictions on physical activity.

THERAPY FOR CHILDHOOD SKELETAL FRAGILITY

It is beyond the scope of this review to discuss therapy in detail. However, treatment options for children with low bone mass and fractures are more limited than those for adults, which underscores the importance of accurate skeletal assessments.[31] General measures to address skeletal risk factors are safe and appropriate first steps for all patients. Calcium intake should meet the current recommended daily intake of 500 mg for children 1 to 3 years of age, 800 mg for children 4 to 8 years of age, and 1300 mg for children and adolescents 9 to 18 years of age.[6] Adequacy of total-body vitamin D stores should be assessed by measuring serum concentrations of 25-hydroxyvitamin D; concentrations of at least 20 to 32 ng/mL (50–80 nmol/L) have been recommended for children.[7] Weight-bearing activity should be encouraged, and even short periods of high-intensity exercise (such as jumping 10 minutes/day, 3 times per week) have produced measurable gains in bone mass.[32] For patients with limited mobility, reducing immobility through physical therapy[33] or use of vibrating platforms can be helpful.[34] Reducing inflammation, undernutrition, or hormone imbalances is necessary as well.

If these general measures fail to prevent further bone loss and fracture, pharmacologic therapy may be considered. None of the drugs used to treat bone fragility in the elderly have yet been approved by the US Food and Drug Administration for pediatric use.[35] Nevertheless, therapy with bisphosphonates is considered reasonable for children with moderate-to-severe osteogenesis imperfecta ($\geq$2 fractures in 1 year or vertebral compression fractures).[36] For secondary osteoporosis attributable to chronic disease, bisphosphonates may be used on a compassionate basis to treat low-trauma fractures of the spine or extremities.[37]

SUMMARY

DXA has been established as a valuable tool as part of a comprehensive skeletal assessment of children and teenagers but not yet of infants. Acquiring and interpreting densitometry data from younger patients remains challenging and should be performed in experienced pediatric densitometry centers. Panels of pediatric experts have set standards

for when and how to perform DXA scans on the basis of the best available data.[10] Ongoing research will serve to refine the best modalities for assessing the bone strength of children and to determine the key clinical variables that influence fracture risk independent of bone.

Thousands of boys and girls younger than 19 years participate in boxing in North America. Although boxing provides benefits for participants, including exercise, self-discipline, and self-confidence, the sport of boxing encourages and rewards deliberate blows to the head and face. Participants in boxing are at risk of head, face, and neck injuries, including chronic and even fatal neurologic injuries. Concussions are one of the most common injuries that occur with boxing. Because of the risk of head and facial injuries, the American Academy of Pediatrics and the Canadian Paediatric Society oppose boxing as a sport for children and adolescents. These organizations recommend that physicians vigorously oppose boxing in youth and encourage patients to participate in alternative sports in which intentional head blows are not central to the sport. *Pediatrics* 2011; 128:617–623

INTRODUCTION

Amateur or Olympic-style boxing is a collision sport that is won on the basis of the number of clean punches landed successfully on an opponent's head and body (Appendix).[1,2] A match is won outright if an opponent is knocked out. Participants in boxing are at risk of serious neurologic and facial injuries.[3–7] Despite these potential dangers, thousands of boys and girls participate in boxing in North America. In 2008, more than 18 000 youths younger than 19 years were registered with USA Boxing (Lynette Smith, USA Boxing, written communication, August 2009).

The societal debate regarding boxing has raged for decades. Many authors and medical organizations have called for boxing to be banned (Table 1), citing medical, ethical, legal, and moral arguments.[8–13] Others state that participants should be allowed to make autonomous decisions about participation and that the role of the medical profession should be restricted to the provision of injury care, advice, and information only.[14]

Supporters of amateur boxing state that the sport is beneficial to participants by providing exercise, self-discipline, self-confidence, character development, structure, work ethic, and friendships.[14] For some disadvantaged youth, boxing is a preferential alternative to gang-related activity, providing supervision, structure, and goals.[14] The overall risk of injury in amateur boxing seems to be lower than[15] in some other collision sports such as football, ice hockey, wrestling, and soccer.[4,16] However, unlike these other collision sports, boxing encourages and rewards direct blows to the head and face.

TABLE 1 Position Statements on Boxing

Organization	Position
American Medical Association[9] (2007)	Recommends that until boxing is banned, head blows should be prohibited
American Academy of Pediatrics[8] (1997)	Opposes boxing as a sport for any child, adolescent, or young adult
Australian Medical Association[10] (2007)	Opposes all forms of boxing; recommends the prohibition of all forms of boxing for people younger than 18 y
British Medical Association[11] (2007)	Opposes amateur and professional boxing; calls for complete ban on boxing; recommends banning boxing for those younger than 16 y
Canadian Medical Association[12] (2002)	Recommends that all boxing be banned in Canada
World Medical Association[13] (2005)	Recommends that boxing be banned

The American Academy of Pediatrics and the Canadian Paediatric Society oppose boxing and, in particular, discourage participation by children and adolescents.[8]

BOXING-RELATED INJURIES

Data are limited on injuries that result from boxing in children and adolescents.[17,18] National organizations, such as Boxing Canada and USA Boxing, do not keep data on the participation or injury rates of their members.

Some data on boxing injuries in children are available from the Canadian Hospitals Injury Reporting and Prevention Program database, maintained by the Public Health Agency of Canada. This database includes data collected from 15 hospitals across Canada, including 10 children's hospitals. From 1990 to 2007, the prevalence of injury from combat sports requiring admission to a hospital was highest for boxing (4.8%),[17] which compares with admission rates of 3.6% for judo, 3.1% for karate, and 2.9% for wrestling.[17] Of those hospitalized for injuries from boxing, 58% had facial fractures and 25% sustained closed head injuries.[17] There was a significant increase in the overall number of injuries from 1999–2007 (16.4 in 100 000), compared with 1990–1998 (11.4 in 100 000). Sixty-eight percent of these injuries occurred during sparring and competition; the remainder occurred during training. Of the 273 injured boxing athletes reported in the Canadian Hospitals Injury Reporting and Prevention Program database, fewer than 1% were 5 to 9 years of age, 29.3% were 10 to 14 years of age, 39.2% were 15 to 18 years of age, and 30.8% were 19 years of age or older.[17]

The National Electronic Injury Surveillance System (NEISS) contained reports of 1263 boxing-related injuries in children and adolescents 5 to 14 years of age and 8082 in adolescents and adults 15 to 24 years of age in the United States in 2007. The types and severity of injuries were not delineated.[18]

Published injury data in amateur boxing (youth and adult participants) do not distinguish injuries according to age, so it is difficult to delineate injuries that specifically affected children and adolescents. Most injuries in boxing, both amateur and professional, occur during competition (57%), compared with training (43%).[4] The authors of 1 cohort study reported an injury rate of 1.0 injury per 1000 hours of participation for amateur boxers (15.1–37.1 years of age).[4] This rate is actually lower than reported high school athlete injury rates of 4.4 per 1000 athlete-exposures in football, 2.5 in wrestling, and 2.4 in soccer.[16] Intentional facial and head injuries, however, are more frequent in boxing.[17]

Types of Injuries

The most common injuries in boxing are to the head, face, and neck regions.[4,5,19,20] One prospective cohort study documented that more than 70% of injuries in amateur (average age: 23.7 years) and professional boxers were to the head.[4] Concussion was the most common injury (33%), followed by open wounds/lacerations/cuts (29%) and fractures (19%).[4] The eyebrow and nose were other common sites of injury (19% each).[4] Most injuries to the eye region were lacerations/cuts, although conjunctival, corneal, lenticular, vitreal, ocular papilla, and retinal lesions were also reported.[3] Canadian Hospitals Injury Reporting and Prevention Program data are similar; one-third of the reported injuries affected the head, face, and neck regions, and almost half of the injuries occurred in the upper extremity (Table 2).[17]

Brain injury is the most significant risk associated with boxing, and acute subdural hematoma is the most common cause of death in amateur and professional boxers.[5,16] Between 1918 and 1997, 659 deaths from boxing have occurred, all from catastrophic brain injury.[6]

There is evidence that amateur boxers are at risk of structural brain injuries, cognitive abnormalities, and neurologic deficits from the sport.[7,21–25] One study of 14 amateur boxers revealed elevated levels of cerebrospinal fluid biochemical markers from neuronal and astroglial injury after bouts.[21] Significant increases in levels of these markers were associated with multiple or high-impact hits to the head.[21] In addition, new MRI techniques have revealed structural brain abnormalities in boxers, including microhemorrhages.[22] Furthermore, electroencephalography studies have found a significantly higher incidence of abnormalities among retired amateur

TABLE 2 Boxing-Related Injuries,[a] Ages 5 to 59 Years: Canadian Hospitals Injury Reporting and Prevention Program, 1990–2007[17]

Body Part/Nature of Injury	Sparring/Competition, *n* (%)	Conditioning, *n* (%)
Upper extremity	87 (47.0)	80 (94.1)
Fracture, dislocation	32 (17.3)	33 (38.8)
Bruise, abrasion, laceration	25 (13.5)	20 (23.5)
Soft tissue	14 (7.6)	9 (10.6)
Sprain/strain	12 (6.5)	18 (21.2)
Other (bite, nerve injury)	4 (2.2)	0 (0.0)
Head, face, neck	62 (33.5)	0 (0.0)
Facial fractures	17 (9.2)	
Closed head injuries	17 (9.2)[b]	
Facial bruise, abrasion; soft tissue	12 (6.5)	
Facial, scalp laceration	7 (3.8)	
Eye injury	5 (2.7)	
Neck sprain/strain	3 (1.6)	
Neck soft tissue	1 (<1.0)	
Trunk	19 (10.2)	0 (0.0)
Bruise, abrasion, soft tissue	13 (7.0)	
Rib fracture	3 (1.6)	
Sprain/strain	2 (1.1)	
Internal abdominal	1 (<1.0)	
Lower extremity	15 (8.1)	4 (4.7)
Sprain/strain/dislocation	6 (3.2)	1 (1.2)
Fracture/dislocation	3 (1.6)	0 (0.0)
Other (bruise, abrasion, soft tissue, nerve injury)	6 (3.2)	3 (3.5)
Other and unknown	2 (1.1)	1 (1.2)
Total	185 (100.0)	85 (100.0)

[a] In 3 cases, the training type was unknown: 2 upper-extremity fractures and 1 lower-extremity soft tissue injury.
[b] $n = 10$ minor closed head injuries, 6 concussions, and 1 intracranial injury.

boxers compared with active soccer players and track-and-field athletes.[23] There is also evidence of diminished neurocognitive functioning on neuropsychological tests in amateur boxers without concussions despite the use of headgear.[23–25] The long-term significance of these findings is yet to be determined.

Concussions

Concussions in sport are a significant public health concern, and they occur frequently in boxing.[4,7,20,25] The exact incidence of concussion in children and adolescents participating in boxing has not been published, because studies of amateur boxers do not separate data according to age. However, reports of concussions in amateur boxing range from 6.5% to 51.6% of all injuries.[5] The authors of 1 study of amateur boxers (older than 16 years) reported that more than half of all injuries sustained in competition were concussions (51.6%), and the incidence was 11.4 concussions per 1000 boxing exposures.[5,20] A prospective cohort study of amateur and professional boxers revealed that 33% of all injuries were concussions.[4] Another source cited a concussion rate in amateur boxing (age not specified) of 0.58 per 100 athlete-exposures, compared with 0.28 in hockey (males 5–17 years old) and 0.38 in high school rugby.[7] Yet another study of amateur boxers (median age: 22 years) documented that 13% of matches ended because of concussions.[25]

Concussions are particularly concerning in children and adolescents, because there is evidence that a child's brain is more vulnerable to injury and that recovery from concussion is prolonged when compared with adults.[26–29] A prospective case-control study comparing neurocognitive recovery after concussion in high school (aged 14–18 years) and college (aged 17–25 years) football and soccer athletes found that high school athletes had more prolonged memory dysfunction. Neuropsychological test values were significantly lower in concussed high school athletes than age-matched controls 7 days after injury, whereas college athletes recovered within 3 days after injury.[26] Another prospective case-control study in high school athletes with concussion demonstrated memory impairment up to 10 days after injury.[29] These findings can be extrapolated to young boxers, which suggests that they may take up to 10 days (or longer) to recover from concussions.

Return-to-play (RTP) guidelines after sport-related concussions is a particular area of controversy. The most recent guidelines proposed by the Concussion in Sport Group, and endorsed by both the American Academy of Pediatrics and Canadian Paediatric Society, recommend that an athlete who has sustained a concussion rest, both physically and cognitively, until the symptoms of concussion have resolved completely.[28,30,31] "Cognitive rest" in children means limiting scholastic and other cognitive stressors such as text-messaging, computer work, and video games.[28,30,31]

Because children may take longer to recover from concussions and because of the risks associated with head impact in younger athletes (ie, cerebral swelling), the Concussion in Sport Group recommends a more conservative approach to RTP decisions for children and adolescents, including no RTP the same day.[30] It is appropriate to extend the length of the asymptomatic rest period to ensure that symptoms have resolved completely and then allow athletes to progress through a medically supervised stepwise graded-exertion protocol (Table 3).[28,30,31] No athlete should return to

TABLE 3 Graduated RTP Protocol (After a Sport-Related Concussion)[30]

Rehabilitation Stage	Functional Exercise at Each Stage of Rehabilitation	Objective of Each Stage
1. No activity	Complete physical and cognitive rest	Recovery
2. Light aerobic exercise	Walking, swimming, or stationary cycling, keeping intensity at <70% of MPHR; no resistance training	Increase HR
3. Sport-specific exercise	Skating drills in hockey, running drills in soccer; no head impact	Add movement
4. Noncontact training drills	Progression to more complex training drills (eg, passing drills in football and ice hockey); may start progressive resistance training	Exercise, coordination, and cognitive load
5. Full-contact practice	After medical clearance, participate in normal training activities	Restore confidence and assess functional skills by coaching staff
6. RTP	Normal game play	

HR indicates heart rate; MPHR, maximum permitted heart rate.

sport without being medically cleared by an experienced physician.[28,30,31]

Concussion management and RTP decisions should be individualized on the basis of resolution of symptoms rather than prescribing RTP on arbitrary time frames. In particular, the current Boxing USA postconcussion boxing restriction period of 30 days or longer does not follow the latest Concussion in Sport Group guidelines (Appendix; Table 3).

Chronic Traumatic Brain Injury

The risk of chronic traumatic brain injury has been a concern of opponents of boxing. Numerous study authors have cited the risks of dementia pugilistica or chronic traumatic encephalopathy (CTE), thought to be caused by the cumulative effects of repeated blows to the head. CTE occurs in up to 20% of professional boxers.[32] Most cases of dementia pugilistica occurred in the 1930s to 1950s, when boxing careers were much longer and involved more bouts.[32,33] It is believed that the incidence of CTE will diminish in the modern era of boxing because of shorter careers, fewer bouts, and improved medical care; however, more longitudinal prospective studies are necessary to determine if there is truth to this assumption or whether other factors may play a role in changing rates of CTE.[32,33]

Although predominantly described in boxing, chronic traumatic brain injury can be associated with any sport in which there is a risk of repetitive head blows, including soccer, football, ice hockey, and martial arts.[34] There is ample evidence indicating a cumulative effect from repeated concussive injuries.[34–36] A prospective study of high school athletes compared neuropsychological evaluations of those with no history of concussion, asymptomatic athletes with 1 previous concussion, asymptomatic athletes with 2 or more previous concussions, and athletes who had sustained a concussion within the previous week. Asymptomatic athletes with 2 or more previous concussions had decreased performance on measures of attention and concentration, similar to athletes with recent concussion.[35] Another prospective study of high school athletes found that those with a history of 3 concussions were more than 9 times more likely than athletes with no previous concussion history to demonstrate 3 to 4 abnormal on-field markers of concussion severity, including loss of consciousness, anterograde amnesia, and confusion.[36] These study results raise the concern that repeated head injuries associated with boxing may similarly lead to long-lasting neurocognitive effects.

The risk of CTE for amateur boxers is believed to be lower than that for professional boxers, because amateur boxers have fewer, shorter fights. Amateur bouts last only 3 rounds, compared with up to 12 in professional boxing matches, and amateur careers tend to be shorter. In addition, amateur boxers are required to wear head guards.[5,23,32,33,37,38] There is no evidence, however, that head guards prevent concussions, and although mouth guards are useful for protecting dentition, they also do not protect against concussion.[25,37,39] More research is needed to determine if there is an association of CTE with amateur boxing.[38–41]

Making Weight

Because boxing athletes participate in weight classes, part of the prebout medical examination involves weighing the athletes. Methods to maintain weight can be dangerous to young athletes. Boxers, similar to wrestlers, may use voluntary dehydration practices such as fluid restriction, diuretics and laxatives, rubber suits, and saunas and steam baths to lose weight.[42] Weight loss by dehydration can result in decreased performance because of impaired reaction time, endurance, and strength as well as electrolyte imbalance and acidosis.[42] Dehydration also negatively affects the acclimation process and thermoregulation during exercise. With increasing dehydration and electrolyte loss, the athlete is at risk of cramps, heat exhaustion, and heat stroke.[42]

CONCLUSION

Despite the ongoing debate regarding boxing and clear opposition from medical associations around the world (Table 1),[8,9–13] boxing continues to be available to youths under 19 years. Because the sport encourages deliberate blows to the head, participants are at risk of head injuries that may be cumulative

and even fatal. Pediatricians should strongly discourage boxing participation among their patients and guide them toward alternative sport and recreational activities that do not encourage intentional head injuries. For those youth who, despite education and counseling, choose to participate in boxing, appropriate medical care should be ensured by boxing organizations, including medical coverage at events, preparticipation medical examinations, and regular neurocognitive and ophthalmologic screening examinations, which should be provided by physicians who are knowledgeable about common boxing injuries and appropriate RTP guidelines after any injury.

RECOMMENDATIONS

The American Academy of Pediatrics and the Canadian Paediatric Society recommend that pediatricians:

1. vigorously oppose boxing for any child or adolescent.
2. educate patients who may be engaged in or considering engaging in boxing, as well as parents/caregivers/teachers/coaches, regarding the medical risks of boxing.
3. encourage young athletes to participate in alternative sports in which intentional blows to the head are not central to the sport, such as swimming, tennis, basketball, and volleyball.
4. advocate that boxing organizations ensure that appropriate medical care is provided for children and adolescents who choose to participate in boxing, ideally including medical coverage at events, preparticipation medical examinations, and regular neurocognitive testing and ophthalmologic examinations.

APPENDIX: DEFINITIONS ABOUT THE SPORT OF BOXING[1,2]

Amateur boxing: A sport in which participants fight and win points for scoring clean blows to the head and body above the belt. Matches consist of 3 or 4 rounds of 2 minutes each. No money is awarded. The age limit is a minimum of 11 years for bouts (none for training); there is no upper age limit.

Head injury management: USA Boxing organization rules state that boxers who sustain head injuries during a match are restricted from further participation. A 30-day restriction is applied if a boxer is knocked down by a blow to the head and gets up quickly, if a boxer fails to demonstrate "normal responses," or if a boxer receives 3 standing 8-counts during a round or 4 standing 8-counts in a match because of head blows. A 90-day restriction is applied if there is a loss of consciousness up to 2 minutes or if the boxer has had a previous concussion-related restriction. A 180-day restriction is applied if there is a loss of consciousness for more than 2 minutes or a previous 90-day concussion-related restriction. During the restriction period, the boxer is prohibited from sparring and competitive boxing but not from conditioning. The boxer must be reexamined by a physician at the end of the restriction period before return. Individual teams/physicians/coaches can implement their own management system in addition to the USA Boxing restrictions.

Medical requirements: Prebout and postbout medical examinations are required for all amateur competitions; these are brief examinations to rule out acute injuries that may limit participation. Ringside physicians must be present for all matches and may stop a match at their discretion at any point during the bout.

Olympic boxing: A form of amateur boxing consisting of a single-elimination tournament in which participants compete for medals (gold, silver, bronze). Matches consist of 4 rounds of 2 minutes each.

Professional boxing: A sport in which participants fight for financial gain. Matches consist of 4 to 12 rounds of 3 minutes each. Professional boxing regulation in the United States varies according to state.

Protective equipment: Amateur boxers are required to wear a form-fitted mouth guard, a head guard, and a foulproof cup (males) or a breast protector (females). Professionals do not wear head guards.

Rounds: Time periods of a boxing match.

Scoring (amateur boxing): Electronic scoring has been used internationally since 1992. Participants are awarded points for clean blows to their opponent. A scoring blow requires that the white part of the glove, covering the knuckles, makes contact within the target area (above the belt).

Standing 8-count: A referee can award a standing 8-count if a hard blow is landed or if a boxer seems to be outclassed. This time allows the referee to determine if the match can continue.

Weight classes: Boxers compete in classes, or divisions, based on weight.

Winning a bout (amateur):

- Win on points: the boxer with the most points wins.
- Win by retirement: if a boxer voluntarily retires the match, the opponent is declared the winner.
- Win by referee stopping the contest (RSC): a referee can stop a bout for a number of reasons:
  - RSC opponent outclassed: referee stops the bout because a boxer is outclassed by his or her opponent.
  - RSC opponent outscored: referee stops a bout because an opponent is outscored.
  - RSC head blows: referee stops a bout because of head blows. Boxers who receive an "H" are evalu-

ated by the ringside physician and issued a 30-, 60-, or 90-day restriction from sparring and competition depending on the severity of the injury. A boxer must be cleared by a physician before returning to boxing.[16]

- RSC injury: referee stops a bout because of injury.

- Win by disqualification: if a boxer is disqualified for dangerous or unsportsmanlike behavior, the opponent is declared the winner.
- Win by walkover: a boxer's opponent wins if a boxer fails to make weight, misses a scheduled bout, or is unable to compete because of medical reasons.
- No contest: a match that is called off for extenuating circumstances (lights fail, ring is damaged, etc).
- Winning a bout (professional): A professional boxer wins a fight by (1) knockout, (2) technical knockout, (3) decision, or (4) disqualification.
- Knockout (KO): occurs when a boxer is knocked down and does not get up within 10 seconds, as counted by the referee.
- Technical knockout (TKO): occurs when a boxer is judged physically unable to continue fighting. This judgment can be made by the referee, the official ring physician, the fighter, or the fighter's assistants. If a boxer is knocked down 3 times in 1 round, the opponent wins on a TKO.
- Decision: results when boxers fight the scheduled number of rounds without a KO or a TKO. The winner is decided by the officials on the basis of a round- or point-scoring system.
- Disqualification: results when a boxer is disqualified for dangerous or unsportsmanlike behavior.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

The Built Environment: Designing Communities to Promote Physical Activity in Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Environmental Health

ABSTRACT

An estimated 32% of American children are overweight, and physical inactivity contributes to this high prevalence of overweight. This policy statement highlights how the built environment of a community affects children's opportunities for physical activity. Neighborhoods and communities can provide opportunities for recreational physical activity with parks and open spaces, and policies must support this capacity. Children can engage in physical activity as a part of their daily lives, such as on their travel to school. Factors such as school location have played a significant role in the decreased rates of walking to school, and changes in policy may help to increase the number of children who are able to walk to school. Environment modification that addresses risks associated with automobile traffic is likely to be conducive to more walking and biking among children. Actions that reduce parental perception and fear of crime may promote outdoor physical activity. Policies that promote more active lifestyles among children and adolescents will enable them to achieve the recommended 60 minutes of daily physical activity. By working with community partners, pediatricians can participate in establishing communities designed for activity and health. *Pediatrics* 2009;123: 1591–1598

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

A child's life is affected by the environment in which he or she lives. Relationships between health and the quality of air, water, and food are well recognized.[1–3] The physical environments of the home and school also influence health through exposures to lead,[4] mold,[5] noise,[6] or ambient light.[7] In addition, the overall structure of the physical environment of a child's community (referred to as the "built environment") can also affect health in diverse ways.

As cities have expanded into rural areas, large tracts of land have been frequently transformed into low-density developments in a "leapfrog" manner. The resultant urban sprawl can increase automobile travel, which increases air pollution[8] as well as passenger and pedestrian traffic fatalities.[9] Some urban areas may have few supermarkets, produce stands, or community gardens, thereby limiting access to fresh fruits and vegetables.[10] The physical environment of a community can support opportunities for play, an essential component of child development,[11] and for physical activity, a health behavior that not only reduces risk of excess weight gain[12,13] but also has many other benefits for overall well-being.

Many factors influence a child's level of physical activity, including individual-level psychosocial factors such as self-efficacy[14,15]; family factors such as parental support[16]; and larger-scale factors such as social norms.[17] Although these are all important contributors, this policy statement is limited to focusing on how the physical design of the community affects children's opportunities for physical activity. Opportunities for recreational physical activity arise with parks and green spaces. "Utilitarian" physical activity, such as walking or bicycling to school and to other activities, is an equally important part of a child's daily life. Environments that promote more active lifestyles among children and adolescents will be important to enable them to achieve recommended levels of physical activity.

BACKGROUND

The term "built environment" refers to spaces such as buildings and streets that are deliberately constructed as well as outdoor spaces that are altered in some way by human activity. This term may be unfamiliar to most clinicians, but with the high prevalence of childhood overweight and obesity,[18] the subject is increasingly relevant.

An individual's lifestyle and behaviors influence weight-gain patterns and physical fitness, and health education through clinicians and public health or community affiliates has long been recognized as important in influencing health behaviors. However, as the relationship between physical activity and obesity unfolds, it has become apparent that certain aspects of the environment influence the adoption of positive health behaviors. For example, a pediatrician's recommendation that a patient get regular physical activity loses its salience if this patient's everyday world lacks opportunities to walk, play, or run.

Physical activity has many health benefits.[12] As an important component of play,[11] physical activity contributes to children's organization and social skills[19] and promotes self-esteem and higher grade achievement among adolescents.[20] The American Academy of Pediatrics recommends that children be physically active for at least 60 minutes/day.[12] This can be met with structured activities, including sports and school-based physical education classes, or through an active lifestyle, including outdoor play and walking or biking for transportation. For preschool-aged children, outdoor play may be particularly important, because their highest levels of physical activity occur outside.[21,22] Environments that support recreational opportunities for children and adolescents also support the engagement of adults as they supervise, coach, and mentor youth.

The physical layout of communities can promote or limit opportunities for physical activity. There is growing research and policy interest in active living, defined as "a way of life that integrates physical activity into daily routines."[23] Under this principle, by establishing communities that support an active lifestyle, neighborhood design can promote physical activity patterns that are sustainable and important to health.

RECREATIONAL PHYSICAL ACTIVITY: PARKS AND RECREATIONAL FACILITIES

Although parks do not guarantee physical activity among nearby residents, they offer the opportunity.[24] In an experimental study in which children were made to decrease their time spent being sedentary, they increased the time spent engaged in physical activity, and the extent of increase was associated with proximity to a park.[25] The same research team has shown that as the percentage of park area within a child's neighborhood increases, so does the physical activity among children 4 to 7 years of age[26] and nonoverweight children 8 to 12 years of age.[27] Park space may vary considerably between neighborhoods. In Los Angeles, California, park acreage within neighborhoods ranges from 0.6 to 31.8 acres per 1000 people.[28,29]

Children living in low-income or predominantly minority neighborhoods may have less access to parks or other recreational facilities. In a national sample, access to a physical activity or recreational facility (including parks) was most often found for adolescents living in areas with higher percentages of the population having a college education. In areas where ≤25% of the population had a college education, higher proportions of minority population were associated with a lower likelihood of having a recreational facility.[30] Youth with low socioeconomic status are more likely than their affluent peers to report that a nearby recreation facility is important for their degree of physical activity,[31] possibly because they have limited access to more remote (or more expensive) opportunities for physical activity.

Examples of successful strategies to promote public space exist. Local communities have created parks and playgrounds in previously unused areas. Nonprofit organizations, such as the Trust for Public Land, have helped communities by assisting them in tasks ranging from park siting to development of funding strategies. Between 1971 and 2002, the Trust for Public Land's work in US cities resulted in the acquisition of 532 properties totaling 40 754 acres of newly created public land.[28] Legislative efforts are also an important mechanism to fund park development and maintenance. Proposition K, enacted in 1996 in Los Angeles, generates funds to provide $25 million annually to the improvement, construction, and maintenance of city parks. In the November 2002 elections, voters in 93 communities in 22 states approved ballot measures that committed $2.9 billion to acquire and restore land for parks and open space.[28] In addition to parks, community gardens are also being created.[32] (Community gardens provide a space for generation of food and the opportunity for gardening, a beneficial physical activity in its own right.)

"INCIDENTAL" PHYSICAL ACTIVITY

An important component of a healthy lifestyle is participation in activities for which exercise is not the primary goal. This might be a "purposeful walk"—an errand to buy groceries or a trip to school. Such incidental physical activities (also known as "utilitarian trips"[33]) play an important role in energy balance and can be influenced by neighborhood design.[34]

Neighborhood Design

The positioning of homes, schools, businesses, parks, and sidewalks within a neighborhood can influence physical activity. Neighborhood design typically considers 4 land uses: residential, industrial, green space, and institutional (eg, schools). Sprawling urban design has less mixing of these types (or less "land-use mix"). Figure 1 illustrates this distinction. Houses and apartments in the lower section of the diagram (the traditional neighborhood) are closer to other types of destinations such as the school or the mall, and the houses in the upper section (suburban sprawl) are more isolated. This figure also demonstrates a second core concept from urban planning known as "connectivity," or the ease of moving between origins (eg, home and work).[35] Street grids with many intersections provide many options for navigating to a destination.[36] In the low-density upper part of the diagram, although there are houses that are not far from the school "as the crow flies," getting to the school requires winding out of the enclave of houses to a busy main road. Thus, a child who lives close to school may still find walking to school prohibitive.

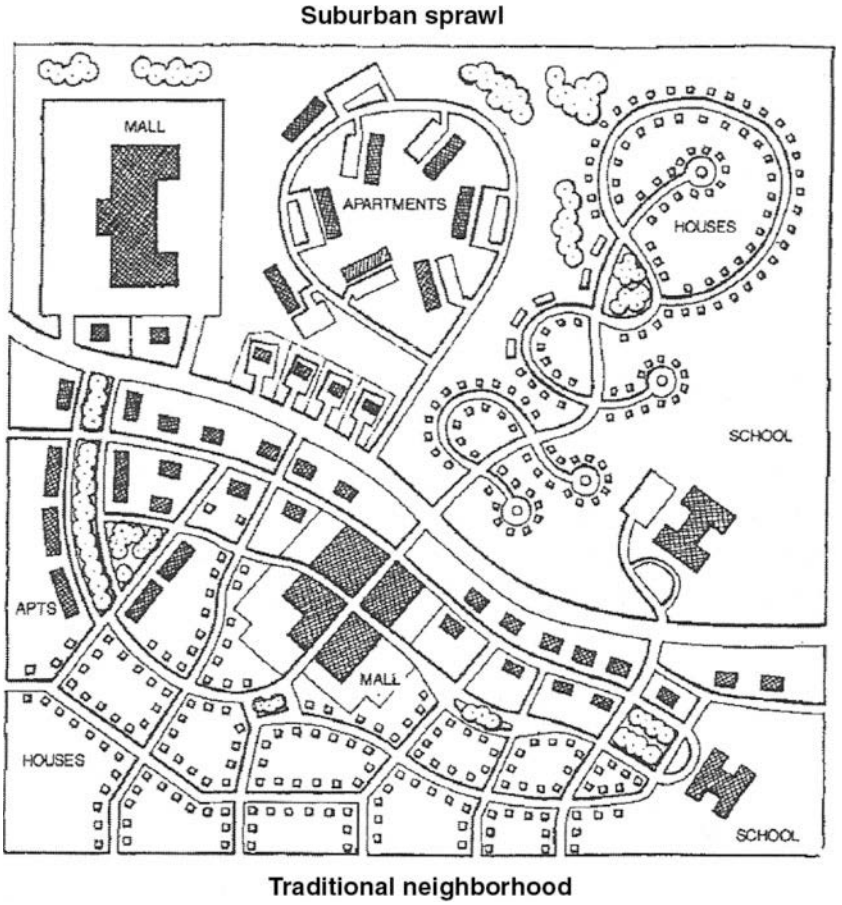

FIGURE 1
Comparison of street networks and land use in sprawled (upper) and traditional (lower) neighborhoods. Source: Drawing by Duany Plater Zyberk as shown in Spielberg F. The traditional neighborhood development: how will traffic engineers respond? *ITE J.* 1989;59:17.

Building new communities that are less car dependent and making existing communities more dense are 2 strategies that can make it easier for people to walk to their destinations of daily life. Higher land-use mix encourages more utilitarian trips among residents and increases their ability to reach their destinations on foot rather than by automobile. Proximity of neighborhood shops to residences promotes trips on foot or by bicycle.[37–39] In addition to mixed-land use, other measures, such as higher residential density, smaller street blocks,[40,41] and access to sidewalks,[42,43] have been reported to translate to increased walking in adults. Increased urban sprawl, by which farther distance between destinations decreases walkability, has been associated with less physical activity and with more obesity in adults,[44,45] as well as higher automobile passenger and pedestrian fatality rates.[9]

Air pollution exposure has been associated with the development and exacerbation of asthma in children.[46–48] Although physical activity is a positive aspect of outdoor play, it is important to recognize that time spent outdoors can make a child more vulnerable to ambient air pollution. Direct exposure to vehicle exhaust can affect a child's health, and higher urban density theoretically can increase one's daily exposure to vehicle exhaust and street traffic. Conversely, low-density sprawl promotes vehicle dependence and long-distance commuting, thus threatening air quality of the population at large. Children will benefit from planning that actively promotes outdoor play and walking while addressing the negative health effects of traffic and air pollution.

Higher housing density with increased land-use mix is a design strategy that promotes more physical activity among residents. However, there are other hybridized approaches that include creative design solutions that blend the benefits of connected streets with green space that is protected from automobile traffic. A street block plan can have "shared outdoor space,"[49] set aside within the heart of a cluster of residences. In this plan, front entrances of homes face the street and the back entrances face the shared outdoor spaces, which are accessible only to the residents. This design promotes a separation of outdoor recreational areas from traffic and an increased sense of ability to supervise children while preserving the community's ability to fit well onto a traditional grid of streets, which promotes walking to nearby destinations.

Walking to School

The most universal opportunity for incidental physical activity among children is in getting to and from school. Walking or biking to school has not yet been documented to lower BMI,[50] but it is a valuable opportunity for activity[51] and promotes higher levels of physical activity in boys.[52] Among middle-school girls in the Trial of Activity for Adolescent Girls (TAAG) study, every mile

that a girl lived farther from school translated to significantly fewer minutes of metabolic activity per week.[53] Closer proximity to school also provides the opportunity for use of school grounds for physical activity in after-school hours, and researchers have shown that provision of an open (supervised) school yard led to increased levels of physical activity and less television and video game use.[54]

In 1969, 40.7% of all American children walked to school. Currently, approximately 12.9% of all American children walk to school,[55] and in some areas as few as 5% of children walk to school.[56] Two national telephone surveys, HealthStyles in 1999[57] and ConsumerStyles in 2004,[58] queried parents about what barriers prevented their children from walking to school. The most commonly cited reason from those surveys and from the National Personal Transportation Survey from 1969–2001[55] was that the school was too far away.

School Sprawl

Suburbanization and decisions about school siting are important determinants of why children now live so far from school. Historically, small neighborhood schools served as "anchors" within the community and places for after-school programs, for social and recreational gathering, and as disaster shelters.[59] However, after the 1950s, many states established policies on the size and location of school buildings that influenced school siting. According to those guidelines, to receive state funding, schools had to have a minimum acreage (eg, elementary schools needed to be on at least 10 acres), and more students translated to larger required school-grounds size (eg, an extra acre for every 100 students).[8,60] Because untapped acreage sufficient to meet these standards is most often at the edge of an urban area, neighborhood schools (typically only 2–8 acres in size)[60] were frequently demolished or closed in favor of "big-box schools" at the outskirts of cities. Recommendations on school size from the Council of Education Facilities Planners International (CEFPI) were revised in 2004[61] and no longer recommend a minimum acreage. There is increasing interest in supporting smaller schools,[62] but change to policies on school land size occurs slowly. It is also important to acknowledge that there may be some trade-offs to consider regarding school size and physical activity. There is some research suggesting that larger school campuses, buildings, and play areas may promote youth physical activity during the school day.[63]

Distance is, of course, not the only barrier preventing children from walking or biking to school. A recent nationally representative study found that even among children who lived within 1 mile of school, less than half walk to school even 1 day/week. The proportion of children walking to school was the lowest among those living in the South, those living in a rural area, or those whose parent had an advanced degree.[64] The ConsumerStyles survey determined that parents' foremost concern was distance from school, followed by concerns about danger from traffic and crime, weather, and other miscellaneous factors.[58] These barriers are important, because they may prevent children not only from walking and biking to school but also from getting other physical activity in their neighborhood. To address these concerns about children's commutes to school, schools and parents in many US cities have organized a "walking school bus."[65] A walking school bus is created when groups of schoolchildren, supervised by volunteer adults, walk together through the neighborhood to "pick up" other children waiting with a parent at designated "bus stops." These programs represent an example of practical solutions to address concerns about environment and safety.

THEMES IMPORTANT FOR BOTH RECREATIONAL AND INCIDENTAL PHYSICAL ACTIVITY

Roads and Traffic

When parents are asked what prevents their children from walking to school, the second most commonly mentioned factor is traffic danger.[57,58] In addition, parental concern about traffic is a major barrier to children having opportunities for active free play.[66] "Traffic calming" refers to a variety of modifications and engineering techniques that can be applied to roads to slow driver speed. For example, road-design interventions can force cars to slow as they pass through undulations of the road surface.[67] A meta-analysis involving studies from multiple countries has shown that traffic calming reduces traffic injuries,[68] and research from the United Kingdom has shown that area-wide traffic-calming programs decreased pedestrian injuries in both affluent and poor areas.[69] There are traffic-calming programs in cities in 39 states, in cities such as Seattle, Washington, and Austin, Texas.[70] Research in Oakland, California, showed that children living near speed humps are less likely to be struck by an automobile in their neighborhood.[71] Measures that facilitate pedestrian crossing, such as single-lane roundabouts and islands in roadways, are effective countermeasures against pedestrian injury.[72] Taken together, there are many existing tools that address this very important parental concern about traffic danger.

Streetscapes, Esthetics, and Crime

Sidewalks and the perceived attractiveness of a neighborhood have effects on walking behaviors that are independent of socioeconomic status.[42] In addition, sidewalk presence seems to be protective for pedestrian safety in urban, residential, and mixed-use settings.[72,73] Although many new housing developments are encouraged to install sidewalks, installation is often waived with the substitution of other amenities.[62]

Safety concerns play an important role in how people respond to the built environment, with perception and fear of crime an important contributor to inactivity. Signs of disorderliness, such as broken windows, cue children to feel unsafe at school.[74] Children of parents who report anxiety about neighborhood safety get less physical activity.[75–77] A recent study that examined data on crime incidents showed that adolescent girls living near high-crime areas participate in less outdoor physical activity.[78] Urban design strategies may be able to foster "eyes on the street" to reduce fears by achieving

natural surveillance with storefronts that face the street or transit facilities (such as bus stops) that can be seen by shop owners or residents.[79] Living in a neighborhood considered "walkable" by objective methods was associated with more walking to school but only among neighborhoods with higher-level socioeconomic status.[80] This disparity may be attributable to the higher levels of concern about child safety found among parents in neighborhoods with lower socioeconomic status.

In 1999, California passed Safe Routes to School legislation, which funded improvements such as pedestrian crossings, sidewalks, and bicycle routes. Subsequent data have demonstrated that children walked to school more frequently after the improvements were made.[81] Because of the proven success of the California program, legislation established the Federal Safe Routes to School (SRTS) program in 2005, permitting communities to compete for funds administered by state departments of transportation.[82] This program funds a range of different approaches to increasing the number of children who walk to school, ranging from programs such as a walking school bus (groups of children walking to school under the supervision of volunteer adult) to traffic-calming engineering interventions or sidewalk improvements.[83]

Built Environment and Physical Activity: Translating Opportunity to Action

Research on relationships between the built environment and physical activity is an emerging field. Most studies are limited in that they are cross-sectional or focus only on adults. Nonetheless, the studies suggest that the built environment has a facilitative role in promoting child physical activity.[84–86] Furthermore, understanding relationships between the built environment and adult physical activity behaviors is important. Urban patterns that lengthen parents' time spent commuting to work may limit the time they have to engage in physical activity with their children. Factors that affect adult physical activity also affect the degree to which parents can serve as positive role models for their children. Ultimately, an environment in which physical activity is prohibitive will mean that our youth inherit a society in which sedentary behavior is the social norm.

Many communities are working to make their communities more walkable and bikeable and to make these activities more accessible and safe. These efforts provide timely research opportunities to examine the effects of built environment changes on children's physical activity.[86] However, the path from inactivity to activity is complex. Research will need to account for attitudes, beliefs, and social factors that influence behavior change, and interventions will require multifaceted approaches to overcome barriers that foster the status quo. Providing opportunities for physical activity through the built environment is only 1 of many important steps toward an active lifestyle.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Ask patients and families about opportunities for recreational and incidental physical activity in nearby parks, playgrounds, or open spaces. Identify barriers that could be preventing children from using community locations and offer suggestions, when possible.
2. Encourage patients to advocate on behalf of their children and their schools for relevant environmental improvements, such as Safe Routes to School programs or a walking school bus. When present in their communities, encourage families to participate and use these programs. Encourage families who are considering a move of residence to consider the opportunities for physical activity at the new location.
3. Advocate for environmental improvements that will promote physical activity in children. Become involved in local community planning processes to encourage cities and local governments to prioritize space for parks. Emphasize the need for built structures, such as playgrounds, which will provide more opportunities for physical activity. Advocate for safe routes for incidental activity opportunities, including walking or biking to school.

RECOMMENDATIONS FOR GOVERNMENT

1. Pass and promote laws and regulations to create new or expand existing efforts to promote active living. Federal programs can incentivize states to incorporate these principles into planning and zoning standards. State and local governments should examine planning and zoning efforts to ensure that children's ability to walk, play, and get to school safely are a top priority.
2. Create and maintain playgrounds, parks, and green spaces within communities as well as the means to access them safely. Prioritize resources to low-income neighborhoods to ensure that all children and adolescents have access to safe and desirable opportunities for play and active lifestyles. Funding should also be prioritized to support specific evidence-based goals, such as building sidewalks in new and existing neighborhoods to create safe corridors to schools and neighborhood parks.
3. Promote legislation and fund programs that allow communities to create programs and environmental improvements to neighborhoods that can support children's active commuting to school. Consider children's ability for active transportation to school in the process of determining the location of a school.
4. Fund research on the impact of the built environment at neighborhood and community levels on the promotion of overall health and active lifestyles for children and families.
5. Serve as a model for communities. Whenever possible, new government buildings should be sited within walking distance of public transportation, walking trails, and residential areas to promote active living.

CLINICAL REPORT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Section on Cardiology and Cardiac Surgery

Cardiovascular Health Supervision for Individuals Affected by Duchenne or Becker Muscular Dystrophy

ABSTRACT. Duchenne muscular dystrophy is the most common and severe form of the childhood muscular dystrophies. The disease is typically diagnosed between 3 and 7 years of age and follows a predictable clinical course marked by progressive skeletal muscle weakness with loss of ambulation by 12 years of age. Death occurs in early adulthood secondary to respiratory or cardiac failure. Becker muscular dystrophy is less common and has a milder clinical course but also results in respiratory and cardiac failure. The natural history of the cardiomyopathy in these diseases has not been well established. As a result, patients traditionally present for cardiac evaluation only after clinical symptoms become evident. The purpose of this policy statement is to provide recommendations for optimal cardiovascular evaluation to health care specialists caring for individuals in whom the diagnosis of Duchenne or Becker muscular dystrophy has been confirmed. *Pediatrics* 2005;116:1569–1573; *cardiovascular.*

ABBREVIATIONS. DMD, Duchenne muscular dystrophy; BMD, Becker muscular dystrophy.

INTRODUCTION

Duchenne muscular dystrophy (DMD) is a common genetic disease that affects approximately 1 in 3000 males. Becker muscular dystrophy (BMD) is less common, affecting approximately 1 in 30 000 males.[1] Both diseases result from a mutation in the gene located at Xp21,[2,3] which encodes dystrophin, a sarcolemmal protein abundant in skeletal and cardiac muscle cells.[4] Dystrophin is typically absent in DMD and reduced or abnormal in size in BMD.[5]

DMD typically is diagnosed between the ages of 3 and 7 years and is characterized by progressive skeletal muscle weakness with loss of ambulation between the ages of 7 and 13 years. The BMD phenotype is clinically more heterogeneous with initial presentation in the teenage years. Death secondary to cardiac or respiratory failure typically occurs in the second or third decade in DMD and in the fourth or fifth decade in BMD. Cardiac disease in both DMD and BMD manifests as a dilated cardiomyopathy and/or cardiac arrhythmia.[6,7] End-stage cardiac disease is characterized by alternating areas of myocyte hypertrophy, atrophy, and fibrosis.[8]

Over the last 20 years, respiratory care of this group of patients has improved as a result of the development of supportive equipment and techniques.[9] Consequently, dilated cardiomyopathy is increasing as the major cause of death.[10–12] The time course for the development of cardiomyopathy has not been well characterized; however, clinical studies demonstrate that the disease process in the heart is underway long before symptoms appear.[13–15] Early manifestations of heart failure often go unrecognized secondary to physical inactivity and a lack of classic signs and symptoms.[16] Signs of cardiac dysfunction may be vague and nonspecific, such as fatigue, weight loss, vomiting, or sleep disturbance. Currently at many medical centers, affected individuals do not come to the attention of the cardiac specialist until late in the disease process when the clinical manifestations of cardiac dysfunction become evident. This reactive, rather than proactive, approach must change if progress is to be made in the treatment of dilated cardiomyopathy in this patient population.[17] Sensitive and specific diagnostic tests to detect early and subtle manifestations of cardiac dysfunction are not available currently and need to be developed. Echocardiography, which remains the standard noninvasive diagnostic modality for cardiomyopathy, is often limited in patients with DMD and BMD by scoliosis and poor echocardiographic acoustic windows.

Cardiac rhythm abnormalities are frequent and play a significant role in morbidity and mortality in both DMD and BMD.[18] Electrocardiographic abnormalities can be seen early in the disease, with an incidence of 26% by 6 years of age.[16] Autonomic dysfunction with increased mean baseline heart rate and decreased rate variability has been well described.[19–21] However, the significance of these findings relative to the course of the cardiomyopathy has not been well established.

Treatment paradigms to date have been individually based and rely on evidence acquired from other patient populations. Cardiac dysfunction is treated by using standard heart-failure strategies that remain suboptimal. Unfortunately, there is minimal evidence-based literature regarding the use and effect of angiotensin-converting enzyme inhibitors or β-blockers

doi:10.1542/peds.2005-2448

on morbidity and mortality in this patient population.[22–24] Prospective clinical trials are required to evaluate the effectiveness of these treatments in this group of patients. Strategies that target the unique molecular etiology of heart failure in dystrophin-deficient individuals need to be developed if the cardiovascular care of patients with DMD and BMD is to improve.

The cardiovascular system must also be considered when addressing the diverse medical and surgical issues faced by patients with DMD and BMD. The administration of systemic glucocorticoids is becoming standard treatment for the skeletal muscle disease.[25–27] In addition to the potential to improve or stabilize cardiac function, there is the potential to increase long-term cardiovascular risk[28,29] including but not limited to the development of obesity and systemic arterial hypertension. Glucocorticoid treatment also may result in the development of left ventricular hypertrophy, with the potential of altering cardiac function.[30] At present, there is no uniformly accepted or standardized treatment protocol for glucocorticoid use.[31,32] Research is required to determine the cardiovascular effects of long-term glucocorticoid use in patients with DMD.

To manage the musculoskeletal complications in DMD and BMD, orthopedic surgical procedures are frequently recommended.[33,34] The patient with DMD or BMD faces unique risks not only in the operating room but also in the postoperative period.[35,36] Potential complications include respiratory failure, pulmonary aspiration, atelectasis or collapse of major lung segments, postoperative pneumonia, congestive heart failure, and cardiac arrhythmias. The patient with DMD or BMD often has a limited ability to increase cardiac output in response to stress and thus is at risk of inadequate oxygen delivery. Blood loss and fluid shifts during surgical procedures further compromise cardiac output and adequate oxygen delivery.[37] As a result, it is essential that baseline cardiac and pulmonary function be evaluated before any major surgical procedure. Patients with DMD or BMD have additional operative risks. Succinylcholine chloride should be avoided because of its predilection to cause a hyperkalemic response, which is different from malignant hyperthermia but is potentially as life threatening. Prolonged exposure to inhaled anesthetic agents should also be avoided, because they may provoke a life-threatening hypermetabolic state similar to malignant hyperthermia. All patients with DMD or BMD should be monitored during surgery by measuring expired carbon dioxide concentration and body temperature.[38–40]

The patient with DMD or BMD continues to be at risk during the postoperative period. Pain may worsen already compromised pulmonary mechanics, leading to additional increases in oxygen consumption. Treatment with narcotics may result in hypoventilation, which affects airway clearance. In addition, anemia or inadequate volume replacement can impair oxygen delivery. After major surgical procedures such as scoliosis surgery, the patient is likely to experience significant, prolonged fluid shifts, which markedly affect ventricular preload. Postoperative maintenance of fluid balance and cardiopulmonary monitoring is critical for this patient population.

Nutrition is also critical in the care and management of patients with DMD, because they require regular monitoring to maintain ideal body weight. Obesity and undernutrition are known to occur in this group of patients.[41,42] Both have been shown to be detrimental to cardiac health in other populations,[43] although there is a paucity of literature regarding the effect of nutrition on cardiovascular health in patients with DMD. Glucocorticoid-induced obesity and osteoporosis will further nutritionally affect the patient with DMD.

Patients with DMD and BMD may also be at increased risk of thromboembolic events secondary to the prothrombotic consequences of muscle degeneration.[44–48] This risk is amplified in the presence of cardiac dysfunction. As a result, anticoagulation therapy should be considered in this subgroup of patients. However, there is minimal evidence-based literature regarding the use and effect of anticoagulation therapy in these patients.

Optimal cardiac care cannot be accomplished without maximizing pulmonary function.[49] Hypoventilation and respiratory muscle weakness are known to increase wall stress.[50] Aggressive pulmonary care not only affects morbidity and mortality as a result of reducing respiratory complications but also functions to decrease afterload and left ventricular wall stress, resulting in improved cardiac output. In 2004, the American Thoracic Society released a consensus statement regarding the respiratory care of patients with DMD.[9] These recommendations should be considered carefully.

Female carriers of DMD or BMD are also at risk of developing cardiomyopathy. The age of onset of clinically significant disease is unclear but is thought to be in the adult years.[51] Cardiac involvement in the carrier can be variable, ranging from asymptomatic to severe heart failure necessitating cardiac transplantation.[52,53] Carriers, therefore, require periodic cardiovascular screening.[54,55] In addition, there is a critical need to research the natural history and outcome of therapies in female carriers.

Mutations in dystrophin clearly place affected individuals at risk of developing cardiac disease irrespective of skeletal muscle disease. The dystrophin gene has been shown to be the cause of X-linked dilated cardiomyopathy and some cases of sporadic dilated cardiomyopathy.[56–60]

Ultimately, investigation of cardiomyopathy in patients with DMD and BMD, as well as carriers, will benefit affected individuals, and new knowledge may lead to the elucidation of novel treatment strategies for dilated cardiomyopathy. Given the number of affected children and limited financial resources available for investigation, medical information must be pooled and shared for maximal effectiveness.

RECOMMENDATIONS FOR CARDIAC CARE IN PATIENTS WITH DMD OR BMD

1. Cardiac care of the patient with DMD or BMD should begin after confirmation of the diagnosis.

The patient should be referred for evaluation to a cardiac specialist with an interest in the management of cardiac dysfunction and/or neuromuscular disorders.
2. A complete cardiac evaluation should include (but not be limited to) a history and physical examination, electrocardiogram, and transthoracic echocardiogram. Consideration should be given to a multigated acquisition study (MUGA) or cardiac MRI in patients with limited echocardiographic acoustic windows.
3. Clinicians should be aware that the typical signs and symptoms of cardiac dysfunction may not be present secondary to the patient's musculoskeletal limitations. Weight loss, cough, nausea and vomiting, orthopnea, and increased fatigue with a decreased ability to tolerate the daily regimen may represent cardiac impairment and should be investigated. However, the development of dilated cardiomyopathy usually precedes the development of heart-failure symptoms by years and must be identified at its earliest onset.
4. Signs and symptoms of cardiac dysfunction should be treated. Consideration should be given to the use of diuretics, angiotensin-converting enzyme inhibitors, and/or β-blockers.
5. Abnormalities of cardiac rhythm should be promptly investigated and treated. Periodic Holter monitoring should be considered for patients with demonstrated cardiac dysfunction.
6. Respiratory abnormalities contribute to the cardiovascular morbidity and mortality of the disease. Concurrent evaluation and treatment of respiratory abnormalities are recommended.
7. Individuals undergoing treatment with glucocorticoids warrant increased cardiac surveillance with specific monitoring for weight gain and hypertension.
8. Complete cardiac evaluation should be undertaken before scoliosis surgery or other major surgical procedures. Consideration should be given to cardiac stress testing (such as a dobutamine stress echocardiogram) if abnormalities of cardiac function are present during resting evaluation. Medical therapy should be optimized before surgery, and the risks and benefits of the procedure should be discussed in detail with the patient and the family.
9. Intraoperative cardiac monitoring should be undertaken in individuals with DMD or BMD during major surgical procedures. Specific anesthetic techniques and decisions about intraoperative ventilation will depend on the patient and the procedure. Agents known to trigger hyperkalemia (eg, succinylcholine chloride) or a hypermetabolic state (eg, inhaled anesthetic agents) should be avoided. Cardiac monitoring should continue in the postoperative period.
10. Anticoagulation therapy should be considered in patients with severe cardiac dysfunction to prevent systemic thromboembolic events.
11. Clinicians who are experienced in the care of patients with DMD or BMD and are knowledgeable about the pathogenesis of the disease should be actively involved when patients are treated in an intensive care setting.
12. Nutritional status should be optimized to the special needs of patients with DMD or BMD.

RECOMMENDATIONS SPECIFIC FOR CARDIAC CARE IN PATIENTS WITH DMD

1. Patients should be routinely managed in early childhood with a complete cardiac evaluation at least biannually.
2. Yearly complete cardiac evaluations should begin at approximately 10 years of age or at the onset of cardiac signs and symptoms. However, individuals demonstrating these signs and symptoms are relatively late in their course.

RECOMMENDATIONS SPECIFIC FOR CARDIAC CARE IN PATIENTS WITH BMD

1. Complete cardiac evaluations should begin at approximately 10 years of age or at the onset of signs and symptoms. Evaluations should continue at least biannually.

RECOMMENDATIONS FOR CARDIAC CARE IN CARRIERS OF DMD OR BMD

1. Carriers of DMD or BMD should be made aware of the risk of developing cardiomyopathy and educated about the signs and symptoms of heart failure.
2. Carriers of DMD or BMD should be referred for evaluation by a cardiac specialist with experience in the treatment of heart failure and/or neuromuscular disorders. Patients should undergo initial complete cardiac evaluation in late adolescence or early adulthood or at the onset of cardiac signs and symptoms, if these signs or symptoms appear earlier.
3. Carriers should be screened with a complete cardiac evaluation at a minimum of every 5 years starting at 25 to 30 years of age.
4. Treatment of cardiac disease is similar to that outlined for boys with DMD or BMD.

POLICY STATEMENT

Cardiovascular Monitoring and Stimulant Drugs for Attention-Deficit/Hyperactivity Disorder

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

James M. Perrin, MD, Richard A. Friedman, MD, Timothy K. Knilans, MD, the Black Box Working Group, the Section on Cardiology and Cardiac Surgery

INTRODUCTION

A recent American Heart Association (AHA) statement[1] recommended electrocardiograms (ECGs) routinely for children before they start medications to treat attention-deficit/hyperactivity disorder (ADHD). The AHA statement reflected the thoughtful work of a group committed to improving the health of children with heart disease. However, the recommendation to obtain an ECG before starting medications for treating ADHD contradicts the carefully considered and evidence-based recommendations of the American Academy of Child and Adolescent Psychiatry[2] and the American Academy of Pediatrics (AAP).[3,4] These organizations have concluded that sudden cardiac death (SCD) in persons taking medications for ADHD is a very rare event, occurring at rates no higher than those in the general population of children and adolescents. Both of these groups also noted the lack of any evidence that the routine use of ECG screening before beginning medication for ADHD treatment would prevent sudden death. The AHA statement pointed out the importance of detecting silent but clinically important cardiac conditions in children and adolescents, which is a goal that the AAP shares. The primary purpose of the AHA statement is to prevent cases of SCD that may be related to stimulant medications. The recommendations of the AAP and the rationale for these recommendations are the subject of this statement.

ECG—electrocardiogram
ADHD—attention-deficit/hyperactivity disorder
AAP—American Academy of Pediatrics
SCD—sudden cardiac death

This statement has been endorsed by the American Academy of Child and Adolescent Psychiatry, the Society for Developmental and Behavioral Pediatrics, the National Initiative for Children's Healthcare Quality, the National Association of Pediatric Nurse Practitioners, and Children and Adults with Attention Deficit/Hyperactivity Disorder.

BACKGROUND

ADHD affects 5% to 8% of children and adolescents,[5,6] and stimulant medications have been shown for decades to be effective for treatment of the disorder.[4] Sudden death is rare in the pediatric population as a whole,[7] and screening to predict and hopefully prevent sudden death in the general population is a frequent topic of discussion. Despite the absence of scientific data to establish an increased risk of sudden death in individuals receiving stimulant medications for ADHD,[8] much attention has been directed to warning about and screening for causes of sudden death in this population.

Substantial evidence exists concerning the efficacy and safety of ADHD treatments, including both stimulant medications and behavior therapies.[4] Limiting children's access to effective treatment for ADHD could have serious implications, because there are substantial risks of not treating ADHD. Untreated ADHD in adolescence is associated with higher rates of substance use and abuse,[9] academic failure,[10] and automobile accidents.[11] Therefore, the evidence supporting any recommendation that may inhibit caregivers from treating ADHD effectively must be considered carefully.

STATEMENT OF THE PROBLEM

The AHA scientific statement[1] is controversial because of its extensive recommendations for children without heart disease and the lack of information on the methods used to arrive at its recommendations. Ultimately, the authors recommended that, in addition to a careful history, family history, and physical examination, "an ECG be added to increase the likelihood of identifying significant cardiac conditions such as HCM [hypertrophic cardiomyopathy], LQTS [long QT syndrome] and WPW [Wolff-Parkinson-White syndrome] that might place the child at risk." However, no data were provided that document a higher risk for patients with these diagnoses who are treated with stimulant drugs. In fact, elsewhere in the report, the authors stated: "We would agree with the conclusion of a recent

special article in *Pediatrics* that states that 'there does not seem to be compelling findings of a medication-specific risk necessitating changes in our stimulant treatment of children and adolescents with ADHD.' "[8]

In addition, the AHA scientific statement's final recommendation stated that "[t]he consensus of the committee is that it is reasonable and useful to obtain ECGs as part of the evaluation of children being considered for stimulant drug therapy. We recognize there are no clinical trials to inform us. . . . There are no widely accepted recommendations or standards of care for cardiac monitoring on stimulant medications. It is not known if the risk of SCD on stimulants is higher than in the general population or that the approach described will decrease the risk." Despite this lack of evidence, the authors assigned the recommendation, using AHA and American College of Cardiology classification, a class IIa (weight of evidence/opinion is in favor of usefulness/efficacy) and level of evidence C (only consensus opinion of experts, case studies or standard of care) label. The AAP and its constituent groups disagree with the AHA statement as to both the classification and the level of evidence. Using AHA criteria, the AAP would, at most, classify this recommendation as IIb ("the level of evidence is less well established by evidence/opinion. . . . Additional studies with broad objectives needed.") In addition, using the AAP classification of recommendations,[12] the AAP would assign the recommendation a category D level of evidence (on the basis of expert opinion without even observational studies.) The AAP avoids making guideline recommendations with level D evidence. Moreover, the substantial expert opinion and reasoning outlined in the AHA statement suggests that harm outweighs the benefit of recommending routine ECGs for healthy children who are starting stimulant medication for ADHD. Accordingly, the AAP would recommend against such routine ECG screening.

No relationship has been established between medicines used to treat ADHD and SCD. Specifically, the US Food and Drug Administration (FDA) has collected 25 anecdotal reports of sudden death documented during industry-sponsored medication trials as well as those reported for individual patients to the FDA. The mechanism that led to the sudden death of these patients is unknown. The frequency of sudden unexpected death among those taking stimulants is no higher than that in the general population of children. Only 19 children and adolescents of the 2.5 million taking stimulants died suddenly over 5 years, suggesting a base rate among children and adolescents of 4 incidents of sudden death per year per 2.5 million children or fewer than 2 incidents per million; however, reported rates of SCD in the general child and adolescent population are substantially higher, with reports varying from 8 to 62 per million.

Screening methods for underlying cardiac abnormalities, which could predispose to SCD, have typically included personal and family history and physical examination but have not routinely included electrocardiography and echocardiography. Assessment of personal and family history and a physical examination seem quite appropriate for a physician evaluating a patient with ADHD, for many reasons unrelated to risk of sudden death. Electrocardiography or echocardiography in this population would not otherwise be routine or recommended. Because the risk of sudden death in the population of patients pharmacologically treated for ADHD is no higher than that in the general population, performance of cardiac screening tests would not seem to be any more indicated than in the general population, and the AHA, along with the AAP, does not recommend routine ECG screening for children and adolescents because of problems with the sensitivity and specificity of the ECG as a general screening test.[13]

The AHA report provided no cost-effectiveness analysis to justify ECG screening of young people receiving ADHD medications or for special evaluation by pediatric cardiologists. It is important to note that, in some communities, difficulties in obtaining an ECG and pediatric cardiology consultation may serve as additional barriers to care for patients with ADHD.

SUMMARY

Although the sudden death of a child is a tragedy, there have been no studies or compelling clinical evidence to demonstrate that the likelihood of sudden death is higher in children receiving medications for ADHD than that in the general population. It has not been shown that screening ECGs before starting stimulants have an appropriate balance of benefit, risk, and cost-effectiveness for general use in identifying risk factors for sudden death. Until these questions can be answered, a recommendation to obtain routine ECGs for children receiving ADHD medications is not warranted.

The AAP recommends that clinicians carefully assess all children for cardiac abnormalities, including those in whom ADHD treatment is being considered, by using history and physical assessment. The AAP does not recommend the routine use of ECGs before initiating stimulant therapy for ADHD. An algorithm developed by the AAP Section on Cardiology and Cardiac Surgery and designed to aid clinicians in the evaluation of children on medicines to treat ADHD is shown in Fig 1.

The AAP shares the concern of the AHA about improving the diagnosis of silent but clinically significant cardiac conditions in children and adolescents and urges additional research into effective methods to detect these conditions and reduce the incidence of SCD.

RECOMMENDATIONS

1. The AAP continues to recommend a careful assessment of all children, including those starting stimulants, by using a targeted cardiac history (eg, patient history of previously detected cardiac disease, palpitations, syncope, or seizures; a family history of sudden death in children or young adults; hypertrophic cardiomyopathy; long QT syndrome) and a physical examination, including a careful cardiac examination (evidence quality: C; strength: recommendation).
2. Given current evidence, the AAP encourages primary care and subspecialty physicians to continue currently recommended treatment for ADHD, including stimu-

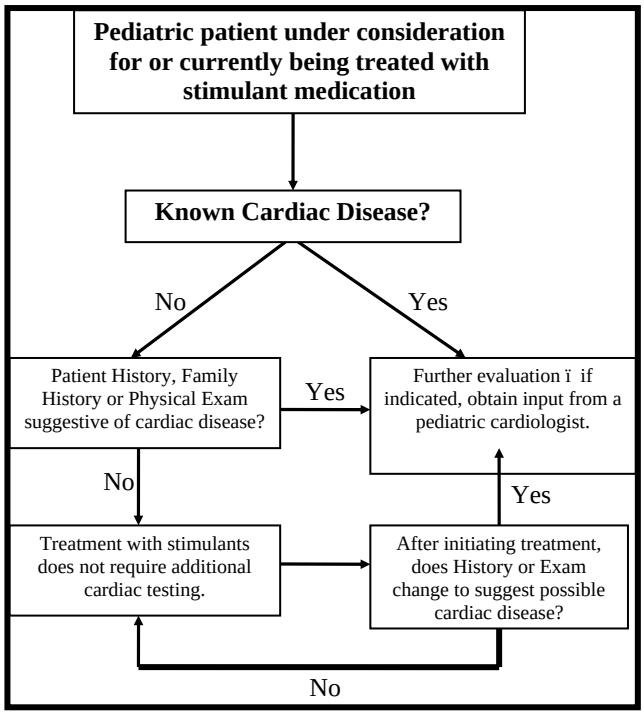

FIGURE 1
Cardiac evaluation of children and adolescents receiving or being considered for stimulant medications.

lant medications, without obtaining routine ECGs or routine subspecialty cardiology evaluations for most children before starting therapy with these medications (see Fig 1) (evidence quality: D; strength: option).

3. The AAP urges additional research on risk factors for SCD among all children and adolescents, including those with ADHD who are treated with stimulant medications. Improved methods for detecting hidden cardiac disease in children should be another focus of such research efforts.

AHA Scientific Statement

Cardiovascular Risk Reduction in High-Risk Pediatric Patients

A Scientific Statement From the American Heart Association Expert Panel on Population and Prevention Science; the Councils on Cardiovascular Disease in the Young, Epidemiology and Prevention, Nutrition, Physical Activity and Metabolism, High Blood Pressure Research, Cardiovascular Nursing, and the Kidney in Heart Disease; and the Interdisciplinary Working Group on Quality of Care and Outcomes Research

Endorsed by the American Academy of Pediatrics

Rae-Ellen W. Kavey, MD, MPH, FAHA, Chair; Vivek Allada, MD; Stephen R. Daniels, MD, PhD, FAHA; Laura L. Hayman, PhD, RN, FAHA; Brian W. McCrindle, MD, MPH; Jane W. Newburger, MD, MPH, FAHA; Rulan S. Parekh, MD, MS; Julia Steinberger, MD, MS

Abstractð Although for most children the process of atherosclerosis is subclinical, dramatically accelerated atherosclerosis occurs in some pediatric disease states, with clinical coronary events occurring in childhood and very early adult life. As with most scientific statements about children and the future risk for cardiovascular disease, there are no randomized trials documenting the effects of risk reduction on hard clinical outcomes. A growing body of literature, however, identifies the importance of premature cardiovascular disease in the course of certain pediatric diagnoses and addresses the response to risk factor reduction. For this scientific statement, a panel of experts reviewed what is known about very premature cardiovascular disease in 8 high-risk pediatric diagnoses and, from the science base, developed practical recommendations for management of cardiovascular risk. (***Circulation.*** **2006;114:000-000.)**

Key Words: AHA Scientific Statements ■ atherosclerosis ■ cardiovascular diseases ■ risk factors ■ prevention ■ pediatrics

The atherosclerotic process begins in childhood, with progression clearly shown to be mediated by the presence of identified risk factors. Pathological studies in children and young adults demonstrate that the extent of atherosclerotic vascular change is associated with both the number of premortem risk factors and their intensity.[1ï6] In vivo noninvasive studies relate each of the known risk factors measured in childhood to abnormalities of vascular structure and function.[7ï19] Finally, a decrease in number or intensity of risk factors is associated with improvement in the vascular abnormalities.[20ï24]

For most children, the degree of vascular involvement is minor, the rate of progression is slow, and the appropriate therapeutic approach is preventive, with an emphasis on healthy lifestyles and behavior modification.[25,26] By contrast, certain pediatric disease states are associated with dramatically accelerated atherosclerosis, with clinical coronary events occurring in childhood or very early in adult life. A classic example is homozygous hypercholesterolemia, in which markedly elevated low-density lipoprotein (LDL) cholesterol levels are associated with coronary disease in the first decade of life.[27] Another is Kawasaki disease, in which

coronary pathology developed as part of the acute disease process predisposes patients to very early coronary events.[28] For children with diagnoses like these, intensive cardiovascular risk reduction is of critical importance. However, awareness of the risk for premature atherosclerosis is often limited when the main focus of medical care is the complex primary diagnosis. The goal of this statement is to summarize the evidence for accelerated atherosclerosis in high-risk pediatric settings and to present guidelines for cardiovascular risk management. The recommendations are directed toward both the pediatric care providers and the subspecialists who manage the primary disease process in these complex young patients.

The statement was developed by a writing group convened under the joint direction of the American Heart Associationõs Expert Panel on Population and Prevention Science and the Council for Cardiovascular Disease in the Young, cosponsored by the Councils on Epidemiology and Prevention, Nutrition, Physical Activity, and Metabolism, High Blood Pressure Research, Cardiovascular Nursing, and the Kidney in Cardiovascular Disease and by the Quality of Care and Outcomes Research Working Group. Members were nominated by ≥1 of these scientific councils and are each recognized experts in premature atherosclerosis beginning in childhood. The group selected 8 pediatric disease settings for inclusion: (1) familial hypercholesterolemia; (2) diabetes mellitus, type 1 and type 2; (3) chronic kidney disease; (4) heart transplantation; (5) Kawasaki disease; (6) congenital heart disease; (7) chronic inflammatory disease; and (8) childhood cancer. For each, the evidence for early coronary disease was reviewed by an expert in the area. On the basis of the risk of manifest coronary disease in childhood and very early adult life, a stratification protocol was established, and each disease was classified as follows (Table 1):

Tier I: Pathological and/or clinical evidence for manifest coronary disease before 30 years of age
Tier II: Pathophysiological evidence for arterial dysfunction indicative of accelerated atherosclerosis before 30 years of age
Tier III: Increased cardiovascular risk factors with epidemiological evidence for manifest coronary disease with or without arterial dysfunction early in adult life but after 30 years of age

Recommendations for cardiovascular risk identification and reduction specific to each disease setting were developed as a consensus of the group, and an algorithm was developed outlining the risk factor evaluation and management strategy by disease tier (Figure). As in current risk-reduction recommendations for adults and for children with type 1 diabetes, critical levels for intervention and goals for risk reduction have been tailored to the risk intensity (Table 2).[29,30] For children with diagnoses in tier I, complete risk factor assessment is recommended, and therapy is instituted essentially at the time of diagnosis, aimed at maximally decreasing risk factor levels; the intervention strategy for tier I patients regards the diagnosis as a ñcoronary heart disease equivalent,ò with recommendations similar to the secondary prevention guidelines for adults with established coronary disease (Table 3). For children in tier II, complete assessment of all risk factors is recommended, with defined therapeutic goals. For children in tier III, complete risk factor assessment is recommended, with therapeutic goals as recommended for children in general.

In this era of evidence-based medicine, most scientific statements require positive results from multiple randomized trials to recommend any intervention. To date, no randomized trials beginning in childhood have demonstrated an improvement in hard clinical cardiac end points in response to risk factor reduction; given the major cost and time limitations, the potential for such trials in the near future seems low. There is, however, a large and growing knowledge base in pediatric populations with regard to the presence of accelerated atherosclerosis, the relationship of the atherosclerotic process to the presence and intensity of risk factors, and the response to risk factor change at the vascular level. The present scientific statement is not intended to preclude or inhibit the design and execution of future randomized treatment trials. Rather, we hope to assist physicians in learning what is already known about increased risk for premature atherosclerosis in children with these diagnoses, as well as the range of approaches to risk assessment and treatment. Until evidence-based data are available, the present statement provides practical interim recommendations based on a consensus of the group after a careful review of the available science for each diagnosis, including all published guidelines. Typical statements about level of evidence and the strength of

TABLE 1. Disease Stratification by Risk

	Risk Category	Rationale	Disease Process/Condition
Tier I	High risk	Manifest CAD <30 years of age: Clinical evidence	Homozygous familial hypercholesterolemia (FH)
			Diabetes mellitus, type 1
			Chronic kidney disease (CKD)/end-stage renal disease (ESRD)
			Post–orthostatic heart transplantation (OHT)
			Kawasaki disease with current coronary aneurysms
Tier II	Moderate risk	Accelerated atherosclerosis: Pathophysiological evidence	Heterozygous FH
			Kawasaki disease with regressed coronary aneurysms
			Diabetes mellitus, type 2
			Chronic inflammatory disease
Tier III	At risk	High-risk setting for accelerated atherosclerosis: Epidemiological evidence	Post–cancer-treatment survivors
			Congenital heart disease
			Kawasaki disease without detected coronary involvement

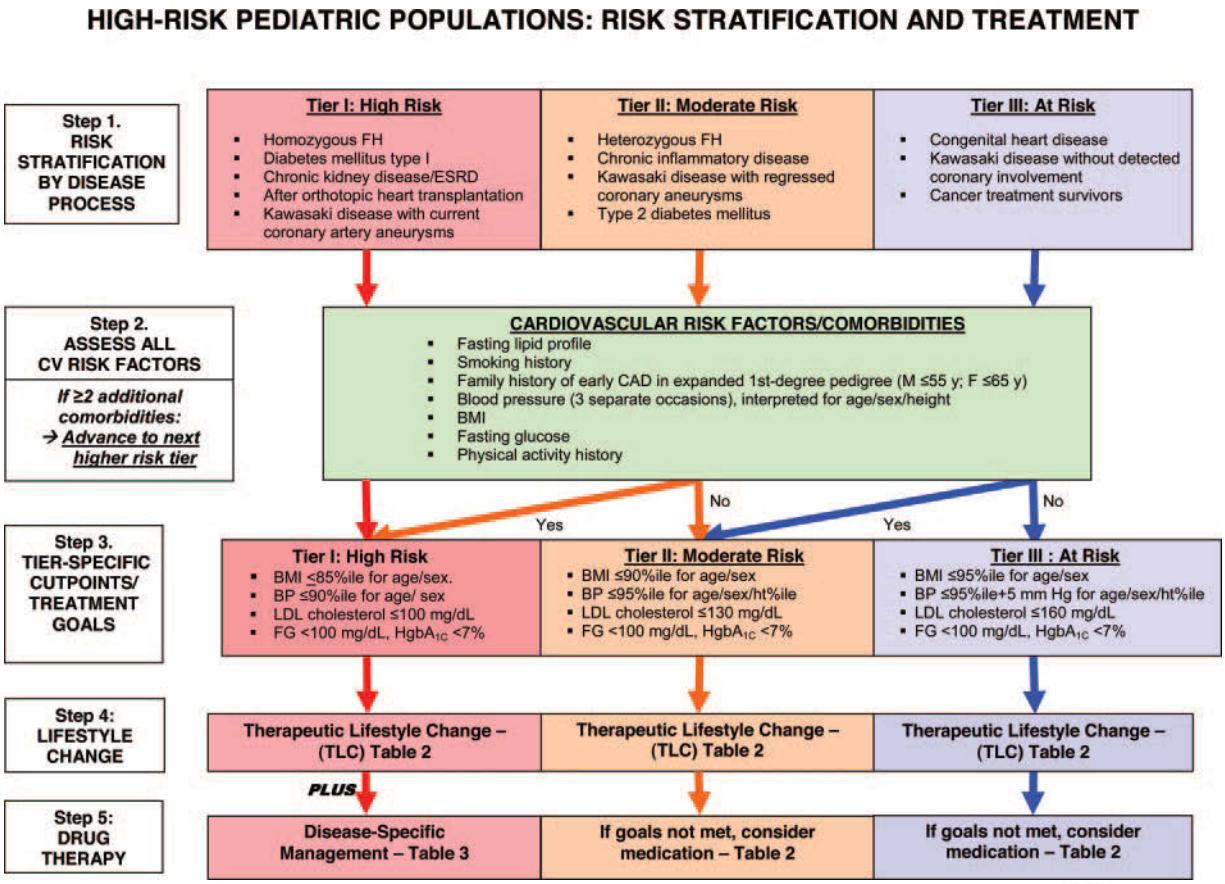

Figure. Risk-stratification and treatment algorithm for high-risk pediatric populations.

Directions: *Step 1:* Risk stratification by disease process (Table 1). *Step 2:* Assess all cardiovascular risk factors. If there are ≥2 comorbidities, assign patient to the next higher risk tier for subsequent management. *Step 3:* Tier-specific treatment goals/intervention cut points defined. *Step 4:* Initial therapy: For tier I, initial management is therapeutic lifestyle change (Table 2) PLUS disease-specific management (Table 3). For tiers II and III, initial management is therapeutic lifestyle change (Table 2). *Step 5:* For tiers II and III, if goals are not met, consider medication as outlined in Table 2.

CV indicates cardiovascular; BP, blood pressure; %ile, percentile; FG, fasting glucose; $HgbA_{1c}$, hemoglobin A_{1c}; ht%ile, height percentile; pt, patient; and TLC, therapeutic lifestyle change.

each recommendation are not included. For easy access, references for each section of the report are grouped together.

Familial Hypercholesterolemia

Introduction

Aggressive management of hyperlipidemia in adults, particularly directed toward lowering LDL cholesterol levels, has led to major reductions in cardiovascular morbidity and mortality. In children and adolescents, hyperlipidemia may be secondary to associated conditions such as medications or obesity, but extreme LDL elevations are more commonly associated with primary or genetic hyperlipidemias.[47] Both types of lipid abnormalities have been shown to be associated with vascular pathology in youth: a greater extent of vascular involvement, with fatty streaks and fibrous plaques at autopsy; higher presence of coronary artery calcium by electron-beam computed tomography; and increased carotid intima-media thickness, reduced arterial distensibility and compliance, and endothelial dysfunction by ultrasound.[7,48,49] Increasing evidence indicates that appropriate therapy can reverse these changes.[20,21] Of the primary hyperlipidemias, familial hypercholesterolemia (FH) is the most common and the most clearly documented to have important cardiovascular consequences beginning in childhood.[49–52] Therefore, the identification and management of FH in children is of great consequence.[53]

Pathophysiology

FH is an autosomal dominant monogenetic condition. Homozygous hypercholesterolemia is rare, with an occurrence of 1:1 000 000 individuals, but the heterozygous state exists in the general population with an incidence of 1:500. It is the most common monogenetic disorder in North America and Europe. Certain populations have a higher frequency and greater concentrations of specific mutations.

The genetic defect is characterized by various mutations that affect the production and processing of cell-surface LDL receptors.[54–56] Defectiveness or deficiency of these receptors results in impaired hepatic clearance of circulating LDL particles, which leads to their accumulation in the bloodstream. A similar phenotype can be produced by mutations in the receptor that recognizes apolipoprotein B100 protein on the surface of LDL particles, known as familial defective apolipoprotein B100.[57,58]

The elevated levels of LDL contribute to accelerated atherosclerosis, with manifest cardiovascular disease within the first 2 decades of life for homozygotes[59] and beginning in early to mid-adulthood for heterozygotes.[60] Elevated LDL levels are evident before birth[61] and persist throughout the lifespan.

Homozygous FH can be distinguished from heterozygous FH clinically by the much more extreme elevations in LDL and can be confirmed by either genetic characterization of the LDL receptor mutations (from leukocytes) or by quantification of LDL receptor activity (from skin fibroblasts). Children with homozygous FH have more severe and earlier functional and structural vascular abnormalities, including clinical coronary artery disease (CAD), aortic valve disease, and aortic disease, beginning in the first decade of life.[59]

Children with heterozygous FH have been shown to have abnormalities on noninvasive vascular assessments, including greater carotid-intima media thickness and abnormal arterial endothelial function.[11,13,49,62–64] Effective lipid-lowering therapy has been shown to improve these abnormalities.[20,21]

Identification

Children with homozygous FH usually present within the first decade of life, most commonly after investigation of physical findings related to cholesterol deposition, such as tendon xanthomata, cutaneous xanthelasma, or corneal arcus, or with clinical manifestations of atherosclerotic cardiovascular disease.[59] Children and adolescents with heterozygous FH are asymptomatic, with no findings on physical examination related to their hypercholesterolemia.[65] Often, they present with either elevated LDL levels noted on blood screening or after investigation prompted by a family history of premature cardiovascular disease or hyperlipidemia.

The lipid profile abnormalities are strikingly abnormal in homozygous patients. Although LDL levels vary between individuals, they are often in the 15- to 25-mmol/L (500- to 1000-mg/dL) range, with high-density lipoprotein (HDL) levels reduced between 0.5 and 1.0 mmol/L (20 to 40 mg/dL). Both parents will have lipoprotein profiles consistent with heterozygous FH. Although not necessary for clinical management, determination of an LDL receptor mutation on skin biopsy or leukocyte culture confirms the diagnosis.

In heterozygous FH, fasting lipoprotein profile characteristics include LDL levels well above the 95th percentile for age and gender, often associated with low HDL and normal triglyceride levels. Additional criteria include the presence of a parent with a similar profile in a family with a history of premature cardiovascular disease in conjunction with tendon xanthomata.[66] Determination of an LDL receptor mutation is not routinely performed.

A Dutch study of 1034 children with heterozygous FH showed that an LDL level >3.5 mmol/L (135 mg/dL) had a 98% posttest probability of the presence of an LDL receptor mutation.[65] Mean LDL levels were 5.8 mmol/L (225 mg/dL) for girls and 5.42 mmol/L (210 mg/dL) for boys. A positive family history of premature cardiovascular disease in a first-degree relative was present for 31% of children. Children of a parent with FH and premature cardiovascular disease had higher LDL, lower HDL, and higher lipoprotein(a) levels. Children with lower HDL levels were heavier and had higher triglyceride levels. LDL levels appeared to be independent of lifestyle or anthropometric characteristics.

Risk Factors/Comorbidities

A study of 2400 heterozygous FH Dutch adults showed that during 112 943 person-years of follow-up, 33% had at least 1 atherosclerotic cardiovascular event, predominantly clinical CAD.[66] Male gender, smoking, hypertension, diabetes mellitus, low HDL, and elevated lipoprotein(a) levels were shown to independently contribute to the development of cardiovascular disease.

Treatment Recommendations for Children With FH

Children With Homozygous FH Who Are at High Risk for Very Early Cardiovascular Disease (Tier I)

- Complete cardiovascular assessment is necessary at diagnosis, because important subclinical cardiovascular disease requiring intervention may already be present.[59]
- Treatment should be instituted as soon as possible.[41,67,68] The cornerstone of therapy in the majority of patients is weekly or biweekly plasmapheresis, preferably LDL apheresis.[67,69] Although the majority of lipid-lowering drugs lower LDL primarily by feedback mechanisms that upregulate LDL receptor activity, patients with homozygous FH may still benefit.[68,70] Use of high-dose statins is therefore recommended, in combination with a cholesterol absorption inhibitor.
- Low-dose anticoagulation may also be indicated. Ongoing surveillance for cardiovascular disease is essential.
- The presence of homozygous FH mandates intensive therapy aimed at reducing LDL levels. Interventions to prevent or reduce associated risk factors are important, but the critical therapy is lipid lowering.

Children With Heterozygous FH Who Are at Moderate Risk for Premature Cardiovascular Disease (Tier II)

- Routine cardiovascular assessment is not generally indicated, although referral to a lipid specialist is recommended.
- The presence of heterozygous FH merits therapy focused primarily at reducing LDL levels.[71,72] Lifestyle interventions are important to prevent or reduce associated risk factors but are insufficient for lipid lowering.[73–76]
- There is uniform consensus that lipid-lowering drug therapy is the cornerstone of management in adults, but considerable controversy exists over when to initiate pharmacological treatment in children.[77] Randomized clinical trial results indicating a decline in future atherosclerotic disease in response to lipid-lowering therapy begun in childhood are not available. However, extrapolation from adult studies suggests that lipid-lowering therapy should be considered when LDL cholesterol levels are severely elevated. The only existing guideline, from 1991, recommends consideration of drug therapy after 10 years of age in children with specific LDL cutpoints.[36] We are in general agreement with this recommendation, but we also recommend tailoring therapy to each child, considering actual LDL levels, sex, presence of other risk

factors, and important family history of premature disease. The wishes of the family with regard to drug therapy also need to be taken into account. Thus, there is room for discretion and clinical judgment.

- When the decision is made to begin drug treatment, initial therapy with a statin is recommended, because bile-acid binding resins[78–81] and cholesterol absorption inhibitors (not yet studied in children) are usually inadequate alone to achieve sufficient LDL reduction.[52,82] Several recent studies of statins in children have shown similar safety and efficacy as in adults.[21,83–87]
- Statin therapy is recommended at age ≥10 years in males and after the onset of menses in females.[77] In selected patients with extremely high LDL levels, associated lipid abnormalities or other risk factors, or the presence of a particularly worrisome family history, statin therapy may be initiated at a younger age. Appropriate safety monitoring and surveillance of growth and development is recommended.[77] The use of bile-acid binding resins and the cholesterol absorption inhibitors should be considered important adjunctive therapy in combination with a statin.
- Some evidence suggests that consumption of plant sterol esters may be a useful adjunct to therapy.[88–91] Other therapies, such as antioxidant vitamins[92,93] and docosahexanoic acid,[94] are more controversial, and some other complementary therapies have been shown to have no therapeutic effect.[95]
- Identification and treatment of comorbidities have been shown to be effective. Specific management is outlined in the algorithm shown in the Figure and in Tables 2 and 3.

Diabetes Mellitus

Introduction

Diabetes mellitus, a metabolic disease characterized by hyperglycemia that results from defects in insulin secretion (type 1) and insulin action (type 2), is associated with accelerated development of vascular disease. Diabetic vascular disease in children and adolescents with type 1 diabetes mellitus is represented mainly by microangiopathy that involves the eye and kidney. In adults with diabetes, microangiopathy persists and is responsible for the high incidence of renal failure; however, a major cause of morbidity and early mortality is macroangiopathy, characterized by clinical cardiovascular, cerebrovascular, and peripheral vascular disease.[96–98]

Because insulin is the only significant hypoglycemic hormone, hyperglycemia is the result of impaired secretion of insulin; resistance to the effect of insulin in liver, muscle, and fat cells; or a combination of these pathophysiological situations. Insulin resistance is very frequently seen in association with obesity, particularly abdominal obesity.

The most recent criteria for diagnosis of diabetes recommended by the American Diabetes Association are as follows[99]:

1. Symptoms of diabetes (polyuria, polydipsia, or unexplained weight loss) plus casual plasma glucose concentration ≥200 mg/dL (11.1 mmol/L). (ñCasualò means any time of day, without regard to time since last meal.) *OR*
2. Fasting plasma glucose concentration ≥126 mg/dL (7.0 mmol/L). Fasting is defined as no caloric intake for at least 8 hours. *OR*
3. Two-hour plasma glucose concentration ≥200 mg/dL (11.1 mmol/L) during an oral glucose tolerance test. The test should be performed as described by the World Health Organization with a glucose load that contains the equivalent of 75 g of anhydrous glucose dissolved in water.
4. Current American Diabetes Association guidelines recommend 100 mg/dL as the upper limit of normal for fasting glucose in adults.
5. In the absence of unequivocal hyperglycemia with acute metabolic decompensation, these criteria should be confirmed by repeat testing on a different day. An oral glucose tolerance test is not recommended for routine clinical testing.

The progression from insulin resistance and impaired carbohydrate metabolism to type 2 diabetes mellitus has been documented in adults[100,101] and children.[102,103] In adults, weight loss has been shown to reverse this, with frank diabetes regressing to insulin resistance.[104] Patients with impaired fasting glucose and/or impaired glucose tolerance are referred to as ñprediabetic,ò which acknowledges the relatively high risk for development of frank diabetes.[105] With the current obesity epidemic and its metabolic consequences, the identification of children with early prediabetes is very important, because appropriate management may decrease the progression to overt diabetes. The Expert Committee on the Diagnosis and Classification of Diabetes Mellitus defines impaired fasting glucose as >100 mg/dL (5.6 mmol/L) but <126 mg/dL (7.0 mmol/L) and impaired glucose tolerance as 2-hour oral glucose tolerance test values >140 mg/dL (7.8 mmol/L).[99,106] Specific guidelines have been defined for screening for type 2 diabetes mellitus in obese children, particularly those from high-risk racial/ethnic groups (Native American, Hispanic-American, black, Asian, and Pacific Islander), those with a positive family history of type 2 diabetes mellitus, and those with physical signs of insulin resistance.[37]

Epidemiology: Type 1 Diabetes Mellitus

Epidemiological data from the Third National Health and Nutrition Examination Survey (NHANES III) reveal that the prevalence of type 1 diabetes mellitus in adolescents is 1.7/1000. Although limited, data show a significant increase in atherosclerosis in adolescents and young adults with diabetes relative to nondiabetics.[107–109]

Adolescents with type 1 diabetes mellitus have increased levels of subclinical atherosclerosis as measured by carotid intima-media thickness and by radial tonometry.[110–112] In children, type 1 diabetes mellitus is independently associated with oxidative modification of LDL cholesterol.[113]

Pathogenesis of Premature Atherosclerosis: Type 1 Diabetes Mellitus

Hyperglycemia is the primary mediator of atherosclerosis in type 1 diabetes mellitus; insulin therapy to control this should be under the direction of endocrinology specialists. Hyperglycemia causes raised levels of atherogenic, cholesterol-

enriched, apolipoprotein Bï containing remnant particles by reducing the expression of heparin sulfate.[114]

Autopsy studies in young adults with fatal myocardial infarction and type 1 diabetes mellitus showed that the atherosclerotic plaque in these patients was more dense in fibrous tissue than the more calcific plaques of nondiabetic individuals; this may influence the timing and severity of clinical disease in these patients.[115] In addition, microalbuminuria is a predictor of increased risk for vascular complications.[116]

In defining risk for adults, the presence of type 1 diabetes mellitus is considered the equivalent of a history of coronary disease.[98] The intensity of lipid-lowering therapy is correspondingly increased in this setting.

Epidemiology: Type 2 Diabetes Mellitus

In 2003, the US Centers for Disease Control and Prevention reported that 40% (5.2 million) of all diabetic individuals >35 years of age had been diagnosed with cardiovascular disease. Although it was previously considered a disease of adults, in the past decade, type 2 diabetes mellitus has become a far more common occurrence in the pediatric population. Depending on the ethnic composition of the population, between 8% and 50% of newly diagnosed adolescent diabetic patients have type 2 diabetes mellitus.[117,118] Data from NHANES III reveal that the prevalence of type 2 diabetes mellitus in adolescents is 4.1/1000. These increases coincide with increasing rates of overweight and physical inactivity in children.[119]

Because type 2 diabetes mellitus is a relatively recent problem in adolescents, few long-term follow-up data exist. One study of Pima Indians followed a cohort of 36 individuals for a mean of 10 years to a median age of 26 years. At baseline (age 5 to 19 years), 85% were obese, and 14% had hypertension, whereas 30% had total cholesterol >200 mg/dL, and 55% had triglyceride concentrations >200 mg/dL. Fifty-eight percent of the patients had microalbuminuria, and 16% had a urinary albumin/creatinine ratio >300 mg/g, which indicates that the renal effects of diabetes were already present at diagnosis. After 10 years of follow-up, the number of patients with increased urinary albumin excretion was increased significantly, as was the magnitude of albuminuria, which is evidence of increased cardiovascular risk over that relatively short period of time.[120]

In adults, the metabolic syndrome is now an extremely common diagnosis. This cluster of findings (abdominal obesity, insulin resistance, dyslipidemia, and hypertension) frequently appears together and has been shown to predict future overt diabetes and early cardiovascular disease.[121] There is no current definition for metabolic syndrome in children, but the components of this diagnosis are known to cluster together as they do in adults.[122] Presence of the components of the metabolic syndrome in adolescence has been shown to predict early cardiovascular disease.[123] Although no current guidelines address management of the metabolic syndrome in children, it is important to identify and address the individual elements of the syndrome whenever a child presents with obesity.

Pathogenesis of Premature Atherosclerosis: Type 2 Diabetes Mellitus

Both hyperglycemia and insulin resistance are implicated in endothelial dysfunction, to a greater degree in type 2 diabetes mellitus than in type 1.[124] Microalbuminuria is a predictor of increased risk for vascular complications.[116]

Insulin resistance has been implicated in the development of dyslipidemia by enhancing hepatic synthesis of very-low-density lipoprotein (VLDL), which results in increased plasma triglyceride and LDL cholesterol levels.[125] Resistance to the action of insulin on lipoprotein lipase in peripheral tissues may also contribute to elevated triglyceride and LDL cholesterol levels.[126,127] Insulin resistance may also be responsible for the reduced levels of HDL cholesterol observed in type 2 diabetes mellitus, and this is accounted for by an increase in the rate of apolipoprotein A1/HDL cholesterol degradation, which exceeds the rate of its synthesis.[128] The increase of triglyceride-rich lipoproteins due to both exaggerated postprandial lipemia and VLDL overproduction in the face of low lipoprotein lipase activity results in long residence time of these particles in circulation and the formation of small, dense LDL.

Insulin resistance is also associated with hypertension through urinary sodium retention, increased sympathetic nervous system activity,[129] and stimulation of vascular smooth muscle growth.[130] Insulin levels have been found to be significantly higher in adult patients with essential hypertension[131ï 133] and borderline hypertension[134] than in normotensive control patients. In addition hyperinsulinemia is known to directly stimulate the formation of the atherogenic plaque by promoting smooth muscle proliferation, connective tissue formation, and LDL deposition in the plaque.

Other intrinsic metabolic factors such as apolipoproteins, lipoprotein(a), and homocysteine are known to influence the development of cardiovascular disease; their potential relationship to insulin resistance remains to be clarified. Free fatty acids may also stimulate, either independently or in concert with hyperglycemia, the production of reactive oxygen species (oxidative stress),[135] which has been associated with target-organ damage such as that related to diabetes and atherosclerotic cardiovascular disease.[136] Finally, oxidative stress is associated with an increase in insulin resistance.[137]

Risk Factors/Comorbidities

Patients with type 2 diabetes mellitus often have other risk factors for cardiovascular disease. It is believed that obesity leads to insulin resistance and increased circulating insulin concentrations over time. At some point, a loss of control of blood glucose begins to emerge, resulting in dietary glucose intolerance and ultimately in type 2 diabetes mellitus. Obese individuals develop different degrees of insulin resistance, and not all those with obesity develop glucose intolerance. Obesity-associated insulin resistance varies significantly with genetic background. Black children are more insulin resistant than age-, sex-, and body mass index (BMI)ï matched white children.[138] The factors that make some individuals more likely to progress to type 2 diabetes mellitus are not well understood at the present time.[139] A strong family predisposition is known to exist, and parental history is therefore

important in risk assessment. In the future, genetic markers may help identify those offspring of diabetic parents who are at greatest risk of developing diabetes. Children with type 2 diabetes mellitus are usually diagnosed after 10 years of age and are almost always obese. The mean BMI in clinical series has ranged from 26 to 38 kg/m^2.[117,118] Current American Diabetes Association guidelines recommend routine glucose testing in obese children >10 years of age with 2 additional risk factors for type 2 diabetes mellitus.[37]

The prevalence of hypertriglyceridemia has ranged from 4% to 32%.[113,114] Weight control improves glucose tolerance, with a recommended weight loss in adults of 10% to 15%.

The prevalence of hypertension has ranged from 17% to 32%. Essential hypertension is known to be associated with diabetes in adults,[139] and it is estimated that the cardiovascular risk doubles when hypertension and diabetes coexist. Prevalence data are not available for hypertension in children with diabetes.

Exercise training improves insulin sensitivity and endothelial vascular function beyond the benefits of glycemic control and blood pressure reduction in children and adults.[140,141] Agents such as metformin and thiazolidinediones have been used effectively in adolescents with type 2 diabetes mellitus and have been shown to decrease BMI and improve glucose tolerance.[142,143]

Recommendations in Children With Diabetes Mellitus

Children With Type I Diabetes Mellitus Who Are at High Risk for Early Cardiovascular Disease (Tier I)

Optimal management of hyperglycemia will modify this risk, but aggressive management of related risk factors has been shown to improve outcome and is recommended. Specific management recommendations are presented in the algorithm (Figure) and accompanying tables.

Children With Type 2 Diabetes Mellitus Who Are at Moderate Risk for Cardiovascular Disease (Tier II)

The differences between type 1 and type 2 diabetes mellitus are significant: Age at presentation for type 1 diabetes mellitus is younger, with 25% of patients diagnosed between 5 and 10 years of age and another 40% between 10 and 15 years of age; typically, the degree of hyperglycemia in type 1 diabetes mellitus is severe, and patients are very symptomatic. By contrast, type 2 diabetes mellitus diagnosed in childhood usually presents asymptomatically, with mild to moderate hyperglycemia in adolescence in combination with obesity, signs of insulin resistance, and other components of the metabolic syndrome. When type 2 diabetes mellitus begins in childhood, the risk for accelerated atherosclerosis is increased beyond that seen in those who develop this diagnosis as adults, but less than when type 1 diabetes mellitus is diagnosed in a child. Specific recommendations for management are contained in the algorithm (Figure) and accompanying tables; using the treatment algorithm, patients with type 2 diabetes mellitus are defined as being at moderate risk but will almost always be managed as ñhigh riskò because of associated comorbidities.

Pediatric Chronic Kidney Disease

Introduction

Success with renal replacement therapy has lengthened the life expectancy of children with chronic kidney disease (CKD) and end-stage renal disease (ESRD). Now, morbidity and mortality in children with CKD/ESRD are not only related to chronic renal failure and renal replacement therapy but also to cardiovascular disease as a result of prolonged exposure to cardiovascular risk factors.

Epidemiology

Cardiovascular disease now accounts for the majority of deaths in adults with ESRD and approximately one fourth of pediatric ESRD deaths.[144–146] The cardiac abnormalities associated with ESRD include pericardial disease, arrhythmias, abnormalities of left ventricular function, and CAD.[144,145] Twenty percent of hospitalizations in pediatric ESRD patients enrolled in Medicare are reported to be due to arrhythmias, 10% to cardiomyopathy, and 3% to a cardiac arrest.[147] The incidence of cardiomyopathy reported among pediatric ESRD patients doubled over the 6-year period from 1991 to 1996.[147]

Pathogenesis

The mechanisms that lead to cardiovascular disease in CKD primarily originate with vascular or myocardial injury from a multitude of highly prevalent cardiovascular risk factors in renal failure, and perhaps uremia itself. Damage to the vascular endothelium and left ventricle manifests as accelerated CAD and cardiomyopathy and has been described extensively in adults undergoing dialysis or after kidney transplantation. In children with CKD, subclinical manifestations of vascular disease have been reported.

Subclinical evidence of atherosclerosis with intimal plaque has been reported in pediatric ESRD. In a series of children with iliac artery biopsy at the time of transplantation, atherosclerosis in the uropathy group was also associated with increased serum calcium and longer duration of dialysis.[148]

Medial vessel calcification and arteriosclerosis or Mönckebergös arteriosclerosis has also been reported in the pediatric ESRD population, with vascular calcification in the coronary arteries, aorta, peripheral vessels, and aortic valve. An autopsy series of subjects with CKD revealed soft tissue calcification in 60% of the pediatric patients, half of whom were undergoing dialysis at the time of death.[149] In a small autopsy series, 4 of 8 had evidence of arteriosclerosis, diffuse vascular calcification, and calcified valves.[150]

There is evidence of significant left ventricular hypertrophy in children with CKD and ESRD.[151] Depending on the setting and the classification system used, hypertrophy is reported in 40% to 75% of the pediatric ESRD population.[152–156] At initiation of dialysis, 69% of subjects 4 to 18 years of age had evidence of left ventricular hypertrophy.[152] Postmortem studies have shown >50% of children with ESRD have evidence of left ventricular hypertrophy.[150]

Decreased arterial wall compliance is also common among dialysis patients, coincident with worsening left ventricular hypertrophy.[157] Stiffness of the aorta has been shown to be higher in children undergoing dialysis than in healthy control subjects.[157] Carotid artery compliance has been shown to be

significantly lower in children undergoing dialysis, with the decrease correlating significantly with age and blood pressure.[157]

Risk Factors/Comorbidities

Most risk factors for the development of cardiovascular disease are highly prevalent in CKD. Hypertension is seen in 49% of children with CKD[158] and 50% to 60% of patients undergoing dialysis.[159] Hypertension is even more common in the transplant population, with 65% to 80% of patients being treated.[159] In the young adult population, 18 to 35 years of age, systolic hypertension occurs in 51% and diastolic hypertension in 35% of the dialysis population.[160]

Approximately 29% to 87% of pediatric peritoneal dialysis patients have elevated cholesterol levels, with LDL >100 mg/dL (>2.29 mmol/L).[44] Similarly, 72% to 84% of pediatric kidney transplant recipients had LDL >100 mg/dL (>2.29 mmol/L).[44] In ESRD, triglycerides are consistently elevated, with average triglyceride levels >150 mg/dL and HDL cholesterol levels reduced. Lipoprotein(a), a lipoprotein associated with a mild increase in cardiovascular risk in the general population, is significantly elevated in ESRD, although the contribution to increased risk is unclear. Lipoprotein(a) is primarily genetically regulated, but increasing levels are also related to worsening renal function.[162,163]

Homocysteine levels also increase with worsening renal function, because metabolism of homocysteine may require intrarenal metabolism.[164] Homocysteine has been shown to be elevated in 65% of children with CKD.[165] Interestingly, the level only increases after 7 years of age and appears to be independent of renal function.[165,166] The higher the homocysteine levels in children with CKD, the lower the vitamin B_{12} and folate levels.[165,166]

C-reactive protein levels are elevated 3-fold in pediatric ESRD patients undergoing dialysis and 2-fold in renal transplant recipients compared with healthy control subjects.[167] C-reactive protein is highly correlated with coronary calcium, especially in patients who also have an elevated parathyroid hormone level. An elevated C-reactive protein level may reflect chronic inflammation from many sources, including overt or occult infectious processes, comorbid conditions such as access complications, and factors associated with the dialysis procedure per se, including bioincompatible membrane and possibly dialysate leak in the membrane.[168]

Coronary calcium burden is increased, as measured by coronary computed tomography with either helical or electron-beam computed tomography. In young adults with a history of pediatric ESRD, higher calcium scores are associated with longer dialysis duration and elevated C-reactive protein levels.[167,169] It is not known to what extent this represents a dramatic acceleration of atherosclerosis in ESRD or an increased propensity for calcium to accumulate in the medial wall of the coronary vessel owing to altered calcium phosphorus metabolism in ESRD.

Endothelial dysfunction assessed by brachial artery reactivity in CKD is independent of lipid levels and hypertension but is correlated with left ventricular hypertrophy expressed as left ventricular mass index.[166,170] In 25 children with CKD, a double-blind, placebo-controlled, randomized crossover trial of folic acid for 8 weeks showed statistically significant improvement in endothelium-dependent dilatation with lowering of homocysteine levels.[171]

Treatment Recommendations for Children With CKD

Children With CKD Who Are at High Risk for Cardiovascular Disease (Tier I)

- The origins of cardiovascular morbidity and mortality are in childhood, when the cardiovascular risk milieu is established. Recommendations are directed toward children with CKD stage 5 (estimated glomerular filtration rate <15 mL·min^{-1}·1.73 m^{-2}), children undergoing dialysis, and renal transplant recipients.
- The risk of cardiovascular disease can be reduced by modifying traditional cardiovascular risk factors and monitoring for end-organ injury through the use of echocardiography to estimate left ventricular mass[172] and, in young adults, computed tomography studies for coronary calcium. Chronic cardiovascular risk factor reduction, begun early in the course of CKD, should be an essential part of clinical management.
- Specific guidelines for cardiovascular risk factor management in children with advanced CKD or ESRD are available from the National Kidney Foundation's Kidney Dialysis Outcomes and Quality Initiative. The guidelines include recommendations for management of cardiovascular disease in dialysis patients and for treatment of hypertension and dyslipidemias in CKD.[44,172,173]

These recommendations were considered in development of the algorithm shown in the Figure and the treatment guidelines described in Tables 2 and 3.

Pediatric Heart Transplantation

Introduction/Epidemiology

Orthotopic heart transplantation (OHT) in children continues to increase in frequency, with ≈400 transplantations performed annually in children in the United States.[174] After heart transplantation, transplant CAD is the most important cause of mortality beyond the first year after surgery in adults.[175] In pediatric survivors of OHT, transplant CAD has been found to be the primary cause of late mortality in 20% to 30% of cases.[176,177] On the basis of combined angiographic and intracoronary ultrasound imaging, 74% of pediatric heart transplant patients have evidence of transplant CAD.[178] In a recent pathology series, 94% of pediatric OHT specimens showed evidence of cardiac allograft vasculopathy.[179]

Pathology/Natural History

The histopathology of transplant CAD is the same in children as it is in adults and differs markedly from the typical atherosclerotic process. Histologically, monocyte and T-cell accumulation plus concurrent smooth muscle proliferation comprise the intimal hyperplasia of the coronary arteries.[180] Some degree of coronary intimal thickening is seen in virtually every heart transplant recipient beginning in the first year after transplantation.[181]

Angiographically, affected coronary vessels demonstrate diffuse concentric narrowing along their entire length. With intravascular ultrasound, the pathological process is characterized by concentric intimal thickening.[182]

When stenosis is diagnosed in the context of transplant CAD, both surgical and catheter revascularization techniques have been used with initial procedural success rate. However, over a very short period of time, the restenosis rate is high, and the long-term outcome is poor.[183] The only other option is retransplantation, with known limitations on organ procurement and potential development of coronary vasculopathy in the retransplanted heart.[184]

Pathogenesis

The pathogenesis of transplant CAD is complex and is still not completely understood. The underlying mechanism has been shown to involve multiple factors including those mechanisms discussed below.

Rejection

Development and progression of transplant CAD have been shown to correlate with evidence of increased rejection.[185] Noncompliance with immune-suppressive regimens correlates significantly with increased transplant CAD in children[186] and adults.[187] Conversely, regression of transplant CAD has been demonstrated with improved immunosuppression in adults.[188]

In children, late rejection is an independent predictor of transplant CAD, and increased immune suppression has been shown to correlate with a decreased incidence of transplant CAD.[189,190] Introduction of novel proliferation signal inhibitors such as sirolimus as part of immunosuppressive therapy has been associated with a decrease in transplant CAD in adults; this type of drug is now being used in children.[191]

Donor Status

In adults, older donor age, donor atherosclerotic disease, donor hypertension, and male sex of either donor or recipient have been shown to correlate with transplant CAD.[192] Donor hearts from patients who suffered explosive brain death have also been shown to have earlier onset of transplant CAD.[193]

Cytomegalovirus Infection

In adults and in children, cytomegalovirus infection has been associated with accelerated coronary vasculopathy after OHT.[194,195] Preemptive treatment with ganciclovir and cytomegalovirus hyperimmune globulin has reduced the incidence and delayed the progression of transplant CAD.[196]

Risk Factors/Comorbidities

Hyperlipidemia

After transplantation, the combination of immunosuppressive therapy, obesity, and an underlying genetic predisposition to hyperlipidemia promotes combined hyperlipidemia, with elevated total and LDL cholesterol, high triglycerides, and reduced HDL cholesterol.[197,198] Hyperlipidemia is present in ≈60% of adults and at least 40% of children in the first year after transplantation.[198,199]

Elevated levels of triglycerides have been shown to correlate directly with increased prevalence of transplant CAD in adults.[200] In adults, a greater increase in LDL cholesterol in the first year after transplantation has been associated with increased severity of transplant vasculopathy.[201] Lipid-lowering therapy with 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (statins) has led to lower total and LDL cholesterol levels and a significantly lower incidence of transplant vasculopathy in both adults and children.[201,202] Benefits have been maximized when lipid therapy has been initiated immediately after transplantation.

Obesity

After transplantation, progressive obesity is common in both children and adults, correlating with the intensity and duration of steroid treatment.[203,204] In adults and children, pretransplantation and posttransplantation BMI have been shown to be strong predictors of transplant CAD.[204] The association of obesity and the metabolic syndrome confers additional risk for transplant CAD and for progression of donor atherosclerosis.[205]

Hypertension

Cyclosporine therapy, a mainstay of immune suppression after heart transplantation, is associated with hypertension and with renal dysfunction. By 3 years after transplantation, 35% of pediatric heart transplant patients are undergoing chronic antihypertensive therapy; however, in cyclosporine-treated children, 83% of long-term survivors required antihypertensive therapy.[174,176]

Both hypertension and renal failure are predictors of progressive atherosclerotic disease and of transplant CAD.[185] Treatment with angiotensin-converting enzyme inhibitors and calcium channel blockers is associated with a reduction in transplant CAD in adults.[206,207]

Use of the antioxidant L-arginine has been shown to reverse endothelial dysfunction and attenuate hypertension after transplantation.[208] Use of omega-3 fatty acids has also been shown to reduce the rise in blood pressure after heart transplantation.[209] Immune suppression with proliferation signal inhibitors, such as everolimus, has resulted in a decrease in cyclosporine dose and in renal dysfunction in adults.[210]

Insulin Resistance/Diabetes Mellitus

Both chronic hyperglycemia as evidenced by elevated hemoglobin A_{1C} and overt diabetes are prevalent in adult patients after heart transplantation.[205,211] Approximately 2% of pediatric heart transplant recipients develop diabetes.[212] In adults, higher glucose and insulin levels and elevated levels of hemoglobin A_{1C} are associated with increased evidence of transplant CAD.[205,211]

Deconditioning

In both children and adults, exercise performance, expressed as measured maximum oxygen uptake, improves from pretransplantation levels but remains significantly reduced compared with normal subjects. This has been attributed in part to chronotropic incompetence caused by cardiac denervation, but deconditioning is also common.[213,214]

In children and adults, exercise training programs result in increased exercise capacity and in decreased resting heart rate and blood pressure, improved endothelial function, and in-

creased lean body mass, all known factors in the pathogenesis of allograft vasculopathy.[215,216] With serial exercise testing, exercise performance deteriorates as transplant CAD develops.

Hyperhomocysteinemia

In adults and children, elevated homocysteine levels are common after OHT.[217,218] In adult subjects with evidence of transplant CAD, homocysteine levels have been shown to be significantly higher than in those without evidence of vasculopathy.[217] Folate supplementation in adults and children after OHT normalized homocysteine levels, with no evidence to date of any impact on development of transplant CAD.[219]

Treatment Recommendations After Pediatric Heart Transplantation

After Pediatric Heart Transplantation, Children Are at High Risk for Very Early Cardiovascular Disease (Tier I)

- Please see the algorithm in the Figure and Tables 2 and 3 for specific treatment guidelines.
- Although the process appears to be primarily mediated by chronic rejection, modification of traditional risk factors, particularly reduction in LDL cholesterol, has significantly affected the disease process in children and adults.
- Risk factor identification and intensive modification are indicated beginning in the early posttransplantation period.[184] Although there are no guidelines for lipid management after heart transplantation in children, usual care in the United States includes initiation of lipid-lowering therapy with 3-hydroxy-3-methylglutaryl coenzyme A enzyme inhibitors in the early posttransplantation period.[220]
- Optimization of immunosuppression, improved compliance, and preemptive treatment of cytomegalovirus are all critical factors in the pathogenesis of transplant CAD that are being addressed by transplantation cardiologists.
- Specific screening for evidence of transplant CAD is recommended every 6 to 12 months with angiography, with optional intravascular coronary ultrasound.[221] Dobutamine stress echocardiography or stress perfusion imaging may be helpful in risk stratification.[222]
- Patients who develop any evidence of graft dysfunction should be screened specifically for transplant CAD.

Kawasaki Disease

Kawasaki disease is an acute, self-limited vasculitis of unknown origin that occurs predominantly in infants and young children. First described in 1967 in Japan, the disease is now known to occur throughout the world in children of all races.[223] Kawasaki disease is characterized by fever, bilateral nonexudative conjunctivitis, erythema of the lips and oral mucosa, changes in the extremities, rash, and cervical lymphadenopathy. The cause of Kawasaki disease remains unknown, and no specific diagnostic test or pathognomonic clinical feature can confirm the diagnosis early in the illness. Kawasaki disease is likely to be caused by an infectious agent(s) that produces clinically apparent disease in genetically predisposed individuals.[224] Coronary artery aneurysms or ectasia develops in approximately 15% to 25% of untreated children with the disease and may lead to myocardial infarction, sudden death, or ischemic heart disease.[225,226] Kawasaki disease has now surpassed acute rheumatic fever as the leading cause of acquired heart disease in children[227]; >4000 hospitalizations associated with Kawasaki disease occurred in the United States in 2000.[228] Therapy of Kawasaki disease in the acute phase is aimed at reducing inflammation in the coronary artery wall and preventing coronary thrombosis. Long-term management is guided by stratification of patients according to the severity of their CAD and consequent risk of myocardial ischemia. Although coronary artery aneurysms produce the most serious sequelae of Kawasaki disease, vascular inflammation during the acute stage of the illness is diffuse. Children with coronary aneurysms, and even those in whom coronary dilatation was never detected, appear to be at increased risk for future atherosclerotic CAD on the basis of abnormalities in arterial stiffness and endothelial function.

Pathology

Kawasaki disease is a generalized systemic vasculitis that involves blood vessels throughout the body. Aneurysms affect medium-sized extraparenchymal arteries and result from segmental destruction of the vessel wall in sites strikingly similar to those affected by atherosclerosis.[229] Although aneurysms in the coronary arteries are the main cause of morbidity and mortality, they can also occur in other vessels, such as the celiac, mesenteric, femoral, iliac, renal, axillary, and brachial arteries.[229]

Early in the illness, coronary arteries demonstrate marked edema and infiltration of the arterial wall, initially by neutrophils,[230] with a rapid transition to mononuclear cells, primarily CD8+ T cells, monocytes, macrophages, and IgA plasma cells.[231–234] This cellular infiltration is accompanied by destruction of the internal elastic lamina and media, which results in aneurysm formation. Matrix metalloproteinases (MMPs) are likely to effect destruction and remodeling in the arterial wall.[235,236] MMP-2 expression is prominent in the thickened neointima and in endothelial cells of new capillaries in areas of angiogenesis, and MMP-9 is expressed in coronary artery aneurysms, nonaneurysmal coronary arteries, and noncoronary arteries.

Coronary arterial remodeling occurs over months to years, sometimes with progressive stenosis due to intimal proliferation and neoangiogenesis; it differs from that seen in adult atherosclerosis by extensive expression of vascular growth factors, such as tumor necrosis factor-β, platelet-derived growth factor-α, basic fibroblast growth factor, and vascular endothelial growth factor, in the microvessels of the intima.[237] These growth factors are prominently expressed at the inlet and outlet of aneurysms, where they are activated by high shear stress.[237]

Few postmortem studies are available in children in whom coronary abnormalities were not detected in the acute phase. Recently, Suzuki and colleagues[238] performed the first immunohistochemical study of the coronary arteries of a child without coronary dilation by echocardiography at any stage of illness and who died of unrelated causes. The coronary artery intima was mildly thickened, and platelet-derived growth factor-α, transforming growth factor-β1, and induc-

ible nitric oxide synthase were expressed in the intimal smooth muscle cells in the child with normal coronary dimensions after Kawasaki disease but not in control subjects.

Natural History

Cardiovascular complications and long-term sequelae of Kawasaki disease depend on the severity of coronary artery lesions. The risk of coronary aneurysms is highest among children who do not receive timely treatment with high-dose intravenous immunoglobulin (≤10 days and ideally 7 days from the onset of fever), who have persistent fever despite treatment with intravenous immunoglobulin, or who have laboratory test results that reflect severe, persistent inflammation. Young (<6 months) or old (>8 years) age and male sex are also risk factors.

Patients With Aneurysms (High Risk)

Among patients with aneurysms, the incidence of coronary stenosis secondary to myointimal proliferation increases linearly with time since illness onset.[225,239,240] The likelihood of progression to coronary artery stenosis is directly related to aneurysm size and is especially high among arterial segments with giant aneurysms (≥8 mm in diameter).[240,241] Patients with persistent aneurysms have systemic inflammation years after disease onset, as evidenced by C-reactive protein levels that are significantly higher than those seen in normal age-matched children or among those who had Kawasaki disease without aneurysms or with regressed aneurysms.[242]

Patients With Regressed Aneurysms (Moderate Risk)

Angiographic regression of aneurysms to normal lumen diameter occurs in ≈50% of vessels by 2 years after illness onset.[225,243] The likelihood of resolution of an aneurysm is inversely related to its size.[243–245] Pathological studies have shown that regression occurs primarily through fibrous intimal thickening.[246–248] Intravascular ultrasound of regressed coronary aneurysms demonstrates either marked symmetrical or asymmetrical myointimal thickening.[249–251] Regressed coronary artery aneurysms are not only histopathologically abnormal but also have reduced vascular reactivity to isosorbide dinitrate and constriction with acetylcholine, which indicates endothelial dysfunction.[252–254]

Intravascular ultrasound has revealed a significant direct correlation between the initial diameters of the coronary arteries and the degree of intimal-medial thickness >10 years later.[250] Individuals with persistent or regressed aneurysms have greater stiffness of the proximal and peripheral arterial beds, as well as higher arterial wave reflection, than normal control patients.[255] Indeed, aortic pressure waveforms of Kawasaki disease patients with persistent or regressed aneurysms late after illness onset resemble those generally observed in the elderly.[255]

The carotid artery wall in patients with coronary artery lesions 6 to 20 years after illness onset has been found to be less distensible and thicker than that in control patients.[256] These changes of arterial properties in patients with Kawasaki disease are not associated with major alterations of the lipid profile and are postulated to be secondary to the changes in arterial walls that occur after the diffuse vasculitis. Extrapolation from these findings in carotid arteries suggests that the coronary arteries may be predisposed to accelerated atherosclerosis in patients with Kawasaki disease and coronary artery lesions.

Patients Without Detectable Coronary Aneurysms (At Risk)

With careful clinical follow-up 10 to 20 years after Kawasaki disease onset, such patients appear to have morbidity and mortality that are similar to those in the normal population.[257] Increased risk for premature atherosclerosis in these children is suggested by research studies that have demonstrated subclinical abnormalities of arterial function and myocardial flow reserve.[258–261]

Kawasaki disease patients with normal coronary arteries have been reported to have higher brachial-radial artery mean pulse-wave velocity than normal children, which suggests increased arterial stiffness.[262,263] Lower myocardial flow reserve and higher total coronary resistance have been found in children without coronary dilation after Kawasaki disease compared with normal controls.[264] Children without detectable coronary abnormalities have been reported to have abnormal endothelium-dependent brachial artery reactivity.[261] Data conflict with regard to impairment of endothelium-dependent relaxation of the epicardial coronary arteries among children in whom coronary artery dilation was never detected.[265,266]

Presence of Comorbidities

With or without overt coronary artery sequelae, Kawasaki disease produces altered lipid metabolism (in particular, lower HDL cholesterol) that persists beyond clinical resolution of disease.[262,267,268] North American children with Kawasaki disease have been reported to have a more adverse cardiovascular risk profile, with higher blood pressure and greater adiposity, than control children.[269]

Recommendations for Children After Kawasaki Disease

Kawasaki disease is associated with significant coronary artery pathology and comorbidities that predispose patients to atherosclerosis. Cardiovascular risk assessment and treatment in children with Kawasaki disease are based on the status of the coronary arteries: patients with persistent aneurysms, high risk (tier I); patients with regressed aneurysms, moderate risk (tier II); and patients without detected abnormalities, at risk (tier III). The algorithm and tables contain tier-specific management. In addition, patients should be encouraged to exercise to the greatest extent possible given coronary artery status, in accordance with the 36th Bethesda Conference recommendations.[41] Prospective counseling and annual assessment of risk factors for atherosclerotic CAD are recommended.

Chronic Inflammatory Disease

Introduction

In adults with chronic inflammatory disease, increased prevalence of cardiovascular disease is well documented. Specifically, patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis experience cardiovascular events at a

significantly greater incidence than age-matched normal controls.[270,271] In women with SLE 35 to 44 years of age, the incidence of myocardial infarction is 50 times greater than for women without the disease. In adults with rheumatoid arthritis, cardiovascular disease is the leading cause of death, with rates that average 2 to 4 times those of age-matched controls. For both SLE and rheumatoid arthritis, the increased incidence of cardiovascular disease is not explained by traditional risk factors alone.[272,273]

For a substantial number of children with chronic inflammatory disease, the process will persist into adult life. Children constitute 15% to 20% of patients with SLE, and survival into adult life is now the norm.[274] In at least 50% of children with rheumatoid arthritis, active disease persists into adult life.[275] To date, no studies have tracked the development of atherosclerotic disease as children with chronic inflammatory disease age. In a small series, 16% of 31 children with SLE were shown to have abnormalities of coronary perfusion with thallium perfusion scanning.[276] Several studies document evidence of increased markers for subclinical atherosclerosis in young adults with both rheumatoid arthritis and SLE.[277,278] Extrapolating from these, the atherosclerotic process appears to begin at an earlier age and progress at an accelerated pace for those with chronic inflammatory disease that begins in childhood.

Pathophysiology of Accelerated Atherosclerosis in Adults With Chronic Inflammatory Disease (Rheumatoid Arthritis and SLE)

Major similarities exist between the inflammatory and immune responses in atherosclerosis and in chronic inflammatory disease.[279] Inflammation is part of the pathology of atherosclerotic plaque, and serum markers of inflammation, including C-reactive protein, cytokines, serum amyloid-α, and tumor necrosis factor-α, have been shown to mediate the development of atherosclerosis.[280–283]

At autopsy, coronary stenotic lesions are typical of traditional atherosclerotic plaque, with the addition of a higher population of cellular components. In a very small number of cases, an acute vasculitic process alone has been associated with a coronary thrombotic event.[284]

The degree of inflammation in adult SLE and rheumatoid arthritis patients as measured by laboratory testing correlates with markers of subclinical atherosclerosis, including increased carotid intima-media thickness and impaired arterial dilation assessed by ultrasound, as well as increased coronary calcification by electron-beam computed tomography.[278,285–288] In adults, increased severity of disease and greater cumulative damage assessed by standard scoring systems have been shown to correlate with evidence for atherosclerosis, which suggests that systemic inflammation itself is a major mediator of the development of atherosclerosis in these disease settings.[278,287–289]

Conflicting reports exist with regard to a potential role for antiinflammatory and immunosuppressive treatment. Several studies have shown a negative correlation between the extent of atherosclerosis and the cumulative dose and duration of immunotherapy. This suggests that optimization of immune therapy is a potential approach to reducing the development of atherosclerosis.[285,290] Conversely, others have reported increased coronary disease in adult patients with more long-term antiinflammatory and immunosuppressive therapy, which implicates either increased severity of the disease process itself or an atherosclerotic response to treatment in the development of CAD.[278,291]

Glucocorticoid, cyclophosphamide, and methotrexate therapy are all associated with metabolic changes that have been shown to increase atherosclerotic risk by augmenting standard risk factors such as obesity, dyslipidemia, insulin resistance, and hypertension, independent of underlying diagnosis.[292] By contrast, methotrexate therapy has been shown to decrease cardiovascular mortality in patients with rheumatoid arthritis.[293]

A prothrombotic state associated with the presence of antiphospholipid antibodies develops in a significant proportion of adult patients with SLE (34% to 44%) compared with only 1% to 5% of the general population. The presence of these antibodies increases the risk of a vascular thrombotic event by a factor of at least 10 times when patients with lupus are compared with those without.[294]

In adult patients with rheumatoid arthritis, several thrombotic markers have also been shown to be elevated.[295] In addition, elevated levels of lipoprotein(a), considered to be a prothrombotic agent, have been demonstrated in patients with both rheumatoid arthritis and SLE.[296,297]

Renal disease is a common complication of SLE, and severe renal involvement with nephrotic-range proteinuria has been suggested to be a major risk factor for early atherosclerosis on the basis of a small series of young adults with juvenile-onset SLE studied by carotid ultrasound. Nephritis is associated with hypertension, and this may be the major mediator of increased carotid intima-media thickness, a subclinical marker of atherosclerosis noted to be abnormal in these patients. Nephritis may simply indicate overall increased severity of disease. Its presence needs to be expressly considered in the evaluation of cardiovascular risk in patients with SLE.[298,299]

Traditional Risk Factors/Comorbidities

Dyslipidemia

Abnormalities of the lipid profile have been identified in children and adults with both SLE and rheumatoid arthritis.[300,301] Typical findings vary with the disease state. During clinical flare-ups, the lipid profile pattern is typical of that seen in diverse inflammatory states, with elevated triglyceride and VLDL levels and reduced HDL cholesterol. After steroid therapy, elevated total and LDL cholesterol levels, with persistent but less impressive elevation in VLDL and triglycerides, have been described.[301,302] In addition, increased LDL susceptibility to oxidation has been reported in patients with chronic inflammatory disease in general and in pediatric patients with SLE in particular.[302,303]

Increased lipoprotein(a) levels are reported in patients with SLE and rheumatoid arthritis.[296,297] Clinical coronary disease and measures of subclinical disease correlate with dyslipidemia in adult patients with SLE and rheumatoid arthritis.[286,304–306] A single study of children with SLE demon-

strated normal endothelial function despite recorded lipid profile abnormalities.[307]

Statin therapy has been shown to have both lipid-lowering and antiinflammatory effects. A randomized, placebo-controlled trial of atorvastatin in adult patients with rheumatoid arthritis showed a reduced disease activity score, decreased levels of inflammation, and decreased levels of total/LDL cholesterol and triglycerides in the statin-treated group after 6 months.[308] A similar trial is ongoing for adult patients with SLE. No trial of lipid-lowering therapy and CAD incidence has been reported.

Hypertension

Hypertension occurs in a significant proportion of patients with SLE. At diagnosis in adults, 18% of patients with SLE have hypertension; by 10 years from diagnosis, this has increased to 59%.[309] In adults with rheumatoid arthritis and SLE, hypertension has been shown to be associated with an increased risk for manifest cardiovascular disease on long-term follow-up.[310,311]

Hypertension is much more prevalent in SLE patients with renal involvement and in children; nephritis is present in as many as 80% of patients. The combination of renal involvement and hypertension predicts an adverse outcome in juvenile onset SLE.[298,312] In addition to hypertension-related renal disease, both steroid and immunosuppressive therapies can be associated with hypertension and on this basis, hypertension occurs with increased incidence in patients with rheumatoid arthritis and is a factor for all children with chronic inflammatory disease. In both SLE and rheumatoid arthritis, hypertension is strongly associated with increased BMI.[313,314]

Obesity

Obesity is a frequent complication of chronic inflammatory disease in adults and children, reflecting the inactivity imposed by the disease process and the effects of steroid treatment. BMI has been shown to be higher in patients with SLE and rheumatoid arthritis who develop coronary disease than in age-matched patients with these diagnoses who do not develop cardiovascular disease.[313,314] The role of obesity is exaggerated by its association with the metabolic syndrome.[305]

Homocysteine

In adults in general, elevated levels of plasma homocysteine have been identified as a potential risk factor for atherosclerosis.[315] In patients with both rheumatoid arthritis and SLE, homocysteine levels have been shown to be increased, particularly in association with methotrexate therapy.[316,317] Oral administration of folic acid reduces homocysteine levels in both groups, but no reduction in atherosclerotic disease has been shown.[316,318]

Recommendations for Children With Chronic Inflammatory Disease

Children with chronic inflammatory disease are at moderate risk for premature cardiovascular disease (tier II) based on the combination of a chronic inflammatory state and the documented presence of multiple traditional risk factors.

- The atherosclerotic process is primarily mediated by chronic inflammation and immune dysregulation, but traditional risk factors are prevalent. Extrapolating from studies of adults with SLE and rheumatoid arthritis and of children in other high-risk settings, reduction in traditional risk factors should ameliorate the atherosclerotic process. A routine rigorous process of risk factor identification and treatment is indicated. Please see the algorithm (Figure) and Table 2 for specific diagnosis and treatment guidelines.
- Per immunology and rheumatology, treatment of the primary disease process with optimization of therapy to suppress the inflammatory response and its contribution to accelerated atherosclerosis is an important focus for disease management.

Congenital Heart Disease

Introduction/Epidemiology

Although the diagnosis of congenital heart disease includes rare and diverse disorders, some specific diagnoses appear to be associated with increased risk for premature atherosclerotic CAD. Children with congenital heart disease represent a growing population: The incidence of congenital heart defects is almost 1 in 100 live births, and of these, ≈23 of 1000 newborns will require invasive treatment or will die as a consequence of their diagnosis by 1 year of age.[319,320] Because of improved interventions, >1 million adults are now living with congenital heart disease.[321] Selected congenital heart defects (or the process of their repair) lead to an increased risk for adult cardiovascular disease compared with the general population. To date, relatively few data exist to provide an understanding of the presence of cardiovascular disease risk factors and the development of atherosclerosis in these patients.

Pathophysiology

Risk of premature atherosclerotic cardiovascular disease in patients with congenital heart defects is based on 2 principal mechanisms: lesions with coronary artery abnormalities and obstructive lesions of the left ventricle and aorta.

Lesions With Coronary Artery Abnormalities

Congenital coronary anomalies (in isolation or in association with other congenital defects) may predispose individuals to coronary events relatively early in life. In addition, surgical repair of congenital heart defects may result in abnormalities of the coronary arteries. The clinical outcome of coronary artery defects depends on the anatomy of the lesion.

Origin of the left main coronary artery from the right sinus of Valsalva, passing between the aorta and pulmonary artery, has been associated with sudden death, particularly during or just after physical activity.[322] In these patients, autopsies may reveal subendocardial scars and occasionally, large myocardial infarction. Importantly, atherosclerosis in a segment of the abnormal artery has been demonstrated even in young individuals.[322]

Other congenital anomalies of coronary origin and course (origin of the left circumflex from the right main coronary artery being the most common) are thought to have little clinical importance. However, these anomalous coronary

arteries have been reported to have a high incidence of coronary atheroma.[322] This high incidence may be due to abnormal blood flow patterns.

Some surgeries for congenital heart disease involve manipulation of the coronary arteries. These surgeries include the arterial switch operation for d-transposition of the great arteries and repair of anomalous origin of left coronary artery from the pulmonary artery. In these settings, coronary ostial stenosis may develop over time, and there may be increased risk of associated atherosclerosis.[323] A recent intravascular ultrasound study demonstrated proximal eccentric intimal thickening, a finding compatible with early atherosclerosis, in all the translocated coronary arteries in a small series of survivors of the arterial switch procedure studied at a median age of 9.5 years.[324] Abnormal epicardial coronary artery dilation in response to pharmacological stimulation has also been demonstrated in a small group of d-transposition subjects evaluated at a mean of 5 years after arterial switch.[325]

Obstructive Lesions of the Left Ventricle and Aorta

One group of congenital cardiac lesions that has been shown to be associated with increased risk of cardiovascular disease in adulthood is obstructive lesions of the left side of the heart.

Coarctation of the Aorta

The pathophysiology for acquired cardiovascular disease associated with coarctation of the aorta is primarily related to systemic hypertension.[326] Arterial abnormalities may persist after correction of the coarctation and result in long-term systemic hypertension and, therefore, increased risk of cardiovascular disease.

A 20-year postoperative follow-up study of patients who underwent repair in an era when coarctation repair was delayed (mean age at repair 20 years) reported a mortality rate of 12% at a mean age of 32.5 years. Deaths were secondary to myocardial infarction, stroke, congestive heart failure, and aortic rupture, which indicates the potential negative impact of the combination of this congenital diagnosis and chronic hypertension.[327]

Upper-body hypertension is related to constriction of the aorta at the site of repair, but coarctation may also be associated with abnormalities of vascular reactivity, arterial wall compliance, or abnormal baroreceptor function.[328–330] The prevalence of hypertension at rest after repair of coarctation is at least 10%.[331] Exercise-induced systolic hypertension may also occur in patients after repair of coarctation of the aorta, even when the blood pressure is normal at rest.[332] To evaluate for this, patients with coarctation should have routine exercise/blood pressure evaluation.

Beyond hypertension, coarctation of aorta is associated with other important sequelae that lead to morbidity and mortality, which suggests a more widespread vascular abnormality. Cerebrovascular accidents occur in association with systemic hypertension[326] and even in its absence, in the setting of berry aneurysms in the circle of Willis. Aortic dissection in the ascending aorta or near the repair site may occur whether or not an aneurysm forms in the aorta at the site of the repair. Persistent hypertension, older age at repair, association with bicuspid aortic valve, aortic atherosclerosis, and dilation of the aorta proximal to the repair site all predispose coarctation patients to this serious risk.[327,332]

Aortic Stenosis

Aortic stenosis occurs most often at the level of the aortic valve but can also be subvalvular or supravalvular and can result in myocardial changes that predispose to cardiovascular disease. Valvular aortic stenosis occurs in 3% to 6% of patients with congenital cardiovascular defects.[333]

Significant aortic stenosis is associated with left ventricular hypertrophy (due to increased left ventricular pressure and peak systolic wall stress, a powerful stimulus for hypertrophy). Left ventricular hypertrophy is known to be an independent risk factor for cardiovascular disease morbidity and mortality in adults.[334]

Myocardial blood flow may be compromised in patients with aortic stenosis, despite normal coronary artery patency. Increased myocardial work results in increased demand for oxygen, exceeding the capacity of the coronary supply (abnormal coronary flow reserve). Furthermore, redistribution of blood away from the subendocardium can result in ischemia in the subendocardium.[335]

Even mild aortic stenosis during childhood can progress and may therefore be associated with increased left ventricular mass and increased risk for cardiovascular disease over time. Increase in the left ventricular outflow tract gradient is caused by progressive calcification of the aortic valve.[333]

Supravalvular aortic stenosis (most commonly associated with Williams syndrome[336]) may confer an additional increased cardiovascular risk because of its association with arterial stenoses. Coronary artery ostial stenoses can result directly in myocardial ischemia and exercise-induced syncope, and renal artery stenosis can lead to hypertension.[337]

Hypertrophic Cardiomyopathy

Hypertrophic cardiomyopathy may occur in as many as 1 in 500 people. It is the most common genetically transmitted form of cardiovascular disease.[338,339] Hypertrophic cardiomyopathy is associated with an increased risk for sudden death in children and in adults.[340] The overall cardiovascular mortality rate is ≈2% per year for those diagnosed in childhood and ≈1% per year for those diagnosed as adults.[341] A number of pathophysiological sequelae may contribute to sudden death and potentially to increased cardiovascular disease risk in general.

Sudden death in patients with hypertrophic cardiomyopathy is usually due to a ventricular arrhythmia.[342] It is the most common cause of sudden death in the young. Vigorous physical activity may contribute to increased risk of sudden death in these patients.

Left ventricular hypertrophy is the major manifestation of hypertrophic cardiomyopathy, with a pathognomonic finding of cellular myocardial disarray. In addition, left ventricular outflow tract obstruction may exacerbate the development of hypertrophy.

Hypertrophic cardiomyopathy may be associated with myocardial bridging, in which epicardial coronary arteries can be compressed by muscle overgrowth. The presence of these vessels may result in increased risk of sudden death,

abnormal myocardial perfusion, and localized atherosclerosis in adjacent coronary segments.

The long-term role of hypertrophic cardiomyopathy in the development of atherosclerotic cardiovascular disease is not known. Similarly, the effect of modification of risk factors for atherosclerosis on the long-term prognosis of hypertrophic cardiomyopathy has not been established. Further study is needed to evaluate these issues.

Traditional Risk Factors/Comorbidities

All the known risk factors for accelerated atherosclerosis will occur at the same incidence as seen in the general population. In the setting of a repaired congenital defect, these may represent even more potent harbingers of premature cardiovascular disease.

Some children with repaired congenital heart defects may have limitation in their ability to perform physical activity. A sedentary lifestyle is an independent risk factor for accelerated atherosclerosis. In addition, such children may be even more prone to obesity in our current obesogenic environment. Cardiac rehabilitation has been shown to improve the exercise performance of children with congenital heart disease, even those with known residual cardiac dysfunction.[343] Published guidelines can be used to determine the level of exercise considered appropriate for specific congenital diagnoses.[41]

Recommendations for Children With Congenital Heart Disease

Because children with congenital heart disease have other abnormalities that may make the heart more vulnerable to both the development of atherosclerosis and the adverse sequelae of a cardiovascular event, it seems prudent to be aggressive about the evaluation of their cardiovascular disease risk status. This is particularly true of those with the congenital cardiac defects presented above. Children, adolescents, and young adults with these specific congenital heart diseases are at risk (tier III) for premature cardiovascular disease. The algorithm in the Figure and Table 2 provide specific management guidelines. Future research will clarify which additional congenital cardiac diagnoses require specific attention to cardiovascular risk reduction.

Childhood Cancer Survivors

Introduction/Epidemiology

The prevalence of childhood cancer has been steadily increasing over the past decades, exceeded only by the adult cancers of prostate, lung, breast, colorectum, and bladder.[344] A newborn child is estimated to have a 1 in 325 chance of developing cancer before 20 years of age.[344] Progressively more effective surgical intervention, radiotherapy, and risk-stratified chemotherapeutic approaches have led to dramatic improvements in survival rates for many childhood cancers during the past 3 decades.[345] The overall 5-year probability of survival for children diagnosed with cancer since 1992 is >77%.[346]

As many childhood cancer survivors progress into adulthood, clinical and epidemiological research is now focusing on an array of long-term medical and psychosocial effects from cancer treatment to characterize and understand the ñconsequences of cure.ò[347] Among 5-year or longer survivors of childhood cancer, the standardized mortality ratio for cardiac-related deaths was found to be significantly elevated at 8.2 (95% confidence interval 6.4 to 10.4).[348] The combination of acquired atherosclerotic disease with a previously damaged myocardium represents a serious late complication for survivors of childhood cancer. In a recent comparative study of 201 long-term childhood cancer survivors and 76 healthy siblings, Lipshultz et al[349] showed that overall, the cancer survivor group had increased cardiovascular risk due to the combination of reduced left ventricular mass and high prevalence of risk factors for atherosclerosis.

Pathophysiology

Both anthracyclines used as chemotherapy for childhood cancers and direct cardiac radiation have been associated with the development of dilated cardiomyopathy. With anthracyclines, the development of cardiac dysfunction is related to cumulative dose. The cardiomyopathy that develops can be severe, with cardiac transplantation required in a small number of cases. Subclinical cardiac dysfunction has been shown to be present in 14% to 47% of patients after anthracycline therapy.[350,351] Late-onset clinical symptoms mandate routine serial evaluation of cardiac function for these patients. Preliminary data suggest that pretreatment with dexrazoxane, a free-radical scavenger, may prevent or reduce cardiac injury related to doxorubicin infusion, but a clinical benefit has not yet been confirmed.[352]

Risk Factors/Comorbidities

Obesity

Obesity is very common in survivors of childhood cancer.[353] In adult survivors of childhood acute lymphoblastic leukemia, various factors, including female sex, genetic predisposition, exposure to steroids, and cranial radiation therapy, have been implicated in the development of excess body fat.[348,354–360]

Leptin, an adipocytokine produced by adipocytes, controls energy metabolism at the level of the hypothalamus by suppressing appetite and stimulating energy expenditure.[361,362] Leptin levels are elevated in otherwise healthy obese adults and children, which indicates resistance to the effects of leptin in these individuals.[363–366] Elevated leptin levels and leptin receptor abnormalities have been reported in childhood cancer survivors.[367,368]

Radiation exposure to the hypothalamic-pituitary axis in children can result in late-onset deficiency of growth hormone secretion and subsequent development of adult obesity.[348,356,368–372] Growth hormone is involved in the determination of fat cell size, fat cell differentiation,[370] and levels of resistin,[369] all of which are important determinants of insulin sensitivity.[368] Impaired growth hormone levels in childhood cancer survivors are potentially operative in the development of obesity, insulin resistance, and type 2 diabetes mellitus.[369–373]

Cachexia acutely affects ≈50% of cancer patients and is characterized by weakness, fatigue, loss of lean body mass, and abnormal metabolism. It may be associated with an increased risk for subsequent cardiovascular disease in child-

TABLE 2. Tiers I, II, and III: Treatment Recommendations

GROWTH/DIET[32–34]

- Nutritionist evaluation, diet education for all: total fat <30% of calories, saturated fat <10% of calories, cholesterol <300 mg/d, avoid *trans* fats; adequate calories for growth.
- Calculate BMI percentile for gender/height.*
  - If initial BMI >95th percentile:
    - → Step 1:
      - Age-appropriate reduced-calorie training for child and family
      - Specific diet/weight F/U every 2 to 4 weeks for 6 months; repeat BMI calculation at 6 months
      - Activity counseling (see below)
  - If F/U BMI >85th percentile for tier I, >90th percentile for tier II, or >95th percentile for tier III:
    - → Step 2:
      - Weight-loss program referral plus exercise training program appropriate for cardiac status

BLOOD PRESSURE (Tiers I, II, and III)[35]

- BP measurement/interpretation for age/gender/height
  - If SBP and/or DBP=90th to 95th percentile or BP >120/80 mm Hg (3 separate occasions within 1 month):
    - → Step 1: Decreased calorie intake, increased activity for 6 months
  - If initial SBP and/or DBP >95th percentile (confirmed within 1 week) *OR* 6-month F/U SBP and/or DBP >95th percentile:
    - → Step 2: Initiate pharmacological therapy per Fourth Task Force recommendations[35]

LIPIDS

- LDL-C (tiers II and III)[36]
  - See Table 3 for recommendations for LDL-C for tier I.
  - If initial LDL-C ≥130 mg/dL (tier II) or >160 mg/dL (tier III):
    - → Step 1: Nutritionist training for diet with <30% of calories from fat, <7% of calories from saturated fat, cholesterol <200 mg/d, avoidance of *trans* fats for 6 months
  - If repeat LDL-C >130 mg/dL in tier II or >160 mg/dL in tier III and child >10 y old:
    - → Step 2: Initiate statin therapy with LDL goal of 130 mg/dL
- Triglycerides
  - If initial TG=150 to 400 mg/dL:
    - → Step 1:
      - Nutritionist training for low simple carbohydrate, low-fat diet
      - If elevated TGs are associated with excess weight, nutritionist referral for weight loss management: energy balance training plus activity recommendations (see below)
  - If TG >700 to 1000 mg/dL, initial or F/U:
    - → Step 2:
      - Consider fibrate or niacin if >10 y old.†
      - Weight loss recommended when TG elevation is associated with overweight/obesity.

GLUCOSE (Tiers I, II, and III, except for patients with diabetes mellitus)[37]

- If fasting glucose=100 to 126 mg/dL:
  - → Step 1: Reduced-calorie diet, increased activity aimed at 5% to 10% decrease in weight over 6 months
- If repeat fasting glucose=100 to 126 mg/dL:
  - → Step 2: Insulin-sensitizing medication per endocrinologist
- Casual glucose >200 mg/dL or fasting glucose >126 mg/dL=Diabetes mellitus → Endocrine referral for evaluation and management
- Maintain HbA_{1C} <7%

SMOKING (Tiers I, II, and III)

- → Step 1: Parental smoking history at every visit; child smoking history beginning at age 10. Active antismoking counseling for all; smoke-free home strongly recommended at each encounter.
- → Step 2: Smoking cessation referral for any history of cigarette smoking.

ACTIVITY (Tiers I, II and III)[38–40]

- For children in all tiers, participation in activity is at the discretion of the physician(s) directing care. For specific cardiac diagnoses such as Kawasaki disease and congenital heart disease, activity guidelines are referenced.
  - → Step 1: Specific activity history for each child, focusing on time spent in active play and screen time (television+computer+video games). Goal is ≥1 hour of active play per day; screen time limited to ≤2 h/d.
- Encourage activity at every encounter.
  - → Step 2: After 6 months, If goals not met, consider referral for exercise testing, recommendations from exercise specialist.

Abbreviations: F/U indicates follow-up; BP, blood pressure; SBP, systolic blood pressure; DBP, diastolic blood pressure; LDL-C, LDL cholesterol; and TG, triglycerides.

Specific treatment goals for each risk factor and each tier are given in the algorithm (Figure). For risk factor–specific guidelines, references are provided.

*Normal BMI values for age and sex are available at http://www.cdc.gov/growthcharts.

†Elevation of triglycerides to ≥1000 mg/dL is associated with significant risk for acute pancreatitis. A fasting TG of 700 mg/dL is likely to rise to >1000 mg/dL postprandially. Treatment recommendation is congruent with guidelines for management of dyslipidemia in diabetic children.[30]

TABLE 3. Tier I Conditions: Specific Treatment Recommendations

- Rigorous age-appropriate education in diet, activity, and smoking cessation for all
- Specific therapy as needed to achieve BP, LDL-C, glucose, and HbA_{1C} goals as indicated for each tier, as outlined in algorithm; timing individualized for each patient and diagnosis. Step 1 and Step 2 therapy for all outlined in Table 2.
- For diagnosis-specific guidelines, references are provided.

Homozygous FH[41]

- LDL management: Scheduled apheresis every 1 to 2 weeks beginning at diagnosis to maximally lower LDL-C, plus statin and cholesterol absorption inhibitor
- Rx per cardiologist/lipid specialist. (Specific therapeutic goals for LDL-C are not meaningful with this diagnosis.)
- Assess BMI, BP, and FG: Step 1 management for 6 months
- If tier I goals not achieved, proceed to Step 2.

Diabetes mellitus, type 1[37,42]

- Intensive glucose management per endocrinologist, with frequent glucose monitoring/insulin titration to maintain PG <200 mg/dL, HbA_{1C} <7%
- Assess BMI, fasting lipids: Step 1 management of weight, lipids for 6 months
- If goals not achieved, proceed to Step 2; statin Rx if >10 y old to achieve tier I treatment goals
- Initial BP >90th percentile: Step 1 management plus no added salt, increased activity for 6 months
- BP consistently >95th percentile for age/sex/height: initiate ACE inhibitor therapy with BP goal <90th percentile or <130/80 mm Hg, whichever is lower.

CKD/ESRD[44]

- Optimization of renal failure management with dialysis/transplantation per nephrology
- Assess BMI, BP, lipids, FG: Step 1 management for 6 months
- If goals not achieved, proceed to Step 2; statin Rx if >10 y old to achieve tier I treatment goals

After heart transplantation[45]

- Optimization of antirejection therapy, treatment for CMV, routine evaluation by angiography/perfusion imaging per transplant physician
- Assess BMI, BP, lipids, FG: Initiate Step 2 therapy, including statins, immediately in all patients >1 y old to achieve tier I treatment goals

Kawasaki disease with coronary aneurysms[46]

- Antithrombotic therapy, activity restriction, ongoing myocardial perfusion evaluation per cardiologist
- Assess BMI, BP, lipids, FG: Step 1 management for 6 months
- If goals not achieved, proceed to Step 2; statin Rx if >10 y old to achieve tier I treatment goals

BP indicates blood pressure; LDL-C, LDL cholesterol; Rx, prescription/treatment; FG, fasting glucose; PG, plasma glucose; ACE, angiotensin-converting enzyme; and CMV, cytomegalovirus.

hood cancer survivors in a manner similar to that of fetal malnutrition in healthy populations.[374–379]

The induction and intensification stages of therapy include prolonged continuous administration of high-dose steroids, which induce hunger and decrease lean body mass.[354,358] The combination of initial malnutrition and muscle wasting from cancer counterposed by treatment-induced intense appetite underlies the potential development of poor eating habits.

Insulin Resistance/Type 2 Diabetes Mellitus

Childhood cancer survivors have higher fasting plasma glucose and insulin levels than age-matched control subjects,[379] and type 2 diabetes is reported to be more common in childhood cancer survivors than among sibling control subjects, with an odds ratio of 1.8 (95% confidence interval 1.1 to 1.29). Cancer types associated with a statistically significant increased risk of diabetes include leukemia, Wilmsô tumor, and neuroblastoma.[380] Impaired glucose tolerance and impaired insulin response were also found in 69% of a cohort of children who survived acute lymphoblastic leukemia, which suggests pancreatic β-cell dysfunction.[381]

Some evidence supports the hypothesis that growth hormone deficiency may play an important role in the pathogenesis of insulin resistance among survivors of childhood cancer.[353,355,382] Both chemotherapy and cranial radiation can cause a variety of chronic endocrine abnormalities. In addition to its effect on growth and development, growth hormone directly and indirectly influences insulin sensitivity and lipid metabolism.

Dyslipidemia

As would be anticipated, obese childhood cancer survivors have the typical lipid pattern associated with obesity: elevated triglycerides and reduced HDL cholesterol.[354] Cyclophosphamide administration in animal models results in hypertriglyceridemia and impairment of vascular lipoprotein lipase.[383,384] The frequently seen constellation of obesity, insulin resistance, and dyslipidemia suggests that the cluster of findings known as the metabolic syndrome is common in survivors of childhood cancer.[385]

Physical Deconditioning

Reductions in cardiac output and cardiorespiratory fitness are prevalent among leukemia survivors, particularly those who are overweight and have features of metabolic syndrome.[386–391] Although resting metabolic rate does not appear to be reduced in cancer survivors, growth hormone deficiency is suggested as a potential mechanism to explain reductions in strength and in exercise capacity seen in adult survivors of childhood leukemia and in children and adults who are cancer free.[392–396] Because of

its effects on body composition and muscle strength, growth hormone deficiency may contribute synergistically to decreased fitness.[397] Lack of adequate physical activity and the approach to a survivor of childhood cancer as a ñvulnerable childò may also contribute to the conditions characteristic of the metabolic syndrome, a common occurrence in this group.

Exercise may attenuate the effects of cachexia in cancer survivors by suppressing inflammatory responses and by improving insulin sensitivity, rates of protein synthesis, and antioxidant activities.[398] A decrease in cardiac output and a reduction in pulmonary elasticity with diminished aerobic capacity have been demonstrated in leukemia survivors, limiting their participation in tasks that require sustained or vigorous activity.[386,399,400]

Other Factors

A recent study in young adult survivors of disseminated testicular cancer who underwent surgery and chemotherapy reported a high prevalence of microalbuminuria and increased levels of endothelial and inflammatory marker proteins compared with both patients who underwent surgery alone and healthy control subjects.[401] To date, it is not clear whether the underlying mechanisms for insulin resistance in childhood cancer survivors are different from those in noncancer populations. However, there is a strong possibility that in addition to obesity, which is very common in this group, other pathways may be activated in childhood cancer survivors. These include growth hormone deficiency (a known outcome after central nervous system radiation), reduced physical activity, inflammatory mediators, and adipocytokines, which may be altered by therapies to treat cancer. Currently, data on specific anticancer drugs are insufficient to allow inferences on causality.

Recommendations for Childhood Cancer Survivors

Survivors of Childhood Cancer Are at Risk for Early Cardiovascular Disease (Tier III)

With the number of childhood cancer survivors increasing, thousands of individuals worldwide every year are faced with a variety of long-term adverse effects. Regular evaluation of cardiac function and identification of risk factors for accelerated atherosclerosis are clearly indicated. The algorithm in the Figure and Table 2 provide specific diagnosis and treatment guidelines.

Conclusions

In contrast to the normal pediatric population, children with specific underlying conditions experience accelerated atherosclerosis that leads to early CAD. In the present statement, we have reviewed what is known about coronary disease and the atherosclerotic process for 8 specific diagnoses and described current approaches to cardiovascular risk identification and treatment. A modified nominal group process was used to risk-stratify the diagnoses and to develop recommendations for risk identification and intervention.[29] Further research is needed to explore the pathophysiology of atherosclerosis unique to each specific diagnosis, to develop improved methods for assessment of preclinical disease, and to critically evaluate therapeutic interventions. Because the time course to clinical disease with some of these diagnoses is short, they offer a unique opportunity in pediatric cardiovascular research to perform randomized trials of the safety and efficacy of interventions.

The recommendations presented here are directed toward the primary care providers and pediatric subspecialists who care for these patients in childhood, as well as to internists, family practitioners, and adult subspecialists who will assume their care as they reach adult life. When published data did not permit evidence-based practice, we suggested practical interim recommendations. As new information develops, the guidelines will need to be modified to effectively provide guidance on cardiovascular risk reduction in these high-risk pediatric settings. Finally, decisions on the management of individual patients must be tailored to their unique circumstances.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

CLINICAL REPORT

Care of the Adolescent Sexual Assault Victim

Guidance for the Clinician in Rendering Pediatric Care

Miriam Kaufman, MD, and the Committee on Adolescence

ABSTRACT

Sexual assault is a broad-based term that encompasses a wide range of sexual victimizations including rape. Since the American Academy of Pediatrics published its last policy statement on sexual assault in 2001, additional information and data have emerged about sexual assault and rape in adolescents and the treatment and management of the adolescent who has been a victim of sexual assault. This report provides new information to update physicians and focuses on assessment and care of sexual assault victims in the adolescent population. *Pediatrics* 2008;122:462–470

www.pediatrics.org/cgi/doi/10.1542/peds.2008-1581

doi:10.1542/peds.2008-1581

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Key Words
sexual assault, victim, victimization, adolescent, violence, dating violence

Abbreviations
GHB—γ-hydroxybutyrate
STI—sexually transmitted infection
NAAT—nucleic acid–amplification test

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

Many terms have been used to describe sexual assault, including rape, statutory rape, acquaintance or date rape, sexual abuse, molestation, and incest. There is great overlap and some confusion in the definitions of nonconsensual sex acts. "Sexual assault" is a comprehensive term that includes any forced or inappropriate sexual activity. Sexual assault includes situations in which there is sexual contact with or without penetration that occurs because of physical force or psychological coercion or without consent, including situations in which the victim would be unable to consent because of intoxication, inability to understand the consequences of his or her actions, misperceptions because of age, and/or other incapacities. These situations can include touching of a person's "sexual or intimate parts or the intentional touching of the clothing covering those intimate parts."[1]

The age of consent for sex varies from state to state. Reporting requirements to child welfare agencies, parents, or the police are also variable, sometimes governed by local jurisdictions, and in flux. In addition, in some states (eg, Texas and California), there are laws mandating that sexual intercourse and sexual contact must be reported if certain age differences exist between a minor (usually defined as younger than 18 years) and his or her sex partner (whether minor or adult), even if the sexual act was voluntary and consensual. Some adolescents may refuse to seek care or disclose personal risk information because of possible reporting of sexual partners.[2–5]

This report only addresses acute sexual assault in the adolescent age group and not sexual abuse that might be chronic and identified long after the fact. For more information about sexual abuse, see the American Academy of Pediatrics clinical report "The Evaluation of Sexual Abuse in Children."[6]

Because of the differences between states and the likelihood of change, physicians need to be familiar with the particular laws in their state and continue to be aware of any changes that may occur. This information is available online through the Child Welfare Information Gateway.[7]

EPIDEMIOLOGY

National data show that teens and young adults have the highest rates of rape and other sexual assaults of any age group. It is widely accepted that statistics on sexual assault reflect substantial underreporting, so the reported rates, in all likelihood, are underestimates. Annual rates of sexual assault per 1000 persons (male and female) were reported in 2004 by the US Department of Justice to be 1.2 for ages 12 through 15 years, 1.3 for ages 16 through 19 years, 1.7 for ages 20 through 24 years, and 1.6 for ages 24 through 29 years.[8] There are significant gender differences in reports of adolescent rape and sexual assault, with the 2005 National Crime Victimization Survey statistics reporting 176 540 rapes and sexual assaults of females 12 years or older and 15 130 rapes and sexual assaults of males 12 years or older.[9] This represents a significant decrease from peak rates of rape and sexual assault reported in this group in 1992.[9,10] These figures may not indicate a true decrease in the rate of rape but may reflect, instead, methodologic differences in reporting rates over time. Studies have demonstrated that two thirds to three quarters

of all adolescent sexual assaults are perpetrated by an acquaintance or relative of the adolescent.[10,11] Older adolescents are most commonly the victims during social encounters with the assailants (eg, a date). With younger adolescent victims, the assailant is more likely to be a member of the adolescent's extended family. Adolescents with developmental disabilities, especially those with mild mental retardation, are at particular risk of acquaintance and date rape.[12]

Adolescent rape victims presenting to emergency departments are more likely than adult victims to have used alcohol or drugs and are less likely to be physically injured during a rape, because assailants in adolescent rape tend to use weapons less frequently.[11,13] Adolescent female victims are also more likely to delay seeking medical care after rape and sexual assault and are less likely to press charges (when given a choice) than are adult women.[11,13] Male victims are less likely to report a sexual assault than are female victims.[14–16] Studies of sexual assault of males have demonstrated that up to 90% of perpetrators are male. Sexual assault of males by females is more commonly reported by older adolescents or young adults, compared with children or young adolescents.[14,16] Male perpetrators of male sexual assault more commonly identify themselves as heterosexual than homosexual.[14] The rate of perpetration by an acquaintance of the victim is similar for male and female victims, but multiple assailants, use of a weapon, and forced oral assaults are more common in assault of males than of females.[4]

SUBSTANCES AND SEXUAL ASSAULT

Alcohol or drug use immediately before a sexual assault has been reported by more than 40% of adolescent victims and adolescent assailants.[15] Adults have been shown to significantly underreport voluntary drug use associated with sexual assault, but the same has not been demonstrated in adolescents.[17] Increasing rates of adolescent acquaintance rape have been associated with the availability of illegal so-called date-rape drugs. The most well known of these is flunitrazepam (Rohypnol, manufactured by Roche Pharmaceuticals Inc outside of the United States), which is a benzodiazepine sedative/hypnotic. The effects of flunitrazepam begin 20 to 30 minutes after ingestion, peak within 2 hours, and persist for up to 8 to 12 hours if given without alcohol and up to 36 hours with alcohol. Drug effects include somnolence, decreased anxiety, muscular relaxation, and profound sedation. There may also be amnesia for the time that the drug exerts its action. Flunitrazepam can go undetected by an adolescent if added to any drink, thus increasing the risk of sexual assault, especially in the adolescent population. Hypotension, visual disturbances, dizziness, and urinary retention are all possible medical complications. After ingestion, it can be found in the bloodstream for 24 hours and in urine samples for up to 48 hours.[18–21] Therefore, urine and blood samples can be sent for toxicology screening, with every effort made to ensure the chain of evidence. Date-rape drugs and many other drugs of abuse are not included in standard drug-screening panels. At the time of evaluation, health care professionals should inquire how to detect the presence of suspected drugs and collect the proper specimens from the victim.

γ-Hydroxybutyrate (GHB) is also used as a date-rape drug. People who are given GHB in low doses are likely to experience drowsiness, euphoria, increased libido, and passivity.[22] In addition, at higher doses, they can experience amnesia, intoxication, dizziness, and visual hallucinations. Medical complications of high doses include hypotension, bradycardia, severe respiratory depression, and coma. GHB acts quickly, usually within 15 minutes of ingestion. The effects last for 3 to 6 hours when taken without alcohol and 36 to 72 hours when mixed with alcohol or other drugs. It is cleared quickly and is undetectable in urine after only 12 hours or even earlier.[23]

Ketamine effects include amnesia, delirium, vivid hallucinations, tachycardia and arrhythmias, mild respiratory depression, confusion, irrationality, violent or aggressive behavior, vertigo, ataxia, slurred speech, delayed reaction time, euphoria, altered body image, analgesia, and coma. Ketamine effects occur within 20 minutes. The effects last for less than 3 hours. Opinion varies on clearance, with sources quoting detectability in urine from 24 to 72 hours after ingestion.[24,25]

Because all of these drugs are detectable for only a short time, if there is suspicion that 1 of them has been used, toxicology screening should be performed as soon as possible, perhaps even before finishing the history and physical examination. The reference concentrations of these drugs are not universally available, and referral to a sexual assault center may be required for drug testing.

In addition to these 3 drugs, common prescription benzodiazepines and over-the-counter antihistamines are also being used to facilitate sexual assault, so testing should be performed for these medications also.[26]

Alcohol is still the most common date-rape drug, and adolescents should be warned of their increased vulnerability to assaults when drinking. If their friends are also drinking, they cannot count on them to notice that an assault is taking place.

SEXUAL ASSAULT OF YOUNG PEOPLE WITH DISABILITIES

Children and adolescents with disabilities are at significantly increased risk of sexual assault: 1.5 to 2 times higher than the general population.[27] Those who have milder cognitive disabilities are at the highest risk.[28,29] A number of factors probably result in the increased risk, including decreased ability to flee or fight off an attacker; an expectation of increased compliance and tolerance of levels of physical intrusion not expected of people without disabilities; dependence on others for personal care; and, in general, ineffective safeguards.[30]

A number of factors apply to the reporting of sexual abuse or assault by those with disabilities, including what significance the victim attaches to the incident; whether the victim has a means of communication; whether they perceive there to be a trustworthy, capable person to whom the information may be disclosed; and issues of being believed and feeling safe.[29,31,32] Some of these factors uniquely affect individuals with disabilities,

but others are shared by individuals without disabilities as well.

Health care professionals should be familiar with counseling agencies, programs that specialize in child abuse, and other services that are physically accessible and that have communication skills that are appropriate for teenagers using augmentative communication devices or who are cognitively impaired. Services should be identified that can provide appropriate genital and pelvic examinations for victims having physical disabilities requiring mobility aids.

ADOLESCENTS' PERCEPTIONS AND ATTITUDES REGARDING SEXUAL ASSAULT

Exploring the perceptions and attitudes of adolescents regarding nonconsensual sexual encounters is important. Because there may have been voluntary participation before the assault occurred, an adolescent might think that he or she will not be believed. Teenagers may be reluctant to report an incident because they feel guilty, are worried that their parents will restrict them from going to social events, or have little memory of the assault because of the use of date-rape drugs. One study demonstrated that male and female adolescents who viewed a vignette of unwanted sexual intercourse accompanied by a photograph of the victim dressed in provocative clothing were more likely to indicate that the victim was responsible for the assailant's behavior, more likely to view the man's behavior as justified, and less likely to judge the act as rape than when the victim was in less-provocative clothing.[33] Also, some aggressive behavior on the part of a male perpetrator may be seen by some adolescents as normative.[34–37]

ADOLESCENT REACTIONS TO RAPE

Unwanted sexual experiences during adolescence are common, with a large survey of middle- and high-school students indicating that 18% of females and 12% of males have had an unwanted experience.[38] Studies of female adolescents have found rape during childhood or adolescence to be associated with increased risky behaviors and mental health problems, including younger age of first voluntary intercourse; higher rates of depression, including suicidal ideation/attempts; and other self-harm behaviors such as self-mutilation and eating disorders.[34,35,37,39–42] When found in the gender less affected, psychiatric or behavioral problems that are more prevalent in the other gender (such as eating disorders in girls, fighting in boys) may be an indication that sexual assault or abuse has occurred.[40]

Rape trauma syndrome is described as consisting of an initial phase that lasts for days to weeks, during which the victim experiences disbelief, anxiety, fear, emotional lability, and guilt followed by a reorganization phase that lasts for months to years, during which the victim goes through periods of adjustment, integration, and recovery.[43,44] Part of rape trauma syndrome is posttraumatic stress disorder, which occurs in up to 80% of rape victims.[45] A 4-question screening tool for posttraumatic stress disorder has been used with some success with adults by gynecologists.[46] Counseling designed to specifically address these issues, as well as additional psychological trauma that results from date or acquaintance rape, should be available. Psychotropic medications may be required in some instances. The physician should be knowledgeable about services available in the community to address these issues and should provide initial psychological support.

Other victim reactions to sexual assault can include the feeling that his or her trust has been violated, increased self-blame, less-positive self-concept, anxiety, alcohol abuse, and effects on sexual activity (including younger age at first voluntary sexual activity, poor use of contraception, greater number of abortions and pregnancies, sexually transmitted infections [STIs], victimization by older partners, erectile dysfunction in males, and sexual dissatisfaction).[41,47–52] Adolescent victims may feel that their actions contributed to the act of rape and have confusion as to whether the incident was forced or consensual.[53–55] Male victims also report fragility of their gender identity and sense of masculinity and confusion about their sexual orientation.[50] All victims should be screened for suicidal ideation and self-harm behavior.

INVESTIGATIONS

Adolescents may report a sexual assault to their physician, sometimes because they came to do so and other times because the question has been asked. Depending on the patient's current age, age at time of the event, the identity and presence of the alleged perpetrator (such as an acquaintance, a relative, teacher/coach, or even health care professional), and state law, the assault may have to be reported even if the teenager does not want it to be reported. At the time of examination after acute assault, an adolescent may have a hard time making a decision to press charges and can be encouraged to have a forensic medical examination to assess for injury and infection and to collect forensic evidence. Before any forensic examination, victims should be advised not to wash their clothes, bathe, or shower until they have been examined. These clothes should be stored in a paper, not plastic, bag. In some facilities, adolescents may have the option of freezing forensic evidence if they are uncertain about filing charges for possible use in the future. A forensic medical examination includes a medical forensic history, documentation of biological and physical findings, collection of evidence from the patient, and follow-up for additional evidence gathering.[56] With DNA-amplification techniques, a forensic examination can be useful for at least 4 days after the assault[57] and possibly longer.[58–60] Between 4 and 7 days, local authorities should be contacted to determine if it is useful to collect evidence. After 1 week, examination, counseling, and treatment can take place without need for forensic collection. Unfortunately, not everyone presenting with the same history may get the same forensics and treatment, with homeless females being a group that has been identified as getting less-than-adequate services.[61] Decreased access to care is likely to lead to increased rates of infections with STIs and their sequelae, unwanted pregnancies, increased psychiatric

TABLE 1 **Investigations According to Site**[62]

Screening	Throat	Vagina	Cervix/Urethra	Anorectal	Blood (Bodily Fluids, Any Site)

complications, and poor reporting of sexual assault. The Centers for Disease Control and Prevention's treatment guidelines for STIs[62] include a recommendation for comprehensive clinical treatment of victims of sexual assault, including emergency contraception and HIV prophylaxis, if indicated. The evaluating health care professional should ensure that specimens are available for timely clinical care and that follow-up plans are communicated and feasible.

Before any examination, the health care professional should address the adolescent's immediate health concerns such as the likelihood of having contracted an STI, the possibility of pregnancy, and worries about acute and permanent physical injury/damage. A referral for examination and treatment should be made to an emergency department or sexual assault treatment center where there are personnel experienced with adolescent assault victims. Physicians involved in the management and forensic examination of adolescent victims of sexual assault should be trained in the forensic procedures required for documentation and collection of evidence. Colposcopic procedures allow examiners to detect and document genital trauma, including microtrauma, with a growing body of literature demonstrating the patterns of genital injury in sexual assault victims.[63–65] Physical examination is unlikely to yield evidence of penetration that, other than the possible presence of seminal fluid, is visible to the naked eye. After the acute period, it is uncommon to find any indication of genital trauma,[66] although as many as 32% of teenagers who have not previously had intercourse may show physical signs after the acute period.[67,68] Adolescents have reported that the experience of video colposcopy may be beneficial, with many accepting offers to watch their own examination on screen.[69]

It is essential that the forensic examination be performed by a person such as a physician who specializes in child abuse or a nurse with sexual assault care training, who can ensure an unbroken chain of evidence and accurate documentation of findings.[43,47,58,70–72] Details of the required examination and documentation are presented in a handbook published by the American College of Emergency Physicians, *Evaluation and Management of the Sexually Assaulted or Sexually Abused Patient* (available online).[73] Physicians who treat sexually abused or assaulted patients need to be aware of the legal requirements, including completion of appropriate forms and maintaining the legal chain of evidence and reporting to appropriate authorities specific to their locale.

Documentation of the history and physical examination is important. Value judgments should not be included, nor should interpretations of the meaning of the adolescent's body language or facial expressions. Descriptions should be exact, and terms such as "hymen not intact" should be avoided. The clinical records from both the referring physician and the assault center are likely to be subpoenaed if there is a prosecution. Again, there is more likelihood of the evidence being accepted if the examiner is an expert in handling cases of sexual assault. Any examination or treatment should be performed only with the consent of the adolescent.

For an examination after acute assault, testing for STIs is somewhat controversial. There is a concern that a speculum examination may be traumatic, especially for a teenager who has not had one before, possibly leading to avoidance of pelvic examinations in the future. Finding an STI, particularly *Chlamydia trachomatis*, may give a defense lawyer an opportunity to introduce the victim's previous sexual history. However, many victims of assault have been reported to have positive culture results and/or samples at the time of the acute evaluation.[74–76] Obviously, positive results may indicate an existing infection as a result of the victim's history of consensual sexual contact, but some cultures or samples may be positive as a result of the assault even when obtained within 72 hours of the assault. Specimen collection should be discussed with the adolescent, who then can choose whether to have cultures performed. If specimens are to be collected, the decision of which sites should be sampled should be based on possible contact with the perpetrator's bodily fluids (see Table 1). Because some courts will only accept positive culture results for gonorrhea and chlamydia (as opposed to nucleic acid–amplification tests [NAATs] and other indirect tests), cultures are preferable over NAATs for any case in which there is likely to be prosecution. However, there may be an advantage to using an NAAT in addition to a culture to detect chlamydia, because the high sensitivity makes it more likely to detect before the end of the incubation period.[77] Vaginal secretions can be microscopically examined for *Trichomonas* species and sent for culture where available.

If prophylactic treatment is given, cultures do not need to be performed at follow-up unless requested by the victim. If there is no prophylaxis prescribed, then

TABLE 2 **Prophylactic Treatment Recommendations**

Condition	Recommended Regimen
Gonorrhea	Ceftriaxone, 125 mg intramuscularly once (for oral and/or anogenital penetration) or may use, if available, cefixime, 400 mg orally once (for anogenital but not oral penetration)
Trichomonas species	Metronidazole, 2 g orally once
Chlamydia	Azithromycin, 1 g orally once, or doxycycline, 100 mg orally twice daily for 7 d
Hepatitis B	Immunize, if not previously completed
Human papillomavirus	Immunize, if not previously completed
Pregnancy prevention or emergency contraception	0.75-mg levonorgestrel tablet: 2 tablets orally, 12 h apart
HIV	See text

cultures are recommended 1 to 2 weeks after the assault.[77]

Serum samples can be obtained for baseline testing for syphilis and HIV in areas or populations in which there is a high incidence of infection or if the victim wishes for these tests to be performed (see below for HIV prophylaxis). Syphilis tests should be repeated after 6 to 12 weeks, and HIV tests should be repeated after 3 to 6 months.[43,58,72,73]

MANAGEMENT

Acute Care

The examining physician should keep in mind that the young person may have nongenital injuries, the treatment of which may be a priority depending on the severity of the injury.

Pregnancy prevention and emergency contraception should be addressed with every adolescent female rape and sexual assault victim. The discussion should include risks of failure and options for pregnancy management. Progestin-only emergency contraceptive pills have the most favorable mix of safety, with fewer adverse effects and increased efficacy.[78] A baseline urine pregnancy test should be performed. Emergency contraception should be offered to females who have been (or may have been) vaginally penetrated or who think that ejaculate has come into contact with their genitalia.[43,47,58,65,70,71] Although package labels suggest a dosage of 0.75 mg of levonorgestrel taken twice, 12 hours apart, taking both tablets at once is an easier regimen and is just as effective without increasing adverse effects.[79]

Prophylactic treatment for chlamydia and gonorrhea should be recommended to adolescent sexual assault victims who have been vaginally or anally penetrated (with or without ejaculation) or orally penetrated (with ejaculation). Current recommendations from the Centers for Disease Control and Prevention are to treat with 125 mg of ceftriaxone intramuscularly, 2 g of metronidazole once orally, and either 1 g of azithromycin once orally or 100 mg of doxycycline twice daily for 1 week.[62] If available, cefixime at a dose of 400 mg once orally can be used instead of the ceftriaxone if only genital penetration occurred (see Table 2).

Teenagers who have not initiated or completed immunization against hepatitis B virus should be offered the vaccine with completion of the series to be facilitated. There are currently no recommendations regarding immunization against human papillomavirus infections in the context of an acute sexual assault; however, all adolescent female victims are within the recommended age group for receiving this immunization, so depending on insurance coverage, immunization can be discussed at this time.

There are only a handful of cases in the literature of HIV being transmitted from a single episode of sexual assault.[80–82] HIV prophylaxis is not universally recommended but should be considered when there is mucosal exposure (oral, vaginal, or anal). Factors to consider include the risks and benefits of the medical regimen, including whether there was repeated abuse or multiple perpetrators; if there is oral, vaginal, or anal trauma, including bleeding; if the perpetrator is known to have HIV infection; or if either the victim or perpetrator has a genital lesion or if there is a high prevalence of HIV in the geographic area in which the sexual assault occurred.[43,58,62,72,73,83,84] If rapid testing of the assailant is available, prophylaxis can be started and then stopped if the test result is negative. In 1 study, only 71 of 258 people who had been sexually assaulted agreed to HIV prophylaxis, 29 continued with the treatment past 5 days, and only 8 completed the full course. Those at higher risk were more likely to complete treatment.[85] A retrospective study found that uncertainties regarding exposure, high rates of psychiatric comorbidity, and low rates of return for follow-up care were all factors in the low rates of adherence to postexposure prophylaxis.[86] Centers that specialize in treatment of sexual assault victims often provide care without cost to their clients and can advise about local resources when payment, confidentiality, and safety are concerns. No large studies examining different combinations of treatment have been performed with sexual assault victims, but on the basis of current occupational-exposure guidelines, 2 nucleoside reverse-transcriptase inhibitors and 1 of either a nonnucleoside reverse-transcriptase inhibitor or protease inhibitor for 4 weeks is recommended.[87] In situations in which significant risk exists, prophylaxis with 3 medications should be offered only if the drugs can be started within 72 hours of exposure.[88]

Follow-Up Care

Follow-up can include a visit within 1 week of presentation to assess injury healing and to ensure that counseling has been arranged. Reassessment for STIs may need to occur depending on medications given at the time of the initial evaluation and the intervening history of consensual sexual activity.[75] At 2 weeks, pregnancy testing can be performed, along with discussion of test results, assessment of adherence to any medications, and the teenager's emotional status. The Centers for Disease Control and Prevention recommends that syphilis and HIV testing be repeated 6 weeks, 3 months, and 6 months after the assault if initial test results were negative and infection in the assailant could not be ruled out.[62]

Because responses to rape can vary, it is important for physicians to address both the physical and psychological needs of the adolescent. Physicians should be aware that self-blame, humiliation, lack of information (ignorance), and naiveté might prevent the adolescent from seeking medical care. Effective screening, referral, and follow-up allow for support of the adolescent rape victim and appropriate delivery of health care services. Because patients treated in emergency departments often do not return for follow-up care,[89] it is important that the emergency treatment team refer the assaulted adolescent back to his or her medical home or a specialty treatment center, if they have one and if the teenager consents to his or her primary health care professional knowing about the assault. Contact with the primary health care professional from the emergency department with the information would relieve the teenager of the burden of introducing the topic and encourage follow-up. The adolescent should be encouraged to share information with a parent or other trusted adult. Although adolescents may want confidentiality and have the right to it, this is a time during which support from an adult is very important, especially when teenagers are being treated in unfamiliar emergency department environments. Involving a support person may help ensure that the adolescent gets supportive help and appropriate counseling, particularly if he or she later becomes depressed and lacks the ability to access help. Parents can be counseled and encouraged to focus on their teenager's needs and not blame themselves or their son or daughter.

Male victims' concerns about their sexuality, in particular their sexual orientation, should be addressed.

Physicians should be prepared to provide follow-up STI testing, completion of the hepatitis B virus and human papillomavirus immunization series, treatment of injuries, screening for mental health problems, and management of substance use issues.

A number of studies have shown that trauma-focused cognitive behavioral therapy is useful for adolescents who have been abused or assaulted,[90] and a call or referral to a sexual assault care center may yield the names of mental health professionals who are more skilled in the care of victims and their families. Under some circumstances, funding may be available to pay for tests and treatments through the Victims of Crime Act (Pub L No. 98–473 [1984]).

SEXUAL ASSAULT AND RAPE-PREVENTION STRATEGIES

Adolescent rape exists in a sociocultural context, including some religious and ethnic values, in which issues of male dominance, appropriate gender behaviors, victimization, violence, and power imbalances in relationships are highly visible. Prevention messages for adolescents need to be designed for males and females.[47,70,91–93] Adolescents need to be able to identify high-risk situations (such as attending parties with unknown people, meeting people with whom they have had contact on the Internet, walking alone at night, allowing themselves to be photographed nude or in sexually explicit poses or situations); they also should be advised that if they are ever assaulted, they should seek medical care. Factors that may increase the likelihood of assaults (eg, use of drugs or alcohol) and strategies to prevent sexual assaults (eg, "buddying up," not drinking from anything that has been left unattended, abstaining from or moderating alcohol intake, not accepting drinks from strangers) should be discussed, and associated educational materials should be available and distributed.[47,70,91–93]

A survey of more than 600 young women in an urban setting showed that the vast majority thought that young women should be screened and counseled by their health care professional regarding dating violence.[94] Physicians should be aware that sexual assault is common and need to be prepared to counsel their adolescent patients to avoid high-risk situations. Screening of adolescents for sexual victimization should be part of visits for psychological problems, sexuality issues, contraception or substance abuse, and health supervision. Physicians should include information about ways to prevent sexual assault as part of anticipatory guidance with adolescents with and without disabilities, tailored to cognitive abilities to understand. Adolescents should be asked direct questions without their parents present regarding their past sexual experiences. These questions should include those that explore age of first sexual experience, use of the Internet to find romantic or sexual partners, and unwanted or forced sexual acts. Exploration of gender roles and relationship parameters (eg, exploitative, nonconsensual versus healthy) are critical. Adolescents who have been sexually assaulted need the opportunity to describe the experience at their own pace and in their own words.[47,63–65,70]

SUMMARY STATEMENTS

1. Physicians are encouraged to routinely discuss with their adolescent patients the potential for sexual and physical violence, including relationship violence. The discussion may help prevent and/or reduce the stigma of revealing such issues if violence occurs.
2. Physicians are encouraged to be aware of the current reporting requirements for sexual assault and laws protecting the confidential rights of adolescents to obtain care at rape crisis care centers in their state.
3. Physicians should be knowledgeable about sexual assault and rape evaluation services available in their communities. This information should include when and where to refer adolescents for a forensic medical examination and sexual assault care as well as for services appropriate for teenagers with disabilities.
4. Physicians are encouraged to routinely screen adolescents, including those with disabilities, for a history of sexual violence, covering the potential of dating violence and sexual assaults.
5. For those adolescents with positive histories, appropriate STI screening, prophylaxis, and treatment should be available on a timely basis, including referrals for care and potential sequelae.
6. Emergency contraception should be offered to female sexual assault victims if reported within 120 hours of

the assault. Given the safety of emergency contraception, it should be offered even if the adolescent is not sure whether penetration occurred. Documentation of pregnancy status should occur at the time of the evaluation with either a blood or urine sample.

7. Because of the potential for long-term psychological consequences, physicians should be prepared to offer psychological support or referral for counseling and should be aware of the services in the community that provide management, examination, and counseling for the adolescent patient who has been sexually assaulted.

Care Coordination in the Medical Home: Integrating Health and Related Systems of Care for Children With Special Health Care Needs

ABSTRACT. Care coordination is a process that facilitates the linkage of children and their families with appropriate services and resources in a coordinated effort to achieve good health. Care coordination for children with special health care needs often is complicated because there is no single point of entry into the multiple systems of care, and complex criteria frequently determine the availability of funding and services among public and private payers. Economic and sociocultural barriers to coordination of care exist and affect families and health care professionals. In their important role of providing a medical home for all children, primary care physicians have a vital role in the process of care coordination, in concert with the family. ***Pediatrics*** **2005;116: 1238–1244;** ***care coordination, case management, children with special health care needs, medical home.***

ABBREVIATION. AAP, American Academy of Pediatrics.

INTRODUCTION

As defined by the Maternal and Child Health Bureau and accepted by the American Academy of Pediatrics (AAP), "children with special health care needs are those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."[1] It has become apparent that these more extensive health and related services require forethought in the development of their structure and coordination. *Healthy People 2010* calls for all children* with special health care needs to receive coordinated, ongoing, comprehensive care within a medical home.[2] The New Freedom Initiative announced in 2001 outlines goals to remove barriers to community living for people with disabilities.[3] Care coordination plays an essential role in ongoing efforts to integrate health and related systems of care for children and youth with special health care needs.[4] In a recent publication, the Institute of Medicine identified overly complex and uncoordinated care as a major reason for "a chasm…that exists between the health care that we now have and the health care that we could have."[5] Although efforts to better define the population continue,[6] data support the fact that children with special health care needs account for a substantial amount of health services utilization. Children with special health care needs are estimated to account for 13% of all children, yet they represent 70% of health care expenditures.[7–9] Individuals with chronic illness need coordinated services to provide chronic care management. Recent research supports the benefits of professional care coordination in clinical and process improvements and in reducing health care costs and improving family satisfaction.[10–13] The importance of these issues is reflected in the work of the National Center of Medical Home Initiatives for Children With Special Needs[14] and in a recent AAP policy statement, "The Medical Home."[4]

The medical home is an optimal setting for family-centered care coordination. Primary care physicians and other professionals caring for children with special health care needs generally acknowledge the importance of and the need for care coordination services. The increasing number of children with special health care needs, complexity of care, and outreach efforts necessary to educate about the medical home result in even greater responsibility for care coordination. Additionally, initiatives from health care reform and managed care have further expanded the role of the primary care physician in the areas of gatekeeper and coordination roles. New trends in the private health care market are reflected in consumer-driven health plans, a concept that has strong advocates and opponents. Arguments against the concept include biased selection of well members for the consumer-driven health plan, with resultant higher premiums for the chronically ill in traditional insurance programs, less preventive care, and a complicated system. Others argue that there will be cost benefits, more consumer choice, and support for health improvement. Another new trend is health savings accounts, which were created through the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (Pub L No. 108–173) and are designed to help individuals save for future qualified medical and retiree health expenses on a tax-free basis. However, these represent a significant potential negative effect on the concept of the medical home if parents are forced to seek low-cost

* In accordance with the policies of the AAP, references to "child" and "children" in this document include infants, children, adolescents, and young adults up to 21 years of age.

PEDIATRICS (ISSN 0031 4005).

health care professionals when their health plan requires significant out-of-pocket expenses. If this becomes the case, then the medical home is fragmented,, and quality care coordination services are put at risk. This transition to managed systems of care from traditional fee-for-service care has important implications for aspects of care coordination.

This policy statement reviews the importance of the primary care physician's role in care coordination in the context of the medical home.

MULTIPLE SYSTEMS OF CARE

Advances in medicine have resulted in more children surviving conditions that were once considered to be life threatening. This is often reflected in an increased demand for all levels of care, from primary care to community and educational services to special health care services required by children with chronic conditions.[15,16] Great variability exists among programs with services for these children. The provision of care includes multiple organizations, often with different missions,[17–20] and consists of independent health care professionals, third-party payers, private organizations, and public agencies funded by a variety of sources. These entities, as currently arranged, do not often function collectively as a system of care. Care coordination is complicated by the lack of a single entry point to gain access to systems of health care, social services, education, public health services, and home services. Furthermore, complex eligibility criteria (ie, family income and the child's age and/or health condition) that determine the availability of funding and services often differ among organizations and agencies. Therefore, families may struggle to access needed services and would benefit from professional assistance.[18] Few health plans offer risk-adjusted capitation or fee-for-service reimbursement rates that would justly compensate professionals for the additional time and effort invested in the provision of coordinated and comprehensive care for children with special health care needs.

Because children spend a substantial amount of time in school and child care settings, the linkages between health care and educational and child care systems are especially important for many children and youth with special health care needs.[18,20] However, each state's educational system uniquely interprets federal laws that mandate services for children with special health care needs, which creates variations in services among states. Although the laws are designed to provide special education and related services for all children with disabilities, some children with special health care needs are excluded from services because they do not meet the categorical definitions stated in these laws.[21]

THE ROLE OF HEALTH PLANS

Historically, public agencies and private organizations involved in human services have helped families determine the needs of their children and access appropriate services. This process is referred to as "case management." Case managers may assist with care coordination. Current payer systems often use case managers in an attempt to control the costs of health care. These case managers work directly for the payer and may help families with access to services and resource utilization, especially less costly out-of-hospital care, but a major role of theirs has been to limit the financial risk of the payer.

During the past 10 to 20 years, children with special health care needs have had greater access to case management services. Families of children with special health care needs frequently demonstrate the ability to participate in the management of their child's care in a cooperative effort rather than as the subordinates in an authoritarian system.[18] As a result, "care coordination" has replaced the term "case management." Care coordination occurs when care plans are implemented by a variety of service providers and programs in an organized fashion. Care coordination is multifaceted. It involves needs identification, assessment, prioritizing, and monitoring. A coordinator is required to communicate, network, and educate as well as advocate for resources.

THE ROLE OF THE PRIMARY CARE MEDICAL HOME

The role of the primary care medical home in care coordination is not fixed or determined by a defined set of tasks. Instead, it is a dynamic process driven by the health status and developmental progress of the child, the specific needs of the child and family, the primary care physician's expertise with children with special health care needs, and the ability of the family and/or other professionals to participate in care coordination. The primary care physician in the medical home should be aware of the array of available subspecialty services, know when these services are needed, know how to gain access to and advocate for subspecialty care within health plans, and know how to use subspecialists' recommendations and communicate the subspecialists' reports to the family.

The medical home is an important means for the primary care physician to provide care for children.[4] Medical homes for children with special health care needs incorporate the same elements of health supervision, community-based preventive care, developmental surveillance, and anticipatory guidance used in the ongoing care of all children. Care should be accessible, comprehensive, continuous, compassionate, culturally effective, and family centered. The medical home reinforces care coordination activities by the primary care practice team: the primary care physicians in collaboration with nurses, families, and support staff.

The AAP policy statement "The Medical Home"[4] lists the desirable characteristics of coordinated care within the medical home, including the following:

1. A plan of care is developed by the physician, practice care coordinator, child, and family in collaboration with other providers, agencies, and organizations involved with the care of the patient.
2. A central record or database containing all pertinent medical information, including hospitalizations and specialty care, is maintained at the prac-

tice. The record is accessible, but confidentiality is preserved.
3. The medical home physician shares information among the child, family, and consultant and provides a specific reason for referral to appropriate pediatric medical subspecialists, surgical specialists, and mental health/developmental professionals.
4. Families are linked to family support groups, parent-to-parent groups, and other family resources.
5. When a child is referred for a consultation or additional care, the medical home physician assists the child and family in understanding clinical issues.
6. The medical home physician evaluates and interprets the consultants' recommendations for the child and family and, in consultation with them and subspecialists, implements recommendations that are indicated and appropriate.
7. The plan of care is coordinated with educational and other community organizations to ensure that special health needs of the individual child are addressed.

"A Consensus Statement on Health Care Transitions for Young Adults With Special Health Care Needs"[22] emphasizes the importance of developing a written transition plan by 14 years of age that will include what services need to be provided, who will provide them, and how they will be financed. Although the pediatrician continues to provide the medical home throughout adolescence, early development of an individualized transition plan that addresses transfer of care as well as educational, recreational, and vocational opportunities will facilitate a successful transition. The plan for transition is often difficult; thus, preparatory time is imperative.

Additional guidelines are outlined in the AAP policy statement "Role of the Physician in Care Coordination for Family-Centered Early Intervention Services,"[23] published in 2001. Training in care coordination and other aspects of the medical home are available through the Every Child Deserves a Medical Home training curriculum of the AAP.[14] Additionally, tools have been developed through the AAP Committee on Coding and Nomenclature to help physicians with the complexities of reimbursement and the determination of the appropriate *Current Procedural Terminology* codes involved with the medical home.

There are increasing time and financial demands on health care professionals. The burdens become even more accentuated in small and rural practices and those dealing with special populations, such as immigrants, for which there is a limited range of available resources.

THE ROLE OF THE FAMILY

The family's role in the medical care of any child is vital. The AAP recognizes that "the family is the child's primary source of strength and support" in its policy statement on "Family-Centered Care and the Pediatrician's Role."[24] Additionally, the policy affirmed that the concept of the family as a primary partner in care coordination is linked to improved health outcomes.

Family members who are knowledgeable about their child's condition often lead the care coordination activities effectively or are active participants in their children's care if they are given opportunities to further develop their skills and strengths.[25] The participation of adolescent patients in the decision-making process should be encouraged. Some families and adolescents require greater efforts to be empowered to function optimally as care coordinators.

There are clearly circumstances in which families may need more assistance with care coordination, reflecting factors such as language barriers, educational level, migrant or immigrant status, economic situation, and insurance benefits. In situations in which family members are unable to perform a leadership role and coordination of care has been insufficient, the only person available may be designated by default. This assigned or default care coordinator may not be qualified or prepared or have the needed support. For the treatment plan to be most effective, the individual in charge of taking the lead in care coordination should be designated before the treatment plan is determined.

Professionals who assume primary responsibility for care coordination are often physicians, nurses, and social workers. Alternatively, physical and occupational therapists and other professionals can lead and participate in the coordination process. Families and children themselves are important participants, advisors, and consultants throughout the process. This collaboration with family members is vital because they know the child's needs best.[26] Positive changes occur when families and professionals work together to support families in their central role as caregivers.[27] In contrast, when they do not work together, the cost of care may increase, patient and family satisfaction may decrease, and patient care may become fragmented and disorganized.[28,29]

THE ROLE OF THE COMMUNITY

In the educational system, care coordination involves a written individual family service plan, individualized education program, 504 plan, or individual health service plan if individualized testing, special education, therapy, nursing services, psychosocial/emotional supports, appropriate transportation, or assistive technology devices are needed. Care coordination in the social service and public health systems may involve locating and accessing financial assistance programs and public health services. Care coordination in the home setting may mean organizing home nursing/therapy services and/or respite care and adapting the home environment to safely support special technology such as a ventilator or motorized wheelchair.

Many children with special health care needs, especially those who are medically fragile, have unique needs during an emergency that require care coordination and planning. Children who are technology dependent, such as those who require ventilator support or who have pacemakers, tracheostomies, gas-

trostomy tubes, or central venous catheters, have unique problems that often require care by emergency medical services personnel. For additional information, refer to the AAP policy statement "Emergency Preparedness for Children With Special Health Care Needs."[30] The primary care physician can facilitate coordination of services by ensuring appropriate communication and advocating for training of emergency medical services personnel. An emergency care form can be completed, including the family's wishes regarding advance directives for end-of-life issues.

BARRIERS TO EFFECTIVE CARE COORDINATION

Several barriers challenge the primary care physician in providing care coordination. These barriers include the following:

- a lack of knowledge and information about the chronic condition, community resources, and/or the coordination process;
- a lack of communication among health care professionals and organizations involved in the child's care;
- a lack of clearly defined roles for each of the members of the practice team, the specialty team, the community agencies, and the family;
- insufficient acknowledgment for the amount of time and work needed to provide quality care coordination services;
- inadequate reimbursement for care coordination because of the additional administrative tasks associated with care coordination, including extensive documentation and counseling;
- a lack of an organized system of care coordination with multiple service delivery systems with multiple care coordinators; and
- language and cultural barriers.

Published reports[31,32] and families themselves[17] have indicated that there is a greater need for involvement of primary care physicians in the care coordination process, in addition to the provision of primary care, for children with special health care needs. The absence of such involvement results in incomplete coordination and episodic, expensive, fragmented care.

The roles of the primary care physician as both gatekeeper and patient advocate may conflict with each other as physicians strive to manage limited economic resources while providing access to necessary subspecialty care and services.[33] Primary care physicians who provide a medical home for children with special health care needs are actively involved in care coordination, thereby improving quality of care.

CHARACTERISTICS OF SUCCESSFUL CARE COORDINATION MODELS

A number of studies have shown significant benefits related to implementation of care coordination models.[10–13] Benefits include reduced hospital admissions, reduced length of hospital stay, reduced inpatient charges, reduced emergency department visits, improved patient satisfaction, and enhanced opportunities for outcome-based clinical process improvement.

Title V of the Social Security Act had its origin in 1935 but has undergone multiple revisions. The amendments of 1989 (42 USC Chapter 7, Subchapter V §§701–710) reinforced the development of case management services.[34] The initial goal of case management was to decrease overlapping of multiple services. Other recognized benefits that accrued were improved access to care and a resultant feeling that the care provided was superior.[35]

Early intervention services were mandated in 1986 as an entitlement program when Congress passed the Education of the Handicapped Act Amendments (Pub L No. 99–457). They were reauthorized under the Individuals With Disabilities Education Act (Pub L No. 101–476 [1990]) as Part C. This legislation required the formation of the individual family service plan and defined community-based, family-centered, multidisciplinary intervention programs for infants and toddlers with developmental delays. Family training and counseling also were provided. New Jersey developed a unique model that combined the funding from Title V and the Individuals With Disabilities Education Act to provide county-based case management units, which provides a single point of entry into an otherwise very complex system when entry is based on need or funding. Many state Title V programs are implementing similar systems of care coordination.[14]

Successful models of care coordination have a number of common characteristics.[10,36–38] Both the Center for Medical Home Improvement[35] and the Institute for Community Inclusion[38] have published guidelines for care coordination in primary care settings. Standardized criteria help to identify children in need of care coordination and should be used.[6,36,38,39] Collaboration between insurers and professionals at the local and state level is critical. Each practice or community should have a designated care coordinator who provides a single point of entry. Nurses, nurse practitioners, physician assistants, and social workers have been successful in this role. One possible advantage for nurse practitioners and physician assistants in some settings is that their services may be reimbursed.[38] Ongoing assessment of the needs of each child and family is essential. The acuity and requirements of services fluctuate depending on the needs and wishes of the family. The process also may vary depending on the extent and multiplicity of the child's needs, family strengths, type of health care services available, limitation of benefits by the payer, and mission of the agency. Updated, standardized educational materials related to the care of children with special health care needs in general, as well as disease-specific information, should be available. The care coordination program should include an outcome-focused quality improvement component.

The care coordinator has the primary responsibility for the child's treatment plan and should document completion of tasks or, conversely, the need to vary from the original plan. The plan should include

the following components: a medical summary for use by emergency and hospital services as well as for medical care by physicians who are not familiar with the patient; patient- and family-centered short-term and long-term goals; role of the family and other supports; locus of implementation; methodology; intensity; and duration. The coordinator may need to communicate with payers such as Medicaid or health plans to obtain preapproval for services. The care coordinator should be knowledgeable about family and medical resources and insurance options, be able to identify and access resources for family support, and act as an advocate when necessary. Throughout the process, patient advocacy in the context of the family is important. High-intensity care coordination is needed at the time of medical diagnosis, hospital discharge, entrance into child care and school settings, transition to young adulthood, and when a change in health care status occurs. At these times, the primary care physician's special relationship with a child and the family can facilitate the appropriate support. At other times, coordination requirements may be less demanding and could be accomplished with a lesser degree of service, such as making a telephone call or forwarding records.

Generally, the goals of care coordination are to (1) develop an anticipatory/proactive plan for appropriate services for the child and family, integrating the recommendations of multiple professionals and service systems, (2) assist the family in accessing needed services and resources, (3) facilitate communication among multiple professionals, (4) avoid duplication of services and unnecessary costs, (5) optimize the physical and emotional health and well-being of the child, and (6) improve the child's and family's quality of life.

CONCLUSIONS

Although care coordination can be complex and time consuming and is always challenging, it is essential for efficient management of the many complex issues surrounding the care of children with special health care needs within the context of the medical home. Becoming aware of available resources, being involved in the care coordination process, and developing unique care coordination approaches within one's own practice and community and in relationship with existing tertiary care centers are essential for providing optimal care for children with special health care needs. Families, primary care physicians, and other professionals can collaborate meaningfully to provide effective coordinated care. Successful care coordination results in optimal outcomes for children with special health care needs and their families and provides an opportunity for professional fulfillment for physicians.

RECOMMENDATIONS

1. Primary care physicians, medical subspecialists and surgical specialists, physician's staff, families, community agencies, educators, early intervention professionals, allied health professionals, tertiary care centers, state Title V agencies, and insurers should work cooperatively to develop effective care coordination models that take into consideration the continuum of health, education, and social services needed to improve the quality of care for children with special health care needs.
2. Families of children with special health care needs should have the opportunity to lead the care coordination team and/or be proactive participants. To do so, the parents (or adolescent patients themselves) must have information about the condition, proper education in care coordination, and access to necessary resources.
3. Primary care physicians caring for children with special health care needs should facilitate access to community-based services through use of the medical home strategies. The AAP National Center of Medical Home Initiatives for Children With Special Needs (www.medicalhomeinfo.org) is a resource that can assist the pediatrician.
4. The primary care physician's role in care coordination should be flexible to meet the dynamic needs of the child and family. The primary care physician, a member of the physician's staff, a family member, or another member of the child's medical home may be designated the leader of the care coordination team. The Center for Medical Home Improvement[36] and the Institute for Community Inclusion[38] have developed kits that provide tools to identify needs and areas for improvement.
5. Successful provision of care coordination is contingent on adequate reimbursement for efforts. Health care professionals should be financially reimbursed by third-party payers for the time spent on care coordination and care plan development and oversight; otherwise, the efforts will fail. *Current Procedural Terminology* codes for telephone calls, prolonged service, team conferences, and care plan oversight and management should be reimbursed in all benefit packages.
6. Research efforts should continue to develop new approaches in care coordination and to investigate the outcomes and benefits of care coordination, especially within the context of the medical home.
7. Interdisciplinary training opportunities in the medical home philosophy and care coordination are available through the National Center of Medical Home Initiatives for Children With Special Needs.[7] Medical students and residents in training should incorporate care coordination skills so that they are better prepared to coordinate care when they begin community practice. (For additional information, refer to the AAP policy statement "The Pediatrician's Role in Community Pediatrics."[40])
8. Barriers to care coordination should be addressed and overcome. These barriers for the family often include cultural/language status, educational level, economic situation, and transportation resources.

Task Force on Sudden Infant Death Syndrome

The Changing Concept of Sudden Infant Death Syndrome: Diagnostic Coding Shifts, Controversies Regarding the Sleeping Environment, and New Variables to Consider in Reducing Risk

ABSTRACT. There has been a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed down for sleep in a nonprone position. Although the SIDS rate continues to fall, some of the recent decrease of the last several years may be a result of coding shifts to other causes of unexpected infant deaths. Since the AAP published its last statement on SIDS in 2000, several issues have become relevant, including the significant risk of side sleeping position; the AAP no longer recognizes side sleeping as a reasonable alternative to fully supine sleeping. The AAP also stresses the need to avoid redundant soft bedding and soft objects in the infant's sleeping environment, the hazards of adults sleeping with an infant in the same bed, the SIDS risk reduction associated with having infants sleep in the same room as adults and with using pacifiers at the time of sleep, the importance of educating secondary caregivers and neonatology practitioners on the importance of "back to sleep," and strategies to reduce the incidence of positional plagiocephaly associated with supine positioning. This statement reviews the evidence associated with these and other SIDS-related issues and proposes new recommendations for further reducing SIDS risk. *Pediatrics* **2005;116:1245–1255;** ***SIDS, sudden infant death syndrome, sudden unexpected infant death, infant mortality, supine position, infant sleep, infant bedding.***

ABBREVIATIONS. SIDS, sudden infant death syndrome; AAP, American Academy of Pediatrics; OR, odds ratio; ALTE, apparent life-threatening event; PWS, plagiocephaly without synostosis.

INTRODUCTION

Sudden infant death syndrome (SIDS) continues to be a phenomenon of unknown cause and, despite marked reductions in rates over the past decade, still is responsible for more infant deaths in the United States than any other cause of death during infancy beyond the neonatal period.[1] This statement endorses elements from the previous statement from the American Academy of Pediatrics (AAP)[2] that have not changed, includes information about recent research, and presents updated recommendations based on current evidence.

doi:10.1542/peds.2005-1499

Although there is ongoing discussion about changing the definition,[3] the current generally accepted definition of SIDS remains as follows:

> The sudden death of an infant under 1 year of age, which remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history.[4]

The occurrence of SIDS is rare during the first month of life, increases to a peak between 2 and 3 months of age, and then decreases. In conjunction with a more than 50% reduction in SIDS deaths since 1992, there has been a small shift in the age of death. A slightly higher proportion of deaths in the neonatal period and after 6 months of age were reported in 2001 than in 1992 (Fig 1).[5]

The following have been consistently identified across studies as independent risk factors for SIDS: prone sleep position, sleeping on a soft surface, maternal smoking during pregnancy, overheating, late or no prenatal care, young maternal age, preterm birth and/or low birth weight, and male gender. Consistently higher rates are found in black and American Indian/Alaska Native children—2 to 3 times the national average.

CHANGE IN SIDS STATISTICS IN THE UNITED STATES

Although SIDS was defined somewhat loosely until the mid-1980s, there was minimal change in the incidence of SIDS in the United States until the early 1990s. In 1992, in response to epidemiologic reports from Europe and Australia, the AAP recommended that infants be laid down for sleep in a nonprone position as a strategy to reduce the risk of SIDS.[6] The National Institute of Child Health and Human Development began conducting national surveys of infant care practices to evaluate the implementation of the AAP recommendation. The "Back to Sleep" campaign was initiated in the United States in 1994 under the leadership of the National Institute of Child Health and Human Development and as a joint effort of the US Public Health Service, the AAP, the SIDS Alliance, and the Association of SIDS and Infant Mortality Programs (800-505-CRIB; www.nichd.nih.gov/sids/sids.cfm).

Since 1992, and consistent with a steady decrease in the prone sleeping rate, there has been a consistent

Fig 1. Percent of SIDS deaths by age of death.[5]

decrease in the SIDS rate.[5] In 1992, the SIDS rate for the United States was 1.20 deaths per 1000 live births. In 2001, the SIDS rate was reported at 0.56 deaths per 1000 live births,[7] representing a decrease of 53% over 10 years. The rate in 2002 remained constant at 0.57.[8] The all-cause postneonatal death rate over this period also decreased 27%, from 3.14 to 2.29 per 1000 live births (Fig 2).[5] However, the all-cause postneonatal mortality rate has not changed since 1999 ($P = .61$), whereas until 2001, the postneonatal SIDS rate had continued to decrease at an average annual rate of 9.0% ($P < .01$).

Postneonatal mortality rates of several other causes of sudden unexpected infant death* have increased significantly, particularly over the years 1999–2001.[9] These observations increase the likelihood that some deaths previously classified as SIDS are now being classified in other categories and the true SIDS rate since 1999 may be static. Categories of SIDS have been proposed with the intent to be more inclusive and reduce potential diagnostic shift.[10] This proposal requires more discussion at the national level.

The apparent leveling of the previously declining SIDS rate is occurring coincident with a slowing in the reduction of the prevalence of prone positioning. The prevalence of prone positioning in the United States, as assessed from an ongoing national sampling, decreased from 70% in 1992 to 11.3% in 2002 and increased slightly to 13.0% in 2004.[11] Racial disparity in the prevalence of prone positioning may also be contributing to the continued disparity in SIDS rates between black and white infants (Fig 3).[5,12] The rate of SIDS among black infants was 2.5 times that of white infants in 2001.[7] The prevalence of prone positioning in 2001 among white infants was 11%, compared with 21% among black infants.[11] Additional work in promoting appropriate infant sleep positions and sleeping-environment conditions may be necessary to resume the previous rate of decline for SIDS and all-cause postneonatal mortality.

* Sudden unexpected infant death: other ill-defined and unspecified causes of mortality (*International Classification of Diseases, Ninth Revision* [ICD-9]: 799[0–9]; International *Classification of Diseases, 10th Revision* [ICD-10]: R99); suffocation-in-bed (ICD-9: E913[0]; ICD-10: W75); suffocation-other (ICD-9: E913[1]; ICD-10: W76-7 and W81-4).

There also has been a decrease in the seasonality of SIDS over the past decade in the United States. SIDS deaths have historically been observed more frequently in the colder months, with the fewest SIDS deaths occurring in the warmest months.[13] In 1992, SIDS rates had an average seasonal change of 16.3%, compared with only 7.6% in 1999,[14] which is consistent with reports from other countries.[15]

ISSUES RELATED TO SLEEP POSITION

The original 1992 sleeping-position recommendation from the AAP identified any nonprone position (ie, side or supine) as being optimum for reducing SIDS risk.[6] In 2000, on the basis of new evidence, the AAP advised that placing infants on their backs confers the lowest risk and is the preferred position. However, the risk of side position was reported as less than prone, and the AAP advised that if the side position is used, caregivers should be advised to bring the dependent arm forward to lessen the likelihood of the infant rolling to the prone position.

With the large decrease in the proportion of infants placed to sleep prone in the years since the initiation of Back to Sleep campaigns around the world, the contribution of side sleep position to SIDS risk has increased. Several studies, including 2 in the United States, have demonstrated that side sleep position confers an increased risk relative to back.[12,16–19] The population-attributable risk reported for side sleep position in the New Zealand[15] and British[16] studies were higher than those for prone position. In addition, the Nordic study[20] reported that the presence of infectious symptoms in combination with the side sleep position increased the risk far greater than the sum of the individual factors.

A study conducted in California[17] after the Back to Sleep era (1997–2000) found that the SIDS risks associated with side and prone position were similar in magnitude (adjusted odds ratios [ORs]: 2.0 and 2.6, respectively). Further examination found that the risk of SIDS was exceptionally high for infants who were placed on the side and found on the stomach (adjusted OR: 8.7). Previous studies have found that side sleep position is unstable. The probability of an infant rolling to the prone position from the side sleep position is significantly greater than rolling prone from the back.[16,21,22]

Diagnosis	ICD-9/ICD-10 Code
SIDS	7980/R95
Sudden unexpected infant death	
Unknown and unspecified causes	799.9/R99
Suffocation in bed	E913.0/W75
Suffocation "other"	E913.1-E913.9/W76-W77 and W81-W85

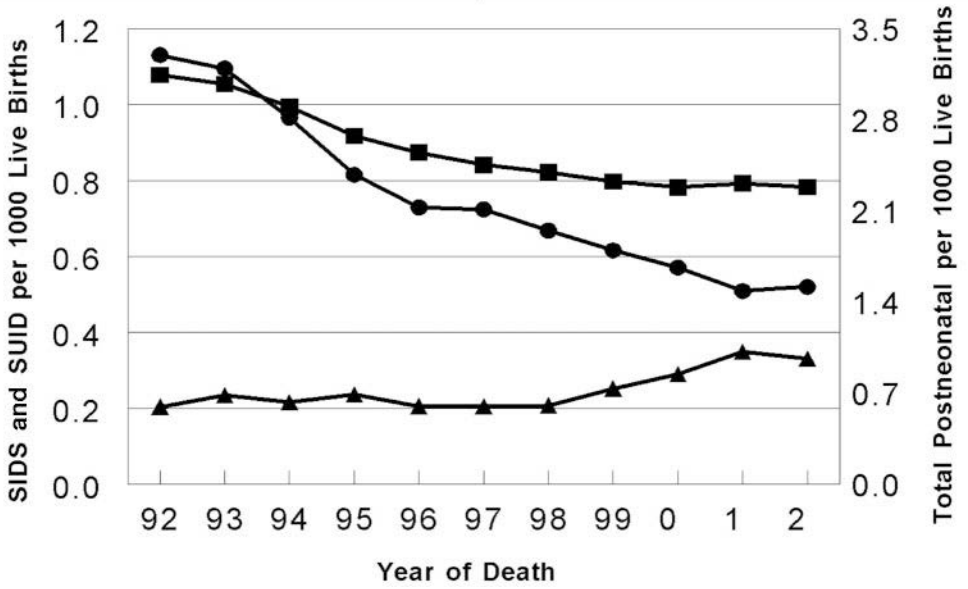

Fig 2. Trends in postneonatal mortality: United States 1992–2002.[5]] indicates all-cause postneonatal mortality; ●, SIDS; ▲, sudden unexpected infant death. SUID indicates sudden unexpected infant death.

The California study also extended 2 previous observations that infants unaccustomed to the prone position and placed prone for sleep were at greater risk than those usually placed prone.[19,23] It was found that infants who were usually placed supine but were placed on their sides or prone for the last sleep were at very high risk of SIDS (adjusted OR: 6.9 and 8.2, respectively),[17] which emphasizes the importance of every caregiver using the back sleep position during every sleep period, particularly when the infant's accustomed position is supine.

BEDDING

In 1944, Abramson[24] reported that approximately 40% of infants in New York City dying suddenly and unexpectedly during sleep were prone, with their nose and mouth burrowed into "soft pillows, mattresses, or mattress coverings." Early reports from the New Zealand Cot Death study[25] suggested that a majority of infants dying prone were on sheepskins. Soft crib mattresses, unfamiliar to North Americans, filled with "natural fibers" such as bark from the ti tree, were mentioned in studies from Australia linking prone sleep to sudden death.[26] Other studies have shown that infants dying from SIDS or "crib death" were more likely to have used a pillow or soft mattress, to have been found with their nose and mouth completely covered by bedding, and/or to have assumed a face-down posture.[27–30] A case-control study from the United States[31] has confirmed the strong association of SIDS and using soft bedding (OR: 5.1) or pillows (OR: 2.5), independent of prone sleep position (adjusted OR: 5.2 and 2.8, respectively). A strong interaction was found between prone sleep position and soft bedding surface, with an adjusted OR of 21.0, indicating that these 2 factors together are very hazardous. Soft surfaces have also been implicated in infant deaths occurring on adult beds.[32–34]

BED SHARING

Bed sharing between an infant and adult(s) is a highly controversial topic. Although electrophysiologic and behavioral studies offer a strong case for its effect in facilitating breastfeeding and the enhancement of maternal-infant bonding,[35,36] epidemiologic studies of bed sharing have shown that it can be hazardous under certain conditions. Several case series of accidental suffocation or death from undetermined cause suggest that bed sharing is hazardous.[34,37–39] A number of case-control studies of SIDS deaths have investigated the relationship of SIDS with parent(s) and/or other adults or children sleep-

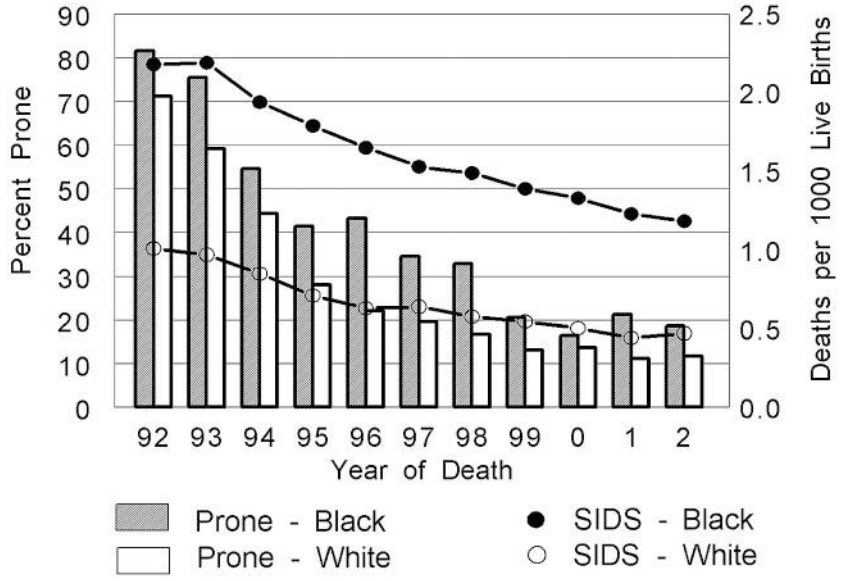

Fig 3. US trends in SIDS rates and prevalence of prone positioning according to race.[5,12]

ing with an infant.[16,31,40–48] Some of these studies have found the correlation between death and bed sharing to reach statistical significance only among mothers who smoked.[41,47] However, the European Concerted Action on SIDS study,[42] which was a large multisite study, found that bed sharing with mothers who did not smoke was a significant risk factor among infants up to 8 weeks of age. Similarly, a more recent study conducted in Scotland[48] found that the risk of bed sharing was greatest for infants younger than 11 weeks, and this association remained among infants with nonsmoking mothers. The risk of SIDS seems to be particularly high when there are multiple bed sharers[31] and also may be increased when the bed sharer has consumed alcohol or is overtired.[42,47] Also, the risk of SIDS is higher when bed sharing occurs with young infants.[40–42] It is extremely hazardous when adults sleep with an infant on a couch.[31,40,41,48] Finally, the risk of bed sharing is higher the longer the duration of bed sharing during the night.[41,47] Returning the infant to his or her crib was not associated with an increased risk in 2 studies,[40,41] and in another, the risk was significant only when the bed sharing occurred for more than 1 hour or for the whole night.[16] There is growing evidence that room sharing (infant sleeping in the parent's room) without bed sharing is associated with a reduced risk of SIDS.[41,42,43,48] Data from the European Concerted Action on SIDS[42] study led to the recommendation by its authors that the most protective sleep setting for an infant is in a crib in the parents' room. On the basis of their study results, investigators in Scotland[48] endorsed the United Kingdom Department of Health's advice that the safest place for an infant to sleep is in a crib in the parents' room for the first 6 months of life.

PACIFIERS

Several studies[31,40,42,49–53] have reported a protective effect of pacifiers on the incidence of SIDS, particularly when used at the time of last sleep (Fig 4). The mechanism for this apparent strong protective effect is still unclear, but several mechanisms such as lowered arousal thresholds have been proposed.[54,55]

Concerns about possible deleterious effects of pacifier use have prevented most SIDS experts and policy makers from making a recommendation for pacifier use as a risk-reducing method.[54–56] Concerns specifically about breastfeeding have led others to recommend pacifiers only for bottle-fed infants.[53] Although several studies have shown a correlation between pacifiers and reduced breastfeeding duration, the results of well-designed randomized clinical trials indicate that pacifiers do not seem to cause shortened breastfeeding duration for term and preterm infants.[57,58] One study reported a small deleterious effect of pacifier introduction in the first week of life on breastfeeding at 1 month of age, but this effect did not persist beyond 1 month.[59] Some dental malocclusions have been found more commonly among pacifier users than nonusers, but the differences generally disappeared after cessation.[60] The American Academy of Pediatric Dentistry policy statement on oral habits[61] states that "nonnutritive sucking behaviors (ie, finger or pacifier) are considered normal in infants and young children … and in general, sucking habits in children to the age of five are unlikely to cause any long-term problems." There is an approximate 1.2- to 2-fold increased risk of otitis media associated with pacifier use, but the incidence of otitis media is generally lower in the first year of life, especially the first 6 months, when the risk of SIDS is the highest.[62–67] However, pacifier use, once established, may persist beyond 6 months, thus increasing the risk of otitis media. Gastrointestinal infections and oral colonization with *Candida* species were found to be more common among pacifier users.[63–65]

SECONDARY CAREGIVERS

Two thirds of US infants younger than 12 months are in nonparental child care. Infants of employed

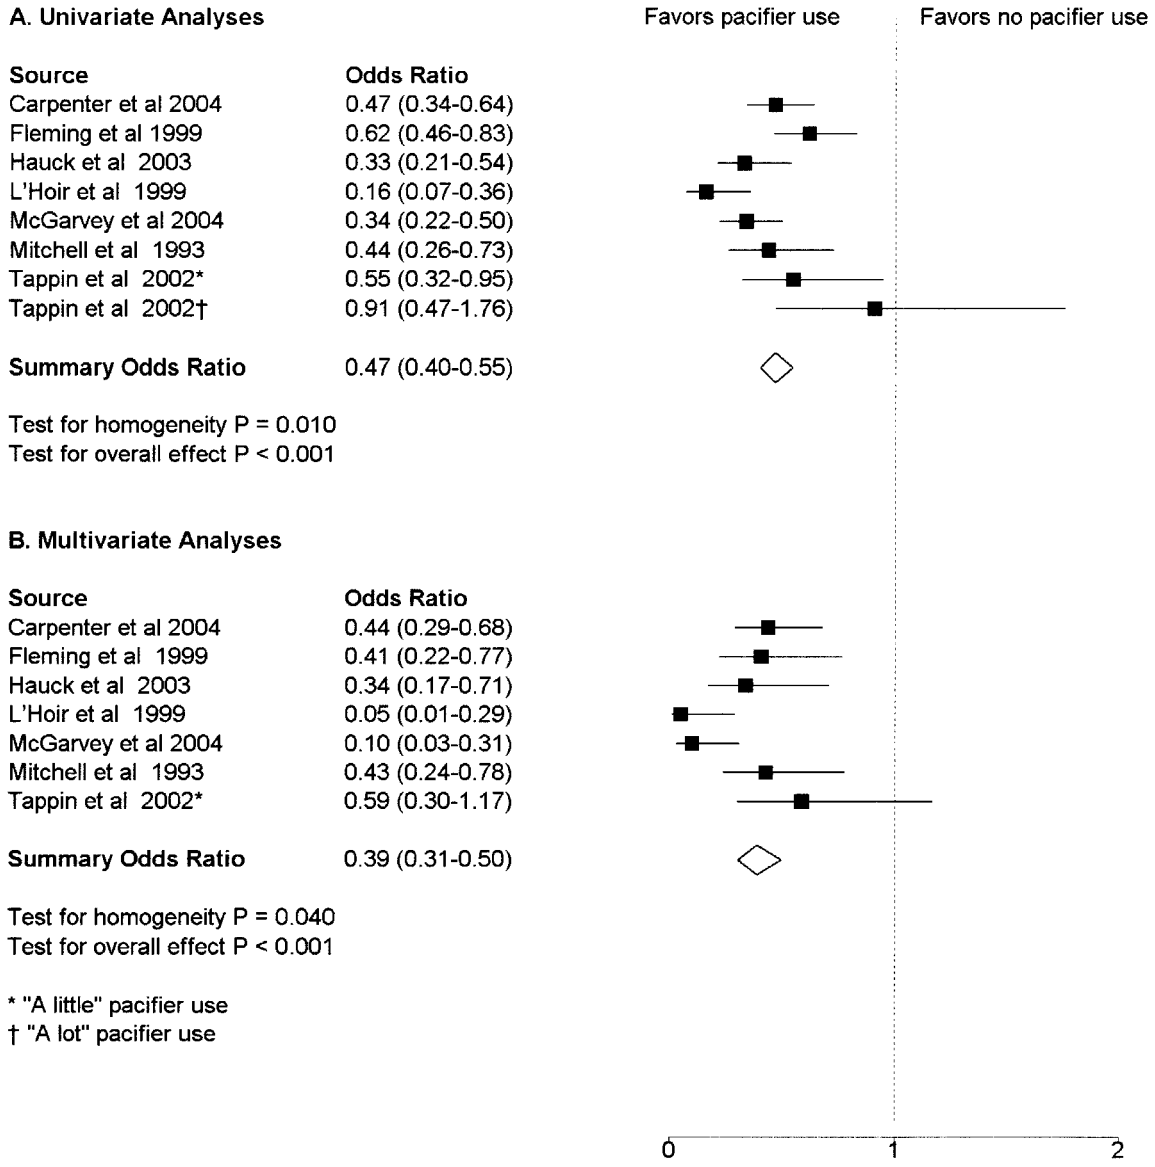

Fig 4. Meta-analysis of studies examining the relationship of a pacifier used during the last sleep in SIDS victims versus controls. mothers spend an average of 22 hours each week in child care, and 32% of infants are in child care full-time (defined as 35 hours or more each week).[68] Of the infants who are cared for by secondary (nonparental) caregivers, approximately 50% are cared for by relatives, 10% are cared for by an in-home babysitter, and the remainder are in organized child care (ie, a child care center or family child care home).[68] In the United States, approximately 20% of SIDS deaths occur while the infant is in the care of a nonparental caregiver. Despite the remarkable decrease in the rate of SIDS and decreased frequency of prone sleeping nationally, the proportion of SIDS deaths occurring in child care remained constant between 1996 and 1998.[69] Many child care deaths have been associated with the prone sleep position, especially when the infant is unaccustomed to being placed in that position. This is particularly concerning, because unaccustomed prone sleep increases the risk of SIDS by as much as 18-fold.[23,70] It is frequently a nonparental caregiver who places the infant in an unaccustomed prone position.

A 1996 study[71] revealed that 43% of licensed child care centers were unaware of the relationship between SIDS and infant sleep position, and subsequent surveys of child care centers have documented that, despite an increased awareness, 20% to 28% of centers continue to place infants prone for sleep,[72,73] reportedly because they are unaware of the dangers of sleeping prone and/or are misinformed of the risks and benefits of various sleep positions. However, licensed child care centers seldom have adequate regulations regarding safe sleep for infants, and most states do not have safe-sleep regulations for child care providers.[74] In addition, many infants are cared for by relatives and nonlicensed caregivers

(babysitters, nannies, unregulated family child care homes) who still may be unaware of the importance of supine sleeping in a safe sleep environment.

HOME MONITORS, SIDS, AND APPARENT LIFE-THREATENING EVENTS

For many years, apnea was thought to be the predecessor of SIDS, and home apnea monitors were thought to be an effective strategy for preventing SIDS.[75] Although there is no evidence that home monitors are effective for this purpose,[76–78] distribution of home monitors continues to be a substantial industry in the United States. An apparent life-threatening event (ALTE) is defined as "an episode that is frightening to the observer and is characterized by some combination of apnea (central or occasionally obstructive), color change (usually cyanotic or pallid but occasionally erythematous or plethoric), marked change in muscle tone (usually marked limpness), choking, or gagging."[4] After interpreting data from the Collaborative Infant Home Monitoring Study Group,[79] the AAP has recommended that infant home monitoring not be used as a strategy to prevent SIDS but may be useful in some infants who have had an ALTE.[80] The AAP recognizes that monitors may be helpful to allow rapid recognition of apnea, airway obstruction, respiratory failure, interruption of supplemental oxygen supply, or failure of mechanical respiratory support. Infants for whom these indications may apply include infants who have experienced an ALTE. The Task Force on Sudden Infant Death Syndrome endorses these recommendations.

IMMUNIZATIONS AND SIDS

Reports of a possible association between diphtheria-pertussis-tetanus immunizations and SIDS[81,82] brought forth a series of reviews and studies that refuted the association.[83,84] Still, of 100 deaths reported to the federally administered Vaccine Adverse Event Reporting System from 1997 to 1998, approximately half were attributed to SIDS.[85] Recent reports, however, continue to show no association between immunizations and SIDS.[86,87]

RELATIONSHIP BETWEEN BREASTFEEDING AND SIDS

Physiologic sleep studies of infants demonstrate that breastfed infants are more easily arousable than their formula-fed counterparts during sleep,[54,88] which may explain a possible protective effect against SIDS. However, epidemiologic studies have not been consistent in demonstrating such a protective effect.[16,18,31,49,89–98] Although some studies show a protective effect of breastfeeding on SIDS,[18,98,99] others do not.[31,49,91,96,97,100,101] In addition, a recent article has demonstrated that although breastfeeding is associated with decreased postneonatal deaths overall, it is not associated with a reduced risk of SIDS.[102] Many of the case-control studies demonstrate a protective effect of breastfeeding against SIDS in univariate analysis but not when confounding factors are taken into account.[31,49,91,96,97] These results suggest that factors associated with breastfeeding, rather than breastfeeding itself, are protective. One of these possible factors is nonsmoking, which is associated with a decreased incidence of SIDS and with both increased initiation and duration of breastfeeding.[103–107] Although breastfeeding is beneficial and should be promoted for many reasons, the task force believes that the evidence is insufficient to recommend breastfeeding as a strategy to reduce SIDS.

POSITIONAL PLAGIOCEPHALY

Over the past decade, several reports have suggested that there has been a dramatic increase in the incidence of plagiocephaly without synostosis (PWS).[108,109] Although there have been no published population-based studies and there has been some debate of whether there has been a real increase or simply an increased awareness,[110,111] it seems likely that both have occurred.[112–115]

Congenital PWS is generally thought to be caused by in utero or intrapartum molding and, therefore, is often associated with multiple births or birth injury.[116,117] Infants born preterm may develop plagiocephaly or dolichocephaly from having fixed head positions during respiratory support administered while receiving neonatal intensive care. Some infants develop PWS as a result of torticollis caused by sternocleidomastoid shortening.[112,118,119] However, a recent case-control study has shown that many cases of PWS are associated with supine sleeping position (OR: 2.51; 95% confidence interval: 1.23–5.16).[119] Such infants are also more likely not to have had the head position varied when put down to sleep, more likely to have had less than 5 minutes per day of "tummy time," and less likely to have been held in the upright position when not sleeping. Children with developmental delay and/or neurologic injury have increased rates of PWS, although a causal relationship has not been demonstrated.[119–123] One study showed that the incidence of PWS in healthy normal children decreases spontaneously from 20% at 8 months to 3% at 24 months of age.[124]

DISCHARGE FROM NEONATAL INTENSIVE CARE UNITS AND NEWBORN NURSERIES

The original Back to Sleep campaign recommendation in 1992 excluded "premature infants with respiratory distress."[6] Subsequent statements[2] and the current statement have removed the preterm infant as a recognized exception from the supine sleep recommendation because of the increased risk of SIDS among infants born preterm[125,126] and evidence that the association between prone sleeping and SIDS among low birth weight infants is equal to, or perhaps even stronger than, the association among those born at term.[19] However, a recent survey of mothers from Massachusetts and Ohio who had delivered preterm infants in 1995–1998[127] disclosed that very low birth weight infants (birth weight of less than 1500 g) were almost twice as likely to be placed prone for sleep at 1 month after hospital discharge than were infants born in the next higher low birth weight category (birth weight of 1500–2500 g). Another study of infants delivered in 15 states during

the same time period[128] also found that very low birth weight infants were especially unlikely to sleep supine. The authors surmised that this increased likelihood of prone positioning is a reflection of the following: (1) very preterm infants in intensive care nurseries are frequently managed in the prone position; (2) such infants and their caregivers become habituated to using this position; and (3) mothers are likely to follow the advice given by physicians and other health care professionals, and such advice is more likely to be conveyed during a long hospitalization. The task force believes that neonatologists, neonatal nurses, and other health care professionals responsible for organizing the hospital discharge of infants from neonatal intensive care units should become more vigilant about endorsing and modeling the SIDS risk-reduction recommendations significantly before the infant's anticipated discharge.

There is also some concern about practitioners in newborn nurseries continuing to place infants on the side after birth. The practice occurs presumably because of the impression that newborn infants need to clear their airways of amniotic fluid and may be less likely to aspirate while in the side position. Although there is no evidence that such fluid will be cleared more readily while in the side position, there is also no compelling evidence that sleep position is related to SIDS during the immediate neonatal period, because the incidence of SIDS at this age is quite rare. However, there is evidence that mothers will tend to copy the practices at home that they observe health care professionals practicing in the hospital and, therefore, may be more likely to use the side position at home when the risk of SIDS and its relationship to sleep position increases.[129,130] If there are concerns about possible choking during the first few hours after birth, hospital personnel can place the infants on their sides, propped up against the side of the bassinet for stability. However, the task force recommends that the infants be placed on their backs as soon as possible.

INFANTICIDE AND SIDS RECURRENCE

Several publications have suggested that the level of suspicion of foul play should be increased on the recurrence of SIDS within a family unit.[131–133] However, on the basis of an in-depth review of recurrent sudden unexpected infant deaths among families that had experienced 1 SIDS death, Carpenter et al[134] calculated an 87% probability that a second SIDS death within a family would be of natural cause. Calculations of the proportion of SIDS deaths attributable to covert homicide range from 6% to 10%, and recurrence risks for SIDS within a family in which 1 infant previously died of SIDS range from 2% to 6%.[135,136] Therefore, the task force supports the position that the vast majority of either initial or second sudden unexpected infant deaths within a family seem to be natural rather than attributable to abuse, neglect, or homicide. However, the task force maintains that a complete autopsy, examination of the death scene, and review of the clinical history are necessary to obtain the most accurate diagnosis.

OTHER ISSUES

There are several issues that were addressed in previous statements that are not revisited in this statement because there have not been new findings, including the effects of overheating, maternal antenatal smoking, and infant environmental smoke on SIDS incidence; cardiac arrhythmias as an etiologic factor in SIDS; and complications of nonprone sleeping, other than plagiocephaly. The reader is referred to the previous statement for discussion of these issues.[2]

The predominant hypothesis regarding the etiology of SIDS remains that certain infants, for reasons yet to be determined, may have a maldevelopment or delay in maturation of the brainstem neural network that is responsible for arousal and affects the physiologic responses to life-threatening challenges during sleep. Recent examinations of the brainstems of infants who died of SIDS have revealed unique deficits in serotonin receptors in a network of neurons throughout the ventral medulla. The medullary regions involved develop in midgestation from a common embryonic anlage and are thought to be involved with arousal, chemosensitivity, respiratory drive, thermoregulation, and blood pressure responses.[137]

RECOMMENDATIONS

The recommendations outlined here were developed to reduce the risk of SIDS in the general population. As it is defined by epidemiologists, risk refers to the probability that an outcome will occur given the presence of a particular factor or set of factors. Scientifically identified associations between risk factors (eg, socioeconomic characteristics, behaviors, or environmental exposures) and outcomes such as SIDS do not necessarily denote causality. Furthermore, the best current working model of SIDS suggests that more than 1 scenario of preexisting conditions and initiating events may lead to SIDS. Therefore, when considering the recommendations in this report, it is fundamentally misguided to focus on a single risk factor or to attempt to quantify risk for an individual infant. Individual medical conditions may warrant a physician to recommend otherwise after weighing the relative risks and benefits.

1. Back to sleep: Infants should be placed for sleep in a supine position (wholly on the back) for every sleep. Side sleeping is not as safe as supine sleeping and is not advised.
2. Use a firm sleep surface: Soft materials or objects such as pillows, quilts, comforters, or sheepskins should not be placed under a sleeping infant. A firm crib mattress, covered by a sheet, is the recommended sleeping surface.
3. Keep soft objects and loose bedding out of the crib: Soft objects such as pillows, quilts, comforters, sheepskins, stuffed toys, and other soft objects should be kept out of an infant's sleeping environment. If bumper pads are used in cribs, they should be thin, firm, well secured, and not "pillow-like." In addition, loose bedding such as blankets and sheets may be hazardous. If blan-

kets are to be used, they should be tucked in around the crib mattress so that the infant's face is less likely to become covered by bedding. One strategy is to make up the bedding so that the infant's feet are able to reach the foot of the crib (feet to foot), with the blankets tucked in around the crib mattress and reaching only to the level of the infant's chest. Another strategy is to use sleep clothing with no other covering over the infant or infant sleep sacks that are designed to keep the infant warm without the possible hazard of head covering.

4. Do not smoke during pregnancy: Maternal smoking during pregnancy has emerged as a major risk factor in almost every epidemiologic study of SIDS. Smoke in the infant's environment after birth has emerged as a separate risk factor in a few studies, although separating this variable from maternal smoking before birth is problematic. Avoiding an infant's exposure to second-hand smoke is advisable for numerous reasons in addition to SIDS risk.
5. A separate but proximate sleeping environment is recommended: The risk of SIDS has been shown to be reduced when the infant sleeps in the same room as the mother. A crib, bassinet, or cradle that conforms to the safety standards of the Consumer Product Safety Commission and ASTM (formerly the American Society for Testing and Materials) is recommended. "Cosleepers" (infant beds that attach to the mother's bed) provide easy access for the mother to the infant, especially for breastfeeding, but safety standards for these devices have not yet been established by the Consumer Product Safety Commission.

   Although bed-sharing rates are increasing in the United States for a number of reasons, including facilitation of breastfeeding, the task force concludes that the evidence is growing that bed sharing, as practiced in the United States and other Western countries, is more hazardous than the infant sleeping on a separate sleep surface and, therefore, recommends that infants not bed share during sleep. Infants may be brought into bed for nursing or comforting but should be returned to their own crib or bassinet when the parent is ready to return to sleep. The infant should not be brought into bed when the parent is excessively tired or using medications or substances that could impair his or her alertness. The task force recommends that the infant's crib or bassinet be placed in the parents' bedroom, which, when placed close to their bed, will allow for more convenient breastfeeding and contact. Infants should not bed share with other children. Because it is very dangerous to sleep with an infant on a couch or armchair, no one should sleep with an infant on these surfaces.
6. Consider offering a pacifier at nap time and bedtime: Although the mechanism is not known, the reduced risk of SIDS associated with pacifier use during sleep is compelling, and the evidence that pacifier use inhibits breastfeeding or causes later dental complications is not. Until evidence dictates otherwise, the task force recommends use of a pacifier throughout the first year of life according to the following procedures:
   - The pacifier should be used when placing the infant down for sleep and not be reinserted once the infant falls asleep. If the infant refuses the pacifier, he or she should not be forced to take it.
   - Pacifiers should not be coated in any sweet solution.
   - Pacifiers should be cleaned often and replaced regularly.
   - For breastfed infants, delay pacifier introduction until 1 month of age to ensure that breastfeeding is firmly established.
7. Avoid overheating: The infant should be lightly clothed for sleep, and the bedroom temperature should be kept comfortable for a lightly clothed adult. Overbundling should be avoided, and the infant should not feel hot to the touch.
8. Avoid commercial devices marketed to reduce the risk of SIDS: Although various devices have been developed to maintain sleep position or to reduce the risk of rebreathing, none have been tested sufficiently to show efficacy or safety.
9. Do not use home monitors as a strategy to reduce the risk of SIDS: Electronic respiratory and cardiac monitors are available to detect cardiorespiratory arrest and may be of value for home monitoring of selected infants who are deemed to have extreme cardiorespiratory instability. However, there is no evidence that use of such home monitors decreases the incidence of SIDS. Furthermore, there is no evidence that infants at increased risk of SIDS can be identified by in-hospital respiratory or cardiac monitoring.
10. Avoid development of positional plagiocephaly:
    - Encourage "tummy time" when the infant is awake and observed. This will also enhance motor development.
    - Avoid having the infant spend excessive time in car-seat carriers and "bouncers," in which pressure is applied to the occiput. Upright "cuddle time" should be encouraged.
    - Alter the supine head position during sleep. Techniques for accomplishing this include placing the infant to sleep with the head to one side for a week and then changing to the other and periodically changing the orientation of the infant to outside activity (eg, the door of the room).
    - Particular care should be taken to implement the aforementioned recommendations for infants with neurologic injury or suspected developmental delay.
    - Consideration should be given to early referral of infants with plagiocephaly when it is evident that conservative measures have been ineffective. In some cases, orthotic devices may help avoid the need for surgery.
11. Continue the Back to Sleep campaign: Public education should be intensified for secondary care-

givers (child care providers, grandparents, foster parents, and babysitters). The campaign should continue to have a special focus on the black and American Indian/Alaska Native populations. Health care professionals in intensive care nurseries, as well as those in well-infant nurseries, should implement these recommendations well before an anticipated discharge.

POLICY STATEMENT

Chemical-Biological Terrorism and Its Impact on Children

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT

Children remain potential victims of chemical or biological terrorism. In recent years, children have even been specific targets of terrorist acts. Consequently, it is necessary to address the needs that children would face after a terrorist incident. A broad range of public health initiatives have occurred since September 11, 2001. Although the needs of children have been addressed in many of them, in many cases, these initiatives have been inadequate in ensuring the protection of children. In addition, public health and health care system preparedness for terrorism has been broadened to the so-called all-hazards approach, in which response plans for terrorism are blended with plans for a public health or health care system response to unintentional disasters (eg, natural events such as earthquakes or pandemic flu or manmade catastrophes such as a hazardous-materials spill). In response to new principles and programs that have appeared over the last 5 years, this policy statement provides an update of the 2000 policy statement. The roles of both the pediatrician and public health agencies continue to be emphasized; only a coordinated effort by pediatricians and public health can ensure that the needs of children, including emergency protocols in schools or child care centers, decontamination protocols, and mental health interventions, will be successful.

INTRODUCTION

In April 2000, the American Academy of Pediatrics (AAP) Committee on Environmental Health and Committee on Infectious Diseases published the technical report "Chemical-Biological Terrorism and Its Impact on Children."[1] Events until that time, including the 1995 sarin attack in Tokyo, Japan, had made clear the possibility that acts of domestic terrorism can occur, with significant impact on the health of children. Since publication of the 2000 technical report, many additional acts of chemical and biological terrorism have occurred, including the release of anthrax spores through the US postal system, intentional food contamination by toxic chemicals in Grand Rapids, Michigan, and Fresno, California, and the identification of ricin-laden letters in a post office in South Carolina.

Immediately after the September 11, 2001, terrorist attacks in the United States, which soon were followed by anthrax releases, the AAP, recognizing the need to address the impact of terrorism on children, initiated a series of unprecedented actions. These actions included (1) formation of the AAP Task Force on Terrorism, (2) creation of a comprehensive Web site on the AAP home page devoted to providing information on terrorism and its impact on children (www.aap.org/terrorism/index.html), (3) publication of the technical report "Radiation Disasters and Children,"[2] (4) publication of a policy statement on smallpox immunization,[3]

(5) an addition to the *Red Book* of descriptions of biological weapons and management of the diseases they produce,[4] (6) publication of a technical report[5] and policy statement[6] on the pediatrician and disaster preparedness, and (7) publication of the CD-ROM *Feelings Need Checkups Too*, designed to address mental health consequences of terrorism in children (www.aap.org/profed/childrencheckup.htm).

The continuing occurrence of chemical and biological terrorism makes clear the ongoing need to improve public health and health care system preparedness in all respects, including the detection of covert events, establishment of comprehensive response protocols for children, and implementation of plans for rapid resource mobilization. At the governmental level, these actions have been facilitated by the passage of key federal legislation (Table 1).[7] However, there remains a need for pediatricians to be knowledgeable about the chemical and biological weapons that could be used against a population that includes children. Moreover, many new principles in the care of children after chemical and biological terrorism have been developed. This policy statement replaces the 2000 policy statement, with an added focus on systems issues that are key in minimizing morbidity and mortality to children after their exposure to a chemical or biological weapon.

AGENTS OF CONCERN

Chemicals

In recent years, there have been 3 significant changes in the traditional concepts of terrorism involving chemical weapons. First, the narrow belief that such weapons would be intentionally manufactured to be instruments of mass destruction has been expanded by the recognition that readily available chemicals (eg, chlorine) manufactured for another purpose can be used for chemical terrorism (so-called weapons of opportunity). Second, the general impression that chemical terrorist events are likely to be dramatic and immediately recognized, such as the sarin incident in Tokyo, has been expanded to include the possibility that these acts can be covert, with delayed recognition. Finally, the concept that single individuals, acting impulsively and having few to no resources, can successfully release a chemical weapon must be considered in addition to the concept that chemical weapons are likely to be released by well-organized and funded terrorist groups after extensive planning.

TABLE 1 **Federal Legislation Enacted Since 2001 to Improve Public Health Response to Bioterrorism and Other Public Health Emergencies**

Date	Legislation
June 2002	Public Health Security and Bioterrorism Preparedness and Response Act of 2002 (H.R. 3448)
November 2002	Homeland Security Act (H.R. 5005)
April 2003	Smallpox Emergency Personnel Protection Act (H.R. 1770)
April 2003	Emergency Preparedness and Response Act of 2003 (S. 930)
July 2003	Community Protection and Response Act of 2003 (H.R. 2878)
July 2003	Enhanced-911 Implementation Act of 2003 (H.R. 2898)
July 2004	Project Bioshield Act of 2004 (S. 1504)
2003	Robert T. Stafford Disaster Relief and Emergency Assistance Act (Pub L No. 106-390)
2003	First Responders Partnership Grant Act of 2003 (S. 466)

Two recent acts of chemical terrorism involving children illustrate these new concepts. In 1999 in Fresno, California, patrons of a restaurant developed severe gastroenteritis. An investigation by public health authorities ultimately found that the carbamate insecticide methomyl had been maliciously added to the salt.[8] More than 100 adults and children became ill with nausea, vomiting, and diarrhea; a perpetrator was never identified. In 2002 in Grand Rapids, Michigan, a disgruntled grocery worker placed a nicotine-containing insecticide into ground beef, making it available for purchase by unsuspecting customers. It was not until widespread illness (nausea, mouth burning, vomiting) was reported and there was a recall and analysis of the meat, revealing the presence of nicotine, that this was recognized as an act of terrorism.[9] Ultimately, more than 100 people became ill, including more than 40 children, in what is now considered the largest act of chemical terrorism in US history.

The chemicals considered the most likely threat for use as chemical weapons are placed into 6 categories: nerve agents, vesicants, irritants/corrosives, choking agents, cyanogens, and incapacitators, including lacrimators (Table 2).

Nerve Agents

Nerve agents are well absorbed through intact skin and even through examination gloves used in clinical settings. All nerve agents act as acetylcholinesterase inhibitors, producing the same signs and symptoms associated with organophosphate poisoning. Manifestations can range from mild (miosis, nausea, diarrhea) to severe (muscle weakness, fasciculations, respiratory failure, coma, seizures).

In the 1995 sarin episode in Tokyo, the most unanticipated sequela was the degree of injury to health care professionals.[10] Several hundred physicians, nurses, and other health care professionals became ill as a result of 2 factors: handling of sarin-contaminated victims without wearing personal protective equipment (PPE) and the entry of contaminated victims into health care facilities, leading to transmission of sarin vapor through the ventilation system.[10,11] This event firmly demonstrated the importance of protecting health care professionals through the use of PPE and the importance of maintaining office or hospital safety by ensuring that victims are adequately decontaminated before entering the building.

TABLE 2 **Chemical Weapons of Concern**

Agent Classification	Built Weapon	Weapon of Opportunity
Nerve agents	Tabun	Pesticides
	Sarin	Nicotine
	Soman	Organophosphates
	VX gas	Carbamates
Vesicants	Lewisite	
	Mustard gas	
	Nitrogen mustard	
Irritants/corrosives		Ammonia
		Bromine
		Chlorine
Choking agents	Phosgene	Perfluoroisobutylene (Teflon) and other chemical polymers
	Nitrogen oxides	Smoke, products of combustion
Cyanogens ("blood agents")	Hydrogen cyanide	Industrial cyanide
		Sodium azide
		Carbon monoxide
Incapacitators	3-Quinuclidinyl benzilate (BZ)	Anticholinergics
	Cannabinoids	
	Barbiturates	
	Fentanyl derivatives	
Lacrimators	Chloroacetophenone (CN)	Capsaicin
	Chlorobenzylidene (CS)	

Management of nerve-agent exposure includes supportive care and, when indicated, prompt administration of the antidotes atropine and pralidoxime.[12] Both of these antidotes are available in autoinjector form, permitting rapid administration; autoinjectors are particularly important in mass-casualty incidents where there is a need to treat large numbers of victims as quickly and efficiently as possible. Until recently, the rapid administration of atropine and pralidoxime to children was complicated by the absence of pediatric autoinjectors; only the forms approved for adults, containing 2 mg of atropine and 600 mg of pralidoxime, were available. A pediatric atropine autoinjector was recently approved by the Food and Drug Administration for use in small children after nerve-agent exposure.[13] However, the continued absence of a pediatric pralidoxime autoinjector, which is key in the successful treatment of central nervous system and muscular toxicity from nerve agents, leaves the use of standard, multidose vials as the only therapeutic option. To address this issue, consensus guidelines now recommend that children weighing 13 kg or more (2–3 years or older) receive a 600-mg dose of pralidoxime from an autoinjector, on the basis of the belief that this pralidoxime dose falls within the range of safety for the drug.[5] Children weighing less than 13 kg should receive the customary weight-based (20–50 mg/kg) dose, administered from a multidose vial; if unavailable, an autoinjector should be used.

Other aspects of care to children who have been exposed to nerve agents are found in recent reviews.[12,14]

Vesicants

Vesicants include sulfur mustard and lewisite, an arsenic-based blistering agent. These chemicals, both of which are released as an aerosol, produce erythema, burning, vesiculation, and then desquamation of the skin. Victims of vesicant exposure typically develop skin tingling followed by burning; within 24 hours, skin sloughing begins to occur, with wounds having the appearance of partial-thickness burns. These agents are also immunosuppressive, further increasing the risk of severe infection. Treatment is largely supportive. Important principles of management include protection of health care professionals through the use of PPE and topical decontamination.[15] Because vesicants are often oil based, a mild soap or shampoo should be used during decontamination.

Choking Agents

Choking agents are created to produce, usually in delayed fashion, pulmonary injury with resulting bronchospasm, pulmonary edema, and respiratory failure. Immediate symptoms include eye burning, tearing, and blepharospasm. The major agent of this group is phosgene; however, common industrial chemicals, including polytef (Teflon) and other chemical polymers, act as choking agents depending on their ambient concentration. Most choking agents are heavier than air, which could result in higher concentrations at the breathing level of the child. Treatment is supportive.

Cyanogens

The cyanogens are similar to cyanide in structure and/or function. Agents in this class include cyanide salts and sodium azide. The cyanogens interrupt cellular utilization of oxygen, producing respiratory distress, coma, and metabolic acidosis. Victims of cyanogen exposure must

be recognized promptly to administer the life-saving antidotes sodium nitrite and sodium thiosulfate.

Incapacitating Agents

Incapacitating agents include several different chemical classes (eg, anticholinergic agents, hallucinogens, cannabinoids, and fentanyl derivatives). In the Russian theater hostage incident in 2002, what is thought to have been a fentanyl-based incapacitating agent was released during the rescue effort. The agent, although successful in overwhelming the hostage-takers, also killed 127 hostages.[16]

Many incapacitating agents are weapons of opportunity, being easily acquired pharmaceutical agents or substances of abuse that are surreptitiously added to common sources of food or drink.

Included among incapacitators are lacrimators. Often referred to collectively as Mace or "tear gas," lacrimators include the chemicals chloroacetophenone and chlorobenzylidene as well as capsaicin ("pepper spray"). Lacrimators are designed to produce incapacitation from irritation of the eye and other mucous membranes. Exposure to Mace results in eye burning, tearing, and blepharospasm; victims may become temporarily blind. Inhalation produces mouth pain, shortness of breath, and, in rare cases, laryngospasm. Because capsaicin is widely sold as a nonlethal weapon, episodes of capsaicin release into the ventilation system of schools and buildings are a relatively common prank, although such incidents meet the definition of terrorism (ie, an act designed to frighten, hurt, or kill).

Biological Agents

Most of the biological agents that could be used as weapons are now discussed in the *Red Book*,[4] although some agents (eg, ricin) are not discussed in detail. Ricin is discussed in a subsequent section of this report.

The biological weapons of concern are listed in Table 3. These agents have been placed by the Centers for Disease Control and Prevention (CDC) into categories A, B, or C. Thirty-nine agents are included in these 3 categories.

Category A agents are considered the greatest public health threat because of their high morbidity and mortality, potential ease of dissemination, and potential to cause public panic. Currently, there are 6 agents in this group: anthrax, plague, smallpox, botulinum, tularemia, and the viral hemorrhagic fevers, including Ebola and Marburg viruses. Detailed descriptions of these agents have been published in *Red Book*[4] and elsewhere.

Smallpox

The most widely discussed category A agent in recent years has been smallpox. In 2001, because of increasing concerns that smallpox was in the hands of terrorists and had the potential to produce widespread morbidity and mortality, the CDC recommended a "ring immunization" (surveillance and containment) strategy in the United States. This strategy of containment was reviewed and endorsed by the AAP Committee on Infectious Diseases in its 2002 policy statement "Smallpox Vaccine."[3] Subsequently, the CDC recommended a 3-phase plan for smallpox immunization of health care professionals and other individuals.[3] During the first phase, health care professionals in acute care facilities were to be immunized. In the second phase, there would be potential expansion to other health care professionals and first responders. In a possible third phase, voluntary immunization would be available to all those interested in being immunized. This campaign, to date, has struggled from several difficulties, including (1) the inability to quantitate the risk of a smallpox release, preventing individuals from making their own risk/benefit analysis, (2) an extensive list of contraindications to the vaccine, (3) general fears about the safety of the vaccine, (4) the appearance of unrecognized adverse effects from the vaccine (eg, fatal cardiac disease[17,18]), (5) lack of endorsement by several medical organizations,[19] and (6) a high rate of vaccine refusal by health care professionals.[20] Currently, the immunization campaign remains underway, still in phase I. Review and updating of the recommendations are ongoing.[21,22]

TABLE 3 Biological Weapons of Concern

Category A
Anthrax (*Bacillus anthracis*)
Smallpox (*Variola major*)
Tularemia (*Francisella tularensis*)
Plague (*Yersinia pestis*)
Viral hemorrhagic fevers (filoviruses [eg, Ebola, Marburg] and arenaviruses [eg, Lassa])
Botulinum (*Clostridium botulinum* toxin)
Category B
Q fever (*Coxiella burnetii*)
Brucellosis (*Brucella* species)
Glanders (*Burkholderia mallei*)
Melioidosis (*Burkholderia pseudomallei*)
Viral encephalitis (alphaviruses [VEE, EEE, WEE])
Typhus (*Rickettsia prowazekii*)
Biotoxins (ricin, staphylococcal enterotoxin B)
Psittacosis (*Chlamydia psittaci*)
Food-safety threats (eg, *Salmonella* species, *Escherichia coli* O157:H7)
Water-safety threats (eg, *Vibrio cholerae, Cryptosporidium parvum*)
Category C
Emerging threat agents (eg, Nipah virus, hantavirus)
Multidrug-resistant tuberculosis
Tick-borne encephalitis viruses
Tick-borne hemorrhagic fever viruses
Yellow fever

VEE indicates Venezuelan equine encephalomyelitis; EEE, eastern equine encephalomyelitis; WEE, western equine encephalomyelitis.

Ricin

Although it is a category B agent, ricin has become a major biological weapon of concern. A plant-derived,

heat-stable toxin, ricin is an extract of the castor bean (*Ricinus communis*). Ricin acts by first entering cells through endocytosis; once in the cell, it is transported to the Golgi apparatus and endoplasmic reticulum. In the cytosol, ricin acts as a protease-resistant, enzymatically active structure that interacts with the sarcin-ricin domain of the large ribosome subunit RNA. This interaction can disturb translation by preventing the binding of elongation factors to the ribosome. Ricin is also capable of inactivating nonribosomal nucleic acid substrates.[23–26] With these effects, ricin produces severe morbidity and mortality. Rapidly dividing tissues, particularly the gastrointestinal epithelium, are most susceptible to ricin actions.

Ricin is a versatile agent that can be administered by ingestion, inhalation, or injection. When ingested, it can produce a syndrome of severe gastrointestinal upset, vomiting, hemorrhagic gastroenteritis, shock, and cardiovascular collapse. After inhalation, respiratory distress with a necrotizing pneumonitis may occur. Injection produces rapid shock and cardiovascular collapse. Treatment is supportive. A vaccine against ricin is currently under development.

Over the last 2 years, ricin has been associated with terrorist activity in the United States on multiple occasions. In October 2003, 2 ricin-containing letters were found in the US postal system.[27] In a third incident, ricin was found in the mail sorter of a congressional post office in January 2004. There have also been multiple confiscations of ricin in the United States and abroad over the last 5 years.

EXPOSURE VECTORS FOR CHEMICAL AND BIOLOGICAL WEAPONS

Exposure to chemical and biological weapons can occur through several potential vectors. Airborne releases of agents have remained the primary concern, because very large populations can be exposed by this route. Potential mechanisms of exposure include crop-dusting airplanes, tainted letters, and release into confined spaces (eg, subway tunnels, office buildings, theaters). Although contamination of the water supply is also a potential vector for exposure, there are very few chemical or biological agents that are both water-stable and resistant to water-purification techniques.[28] Finally, the contamination of food that is either unprocessed (eg, uncultivated grain) or processed (eg, a consumer product) is considered a potential means of exposure to chemical or biological weapons.[29]

SPECIFIC VULNERABILITIES IN CHILDREN

After events of chemical or biological terrorism, children have a greater risk of both exposure and harm, the result of key developmental and physiologic vulnerabilities.

For each of the vectors of exposure to biological or chemical weapons (air, water, or food), children possess a significantly greater likelihood of exposure because of their intake patterns. Children inhale considerably more air on a per-weight basis than adults (400 vs 140 mL/kg per minute, respectively). Consequently, for any concentration of airborne toxin, a child will inhale more of the substance on a per-weight basis than an adult. Also, substances that are heavier than air have their highest concentration near the ground, closer to the breathing zone of the child. Because children have less-keratinized, more-permeable skin and/or a proportionately greater body-surface area, they have both greater exposure and a greater likelihood of systemic toxicity to agents that fall on their skin.[30] Children have fluid and food intakes that differ significantly from adults. For example, children ingest approximately 100 mL/kg per day of water, compared with the 40 to 60 mL/kg per day that adults ingest. Children drink more milk than adults, placing them at risk of exposure to agents that can enter the milk supply through contamination of the grass on which cows feed; in the Chernobyl radiation disaster, cows grazed in contaminated pastures, resulting in excess radioactivity in their milk. Children drinking this milk sustained significant exposure to radioisotopes, including iodine and strontium. Finally, children not only eat more food on a per-kilogram basis but also have diets that are distinctly different from adults (eg, greater consumption of fruits).

Once exposed to a chemical or biological agent, children have numerous physiologic vulnerabilities that could lead to a greater risk of harm.[1] These vulnerabilities include undeveloped self-preservation skills that make them less able to flee danger; an immature immune system that makes them less able to contain infection (eg, plague)[31]; less fluid reserve, which can result in a greater risk of severe dehydration after exposure to agents that produce excess gastrointestinal fluid loss; and a greater risk of anxiety reactions and posttraumatic stress disorder after witnessing or being victim to a terrorist act.[32–34]

PUBLIC HEALTH PREPAREDNESS

The All-Hazards Approach

Over the last 5 years, a massive public health effort to improve response capability to future acts of biological terrorism has appeared. Such efforts have included antibiotic stockpiling, resurrection of smallpox immunization, and an unprecedented level of added support to state and local public health departments. Similarly, to respond to a possible chemical attack, extensive resources have been provided to public health authorities and first responders (fire, police, and emergency medical services) to create systems that will provide effective mitigation efforts. The initiation of these response campaigns revealed large-scale weaknesses in state and local public health infrastructure. Moreover, it became evi-

dent that intense effort was being directed toward events that might never occur rather than public health threats of much greater likelihood (eg, the appearance of an emerging infection or an unintentional hazardous chemical release).[35] Finally, it became clear that a fragmented and reactive public health–response plan is more expensive and inefficient than a single, comprehensive plan. As a result, disaster-response agencies and public health authorities have increasingly embraced the concept of the "all-hazards approach." Representing a dramatic paradigm shift in the preparation for chemical and biological terrorism, the all-hazards approach is designed to augment public health infrastructure, using an integrated model of disaster response.

Creation of all-hazards response systems has led to significant enhancements in public health–response capabilities. For example, the same protocol created to respond to the appearance of smallpox can be easily modified to contain an outbreak of severe acute respiratory syndrome (SARS). Similarly, an effective public health–response protocol for a sarin release would be equally effective for a hazardous-materials ("HAZMAT") release in the community.

Syndromic Surveillance

Overt acts of chemical and biological terrorism such as the sarin release in Tokyo present the challenge of rapidly identifying the agent and mobilizing the proper interventions. However, acts of chemical and biological terrorism may also be covert. Examples include the release of anthrax in 2001 and contamination of ground beef with nicotine in 2002. Covert incidents pose a significantly greater public health challenge and are more likely to induce widespread fear than overt events. Mechanisms for early recognition of a covert chemical or biological event, therefore, are necessary to contain the incident and minimize its impact.

Syndromic surveillance, a specialized type of outbreak detection, is a term used to describe mechanisms for monitoring health indices or events that reflect the early stages of an infection or disease of public health importance in an effort to minimize consequences.[36,37] Syndromic surveillance is considered an important means of identifying public health emergencies in their initial stages. Syndromic surveillance techniques can be clinician based or automated. Many syndromic surveillance systems are emergency department based. In addition, most state and local health departments are pursuing automatic electronic laboratory disease reporting.

The traditional mechanism of syndromic surveillance has been the clinician who recognizes unusual patterns of disease and reports them to public health authorities. The "astute clinician" principle places all health care professionals (including physicians, nurses, emergency medical technicians, epidemiologists, and health educators) in the role of sentinels for the appearance of disease clusters or other clinical abnormalities. The pivotal role of physicians and other health care professionals in syndromic surveillance, particularly for acts of terrorism, has led the CDC and other agencies to educate clinicians about chemical and biological weapons release and the diseases they produce. Clinical cues, case definitions, and syndromes for chemical weapons exposure have been published (Table 4), along with numerous resources to expand clinicians' ability to recognize covert terrorist incidents.[37,38]

Over the last few years, there has also been a rapid increase in the development of real-time, automated syndromic surveillance tools. A rapidly proliferating area, such automated decision support uses software to identify sentinel events such as an unusual amount of work or school absenteeism, changes in consumer purchase of over-the-counter products (eg, cough syrups or antipyretics), and changes in the chief-complaint profile among those who visit primary care physicians or emergency departments.[39–41] For example, the CDC has de-

TABLE 4 **Clinical Syndromes Associated With Chemical and Biologic Agents**

Category	Clinical Syndrome	Potential Etiologies
Cellular hypoxia	Altered mental status, dyspnea, seizures, metabolic acidosis	Cyanide, carbon monoxide, hydrogen sulfide, sodium azide
Cholinergic crisis	Salivation, diarrhea, lacrimation, bronchorrhea, diaphoresis, miosis, fasciculation, weakness, bradycardia, altered mental status, seizures	Nicotine, nerve agents, organophosphates
Gastrointestinal illness	Abdominal pain, vomiting, profuse diarrhea, hypotension, cardiovascular collapse	Ricin, staphylococcal enterotoxin E, arsenic
Lacrimation	Tearing, blepharospasm, incapacitation	Lacrimators ("Mace"), ammonia, halogens (chlorine, bromine)
Mucosal irritation	Tearing, nose and mouth burning, sore throat	Ammonia, halogens
Muscle rigidity	Generalized muscle contractions, painful neck/limb spasm, seizure-like activity	Strychnine
Muscle weakness	Generalized muscle weakness, ptosis, respiratory embarrassment	Botulism
Peripheral neuropathy	Muscle weakness or atrophy, "stocking-glove" sensory loss, depressed or absent deep tendon reflexes	Arsenic, thallium
Respiratory distress, acute onset	Cough, wheeze, shortness of breath, generalized mucosal irritation	Ammonia, halogens
Respiratory distress, delayed	Cough, respiratory distress, wheeze, hypoxia, pulmonary edema	Phosgene, sulfur mustard

veloped the Early Aberration Reporting System as a software tool available to clinicians and health departments around the nation (www.bt.cdc.gov/surveillance/ears).

New Governmental Roles in Emergency Preparedness

Although emergency-preparedness legislation existed before 2001, passage of additional rules between 2002 and 2005 resulted in massive efforts by the federal government to improve public health readiness across the nation (Table 1). Over the last 4 years, appropriations from federal to state public health agencies have been substantial. The Department of Homeland Security was established as a new member of the federal cabinet. Several departments within the Department of Health and Human Services have undergone extensive change, such as the CDC, Food and Drug Administration, and National Institutes of Health, all of which have reorganized their practice, regulatory, and research priorities to include chemical and biological terrorism, along with other public health threats; in 2002, the CDC established the Office of Terrorism Preparedness and Emergency Response. At state and local levels, planning for chemical and biological terrorism is now coordinated by multiple agencies, including departments of health, emergency-management agencies, poison control centers,[42] and law enforcement authorities.

The Strategic National Stockpile (SNS) has become one of the most important initiatives in mass-casualty disaster response.[5] Designed to respond to disasters that overwhelm local resources, the SNS includes such capabilities as the delivery of medications and supplies to areas of need within 12 hours of the request. SNS supplies include a pediatric formulary and materials for compounding tablets and capsules into liquid formulations (www.bt.cdc.gov/stockpile/index.asp).

SYSTEMS ISSUES IN PREPAREDNESS FOR CHEMICAL AND BIOLOGICAL TERRORISM

School and Child Care Center Preparedness

Children spend most of their waking hours in school or child care centers, away from their parents and guardians. Despite the fact that the majority of most children's day is spent in the care of the school system, efforts to create a blueprint that assists schools in developing comprehensive disaster-response protocols have been weak. School districts remain highly variable in the extent of their preparation for public health emergencies of any type, including chemical and biological terrorism.

Ideally, every school should produce its own response protocols rather than following a one-size-fits-all disaster plan that fails to take into account the school's physical plant, student size and characteristics, the presence of children with special needs, school nurse availability, and proximity to certain areas such as industries, rail yards, or highways.[40] All schools, in conjunction with local public health officials, should develop comprehensive evacuation and sheltering-in plans. Because local school bus fleets can typically evacuate only a fraction of children at one time, a means of mobilizing additional transport vehicles should be developed. General outlines for the development of a school emergency-response plan are found in Table 5.

Hospital Preparedness

Hospital protocols for pediatric victims of chemical or biological terrorism must be established in both pediatric and nonpediatric hospitals. These disaster protocols require an integrated response from the emergency department, ICU, operating rooms, and other key clinical areas within the hospital. Response needs include an adequate number of pediatric supplies, and a staff trained in the care of ill children will be needed to minimize morbidity and mortality.[5,6] All hospitals should have disaster protocols for pediatric patients, including mobilization of child life specialists, volunteers, and others who can provide comfort and distraction to children, particularly if those children are not yet united with their parents.

To be fully prepared for chemical or biological terrorism, pediatric and general hospitals must also have an evacuation plan should the hospital environment become uninhabitable. Although protocols for "vertical evacuation" (ie, the removal of patients to other floors within the same building) are well established in hospital-based disaster response, comprehensive plans for complete building evacuation are less well developed. Pediatric hospitals requiring full evacuation may have the additional challenge of transporting pediatric pa-

TABLE 5 **Key Aspects of School Response to Chemical-Biological Terrorism and Other Public Health Emergencies**

Assembly of the school crisis-response team
Principal, counselors, nurses, custodians
Contact and coordination with local public health–response team(s)
Evacuation[52]
Plan includes plans for rapid evacuation of physically and developmentally disabled children from all floors
Plan includes strategy for evacuation/relocation in inclement weather
Relocation
Plan includes the transport of medications, contact telephone numbers, and other essential material
Plan informs parents in advance of relocation site
Sheltering-in[53]
Designed for response to outdoor threats
Lockdown
Designed for response to a threat within the school
Communication with parents
Anticipates inability of parents to reach the school by telephone
Potentially includes automatic callout system, voice mail, parent contact "tree," or Web-based communication system
Policy for use of cellular phones by students during a disaster
Protocols for disaster response by after-school programs, including athletics

tients to health care facilities with relatively few pediatric resources. Nonetheless, memoranda of agreement with nearby or affiliated institutions are a key part of a comprehensive pediatric hospital disaster plan.

After exposure to a chemical or biological weapon, children may become covered by toxic material that can produce skin injury or be absorbed, producing systemic toxicity. In the case of infectious material, the contamination of skin could be sufficient to represent a threat to health care professionals as well as the victim. When children are covered with unknown but potentially dangerous chemical or infectious material, immediate decontamination is required.[43] Topical decontamination has 2 distinct components: disrobing and showering. To minimize exposure to health care professionals and patients within the health care facility, the child should be disrobed outdoors, before entering the ambulance or building. Disrobing alone accounts for more than 85% of topical decontamination and is an extremely effective means of ending exposure. When possible, the victim should disrobe himself or herself to minimize exposure to others. Health care professionals should not assist in disrobing unless they are wearing appropriate PPE.

Showering complements disrobing by further removing chemicals, microbes, and debris. As with disrobing, showering must occur outdoors; protocols should include strategies for preventing hypothermia in children. Principles of showering include the establishment of 3 management zones in the decontamination staging area (so-called hot, warm, and cold in reference to the site's degree of contamination), use of water that has been warmed to a temperature of 100°F, a water pressure of 60 psi, and, if possible, containment of the wastewater. If the toxic material is oily or firmly adherent to the child's skin, soap or a mild shampoo should be used; solutions such as mild bleach should not be used on children because of the risk of skin injury.[5] If an outdoor shower is not available, the child can be simply disrobed before being brought into the health care facility for care. Decontamination can be a frightening procedure for children, exacerbated by the identity-concealing PPE that clinicians are wearing. Efforts should be made to keep parents nearby; when possible, parents should be used to assist with their child's decontamination.

All health care professionals who assist in decontamination must protect themselves by wearing appropriate PPE. Currently, there are 4 levels of PPE, ranging from level A, which is the highest level of protection, to level D, which consists of simple gown, gloves, and surgical mask. For hospital personnel, level C PPE (a chemical-resistant suit and gloves, with an air-purifying respirator) is considered adequate for hospital-based management of most contaminated victims. Health care facilities should develop plans for rapid access to such equipment. Staff should be appropriately trained. Other principles of decontamination and PPE are outlined in Table 6 and have been published recently.[44,45]

Community Health Center Preparedness

Community health centers (CHCs) and local health departments are, in most major metropolitan areas, an important source of "safety-net" health care and social support to a community. In a large-scale terrorist disaster, CHCs could play a pivotal role in supporting the community and nearby hospitals. First, in the event of an infectious outbreak, families will likely go to their CHC for treatment and to obtain information from professionals whom they trust and who are more likely to provide culturally competent care. In addition, after a multiple-casualty incident, hospitals may become too crowded to treat every patient. In such cases, CHCs could potentially be used as alternate care sites, providing care to those with minor injury and assisting in interventions (eg, mass administration of antimicrobial agents). CHCs, therefore, should be included in planning by local public health authorities.[5]

Office Preparedness

The pediatrician should have an important role in the community response to any disaster involving children. First, the pediatrician's office may be the preferred site of care for many victims who are transporting themselves for treatment. Both chemically contaminated children and children with suspected illness from a biological weapon might go directly to the pediatrician's office. Consequently, pediatricians should consider the development of office protocols for disasters, including (1) management of a child who requires decontamination, (2) management of a child with a potentially transmis-

TABLE 6 Principles of Decontamination

All decontamination should occur outside the health care facility.
All health care professionals should wear appropriate PPE, as determined by their safety officer and occupational health specialist.
All levels of health care professionals should be trained to use PPE, including physicians, nurses, clinical assistants, security, and environmental services.
Remove clothing from the victims as quickly as possible. Victims should disrobe themselves when possible.
Discarded clothing should be placed in labeled plastic bag and stored for possible use by law enforcement.
Shower water should have a temperature of approximately 100° F and a pressure of 60 psi.
Water alone is used routinely. If material is oily, a mild soap or shampoo can be added.
Victims should shower for 5 minutes unless specific alternative recommendations are given.
If possible, water effluent should be contained rather than placing it in the local wastewater stream.
Use heat lamps, blankets, and other mechanisms to prevent hypothermia.
Critically ill victims should simply be disrobed and not showered before entering the health care facility. Cover hands, feet, and other exposed areas if there is evidence of gross contamination.
If there are multiple victims, anticipate the need to perform out-of-hospital triage.

sible infection, and (3) management of a sudden influx of pediatric patients after a large-scale incident.[5] The AAP textbook *Childhood Emergencies in the Office, Hospital, and Community*[46] is a useful resource to assist in office planning for such emergencies. Pediatricians should also consult their state and local health departments, because most have electronic health alert networks.

Surge Capacity

An effective response to large-scale chemical or biological terrorism (ie, an incident with more casualties than routine operations can accommodate) requires the creation of surge-capacity protocols. Federal, state, and local public health authorities are essential in assisting health facilities during crises of large magnitude. Nonetheless, both pediatric and nonpediatric hospitals should consider how a large-scale event would affect their facility. Plans for such an event might include (1) the creation of additional bed spaces through cohorting, (2) mechanisms for the rapid discharge of inpatients to increase capacity, (3) an inventory of all sites in the hospital where critical care can be provided, (4) establishment of a site, ideally out of the hospital, for patient triage, (5) identification of care sites for those whose injuries are minor, (6) mechanisms for labeling and tracking patients, particularly children who arrive without personal identification, and (7) plans for maintaining hospital security by preventing the entry of contaminated victims and other unauthorized individuals. For nonpediatric hospitals, surge-capacity plans for a mass-casualty chemical or biological incident involving children should also include mechanisms for mobilizing health care professionals with pediatric expertise. Surge-capacity principles are summarized in Table 7. Disaster medical assistance teams (DMATs), supported by the US Public Health Service, have been created by the National Disaster Medical System to provide assistance to regions after a large-scale disaster. However, among the 27 DMATs in the United States, only 2 are dedicated pediatric DMATs, significantly limiting the federal response capability to a pediatric mass-casualty incident. The Metropolitan Medical Response System, another federal effort designed to create regional "medical strike teams," has no clearly established pediatric capability or standards.

TABLE 7 **Surge-Capacity Principles for Hospitals**

Preparation
Obtain PPE, showers, and other emergency-response equipment
Stockpile supplies
Stockpile or plan for additional pharmaceuticals
Perform drills; consider tabletop exercise
Response
Anticipate a 1:5:7 ratio of critically ill/urgently ill ("walking wounded")/well ("worried well") casualties
Anticipate the "second-wave" phenomenon
Reserve the emergency department for critically ill patients
Perform triage and decontamination outside the hospital
Ensure campus security from unauthorized intrusion
Identify and utilize alternate sites of care; identify transportation options

Mental Health

The mental health consequences of terrorism are extensive and, in many cases, enduring. Children have a disproportionate risk of developing emotional and behavioral sequelae; investigations after the September 11th attacks found that as many as 25% of children developed acute anxiety followed by posttraumatic stress disorder.[33,47,48] Children can develop a broad range of behavioral problems after a disaster, whether they witness the incident or simply observe their parents' response to an incident (eg, from a television broadcast). Overt manifestations may include emotional lability, insomnia, frequent crying, depression, fear, and "anniversary grief." Alternatively, mental health consequences may also be subtle and elusive (eg, manifesting as multiple somatic complaints).

Parents may similarly become psychological casualties after chemical or biological terrorism. Visual replay of events on television may contribute to the development of long-term behavioral disturbances. As with children, the parent may have overt or subtle signs of distress. Adults typically display loss of appetite, insomnia, depression, hopelessness, and acute anxiety.

Finally, health care professionals who care for victims of chemical or biological terrorism can develop mental health consequences. There is an extensive body of literature indicating that health care professionals can become extremely depressed, developing posttraumatic stress disorder after caring for victims. To reduce the risk of this occupational hazard, the concept of critical incident stress debriefing (CISD) was created many years ago. In principle, a prompt debriefing session can be therapeutic by permitting staff to verbalize their feelings and anxieties about what they have experienced. CISD has become a common part of postevent disaster management. Recently, however, questions about the efficacy of CISD in reducing mental health sequelae among health care professionals have been raised.[49] There are increasing concerns that the process of debriefing forces health care professionals to relive events, undoing internal resolution that is already underway. In addition, the process of group debriefing may carry the risk of having health care professionals hear about disturbing events that they themselves did not witness, creating anxiety and depression that was not present initially. Although this issue remains controversial, there is consensus that efforts should be made to identify health care professionals who are suffering psychological sequelae from their involvement in responding to an act of chemical or biological terrorism.

Individual/Family Preparedness

Large-scale disasters, whether they are natural (eg, hurricanes or floods), unintentional (eg, hazardous-materials release), or intentional (ie, terrorist), can occur at any time. All families, particularly families with children, should have a disaster plan. Such plans should include communication in the event of cellular phone failure, a reunification plan if disaster occurs when family members are not together, and emergency provisions in the home. Multiple resources are available to assist families in home disaster planning (www.ready.gov/index.html and www.fema.gov/plan/index.shtm).

RECOMMENDATIONS TO PEDIATRICIANS

1. Because the threat of chemical or biological terrorism continues and children are likely to be affected disproportionately by such acts, pediatricians should be knowledgeable about agents of concern and their management and the response systems that are needed to minimize physical and mental trauma to children. Following the principle of the all-hazards approach, pediatricians should become and remain knowledgeable about principles of preparation and response to similar public health emergencies (eg, hazardous-materials incidents or emerging infections).
2. Pediatricians should participate, as need and opportunity arises, in local public health activities in chemical and biological terrorism preparedness. The pediatrician can be a valuable resource to public health authorities in issues such as first-responder training and hospital preparedness. In addition, involvement of pediatricians in these activities increases the likelihood that the needs and vulnerabilities of children will be considered.
3. Pediatricians should work, where possible, with local school systems to develop plans for rapid evacuation, relocation, triage, and initial care of children who are in school when an act of chemical or biological terrorism occurs.
4. Because pediatric victims of chemical or biological terrorism may present to their pediatrician's office, there should be consideration of plans and protocols for management of such children on site. Such preparation may include the establishment of out-of-building decontamination protocols and isolation of potentially infectious patients from others.
5. Pediatricians should be prepared to assist families in disaster planning by providing education on key principles such as basic emergency equipment in the homes, including flashlights, alternative heating, lighting, and a supply of water, food, and clothing. Discussion about how to talk to children about war and terrorism should be included.[50]
6. Pediatricians should evaluate and ensure proper treatment for children for mental health sequelae after chemical-biological terrorism, particularly because these sequelae can develop days to months after the event.[51] The AAP Web site offers multiple resources for pediatricians and families (www.aap.org/terrorism/index.html, www.aap.org/profed/childrencheckup.htm, www.aap.org/advocacy/releases/disastercomm.htm, and www.aap.org/terrorism/topics/psychosocial_aspects.html).

RECOMMENDATIONS TO GOVERNMENT

1. The needs of children should be addressed in all preparedness efforts at the federal, state, regional, and local levels.
2. All recommendations made by the National Advisory Committee on Children and Terrorism (www.bt.cdc.gov/children/recommend.asp), designed to ensure that children are included in emergency-response planning, should be implemented.
3. Public health agencies should make a concerted effort to assist schools and school districts in their preparedness efforts. Emergency-response plans for schools should be tailored to the individual school and its location, population, staff, and resources.
4. DMATs created by the National Disaster Medical System will play a key role in a mass-casualty incident involving children. The pediatric training of these teams should be comprehensive. Creation of additional pediatric DMATs should be considered.
5. Public health agencies should continue to actively provide assistance and resources to hospitals, pediatric offices, CHCs, and other health care facilities to ensure that they are prepared to respond to a chemical or biological terrorist incident that involves children.
6. As funding for emergency preparedness continues, the needs of children should always be included among the deliverables and performance benchmarks.

abstract

FREE

The American Academy of Pediatrics recommends that chemical-management policy in the United States be revised to protect children and pregnant women and to better protect other populations. The Toxic Substance Control Act (TSCA) was passed in 1976. It is widely recognized to have been ineffective in protecting children, pregnant women, and the general population from hazardous chemicals in the marketplace. It does not take into account the special vulnerabilities of children in attempting to protect the population from chemical hazards. Its processes are so cumbersome that in its more than 30 years of existence, the TSCA has been used to regulate only 5 chemicals or chemical classes of the tens of thousands of chemicals that are in commerce. Under the TSCA, chemical companies have no responsibility to perform premarket testing or postmarket follow-up of the products that they produce; in fact, the TSCA contains disincentives for the companies to produce such data. Voluntary programs have been inadequate in resolving problems. Therefore, chemical-management policy needs to be rewritten in the United States. Manufacturers must be responsible for developing information about chemicals before marketing. The US Environmental Protection Agency must have the authority to demand additional safety data about a chemical and to limit or stop the marketing of a chemical when there is a high degree of suspicion that the chemical might be harmful to children, pregnant women, or other populations. *Pediatrics* 2011;127:983–990

INTRODUCTION

Over the past several decades, tens of thousands of chemicals have entered commerce and the environment, often in extremely large quantities (eg, multiple millions of pounds per year). There has also been an explosion of knowledge about special vulnerabilities and differential exposures that children and pregnant women have to environmental toxicants. A growing body of research indicates potential harm to child health from a range of chemical substances.

The primary federal law that governs chemical management in the United States, the Toxic Substances Control Act (TSCA) (Pub L No. 94-469 [1976]), is not protective of the health of children and pregnant women and has not undergone any meaningful revision since its passage almost 35 years ago. Since then, of the tens of thousands of chemicals that are in commerce, the TSCA has been used to regulate only 5 chemicals or chemical classes: polychlorinated biphenyls (PCBs); fully halogenated chlorofluoroalkanes; dioxin; asbestos; and hexavalent chromium.[1] The TSCA is so ineffective that it took a separate act of

Congress to amend the TSCA so that the US Environmental Protection Agency (EPA) could regulate asbestos, one of the most dangerous toxic substances. It is because of the inadequacies of the TSCA that parents and pediatricians have been subjected to multiple high-profile media blitzes about specific chemicals, such as phthalates in toys and bisphenol A in infant bottles,[2,3] that create anxiety without solving the problems of risky chemical exposures.

The American Academy of Pediatrics recommends that chemical-management policy in the United States be substantially revised to better protect children and pregnant women.

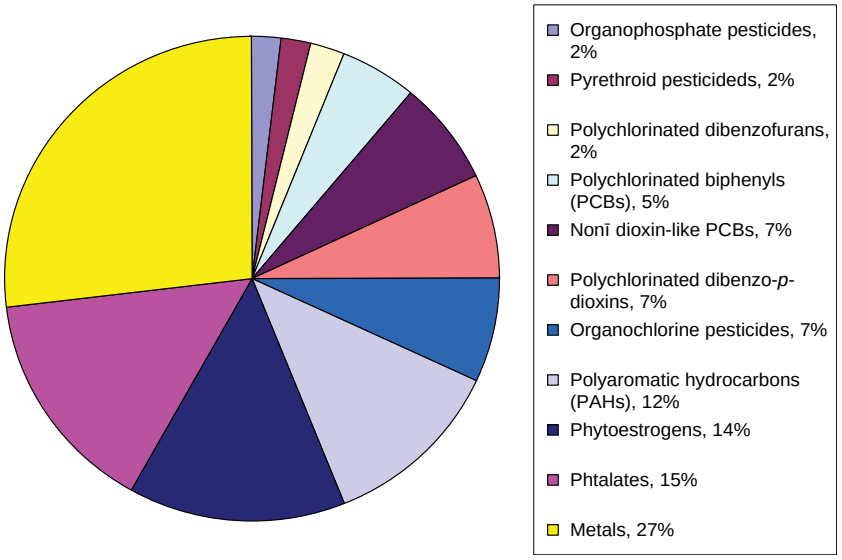

FIGURE 1
Distribution of detected chemicals in the Centers for Disease Control and Prevention biomonitoring study, 2005. (Modified with permission from Rushing R. *Reproductive Roulette: Declining Reproductive Health, Dangerous Chemicals, and a New Way Forward.* Washington, DC: Center for American Progress; 2009. Available at: www.americanprogress.org/issues/2009/07/reproductive_roulette.html.)

THE HOPE OF "BETTER LIVING THROUGH CHEMISTRY"

From the mid-19th century until today, there has been phenomenal growth in our knowledge about chemistry. Currently, there are more 80 000 chemicals in commerce in the United States, more than 3000 of which are considered to be "high-production volume" chemicals (chemicals produced in or imported into the United States in quantities of ≥1 million pounds/year). Under the EPA Inventory Update Reporting program, the chemical-manufacturing industry estimated that approximately 27 trillion pounds of chemicals were produced in or imported into the United States per year in the early part of this decade, which is the equivalent of approximately 74 billion pounds/day (nearly 250 pounds per person) and does not include fuels, pesticides, pharmaceuticals, or food products.[4] Many of these chemicals are in the environment, and some affect the health of children.

From biomonitoring data from the Centers for Disease Control and Prevention[5] and other documentation[6–11] it is known that there is widespread human exposure to many of these substances (see Fig 1). These chemicals are found throughout the tissues and body fluids of children and adults alike, including blood, cord blood, and human milk.

Few of the chemicals that are supposed to be controlled by the TSCA were intended for human consumption. Because the TSCA does not require premarket testing of these chemicals, scientific studies of their effects on the human body may be scarce or nonexistent. Food additives, pesticides, and pharmaceuticals, all of which are intended for human consumption (although at low levels in the case of pesticides), do require premarket testing and, depending on the product, some postmarket follow-up. However, the paradigm established for food additives, pesticides, and pharmaceuticals should not be taken as a model for chemical management. There are too many chemicals and too many tests that would need to be performed to use individual chemical testing as a means of ensuring safe chemical management.

CHILDREN ARE NOT LITTLE ADULTS

Children have unique physiologic, developmental, and behavioral differences that influence their environmental exposures. Because children are smaller than adults, their surface area–to–body mass ratio is greater. Children eat more food and drink more water per unit of body weight than do adults.[12] The respiratory minute ventilation—inspired air per unit time adjusting for weight—is greater in young children than in adults.[13]

Children's behavior changes with age, and with it, the routes of exposure to chemicals change.[14] Infants are incapable of independent locomotion, which makes it impossible for them to remove themselves from environmental hazards such as heat and cold. Children of all ages spend more time on the floor or ground than do adults. Therefore, children will come into more contact with contaminants on these surfaces.

Exposure of people to environmental toxicants may affect fertility. A recent

study of blood levels of polybrominated diphenyl ether (PBDE) flame retardants in women found that it took significantly longer for women with higher PBDE levels to get pregnant.[15] Exposure of the fetus in utero to at least 1 pharmaceutical, diethyl stilbestrol (DES), is recognized to produce adverse health effects on the children and even the grandchildren of that fetus.[16] Further research may reveal that there may be such a concern with chemicals in the environment as well.

As children grow and mature, their bodies may be especially vulnerable to certain chemical exposures during critical windows of development. Neurologic and endocrine systems have demonstrated particular sensitivity to environmental toxicants at certain stages of growth. These differences in biological susceptibility and exposures in children versus adults support the need for strong consideration of children in chemicals policies. This principle must underpin all chemical-management legislation and regulation.

THE TSCA FAILS TO PROTECT CHILDREN AND PREGNANT WOMEN

A number of federal laws govern the safety of food additives, cosmetics, pharmaceuticals, and pesticides (Table 1). The TSCA, which was passed in 1976, with subsequent modifications, sets out the current federal framework for the regulation of most chemicals. Congress established the following as the original goals of the TSCA:

1. to develop adequate data about the effects of chemical substances and mixtures on health and the environment and to ensure that the manufacturers and processors of such chemical substances and mixtures be responsible for the development of such data;
2. to provide adequate authority to regulate chemical substances and mixtures that present an unreasonable risk of injury to health or the environment and to take action with respect to chemical substances and mixtures that are imminent hazards; and
3. to ensure that authority over chemical substances and mixtures does not impede unduly or create unnecessary economic barriers to technologic innovation while ensuring that the innovation and commerce of chemical substances and mixtures do not present an unreasonable risk of injury to health or the environment.[17]

TABLE 1 US Legislation Concerning Chemicals

Act	Year Passed	Subject
Federal Food, Drug, and Cosmetics Act (FFDCA)	1938	Gives authority to the US Food and Drug Administration to oversee the safety of food, drugs, and cosmetics
Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)	1972	Pesticides
Toxic Substances Control Act (TSCA)	1976	Chemicals 1988 and 1990: asbestos and radon 1992: lead-based paint 2002: healthy and high-performance schools
Food Quality Protection Act (FQPA)	1996	Pesticides

Unfortunately, the TSCA has not met its goals. The law suffers from a number of defects that render it ineffective in assessing the risk posed by chemicals. Without sufficient information on the safety or health effects of chemicals, it is impossible for the EPA to engage in appropriate regulation. Key weaknesses of the TSCA include the following.

- Costs of TSCA safety testing are often borne by the public sector. Manufacturers of chemicals are not required to test chemicals before they are marketed or to collect data from tests that may have been performed by others. The TSCA places the burden of obtaining information about the potential toxicity of a chemical on the public rather than the manufacturer. The EPA is charged with developing information on toxicity, but the agency has neither the technical nor the financial resources to perform extensive research on even a fraction of the tens of thousands of chemicals in commerce.
- The TSCA has created a non–evidence-based system for chemical management. Manufacturers are required to notify the EPA of their intent to market a new chemical; however, they are not required to perform any safety testing before notifying the EPA. The EPA estimates that most such notifications do not include test data of any type, and only approximately 15% include health or safety test data.[18] It is ironic that companies may harm themselves by performing premanufacture testing, because they must disclose any health or safety data they obtain. This system discourages manufacturer safety testing and also results in chemicals for which there are less data seeming to be safer than chemicals for which there are more data.
- Concerns about chemicals are permitted to be kept from the public. In their notifications to the EPA, chemical companies may declare large amounts of information to be "confidential business information." This broad exemption has effectively prevented the EPA from sharing information about potentially hazardous chemicals with community groups, local and state governments, and foreign governments or international organizations.

- Chemicals introduced before 1976 have little oversight. The TSCA distinguished between chemicals in existence in 1976 and those introduced after passage of the law. Those on the market in 1976 were assumed to be relatively safe and in need of less testing than "new" chemicals. To pursue regulation of these "grandfathered" chemicals, the EPA must demonstrate that a chemical has a high likelihood of causing harm before it can order testing to determine if there is a health risk. Between 1979 and 2005, the EPA used its authority to require testing on fewer than 200 chemicals in commerce.[1]
- Implementation of TSCA regulatory action is unwieldy. Rule-making under the TSCA is extremely time-consuming and labor intensive. After a nearly decade-long effort to ban asbestos, the EPA found its initiative struck down by the courts on the basis that the agency had overstepped its authority under the TSCA. Since passage of the TSCA, the EPA has issued regulations to ban or limit only 5 existing chemicals or chemical classes.[18]
- The TSCA does not allow review of chemicals by group. The TSCA requires regulation on a chemical-by-chemical basis. With tens of thousands of chemicals in need of review and the multiyear process for each such undertaking, it would require many decades to review just the high-production chemicals. For example, the finding of toxicity of a radioactive substance such as plutonium would not allow another similar substance such as uranium to be defined as toxic. The TSCA would require that testing on the second compound be conducted completely anew.

THE EPA HAS ATTEMPTED TO IMPLEMENT THE TSCA THROUGH VOLUNTARY ACTION

The EPA has implemented several voluntary programs in attempts to compensate for inadequacies of the TSCA. These programs include the Endocrine Disruptor Screening Program, the Voluntary Children's Chemical Evaluation Program, and the Chemical Assessment and Management Program. Because these programs are voluntary, the EPA cannot require companies to produce information about the health and safety risks of these chemicals. Each of these programs has produced few data over long periods of time, and none has led to any significant regulatory changes.[1,19] For example, the Endocrine Disruptor Screening Program was called for in legislation passed in 1996, but the EPA only issued its first test orders, the first step in a multistep process, in October 2009.[20] The Voluntary Children's Chemical Evaluation Program was launched by the EPA at the end of 2000. It had the meager goal of gathering information on health effects, exposure, risk, and data needs for 23 chemicals to which children have a high likelihood of exposure. More than a decade later, for various reasons, complete data are not available for any of those chemicals.[21] Because of its inadequacies, in September 2009 the EPA replaced the Chemical Assessment and Management Program with what it hopes will be a "more comprehensive approach to chemicals management."[22]

CALLS TO REFORM THE TSCA

The American Medical Association,[23] the American Public Health Association,[24] and the American Nurses Association[25] have all endorsed the need for changes to the TSCA. Recognizing that "[t]he science of testing chemicals and understanding their health or environmental effects has evolved considerably since TSCA was enacted," the American Chemistry Council has also called for the modernization of the TSCA to ". . . help assure that we protect . . . our children . . ."[26]

TABLE 2 Six Essential Principles for Reform of Chemical-Management Legislation (EPA[36])

Chemicals should be reviewed against safety standards that are based on sound science and reflect risk-based criteria protective of human health and the environment.
Manufacturers should provide the EPA with the necessary information to conclude that new and existing chemicals are safe and do not endanger public health or the environment.
Risk-management decisions should take into account sensitive subpopulations, cost, availability of substitutes, and other relevant considerations.
Manufacturers and the EPA should assess and act on priority chemicals, both existing and new, in a timely manner.
"Green" chemistry should be encouraged, and provisions that ensure transparency and public access to information should be strengthened.
The EPA should be given a sustained source of funding for implementation.

A number of environmental health policy entities have been critical of the TSCA.[4,27–30] In addition, the US Government Accountability Office has issued a number of reports in which the TSCA was criticized.[1,18,31–33] In 2009, the Government Accountability Office added the TSCA to its high-risk list for federal legislation that needs to be updated.[34]

In 2009, the EPA established 6 essential principles for reform of chemicals management legislation (Table 2).[35] The proposed principles address many of the deficiencies of the TSCA discussed above.

STATE ATTEMPTS AT CHEMICAL-MANAGEMENT POLICY

In the absence of up-to-date federal regulatory policy, many states have attempted to fill the gap. A handful of state legislatures have undertaken measures to control individual chemicals, such as bisphenol A, or attempted the comprehensive identification, pri-

TABLE 3 State-Proposed Principles on Reform of the TSCA[38]

Require chemical data-reporting
Demonstrate that chemicals and products are safe
Prioritize chemicals of concern
Protect the most vulnerable
Promote safer chemicals and products
Address emerging contaminants
Strengthen federal law and preserve states' rights
Fund state programs

oritization, and regulation of chemicals.[36] Some states have targeted their efforts specifically at chemicals of concern in children's products. Chemicals that have been the subject of state laws include phthalates and fire retardants. Officials from California, Connecticut, Illinois, Maine, Maryland, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Oregon, Vermont, and Washington have issued a list of principles on reform of the TSCA (Table 3).[37]

EXAMPLES OF INTERNATIONAL EFFORTS TO REGULATE CHEMICALS

Over the past decade, an increasing number of nations have attempted to exert greater control over the entrance of new chemicals into commerce and their use in various contexts. A number of treaties have addressed certain classes of pollutants (eg, the Stockholm Convention on Persistent Organic Pollutants), and more comprehensive approaches have been attempted by individual nations or international entities.

In 1999, Canada passed legislation that requires the development of a categorization and prioritization system for the Domestic Substances List, its chemicals registry. The Domestic Substances List catalogued approximately 23 000 chemicals known to be in commerce in Canada since the mid-1980s. The review, which was completed in 2006, methodically categorized the chemicals to prioritize those of greatest concern for review and possible restriction. On the basis of a screening assessment, chemicals were: designated as Canadian Environmental Protection Act (CEPA)—toxic, in which case they were subject to additional regulation and restriction; added to the priority substances list, which requires an in-depth assessment to be completed within 5 years; or set aside as not requiring further study at the time.[38] This process resulted in the designation of 85 substances as CEPA-toxic[39] and the placement of 67 on the priority substances list.[40] Although the Domestic Substances List categorization has been hailed as a model, critics have stated that Canadian law does not permit aggressive enough regulation to occur on those substances considered to be CEPA-toxic.

In early 2006, the United Nations Environment Program's Governing Council adopted the Strategic Approach to International Chemicals Management (SAICM), a strategy developed and negotiated with the participation of a wide range of stakeholders from more than 140 countries. The SAICM global plan of action sets out nearly 300 different activities that will help countries reach the plan's overall objective of achieving the sound management of chemicals throughout their life cycle so that, by 2020, they are used and produced in ways that reduce major adverse effects on health and the environment.[41,42] The SAICM includes activities in the area of policy change, research, and capacity-building, among others. It must be noted, however, that the strategy is purely voluntary for all participating nations, and each country is free to adapt and alter the approaches used. There is no formal oversight of the strategy or any enforcement of its recommendations.

In perhaps the most ambitious regulatory effort to date, the European Union (EU) established the new Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH) regulation in 2006.[43] The stated aim of REACH is to "to improve protection of human health and the environment from the risks of chemicals while enhancing the competitiveness of the EU chemicals industry."[44] This system, which began to phase in during 2007 and will continue its staged implementation over a decade, sought to develop a comprehensive regulatory regime for chemicals with the ultimate goal of restricting the use of the most toxic substances. Companies must register all chemicals that are sold in the EU market in quantities above 1 metric ton. A list of substances of very high concern is under development, which will constitute chemicals for which substitution is required whenever feasible and which will require an authorization for each individual use of a substance of very high concern. As of late 2009, 16 substances had been officially identified as substances of very high concern,[45] but nonprofit organizations were pressing for the addition of at least 350 more substances to this designation.[46] Although REACH was developed as a system that will cover all EU countries, there is some flexibility for member nations to opt out of or alter certain provisions. Many key provisions of REACH have not yet been implemented, so its full impact is, as yet, unclear.

RECOMMENDATIONS FOR GOVERNMENT AND ADVOCACY

1. Whenever a new chemicals policy is developed or existing policy is revised, the wide range of consequences of chemical use on children and their families should be a core component.
2. Federal, state, and local policies should support and enforce sound chemical management. Policies should incorporate the following principles.

a. The regulation of chemicals must be based on evidence. However, decisions to limit or ban chemicals or classes of chemicals from commerce or to promote the substitution of demonstrably less hazardous chemicals should be based on reasonable levels of concern and not depend on demonstrated negative health effects after release.
b. "Old" and "new" chemicals must meet the same requirements for evidence.
c. Although testing of individual chemicals should not be the sine qua non for decisions to limit or ban chemicals or classes of chemicals, when testing is appropriate, those who propose to market a chemical must be mandated to provide evidence that the product has been tested in systems that provide information that is relevant to the special needs of pregnant women and children, including data on reproductive toxicity; developmental toxicity, including but not limited to neurodevelopmental toxicity; and endocrine disruption, as it relates to reproduction, neurotoxicity, and puberty.
d. Decisions should be based on information about hazards, proposed use, and potential exposures. Hazard implies intrinsic properties of chemicals or classes based on molecular structure (eg, persistence, carcinogenicity, or neurotoxicity). When appropriate for hazard determination, there must be consideration of aggregate (exposure to a single pollutant via multiple pathways) and cumulative (concurrent exposures to multiple pollutants with a common mechanism of action via multiple pathways) exposure concepts similar to those of the Food Quality Protection Act.
e. Chemicals must meet safety standards similar to those met by pharmaceuticals or pesticide residues on food, that is, "reasonable certainty of no harm." Exceptions should be available for chemical use when no safer alternatives exist. Such exemptions should require individual regulatory approval and biannual review to ascertain whether the exemption is still necessary.
f. There must be postmarketing surveillance of the effects of a chemical, and the EPA must have the authority and means to remove a chemical if postmarketing surveillance indicates that it no longer meets the standard for being released to the market.
g. Companies that propose to place a new chemical on the market must develop a means for biomonitoring of that chemical before it is marketed.
h. Companies must develop a public information document for each new chemical marketed. This document must be in lay language and approved by the EPA before the chemical is marketed. A companion document must be developed for all consumer products that contain the chemical and must be updated with each new formulation of the product or every 3 years. This document must include the results of any premarket testing and any postmarket surveillance. It must include information about risks associated with acute, high-dose exposure and chronic low-dose exposure as well as contact information for people who need additional information.

3. The EPA must have a relatively simple process to require additional testing when information suggests the need for such testing.
4. Federal biomonitoring programs, such as the Centers for Disease Control and Prevention National Biomonitoring Program, must be expanded. It is recognized that this program provides secondary prevention, but it may serve as an early warning system. Stored samples may allow look-backs when new problems develop in the future.
5. Federal funding should be provided for research to prevent, identify, and evaluate the effects of child exposures to chemicals. Development of additional chemical testing methodologies is needed to ensure that exposures to existing and new chemicals can be identified. Consensus in the scientific community is needed on methods and biomarkers to identify and evaluate chemicals for adverse effects through endocrine disruption. Funding to support studies to examine long-term and subclinical chemical effects is needed.
6. Federal policies should reward and promote developments in green chemistry that serve to replace existing chemicals of concern and their commercial applications.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Pediatricians should familiarize themselves with the information about chemicals in the environment and their effects on child health. Many chemicals are reviewed in the

American Academy of Pediatrics manual *Pediatric Environmental Health*.[47] The third edition of this book will be available in 2011.

2. Pediatricians should learn about the resources contained in the Environmental Health and Toxicology pages of the National Library of Medicine Web site. (http://sis.nlm.nih.gov/enviro.html). Those portions that will be of most use in counseling families include LactMed (http://toxnet.nlm.nih.gov/cgi-bin/sis/htmlgen?LACT) (a peer-reviewed and fully referenced database of drugs to which breastfeeding mothers could be exposed) and the Household Products Database (http://householdproducts.nlm.nih.gov) (which links >8000 consumer brands to chemicals they may contain on the basis of Material Safety Data Sheets provided by the manufacturers).
3. Pediatricians with questions about acute chemical exposures and toxicity should call the Poison Control Center at 800-222-1222. For questions about long-term, low-dose exposure or other issues related to children and chemicals, pediatricians should contact their regional Pediatric Environmental Health Specialty Unit (www.pehsu.net).
4. Pediatricians should advocate for chemical policies that consider the special vulnerabilities of children and pregnant women. The American Academy of Pediatrics, through its chapters, committees, councils, sections, and staff, can provide information and support for public policy advocacy efforts. See www.aap.org/advocacy.html or contact your chapter leadership for further information.

abstract

The federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 has significantly affected clinical practice, particularly with regard to how patient information is shared. HIPAA addresses the security and privacy of patient health data, ensuring that information is released appropriately with patient or guardian consent and knowledge. However, when child abuse or neglect is suspected in a clinical setting, the physician may determine that release of information without consent is necessary to ensure the health and safety of the child. This policy statement provides an overview of HIPAA regulations with regard to the role of the pediatrician in releasing or reviewing patient health information when the patient is a child who is a suspected victim of abuse or neglect. This statement is based on the most current regulations provided by the US Department of Health and Human Services and is subject to future changes and clarifications as updates are provided. *Pediatrics* 2010;125:197–201

OVERVIEW AND PURPOSE OF THE HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT

The overarching purpose of the federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 (Pub L No. 104–191) is to protect health insurance coverage for individuals who change or lose their jobs (Title I) and to establish national standards for electronic health care transactions that ensure the security and privacy of patient information (Title II). The latter goal required the US Department of Health and Human Services to establish such standards, which were enacted in April 2003. Title II also addresses the release of information about children and minors who are suspected victims of child abuse. Although HIPAA generally overrides state laws, HIPAA rules do not apply where the "provision of state law. . .provides for the reporting of disease or injury, child abuse, birth, or death, or for the conduct of public health surveillance, investigation or intervention" (Section 160.203[c]) or where state laws are more stringent than HIPAA rules.[1] Pediatricians are responsible for updating their practice in concurrence with changing HIPAA statutes, such as Health Information Technology for Economic and Clinical Health (HITECH), which was signed into law in February 2009.

DEFINITIONS

Covered Entity

HIPAA regulations apply to "covered entities." Covered entities include a health care professional (examples include "doctors, clinics, and psychol-

ogists"; see www.hhs.gov/ocr/privacy/hipaa/understanding/coveredentities/index.html) who documents and exchanges at least some patient information in electronic form (eg, via the Internet or an intranet), a health care clearinghouse that processes health care information from one format to another, and an individual or group health plan (eg, insurance plan) that provides or pays for medical care. A health care professional or a practice group that requests payment from a health care plan conducts electronic exchange of information and is, therefore, a covered entity. Covered entities cannot disclose certain patient information without written authorization from the patient or the patient's legal guardian unless exceptions are provided through HIPAA or state laws that override HIPAA.

Physicians who are employed by covered entities, including governmental organizations, but who work at a facility that may not be a covered entity, such as a children's advocacy center, may still be required to comply with HIPAA regulations. If there is a contract, such as a business associate agreement, between the physician's employer, a covered entity, and any other agency or facility, the physician is required to comply with HIPAA to the same extent as the covered entity is required to comply.

Protected Health Information

Information governed by the rules of HIPAA is called protected health information (also referred to as individually identifiable health information) and is defined as information, including demographic data, that relates to an individual's past, present, or future physical or mental health care; the provision of such health care; and the payment related to such health care.[1] A covered entity may disclose protected health information without patient or legal guardian authorization for the purposes of treatment, investigation, intervention, and public health–related functions. Treatment is defined as the provision, coordination, or management of health care and related services by a health care professional, including consultation between health care professionals regarding a patient.[1] Therefore, it is permissible under these exceptions to disclose protected health information to other health care professionals who care for, or consult on, the patient and to public health authorities without patient or parent authorization.

Public Health Authority

Public health authorities include appropriate government authorities who are authorized by law to receive reports of child abuse and neglect.[1] In most states, child protective services (CPS) and/or law enforcement agencies are designated to receive such reports.

PATIENT/PARENT RIGHTS TO CONFIDENTIALITY

Physicians who are covered entities are required to give their patients written notice of their privacy rights, and patients are expected to acknowledge receipt and understanding of these rights. Informing patients of their rights to have protected health information kept private (which only requires acknowledgment that they have received and understood the information) is distinct from obtaining authorization for disclosure of such information. An authorization for release of information that is not exempt by HIPAA is different from an informed consent to release information for treatment, payment, and health care operations, which are generally exempted by HIPAA.[2] Authorization is written permission from the legal guardian to use or disclose the child's protected health information to another person, entity, health care professional, or agency for purposes other than those not exempted (eg, treatment, payment, and health care operations) by HIPAA rules or state law. Authorization may be required when a physician is asked to disclose or discuss a patient's protected health information in legal proceedings. Authorization must include:

1. a description of the information used or disclosed;
2. the person authorized to make the disclosure;
3. the person to whom the disclosure is made;
4. an expiration date;
5. the risk of redisclosure once protected health information is disclosed and no longer protected by HIPAA; and
6. the purpose for which the information is used or disclosed.

If information regarding substance abuse is involved, federal law requires additional statements in the authorization as well as the signature of a minor aged 16 years or older.

SPECIFIC EXCEPTIONS TO HIPAA REGULATIONS RELATED TO CHILD ABUSE

In general, HIPAA permits disclosure of information without legal guardian authorization in matters that affect the treatment of, and medical intervention for, the child and the intervention and investigation of matters that relate to abuse or neglect, public health, and safety. HIPAA also regulates release of information to the legal guardian of the child for situations in which such disclosure may jeopardize the safety of the child.

Child Abuse Reports and Investigation

All states have laws that mandate reporting of suspected child abuse or ne-

glect, and HIPAA rules allow disclosure of protected health information without legal guardian authorization under these circumstances. In general, if a pediatrician suspects abuse or neglect, as defined within state statutes, then he or she is obligated to disclose information to the appropriate investigative agencies, which in most states includes CPS and law enforcement agencies.

Section 164.512(f) places limitations on the information released to law enforcement but not to CPS agencies.[1] However, if a law enforcement agency is a designated authority by the state to receive and investigate child abuse reports, the pediatrician may disclose all protected health information important to the investigation without legal guardian authorization. In other circumstances, the physician may disclose protected health information to law enforcement without authorization if there is a probability of imminent physical injury to the patient, physician, or another person or if the child is missing and a law enforcement agency confirms it is investigating a missing person.

Disclosing Information When the Pediatrician Is Not the Child Abuse Reporter

If the pediatrician is not the reporter, he or she is still able to disclose information about a child who is a suspected victim of abuse or neglect without parent authorization, but only if such disclosure (1) is permissible by state law "for the conduct of . . . investigation" (Section 10.203[c]), or (2) is deemed to be necessary to prevent serious harm to the child and other potential victims, and (3) is limited to the information relevant to the suspected abuse or neglect of the child (Section 164.512[c]).[1] The legal guardian of the child should be verbally notified of the disclosure unless informing him or her would place the child at risk of harm or would not be in the child's best interest.

HIPAA rules and state laws that govern release of protected health information pertain to treating physicians who are also covered entities. In addition, CPS agencies may contract with a child abuse pediatrician who does not treat the child but who may review medical and/or investigative records and photographs to provide an expert opinion. In these circumstances, written authorization from parents (who may retain custody of the child) to review such information is not needed, because CPS agencies (and, often, law enforcement agencies) are authorized by statute to investigate abuse and contract with an expert. However, the pediatrician would need parental authorization or a court order to provide such information to others outside the CPS agency, even when such parties have a copy of the physician's report or other protected health information of the patient.

DISCLOSING PROTECTED HEALTH INFORMATION BEYOND REPORTING AND INVESTIGATING CHILD ABUSE

HIPAA rules do permit disclosures "made pursuant to court or administrative orders or by subpoena, discovery, or other legal processes."[3] State laws that are more stringent than HIPAA may take precedence in these situations and may require a court order signed by a judge before disclosures of protected health information are made to attorneys or in court. State laws may also require the court to make a determination of relevancy before issuing a court order that allows the physician to disclose confidential information during testimony. When state laws do not override HIPAA, the physician is required to receive a written notice from the party sending the subpoena that the legal guardian of the child has been informed that the physician is going to disclose the child's information (Section 164.512e1iii).[1] Whenever a request or subpoena is received for release of medical records for the purpose of a child abuse investigation, the subpoena should be retained in the records and a description of the information provided, and the date of release should be documented.

Child fatality review teams usually comprise professionals from CPS, pediatrics, the medical examiner's office, emergency medical services (EMS), law enforcement, the district attorney's office, and children's advocacy centers, the duties of which are to review medical records and autopsy and investigation findings related to a child's death. The purpose is to exchange information, identify any trends, and identify preventable deaths, including those attributable to child abuse or neglect. Disclosure of a child's protected health information during child fatality reviews is a permissible HIPAA exception that relates to public health matters and surveillance. It is also permissible to disclose such information to multidisciplinary teams and organizations that review child abuse cases.

ISSUES SPECIFIC TO CHILD ABUSE

Parent Rights

Although HIPAA regulations more clearly exempt disclosure of information about children who are suspected victims of abuse or neglect, exceptions regarding disclosure of medical and mental health information about the parents, caregivers, and siblings of the child are not as clearly defined or inclusive. For example, HIPAA specifies the type of information that a physician can release to law enforcement about a patient who may be an abuser, which includes distinguishing physical characteristics, blood type, name, and address. Because the pediatrician's

patient is the child, any statements made by the parent to the pediatrician that relate to the child's health or injuries are considered part of the child's protected health information and can be disclosed to investigative agencies; this information may include intimate partner abuse, mental illness, admission to causing injury to the child, and explanations for the child's injuries.

Child Rights/Media Exposure

When a pediatrician discloses verbal or written information to law enforcement about a child who is a suspected victim of abuse or neglect, this information may become public. For example, if a warrant is issued for a person's arrest related to an injury to a child, information about the child's injury and the source of the information may be contained in the warrant and accessed by the media. In addition, if a pediatrician testifies about the child's protected health information, this information is also accessible to the public. Although these disclosures of information by others are beyond the pediatrician's control, the pediatrician should release information only to the appropriate individuals involved in the treatment, intervention, or investigation of child abuse and provide accurate and verifiable information. The pediatrician should not speculate beyond the realm of his or her expertise or the facts of the case. Physicians are not permitted to release any information about a patient to the media.

EFFECT OF HIPAA ON PEDIATRIC PRACTICE

Consent for Release of Protected Health Information

When a parent brings his or her child to a pediatrician for care, pediatric offices are required to provide the parent with information regarding his or her rights to confidentiality and protection of the child's health data. Parents are requested to sign a form that indicates they have received and understand this information; in some cases, the parent is requested to sign consent to release the child's protected health information under the HIPAA exceptions for the purposes of treatment, payment for services, and health care oversight. The form is retained in the child's health record. In the case of suspected child abuse or neglect, the pediatrician must decide whether release of information to the parent or to a person that the parent designates could endanger the child. Section 164.502(g) (5) [1] indicates that when there is a reasonable belief that the child "has been or may be subjected to domestic violence, abuse or neglect by [the parent or legal guardian]" or "it is not in the best interest of the [child] to treat the person as the [legal guardian]," then the pediatrician is not required to provide information or access or control of the child's protected health information to the legal guardian. The pediatrician, therefore, is not required to provide the child's information to a parent who could be a suspected abuser or to a parent who seems to be protective of a suspected abuser, because this would not be in the best interest of the child. If the pediatrician is unsure whether the parent is a suspected abuser or does not know the results of the investigation, then the pediatrician may wish to confirm with the investigative agencies whether it is safe to disclose information to the legal guardian.

Obtaining and Documenting Consent

Although HIPAA specifies that consent is voluntary for use and disclosure of information related to treatment, payment, and health care operations, a physician may wish to document when they do obtain consent, including whether the parent was informed verbally or in writing of the disclosure of information. Again, the parent should be informed of information disclosure only if the child's well-being and safety are not jeopardized by such.

Documentation of Ongoing Disclosures Related to Child Abuse Investigations

The physician may receive requests for the protected health information of a child from individuals involved in the investigation of, or legal proceedings related to, suspected abuse or neglect. The physician or facility's custodian of records is responsible for ensuring that the release of such information is permissible without specific parent authorization, is provided in response to a court order or subpoena, and is disclosed confidentially only to the acceptable individuals or agencies. For example, if the information is transmitted via facsimile, the physician should take all reasonable steps to verify that the recipient is available to receive the information as it is transmitted.[4] Whenever information is disclosed, the physician should document what was disclosed, how it was disclosed (verbally or in writing), and to whom the information was disclosed.

RECOMMENDATIONS

1. Pediatricians should become familiar with their state laws regarding disclosure of a child's protected health information when child abuse or neglect is reported or investigated and should know when HIPAA or state laws take precedence. Specifically, the pediatrician should know which agencies are authorized to receive and investigate child abuse reports and which laws govern release of protected health information after an investigation is completed. When HIPAA regulations were announced, attorneys general from each state were required to do a preemption analysis for their state; physicians may

consult their state's attorney general's office for information on state laws and HIPAA. In addition, the American Academy of Pediatrics has developed a HIPAA toolkit for medical practices to facilitate implementation of HIPAA rules; a glossary of terms is included in this resource (http://practice.aap.org/hipaa.aspx).

2. When abuse or neglect is suspected, the pediatrician must report and may disclose a child's protected health information to the CPS (and/or law enforcement) agency without parent authorization. When child abuse has already been reported and is being investigated, it is permissible for the pediatrician to disclose information to the appropriate investigative agencies without parent notification or authorization.
3. When disclosures of protected health information are made, the pediatrician should attempt to inform the parent unless doing so could result in danger to the child. The pediatrician must recognize situations for which disclosure of information is necessary and obtaining authorization from the legal guardian may delay the child's treatment or jeopardize the child's safety. It is permissible for pediatricians to withhold the child's information from the parent if there is a possibility that the parent is the abuser or is protective of a suspected abuser.
4. HIPAA privacy rules apply to physicians of record. If a physician reviews records made by another health care professional to assist in the investigation of child abuse or neglect or to contribute to a child abuse case review related to public health matters or surveillance, it does not require authorization from the child's legal guardian.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Psychosocial Aspects of Child and Family Health

The Child in Court: A Subject Review

ABSTRACT. When children come to court as witnesses, or when their needs are decided in a courtroom, they face unique stressors from the legal proceeding and from the social predicament that resulted in court action. Effective pediatric support and intervention requires an understanding of the situations that bring children to court and the issues that will confront children and child advocates in different court settings.

When children pass through the doors into a courtroom, they enter a formal adult setting that is designed for the resolution of often contentious adult arguments. All children are anxious in a courtroom, but the setting and the nature of the stressors on the child depend on the nature of the court proceeding and the child's role in the process. Three situations typically bring children into court: child protection actions, contested parental divorce, and delinquency offenses. A child also might be a witness in a criminal proceeding as the result of an abusive incident. Only rarely will children need to be present for other types of cases, such as adoptions or traffic offenses.

This statement outlines common events affecting children in the US judicial system and delineates the different settings, events, expectations, and sources of conflict and stress that children are likely to experience. Key advances in law enforcement techniques, investigation of cases involving children, and state law and judicial policy have improved the ways that children participate in most courts. This statement reviews the new policies and procedures and provides guidance for pediatricians who work with children who must become witnesses.

CHILDREN AND THE TYPICAL COURT SYSTEM

Each state court system makes some provision for handling legal matters involving children. The legislature of Illinois was the first to recognize, in 1899, that matters involving children need to be handled differently from those involving adults. First, children are dependent on adults. Children also are developing emotionally and cognitively and have varying levels of understanding. Illinois founded the first "juvenile court," not a new court with its own administration and infrastructure, but a set of rules for Illinois county courts that would consider cases of children accused of crimes. After this institution was developed, young offenders were not convicted as criminals but were found to be, or adjudicated, delinquents. This judgment emphasized education and rehabilitation rather than punishment. Juvenile courts were gradually adopted by all states.[1]

In recent years, the number of children involved in the court system has increased owing to the meteoric rise in child abuse and neglect cases during the 1980s, the increased number of divorces with disputes about child custody, and the escalated number of serious crimes committed by children. These increases and the recognition that legal matters involving children and families need to be addressed differently than criminal matters or money disputes led many states to establish a specific family court with its own infrastructure and administration. This family court system addresses all types of cases that involve children: abuse and neglect or child protection, divorce, juvenile delinquencies, parentage, guardianship, and adoptions. Other states may continue to handle family cases by a court structure that primarily addresses civil or criminal matters. Pediatricians need to familiarize themselves with the court structure of their state and how it works for families.

Children are involved in the US court system in the following matters:

- *Child protection cases* involve children who are alleged victims of abuse or neglect. These matters include hearings involving the disposition of and/or placement of children, as well as the termination of parental rights, if there is a finding of child abuse or neglect, including child sexual abuse.
- Some states also include so-called status offenses in their child protection laws. A *status offense*, eg, truancy, underage drinking, is a crime because of the child's status as a minor.
- *Parental divorce* or *parentage* cases rarely require a child to testify; however, a child's testimony might be sought in acrimonious contested cases, in which there may be multiple opportunities for the pediatrician to act as a problem solver to prevent the child from unnecessary testimony.
- *Delinquency cases* involve children who would have been charged for a criminal act as adults. They also can be charged for status offenses.

In all these cases, the juvenile court system uses a process in which the aim is treatment and reparation, not punishment. Children, however, are increasingly being charged as adults for serious crimes, especially crimes involving acts of violence, and tried in the adult criminal justice system, where treatment and

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

reparation may not be available. If found guilty as adults, children may be sent to adult criminal correctional institutions.

CHILD PROTECTION CASES: CASES OF ABUSE, NEGLECT, AND CHILD SEXUAL ABUSE

Child protection cases are under the jurisdiction of juvenile or family court under the *parens patriae* role of the court, the state's interest in and responsibility for the well-being of all children in the state. The state, recognizing that the *parens patriae* role conflicts with common law reflecting children as chattel (personal property) of their parents, will exercise its authority with caution. Although no state now recognizes parental ownership and unrestricted control of children, each state is committed to protecting a family's autonomy and privacy and the parents' right to decide how to raise their children.

In this arena, a child witness may be asked to provide factual information to the court that might result in a determination to take the child into state custody. Depending on the state, the child may or may not be a witness and will be a party to the proceeding only on rare occasion. The child's case is brought to court by the state child protective agency that files suit against the parents. The child may or may not be represented by an attorney or have an appointed *guardian ad litem. Guardians ad litem* may be attorneys, or in some courts lay *guardians* are used. It is their responsibility to assess the child's interest and needs and present them to the court on behalf of the minor child; they serve as guardians only for the court proceeding.

The investigation of alleged child maltreatment leads to court action and also may have implications for how the court is able to proceed in making its judgment. Allegations of child abuse are brought by the state child protection agency after its investigation. When there has been serious physical harm and for almost all allegations of child sexual abuse, a law enforcement investigation also is accomplished. Many jurisdictions have developed programs to allow child protective service workers and police to do a joint investigation, thereby reducing the number of times that children must retell their experiences, while providing a gentle and supportive environment for the children. Some jurisdictions now have data indicating that a thorough and complete investigation reduces the need for child testimony (Unpublished data, the Chittenden Unit for Special Investigation, year-end report, 1996 [CUSI, 50 Cherry St, Suite 102, Burlington, VT 05401]).

Whether children should testify is a difficult decision in cases of physical abuse and neglect. Several studies have described the emotional effects of testimony on children who have been sexually abused. Some researchers believe that children benefit from facing their abuser.[2] They suggest that when children see the abuser take responsibility for his or her acts, their sense of self-worth and personal safety improves. Others are concerned that child witnesses will experience distress sufficient to affect the reliability of their testimony and exacerbate their feelings of victimization and stigmatization.[3] In addition, when children are asked to serve as a witness against a family member with whom they might have positive attachments and negative experiences, they are being placed in the awkward position of "sentencing" a family member.[4]

This question was recently reviewed by the National Institute of Justice of the US Department of Justice.[2,5–7] Of the studies published to date, no agreement has been reached as to whether the effect of testimony on children is positive or negative. All children had high levels of anxiety before testimony. Maternal support of the child witness, if available, contributed to improvement in the child's mental health, and, perhaps most important, the emotional health of most children improved with time regardless of a positive or negative court experience.

Pediatricians need to be aware of the possible emotional effects of being a child witness in the child protection system and be prepared to work with child protective service workers, other human service professionals, and lawyers to help determine if a child should testify and to help find solutions that protect the child.

DIVORCE PROCEEDINGS

In 1994, there were 1 191 000 divorces in the United States.[8] It is estimated that approximately 10% of divorces with minor children involve court-contested custody. The rate of return to court for changes in custody agreements for these initially contested cases is quite high.

Divorce proceedings exist to sever the marriage contract between a husband and wife; legal precedent is traced to contract law. Because children were not part of the contract, they are not parties to the divorce proceeding. The state, in its *parens patriae* role of protecting the well-being and best interest of all children in the state, has an interest in how the parties (parents) provide for children of the marriage as the marriage contract is dissolved. But the state expects that parents will make appropriate plans for their children and will intervene only when it views that the children are at risk of harm. When parents cannot decide, the judge will write an order to provide for the children, and the parents are expected to comply with the divorce decree. Visitation is seen in most jurisdictions as a parental right that will be restricted or denied only when harm to the child is likely to result.

In a contested divorce complicated by parental acrimony, anger, or allegations of abuse, most courts will take a much stronger interest in providing for the future safety and nurturance of children. Many courts will appoint *guardians ad litem* for minor children. In highly contested matters, attorneys may be appointed to represent children directly. Occasionally, *guardians ad litem* will seek information from professionals involved with their charges, and pediatricians might be asked for information about a child's health and factors that might assist the court to decide about the competency and appropriateness of the parents. *Pediatricians are cautioned to be knowledgeable of laws of confidentiality, which are state-specific.* Sharing information with any party requires written

permission provided by *both* parents or the direction of a court order. Even a subpoena for records requires caution and clarification. If the subpoena is not from the court but on behalf of one parent (party), the written permission of the court or the other parent is recommended. Although information that the pediatrician might share is important to the court, it rarely will constitute the full and thorough evaluation the court may require for determination of custody.

In some instances, a court may order a formal custody evaluation. This evaluation generally will be performed by mental health professionals, sometimes in a team, who will assess the child and each parent individually. Such an evaluation often will include a visit to each parental home, psychological testing, and child and parent interviews. The mental health professional performing this evaluation may contact a pediatrician for information that can be most useful in the preparation of the custody evaluation. *Again, appropriate permissions to share information must be provided to the pediatrician.* In some cases, a parent will hire a mental health professional or other expert solely for the purpose of testifying at the custody trial. Owing to the lack of input from the other parent, the pediatrician should view an involvement with such one-sided evaluations with caution. Although the professional services of the pediatrician are not covered by the family's health insurance, the court will direct one or both parties to pay for the evaluation. It is appropriate to ask the interviewer who will bear financial responsibility for pediatric consultation and reports.

The role of the pediatrician in family divorce has been discussed in a previous statement by the American Academy of Pediatrics.[9] It involves anticipatory guidance and support during the various stages of the divorce process and reconstitution of family function. If children are to serve as witnesses in divorce cases, the pediatrician needs to address with the family issues specific to child witnesses.

Generally, children will not be asked to testify in a divorce proceeding except those that are hotly contested. The fact that the child is asked to testify should alert the pediatrician to the possibility of severe family dysfunction and is an indication to consider a mental health referral to support the child during this period of stress and adjustment.

Most court jurisdictions make strong efforts to avoid testimony by children in court, believing that this asks children to choose one parent over the other. Although only limited published data support this view, it seems prudent to avoid the risk of a guilt reaction about the parent not chosen. For example, Vermont has statutory limitations on children's testimony. For any child to testify, the judge must be convinced that the child's testimony is necessary to assist the court in determining the issue before it, that the value of the child's testimony outweighs the potential detriment to the child, that the evidence sought from the child is not reasonably available by any other means, and that an attorney will be appointed for the child to protect the child's specific interest.[10]

JUVENILE CASES: DELINQUENCY

Children are charged with delinquency when their acts would have been criminal had they been committed as adults. A child charged with a crime should be represented by an attorney, who is court-appointed if necessary.

Minor children are unable technically to tell their attorneys how they would like the case handled. For example, if the attorney presents a plea bargain, can a minor child make the decision to accept or reject the attorney's recommendation? Many states provide for the emancipation, by statute or judicial rule, of older minors charged with certain crimes, just as states provide for emancipation in certain decisions about health care. Younger children will need a *guardian ad litem* in this setting, which ideally would be the child's parent. If necessary, a court-appointed *guardian ad litem* might be provided.

The extent of the authority of the *guardians ad litem* or when the child's wishes should be a determinative factor is not settled in most states. If the child is a teenager and the *guardian ad litem* wants to proceed differently than the child wants, different states will resolve this dispute in different ways. If the *guardian ad litem* is a parent, the court may dismiss the parent and appoint a disinterested *guardian ad litem,* while another court will determine that the child is old enough to direct a legal defense.

COMPETENCY

The legal system is especially interested in 3 questions about a child's competence as a witness: 1) Can the child receive and relay information accurately? 2) Does the child know the difference between telling the truth and telling a lie? 3) Does the child understand the need to tell the truth in court?

Children can be competent witnesses. Younger children may not remember with as much accuracy as older children, but the poignancy of an event may enhance their memory. A 3- or 4-year-old's ability to recall major events is excellent, although less important information is less well remembered. A lack of accuracy may be attributable to the following: 1) poor recall of an event or sequences in an event, 2) misinterpretation or confusion about an event, 3) suggestibility, 4) delusion or other mental disorder, 5) intellectual disabilities, and 6) intentional deception initiated by the child or resulting from adult coercion. Nurcombe[4] has reviewed the competency and creditability of child witnesses, and the literature in this field is growing.[11]

SUPPORT IN THE PEDIATRIC OFFICE

Pediatricians are an important source of support for children who may be witnesses, from the initial contact through preparation for court appearance and the legal negotiation process until after the court proceedings. Most legal cases are settled without trial. If the pediatrician has had a long-term relationship with the child and the child's family, the pediatrician may be able to help parents find out-of-court solutions to family issues. The pediatrician should attempt to keep the legal process in the child's best

interest and to help the child maintain a healthy adaptation to a stressful experience. The pediatrician also should address the psychological effect of the event responsible for the child's court appearance. Mental health referrals might be the most appropriate way to assist the child and family in their adjustment about the court proceedings. However, pediatricians who are experienced and knowledgeable about court proceedings and children's common reactions may successfully provide brief interventions that help the child and family.

The role of the pediatrician in child abuse and neglect, child sexual abuse,[12] and family divorce[9] has been discussed in previous statements published by the American Academy of Pediatrics. Separate attention must be devoted to preparing a child for the stress that accompanies a legal hearing or other out-of-court involvement with the legal system. Pediatricians can help prepare children for court appearances by explaining what will occur and that the child will always be accompanied by a supportive person, such as a parent. Pediatricians can help minimize the anxiety of children by explaining that they will not be judged on their performance in the courtroom, that efforts will be made to ensure safety from recrimination, and that questions should be answered to the best of their ability. Pediatricians can also help parents, lawyers, and judges to find solutions to protect children.

Because of the stressful events before and surrounding a court appearance by a child, a follow-up visit with the pediatrician is indicated after a child appears as a witness. Children should be assessed for behavioral manifestations of acute stress (eg, sleep disorders, somatic complaints), adjustment, and functional status (eg, school performance, resumption of usual activities, physical functioning, social functioning, and mental health).

CONCLUSION

Pediatricians can provide important guidance and support for children involved in the legal system. With their understanding of child development and the special knowledge and relationship with the child and knowledge of the legal proceedings, pediatricians are equipped to be a unique resource for support, consultation, care, and advocacy. With some families, the pediatrician's involvement may encompass the entire process, from the initial stressful event to the resolution of the proceeding and healing of the family. In other cases, the pediatrician will be involved only for brief interventions during the often extended court proceedings. Mental health referrals may be indicated, including referrals to therapists with special legal expertise. Application of the principles outlined in this statement can lead to more effective support and to a better outcome during and after the child's experience as a witness in a legal proceeding.

ACKNOWLEDGMENT

The Committee thanks Trine Bech, Esq, and Judge Sol Gothard for their critique of this statement.

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Policy Statement—Child Fatality Review

abstract

FREE

Injury remains the leading cause of pediatric mortality and requires public health approaches to reduce preventable deaths. Child fatality review teams, first established to review suspicious child deaths involving abuse or neglect, have expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence. Approximately half of all states report reviewing child deaths from all causes, and the process of fatality review has identified effective local and state prevention strategies for reducing child deaths. This expanded approach can be a powerful tool in understanding the epidemiology and preventability of child death locally, regionally, and nationally; improving accuracy of vital statistics data; and identifying public health and legislative strategies for reducing preventable child fatalities. The American Academy of Pediatrics supports the development of federal and state legislation to enhance the child fatality review process and recommends that pediatricians become involved in local and state child death reviews. *Pediatrics* 2010; 126:592–596

INTRODUCTION

The preventable death of a child is an unparalleled tragedy for a family. Similarly, a nation's ability to reduce child mortality rates is a measure of that society's overall well-being, and failure to address preventable causes of child mortality is a national tragedy. Each year in the United States, more than 17 000 infants and children die from injury, which remains the leading cause of child mortality in the United States.[1] Add to this the number of preventable noninjury deaths, including many deaths related to prematurity, and it becomes clear that a majority of American child deaths are preventable. The 1999 American Academy of Pediatrics (AAP) policy statement "Investigation and Review of Unexpected Infant and Child Deaths"[2] supported analysis of child deaths, standards for adequate investigations for individual deaths, and the importance of child death review. The purpose of this AAP policy statement is to highlight the importance of child fatality review in the public health approach to prevention of child deaths and to advocate for improving this process through attention to better training, data collection, and data dissemination.

Reducing preventable child mortality requires a systematic and integrated evaluation of fatality causes, which begins with accurate vital statistics data. Vital statistics data do not, however, accurately capture all causes of child fatality (eg, deaths attributable to child maltreatment). National and state mortality statistics, which rely on the *International Classification of Diseases* (ICD) coding system to define cause of death on death certificates, underestimate child fatalities attribut-

able to homicide and unintentional death. Detailed review of child deaths in Missouri, North Carolina, Colorado, and, more recently, Michigan, California, and Rhode Island has revealed that approximately half of child abuse fatalities are unrecognized in vital statistics data.[3–6] The incidence of sudden infant death syndrome (SIDS) has decreased significantly since the 1992 AAP recommendations for safe sleeping positions for infants.[7,8] Evaluation of more recent declines in SIDS rates in the United States suggest that, despite the significant decreases in SIDS deaths over the past 15 years, more recent declines might be attributable to an increase in diagnostic coding of asphyxia, suffocation, and other causes of sudden, unexpected infant death. These discoveries have resulted from coordinated, multidisciplinary investigations of child deaths at local and state levels through a child fatality review process. Ultimately, the purpose of child fatality review is to identify effective prevention and intervention processes to decrease preventable child deaths through systematic evaluation of individual child deaths and the personal, familial, and community conditions, policies, and behaviors that contribute to preventable deaths.

CHILD FATALITY REVIEW TEAMS

Child fatality review teams (CFRTs), multidisciplinary committees comprising representatives from law enforcement, child protective services, the office of the coroner/medical examiner, prosecuting attorney's office, the medical community, and/or public health and other community stakeholders, were first established to review suspicious child deaths involving possible abuse or neglect.[9] Although originally developed to improve identification and prosecution of fatal abuse,[10] the role of CFRTs has expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence.[11] In addition to reviewing child fatalities related to maltreatment, many CFRTs now review all child fatalities in the jurisdiction covered by the team.[12] Approximately half of all states report reviewing child deaths from all causes.[11] This expanded approach can be a powerful tool in understanding the epidemiology and preventability of child death locally, regionally, and nationally; improving accuracy of vital statistics data; and identifying public health and legislative strategies to reduce preventable child fatalities. In addition, CFRTs remain an effective surveillance tool for identifying victims of fatal maltreatment.[6]

Another challenge in reducing preventable child deaths is to find ways to implement prevention strategies that have been determined to be effective. In general, identifying public health problems and increasing public and professional awareness of them is more easily accomplished than planning and implementing reasonable and well-tested solutions.[13] CFRTs can serve to highlight local, state, or national contributors to preventable child deaths and serve to catalyze action to prevent these deaths and provide a means of monitoring the effectiveness of these changes. These functions of scientific data collection in evidence-based decision-making form a cornerstone of evidence-based public health[14] and provide the type of data described in a recent Institute of Medicine report on evidence-based decision-making.[15]

In the few years since their establishment, child fatality review processes have been used to inform local and state prevention strategies to reduce child deaths. For example, Rimsza et al[16] published the experience of a statewide review process that examined 95% of child deaths in Arizona over a 5-year period. Evaluation of local CFRT data revealed that 29% of the 4806 child deaths were preventable and that preventability increased with age. Leading causes of preventable deaths included motor vehicle crashes, medical illness, and drowning. The ability to accurately assess local and regional causes of death enabled the Arizona chapter of the AAP, in partnership with other advocates, to work with state legislators to establish a graduated driver's license program for teenagers.

In Massachusetts, the state CFRT found that a large proportion of sudden, unexpected infant deaths occurred while bed-sharing with adults. As a result, the state launched a publicity campaign to highlight this danger and included letters to all 3500 child health care providers in the state.[17] Georgia enacted improved child restraint laws as a result of a statewide child fatality review process that identified large numbers of child fatalities that were related to the inappropriate use of child restraints in motor vehicles.[18] The state of Nevada, after focused child fatality reviews in Las Vegas, Reno, and rural Nevada, instituted widespread changes to its child welfare system, including additional funding, training, policy improvements, interagency protocols, new laws, and improvements to the medical examiner/coroner, child protective services, and health systems throughout the state.

These examples illustrate the promise of using local data to prompt public policy discussion and action. In fact, the determination of many of the leading causes of preventable deaths have resulted in implementation of prevention procedures (eg, child safety restraints and pool fencing), and child fatality data have been used to emphasize the need for enforcing existing

laws and improving public education related to existing strategies.[13,19]

In addition to improved surveillance of child mortality data, the child fatality review process can improve interagency collaboration and coordination of public health and law enforcement efforts, improve accuracy of death-certificate data, decrease misclassification of deaths, uncover missed child homicides, and foster the development and implementation of interventions to prevent mortality and morbidity attributable to injury.[5,6,20–22]

Fatality review can also identify failures or oversights in medical care; gaps in community services, including emergency medical services for children; improve allocation of limited resources; improve policy and procedures at local and state agencies; and identify legislative initiatives to improve child health.[23,24] Both the AAP and American Bar Association have endorsed child death reviews.[2,25]

ESTABLISHMENT OF CFRTs

In the past, a variety of mechanisms were used to establish CFRTs, including state legislation that enabled or mandated child death reviews, executive orders established by governors, or community establishment of teams that were not legislated or mandated. This variability—from legislative mandate to grass roots community efforts—engendered great differences in program organization and process. Most states have CFRTs that are established by statute, and approximately three-quarters of state laws include mandatory review; the remainder of them provide for discretionary formation of teams. CFRTs exist at both the state and local levels but vary by state in the membership of teams, the relationship of the state and local teams, the criteria for case review, the timing of the reviews, the data collected, and team policies and procedures.[11] Within the past few years, however, there has been a national effort to develop standards for child death review, and many states are working to implement these standards.[26,27] In addition, the Maternal and Child Health Bureau funded a National Center for Child Death Review in 2001, and the Health Resources and Services Administration has provided funds for the development of an Internet-based case-reporting system, which is now in use by slightly more than half of the states in the United States.

Despite these recent efforts, no federal funds have been directly appropriated for state or local child death review, and not all states have attained the level of funding or leadership commitment necessary to meet national standards.

In contrast to the local variations in definitions and procedures inherent in the current child fatality review system, the long-established transportation-related Fatality Analysis Review System and the newer National Violent Death Reporting System (NVDRS) both illustrate the power of developing and implementing national standards for data collection in addressing preventable deaths. The NVDRS, which is currently active in approximately one-third of the states, collects data on fatalities associated with child maltreatment and has potential synergy with CFRTs.[28]

CFRTs support the public health approach of using data collection or surveillance to define the issues; identify risk factors, protective factors, and barriers within individual families and the greater community; develop interventions that are based on analysis; implement interventions at the community level; and use evaluation results to modify and improve the initial interventions.[16]

SUMMARY

A national network of CFRTs offers the potential to harness public health models to reduce the large number of preventable child deaths in the United States. National leadership and support are critical for expanding child death review and preventing unnecessary childhood deaths. Measures that require a uniform national approach that could improve the child fatality review process include:

1. standardizing the process of child death review;
2. providing standardized definitions for fatality coding and structure for standard data collection;
3. providing training, technical assistance, and support for CFRTs that review deaths and for public health officials in collecting, accessing, and using these data;
4. establishing criteria for quality improvement in CFRT data collection, evaluation, and dissemination;
5. providing mechanisms to enable interstate and cross-jurisdictional data-sharing;
6. establishing standardized confidentiality protocols and legal protections for team members; and
7. publishing online annual reports of CFRT data to compare program effectiveness across states and to provide robust data regarding national child fatality causes.

THE PEDIATRICIAN'S ROLE

The pediatrician can influence the child fatality review process for individual patients and, more broadly, for their communities and states. The following recommendations are based on the epidemiologic evidence discussed above and the expert opinions of the authors and the AAP committees involved in preparing this statement. The AAP recommends the following.

1. Pediatricians should advocate for proper death certification for children. Recognize that such certification is only possible for sudden, unexpected deaths after comprehensive death investigation that involves an immediate evaluation at the scene of the death and includes an autopsy.
2. Pediatricians should work with their state AAP chapters to advocate for and support state legislation that requires autopsies in deaths of children younger than 6 years that result from trauma; that are unexpected, including sudden, unexplained infant death; and that are suspicious, obscure, or otherwise unexplained. These same guidelines for unexplained deaths should apply to all children, including those with chronic diseases.
3. Pediatricians should work with their state AAP chapters to advocate for and support state legislation and other public policies that establish comprehensive and fully funded child death investigation and review systems at the local and state levels and that the data from child death investigations be aggregated, analyzed, and disseminated nationally.
4. Child fatality review committees at both the state and local levels should include pediatricians who serve as expert members in reviewing case files of the medical examiner or other agency investigating the deaths of children who were patients. Pediatricians should also serve as consultants to the child fatality teams on medical issues that need clarification as well as on social issues and community resources that might contribute to the prevention or causation of preventable child deaths. Physicians should receive payment commensurate with the time and value of their services on such teams. Primary care physicians, emergency medicine physicians, and child abuse specialists are ideally suited for participation on such review teams. Other physicians, such as obstetricians, would be valuable partners in reviewing deaths from prematurity.
5. Pediatricians should work collaboratively to ensure that information from child fatality reviews is used to inform local, state, and national policies to reduce preventable child deaths.
6. Public policy initiatives directed at preventing childhood deaths should be supported at the national and chapter levels provided that they are based on information acquired at the local and state levels from adequate death investigations, accurate death certifications, and systematic death reviews. The AAP Division of State Government Affairs offers assistance and guidance to AAP chapters in developing state public policy on CFRTs; for more information, call the division at 800-433-9016, extension 7799, or e-mail stgov@aap.org.

POLICY STATEMENT

Child Life Services

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Child Life Council
Committee on Hospital Care

ABSTRACT

Child life programs have become standard in most large pediatric centers and even on some smaller pediatric inpatient units to address the psychosocial concerns that accompany hospitalization and other health care experiences. The child life specialist focuses on the strengths and sense of well-being of children while promoting their optimal development and minimizing the adverse effects of children's experiences in health care or other potentially stressful settings. Using play and psychological preparation as primary tools, child life interventions facilitate coping and adjustment at times and under circumstances that might prove overwhelming otherwise. Play and age-appropriate communication may be used to (1) promote optimal development, (2) present information, (3) plan and rehearse useful coping strategies for medical events or procedures, (4) work through feelings about past or impending experiences, and (5) establish therapeutic relationships with children and parents to support family involvement in each child's care, with continuity across the care continuum. The benefits of this collaborative work with the family and health care team are not limited to the health care setting; it may also optimize reintegration into schools and the community.

CHILD LIFE PROGRAMS

Most hospitals specializing in pediatric care have child life programs,[1] and the number of these programs has doubled since 1965. There are now more than 400 child life programs in the United States and Canada.[2] A 2001 survey by the National Association of Children's Hospitals and Related Institutions found that 95% of 118 responding hospitals employed child life specialists (S. Dull, RN, MSN, MBA, National Association of Children's Hospitals and Related Institutions, verbal communication of unpublished data, June 30, 2005). Child life services are offered in inpatient pediatric health care settings as well as ambulatory clinics, emergency departments, rehabilitation settings, hospice programs, and even some dental and physician offices.[2–4] The provision of such services is a quality benchmark of an integrated child health delivery system and an indicator of excellence in pediatric care.[5,6] Child life programs and the kinds of services they provide are a component of family-centered care.[7,8] Child life services are also recommended for community hospitals with pediatric units.[9] Some states have identified the importance of child life services through the regulatory process; for example, a 1999 California statute allowed for the reimbursement of bereavement services by a certified child life specialist for someone who experienced trauma.[10] In addition, hospital licensing standards in New Jersey require the services of a child life specialist in PICUs.[11]

A ratio of 1 child life specialist to 15 or 20 inpatients has been used successfully in some institutions; however, the patient's age and mobility, the patient popula-

child life, play, preparation, psychological preparation, family-centered care, medical home

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

tion on the unit, and the institution's needs should influence actual staffing allocation.[12,13] An increasing number of child life specialists are employed in outpatient settings. There are no standardized ratios for outpatient areas, but the same factors should be considered as those for inpatient settings, and thought should be given to providing maximal services during peak visit hours (eg, the emergency department may be busier in the afternoon and evening, and the perioperative area may be more active in the early morning). Child life specialists are generally supervised by a child life manager who, in turn, may report to the hospital or division leadership.

The credentials of a certified child life specialist include the minimum of a bachelor's degree in child life, child development, human development, or a closely related field; the successful accomplishment of a 480- to 600-hour child life internship under the supervision of a certified child life specialist; and the satisfactory completion of the standardized certification examination. The child life specialist should have an understanding of children of all ages and the family, good communication skills, experience with diverse groups of patients, developmental assessment expertise, and collaborative teamwork abilities. Child life specialists often develop specific areas of expertise related to the patient population they serve, such as infants, toddlers, elementary school–aged children, adolescents, oncology patients, critically ill children, radiology patients, technology-dependent children, etc. They recognize the developmental issues specifically related to illness and health care experiences and understand how to mitigate fears, fantasies, and concerns through adaptive role play, education, and behavior-management techniques. Information about the child life profession and certification of child life specialists is available from the Child Life Council (see "Additional Resources").

An effective child life program provides developmentally appropriate play, offers informative and reassuring psychological preparation before and during procedures, and helps children plan and rehearse coping skills.[14] Child life specialists are part of an interdisciplinary and family-centered model of care, collaborating with the family, physicians, and other members of the health care team to develop a plan of care.[8,15] The child life component of this plan is based on the individual patient's perception and understanding of the anticipated health care experience with the goal of enhancing coping.[16,17] Child life specialists support these goals by, for example, teaching the child coping strategies for adjusting to a life-changing injury or dealing with impending death, offering nonpharmacologic pain-management techniques, and communicating the child's developmental and individual needs and perspective to team members.

The therapeutic interventions of child life staff are most effective when delivered in collaboration with the attending physician, primary care physician, and other members of the health care team as part of the medical home* for the hospitalized child. Child life programs offer services that support the medical home, defined by the American Academy of Pediatrics as care that is "accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective."[18(p184)]

PLAY AND NORMALCY

Play is the primary modality of a child life program because it is both familiar and reassuring for children. It helps make the health care experience less intimidating and more comfortable.[19–22] Experts state that play is believed to be "used by children as a means of reducing anxiety produced by stressful conditions."[17(p213)] Child life programs provide opportunities for play in inpatient medical and surgical areas, ICUs, outpatient clinics, emergency departments, presurgical waiting areas, radiology departments, laboratory waiting rooms, and sibling care centers. Play is adapted to the many age groups in pediatrics. Young children are given opportunities for make-believe play, whereas school-aged children enjoy games with rules.[23] Adolescents will seek to continue their relationships with peers outside the hospital through Internet access and must be provided with opportunities to form new friendships within the hospital. This is particularly important for adolescents with chronic illnesses who may have multiple hospitalizations.[24,25] Activities that promote self-esteem are vital, as is continuation with schooling.

Engaging in developmentally appropriate play, creative or expressive arts (including music therapy, art therapy, drama, video work, and creative writing), and reading activities all help moderate children's anxiety and decrease the possibility that health care encounters will disrupt their normal development.[3,26–28] Auxiliary programs, such as animal-assisted therapy, therapeutic clowning, or electronic networks for hospitalized children, when used in conjunction with child life services, provide additional supportive activities for all ages of pediatric patients.[29–31]

To help children cope with their feelings, a child life specialist often uses health care play or "medical play." This child-directed play allows children to be active and exert control over their experiences.[1,12,31–34] These exercises may offer insight into the patients' concerns and levels of understanding of the health care events. Some examples of child-directed medical play are the exploration of medical equipment, dramatic (or dress-up) play,

* The American Academy of Pediatrics believes that the medical care of infants, children, and adolescents ideally should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. It should be delivered or directed by well-trained physicians who provide primary care and help to manage and facilitate essentially all aspects of pediatric care. The physician should be known to the child and family and should be able to develop a partnership of mutual responsibility and trust with them. These characteristics define the "medical home.[18(p184)]"

games or puzzles depicting medical themes, and the creation of artwork using health care materials such as bandage strips, tongue depressors, and syringes.[1,3,20,34–36] Such activities allow pediatric patients of all ages to approach a threatening situation with greater familiarity and gain a sense of mastery of the experience, which will help build a basis for future difficult experiences.[37]

PSYCHOLOGICAL PREPARATION

Preparing children for hospitalizations, clinic visits, surgeries, and diagnostic/therapeutic procedures is a second important element of a child life program.[38] Psychological preparation is a "process of communicating accurate and developmentally appropriate information, identifying potential stressors, as well as planning and practicing coping strategies."[37(p18)] Many hospitals and other health care facilities have developed preparation programs on the basis of this process that familiarize the children and their families with the circumstances and procedures they will encounter. These developmentally supportive programs help reduce emotional disturbances in hospitalized children.[1,8,39,40] Two studies with children in a perioperative setting indicated that preparation programs before surgery lowered the children's anxiety and increased their comfort levels.[35,41] Oncology clinics, day surgery units, radiology departments, dialysis units, primary care clinics, emergency departments, eating disorder programs, dental clinics, and other health care settings have used child life specialists to help children anticipate and manage health care experiences.[38,42–55] An emergency department study reported that child life specialists play a major role in calming fears of children, particularly 11- to 14-year-olds requiring sutures, and lead to a higher parent satisfaction rating of the entire care experience.[52]

The child life role in children's perioperative experiences is important. When preparing children and families for procedures, child life specialists not only share accurate descriptions of the experiences children will have but assist children in expressing what they think is going to happen.[37] Plain body-outline dolls and other dolls are useful tools of the child life specialist during psychological preparation before procedures occur.[33,56] Misconceptions can be corrected, and a child's understanding can be clarified. In addition, child life specialists provide opportunities for children to examine equipment and give them developmentally appropriate explanations of their use.[8,20,55] Information and opportunities to handle equipment help make the unpredictable events more manageable, reduce anxiety, and enable the child to plan and rehearse coping strategies.[57,58] Strategies used may include relaxation, visualization, guided imagery, and pain-management techniques. Such observations are shared with the rest of the health care team so that all are better prepared to respond supportively to the individual patient.

A child life specialist who is present with a parent during a procedure also can enhance the parent's ability to support the child. This can contribute to a patient's ability to cope more effectively, often resulting in greater cooperation and success during the procedure.[59] In the absence of parental support, a child life specialist can provide support, enabling staff members to use their time more efficiently.

FAMILY SUPPORT

The third major area of child life services involves education and support of parents and family members, including siblings. Because the presence of family members has an important positive effect on a child's adjustment to the health care experience, pediatric health care teams encourage family involvement in patient care.[60] Parents and other family members may be highly anxious about the child's illness or the various diagnostic and treatment regimens, and such anxiety can be transmitted easily to the patient.[20,39] Child life specialists and other members of the health care team collaborate to facilitate the family's coping with and adjustment to the child's illness and health care experience. Child life specialists help family members understand their child's response to treatment and can help parents maintain their caregiving roles by promoting parent/child play sessions and by sharing strategies for comforting their children during medical procedures, for example. Well siblings can be helped to comprehend a brother's or sister's illness via developmentally appropriate teaching sessions and by offering support during visits to ICUs. In collaboration with the primary care physician and other members of the interdisciplinary team, child life services may be integrated within some palliative care teams, hospice services, and home care programs. Specially trained child life specialists can offer grief support activities for siblings in the event of catastrophic injury or death. They also have assisted children during episodes of terrorism.[8,61–64] It is important to protect children and families from prolonged or repeated exposures to situations in which they feel overwhelmed, unable to escape, or unable to have choices. The health care experience can become complicated by these scenarios, and child life specialists can help ameliorate the effects that these adverse experiences have on children and families.

CHILD LIFE SERVICES IN A CHANGING HEALTH CARE ENVIRONMENT

There are almost twice as many hospitalized children in the 0- to 4 year-old age group as there are in the 5- to 14 year-old age range.[65] In addition, although fewer children are hospitalized, the children who are admitted are more seriously ill and often require longer stays.[66] Child life programs have had to adapt to younger, less mobile patients who have more complex medical problems. As

a result, fewer group interactions are possible, and greater individualization of care is needed. Child life staff members are challenged to meet each child's emotional, developmental, and educational needs more quickly and efficiently than before and to provide as many normal life experiences as possible. In a continued effort to create "normalcy" for patients, child life specialists often assist parents in arranging for tutoring services for children.[9]

The adolescent population must also be considered. The increased survival rate of chronically ill patients has resulted in an expanded need for child life specialists in adolescent care. Teenagers with spina bifida, cystic fibrosis, and other chronic diseases are living longer now.[67] A new challenge has emerged as more chronically ill adolescents are making the transition to the adult health care system.[67,68] Child life specialists have often played a role with the health care team in helping with that transition.

The expansion of outpatient care has resulted in more demands for ambulatory child life activities as their value and benefits have become recognized. Both direct and indirect interventions are used to support patients and families across the continuum of care. For example, posters may be mounted in treatment areas to educate staff and parents about effective positioning or coping techniques to use with children of different ages. In some cases, a telephone consultation made by a child life specialist can help parents prepare their child for an outpatient procedure.

As health care costs escalate, there is an ongoing effort to justify the cost of child life services. It is clear that more empirical data are needed to explore the value and effectiveness variables of child life services. An experimental evaluation of one child life program model showed that its presence had a significant positive effect on the pediatric patients.[39] Specifically, the children in the experimental study had less emotional distress, better overall coping during the hospital stay, a clearer understanding of the procedures, and a more satisfactory posthospital adjustment and physical recovery. The children spent less time on initial pain-management narcotics, the length of stay was slightly reduced, and parents were more satisfied. In another study, child life specialists taught parents in the emergency department how to use distraction and "positioning for comfort" before their child's venipunctures. The combination of interventions resulted in lower fear and distress scores.[69]

ADDITIONAL CONTRIBUTIONS

Child life services contribute to an organization's efforts to meet the standards of the Joint Commission on Accreditation of Healthcare Organizations such as developmentally appropriate care, effective communication for patient education, safety issues, age-appropriate environments, and assessment of patients. These specialists assist health care team members to communicate with patients and families on the basis of the child's developmental and individual needs.[70] Child life programs can assist in the education of students and professional staff in medical, nursing, and other fields regarding psychosocially sound and developmentally appropriate care.[53,71,72] The role and competence of pediatric unit volunteers are enhanced when they are educated, guided, and supervised as part of a child life program.[73]

Child life specialists are keenly aware of the perspective and concerns of children and the benefits of family-centered care and, thus, are valuable consultants regarding the physical environment of pediatric settings and the effect of these settings on the behavior and adaptation of children. Child life specialists offer a useful perspective on hospital committees such as ethics or bereavement committees.

Child life expertise has applications beyond conventional hospital care. Child life interventions can help children transition back to home, school, and community. Child life specialists can actively help with school reentry and facilitate a variety of support groups for patients and their siblings.[74,75] In addition, child life specialists in pediatric programs located within larger adult-oriented institutions often are called on to work with children of adult patients.[76] They are able to help children deal with a parent's illness or impending death. Child life specialists also use their skills and training for positions in disease-specific camps, hospice programs, supplemental child care for technology-dependent children, programs for high-risk infants, and courtrooms for pretrial support of juvenile victims.[13]

CONCLUSIONS

Child life services make a difference in pediatric care. Although more research is needed, there is some evidence that child life services may help to contain costs by reducing hospital length of stay and decreasing the need for analgesics.[39,59] Observation and consumer satisfaction feedback further confirm the positive effects of child life programs on children, families, and staff. It remains essential for child life specialists to adapt and grow with the changing health care system in support of the emotional well-being of children and families.[77,78]

RECOMMENDATIONS

1. Child life services should be considered an essential component of quality pediatric health care and are integral to family-centered care and best-practice models of health care delivery for children. Child life services should be performed in collaboration with and give support to the child's medical home.
2. Child life services should be provided directly by or in consultation with qualified child life specialists in pediatric inpatient units, ambulatory areas, emergency

departments, and chronic care centers to the extent appropriate for the population served.

3. An appropriate ratio of child life specialists to patients should be developed for inpatient and ambulatory areas. Both inpatient and ambulatory ratios should be adjusted as needed for the severity and acuity of illnesses of the patients served.
4. Child life services should not be withheld for lack of reimbursement. Advocacy for financing of child life services should occur at the facility, local, state, and federal levels.
5. Home health, hospice, and bereavement programs should be encouraged to include child life services.
6. Additional research should be conducted to validate the effect of child life services on patient care outcomes with attention to outcomes of specific interventions as well as cost-effectiveness.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Policy Statement—Child Passenger Safety

abstract

FREE

Child passenger safety has dramatically evolved over the past decade; however, motor vehicle crashes continue to be the leading cause of death of children 4 years and older. This policy statement provides 4 evidence-based recommendations for best practices in the choice of a child restraint system to optimize safety in passenger vehicles for children from birth through adolescence: (1) rear-facing car safety seats for most infants up to 2 years of age; (2) forward-facing car safety seats for most children through 4 years of age; (3) belt-positioning booster seats for most children through 8 years of age; and (4) lap-and-shoulder seat belts for all who have outgrown booster seats. In addition, a fifth evidence-based recommendation is for all children younger than 13 years to ride in the rear seats of vehicles. It is important to note that every transition is associated with some decrease in protection; therefore, parents should be encouraged to delay these transitions for as long as possible. These recommendations are presented in the form of an algorithm that is intended to facilitate implementation of the recommendations by pediatricians to their patients and families and should cover most situations that pediatricians will encounter in practice. The American Academy of Pediatrics urges all pediatricians to know and promote these recommendations as part of child passenger safety anticipatory guidance at every health-supervision visit. *Pediatrics* 2011;127:788–793

Improved vehicle crashworthiness and greater use of child restraint systems have significantly affected the safety of children in automobiles. Major shifts in child restraint use, particularly the use of booster seats among older children, have occurred in response to public education programs and enhancements to child restraint laws in nearly every state.[1–3] In addition, there has been a substantial increase in scientific evidence on which to base recommendations for best practices in child passenger safety. Current estimates of child restraint effectiveness indicate that child safety seats reduce the risk of injury by 71% to 82%[4,5] and reduce the risk of death by 28% when compared with those for children of similar ages in seat belts.[6] Booster seats reduce the risk of nonfatal injury among 4- to 8-year-olds by 45% compared with seat belts.[7] Despite this progress, approximately 1500 children younger than 16 years die in motor vehicle crashes each year in the United States, nearly half of whom were completely unrestrained.[8]

The American Academy of Pediatrics (AAP) strongly supports optimal safety for children and adolescents of all ages during all forms of travel.

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

This policy statement provides 5 evidence-based recommendations for best practices to optimize safety in passenger vehicles for all children, from birth through adolescence (a summary of recommendations is listed in Table 1):

1. All infants and toddlers should ride in a rear-facing car safety seat (CSS) until they are 2 years of age

TABLE 1 Summary of Best-Practice Recommendations

Best-Practice Recommendation	Complementary Information
 All infants and toddlers should ride in a rear-facing car safety seat (CSS) until they are 2 y of age or until they reach the highest weight or height allowed by the manufacturer of their CSS.	Infant-only seats usually have a handle for carrying and can be snapped in and out of a base that is installed in the vehicle. They can only be used rear-facing. Convertible CSSs can be used either forward- or rear-facing and typically have higher rear-facing weight and height limits than infant-only seats. When children using infant-only seats reach the highest weight for their seat, they should continue to ride rear-facing in a convertible seat for as long as possible. Most currently available convertible seats can be used rear-facing to at least 35 lb. Combination CSSs are seats that can be used forward-facing with a harness system and then, when the child exceeds the height or weight limit for the harness, as a booster seat with the harness removed.
 All children 2 y or older, or those younger than 2 y who have outgrown the rear-facing weight or height limit for their CSS, should use a forward-facing CSS with a harness for as long as possible, up to the highest weight or height allowed by the manufacturer of their CSS.	Several models of convertible and combination CSSs can accommodate children up to 65 or 80 lb when used forward-facing. The lowest maximum weight limit for currently available forward-facing CSSs is 40 lb.
 All children whose weight or height is above the forward-facing limit for their CSS should use a belt-positioning booster seat until the vehicle lap-and-shoulder seat belt fits properly, typically when they have reached 4 feet 9 inches in height and are between 8 and 12 y of age.	There is a safety advantage for young children to remain in CSSs with a harness for as long as possible before transitioning to booster seats.
 When children are old enough and large enough to use the vehicle seat belt alone, they should always use lap-and-shoulder seat belts for optimal protection.	Booster seats function by positioning the child so that both the lap and shoulder portions of the vehicle seat belt fit properly; the lap portion of the belt should fit low across the hips and pelvis, and the shoulder portion should fit across the middle of the shoulder and chest. They come in both high-back (a seat back that extends up beyond the child's head) and backless models. The lap portion of the belt should fit low across the hips and pelvis, and the shoulder portion should fit across the middle of the shoulder and chest when the child sits with his or her back against the vehicle seat back. If they do not, then the child is likely too small to use the vehicle seat belt alone and should continue to use a belt-positioning booster seat.
 All children younger than 13 y should be restrained in the rear seats of vehicles for optimal protection.	CSSs should be installed tightly either with the vehicle seat belt or with the LATCH system, if available. LATCH is a system of attaching a CSS to the vehicle that does not use the seat belt. It was designed to ease installation of the CSS. Whether parents use LATCH or the seat belt, they should always ensure a tight installation of the CSS into the vehicle.

LATCH indicates lower anchors and tethers for children.

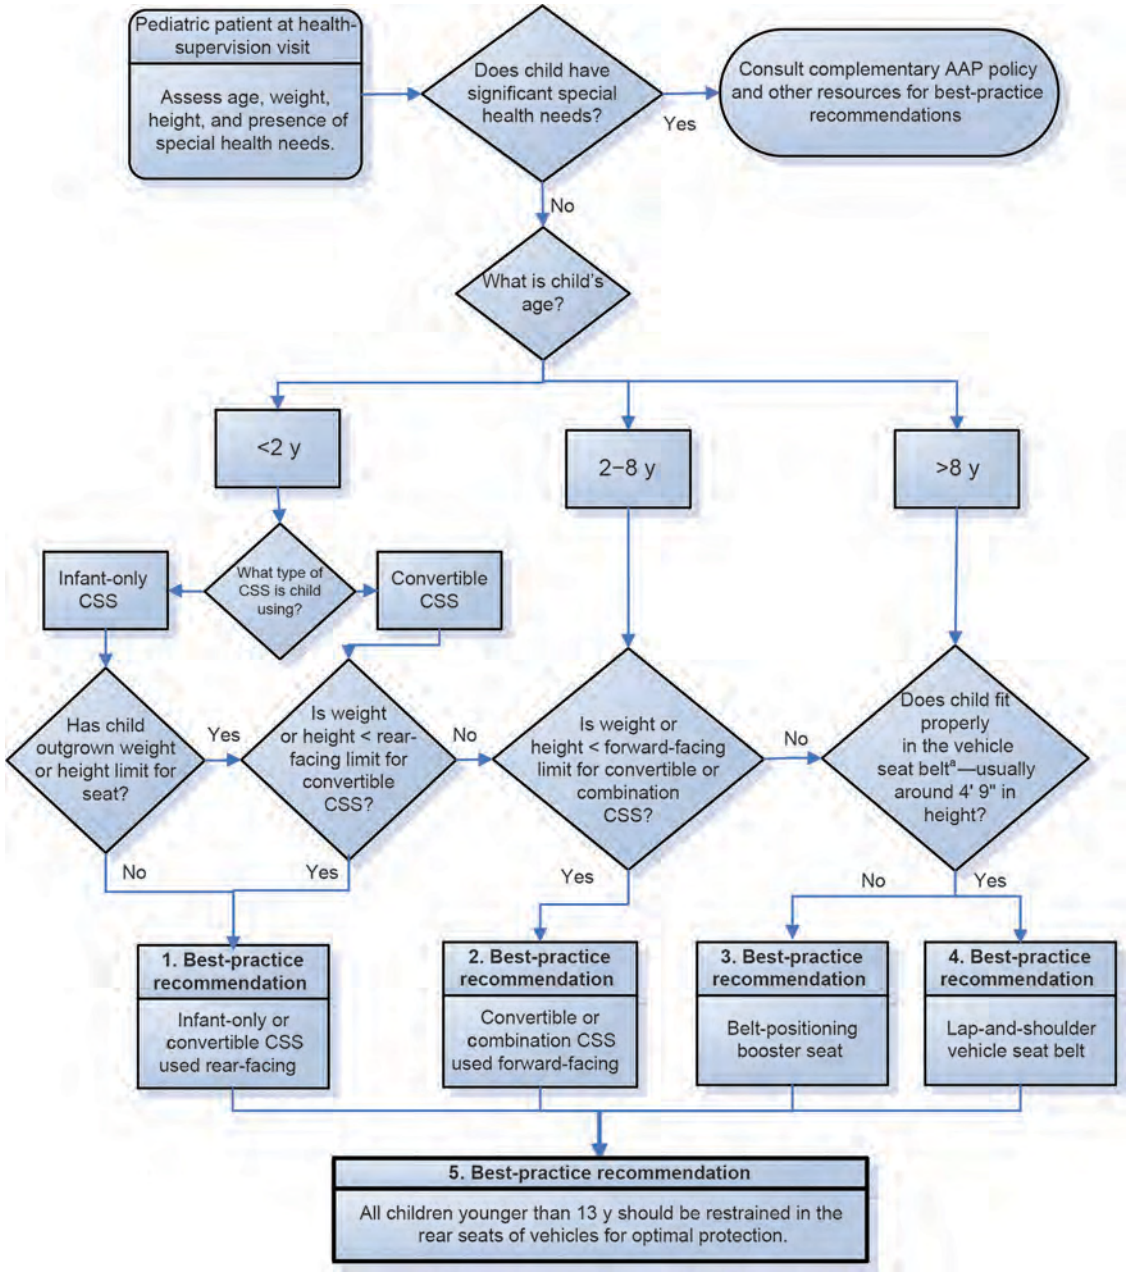

FIGURE 1

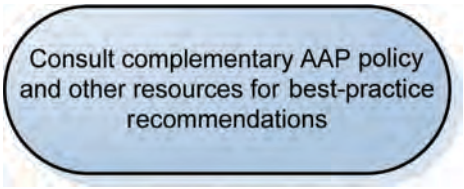
or until they reach the highest weight or height allowed by the manufacturer of their CSS.

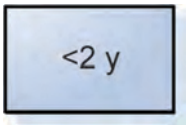
2. All children 2 years or older, or those younger than 2 years who have outgrown the rear-facing weight or height limit for their CSS, should use a forward-facing CSS with a harness for as long as possible, up to the highest weight or height allowed by the manufacturer of their CSS.
3. All children whose weight or height is above the forward-facing limit for their CSS should use a belt-positioning booster seat until the vehicle lap-and-shoulder seat belt fits properly, typically when they have reached 4 feet 9 inches in height and are between 8 and 12 years of age.
4. When children are old enough and large enough to use the vehicle seat belt alone, they should always use lap-and-shoulder seat belts for optimal protection.
5. All children younger than 13 years should be restrained in the rear

TABLE 2 Explanations of Decision Points and Additional Resources

Children with certain temporary or permanent physical and behavioral conditions such as altered muscle tone, decreased neurologic control, skeletal abnormalities, or airway compromise may preclude the use of regular CSSs and may require the use of regular CSSs may require specialized restraint systems.



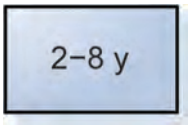
The AAP has issued a policy statement that provides specific guidance on best-practice recommendations for children with special health care needs (www.pediatrics.org/cgi/content/full/pediatrics%3B104/4/988). To locate a child passenger safety technician in your area with special training in special health needs, go to http://cert.safekids.org.



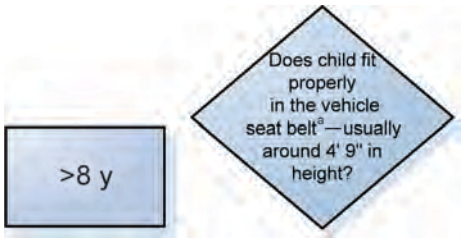
Infants younger than 2 y have relatively large heads and several structural features of their neck and spine that place them at particularly high risk of head and spine injuries in motor vehicle crashes. Rear-facing CSSs provide optimal support to the head and spine in the event of a crash, and evidence indicates that this benefit extends to children up to 2 y of age or longer.

Children who are 2 y of age or older and small for age may need to be evaluated like children younger than 2 y. Consult a child passenger safety technician with enhanced training in special needs or other resources for assistance.

The AAP annually updates information on child restraint systems currently available in the United States (http://aap.org/family/carseatguide.htm). More recent products have higher weight limits and should be used when possible. In general, children should remain in a child restraint system until they outgrow the weight or height limits for its intended use.



Most children 2 to 8 y of age are not large enough to fit properly in the vehicle seat belt and will require a CSS or booster seat for optimal restraint. A belt-positioning booster seat positions a child so that the lap and shoulder portions of the seat belt fit properly: the lap portion low across the hips and pelvis and the shoulder portion across the middle of the shoulder and chest.



Most children shorter than 4 feet 9 inches in height will not fit properly in vehicle lap-and-shoulder seat belts.

These 3 questions are an evaluation to determine whether a child is ready to be restrained by the vehicle seat belt without a booster seat. If the answer is "no" to any of these questions, the child should use a booster seat:

Is the child tall enough to sit against the vehicle seat back with his or her knees bent at the edge of the vehicle seat without slouching and stay in this position comfortably throughout the trip?

Does the shoulder belt lie across the middle of the chest and shoulder, not against the neck or face?

Is the lap belt low and snug across the upper thighs, not the abdomen?

seats of vehicles for optimal protection.

It should be noted that the recommendation that all children younger than 2 years be restrained in an infant-only or convertible CSS used rear-facing represents a significant change from previous AAP policy and is based on new data from the United States[9] as well as extensive experience in Sweden.[10,11] It is important to note that most currently available CSSs have weight limits for rear-facing use that can accommodate the new recommendations.[12]

Certain considerations contained in this policy statement are relevant to commercial airline travel as well and are noted in the accompanying technical report.[13] Other AAP policy statements provide specific recommendations to optimize safety for preterm and low birth weight infants,[14] children in school buses,[15] and children using other forms of travel and recreational vehicles.[16–18] In addition, complementary AAP policy statements provide recommendations for teenaged drivers[19] and the safe transport of newborn infants[20] and children with special health care needs.[21,22]

Pediatricians play a critical role in promoting child passenger safety. To facilitate their widespread implementation in practice, evidence-based recommendations for optimal protection of children of all ages in passenger vehicles are presented in the form of an algorithm (Fig 1) with an accompanying table of explanations and definitions (Table 2). A summary of the evidence in support of these recommendations is provided in the accompanying technical report.[13] Because pediatricians are a trusted source of information to parents, every pediatrician must maintain a basic level of knowledge of these best-practice recommendations and promote and document them at every health-supervision visit. Prevention of motor vehicle crash injury is unique in health-supervision topics, because it is the only topic recommended at every health-supervision visit by *Bright Futures*.[23] Pediatricians can also use this information to promote child passenger safety public education, legislation, and regulation at local, state, and national levels through a variety of advocacy activities, including ensuring that their state's child passenger safety law is in better alignment with the best-practice recommendations promoted in this policy statement.

Because motor vehicle safety for children is multifaceted and will continue to evolve, all pediatricians should familiarize themselves with additional resources to address unique situations for their patients that may not be covered by the algorithm and to maintain current knowledge. In particular, many communities have child passenger safety technicians who have completed a standardized National Highway Traffic Safety Administration (NHTSA) course and who can provide hands-on advice and guidance to families. In most communities, child passenger safety technicians work at formal inspection stations; a list of these stations is available at www.seatcheck.org. If your community does not have an inspection station, you can find a child passenger safety technician in your area on the National Child Passenger Safety Certification Web site (http://cert.safekids.org) or the NHTSA child safety seat inspection station locator (www.nhtsa.dot.gov/cps/cpsfitting/index.cfm). Car seat checkup events are updated at www.safekidsweb.org/events/events.asp. In addition, additional resources for pediatricians and families can be found at www.aap.org or www.healthychildren.org.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

Technical Report—Child Passenger Safety

abstract

FREE

Despite significant reductions in the number of children killed in motor vehicle crashes over the past decade, crashes continue to be the leading cause of death for children 4 years and older. Therefore, the American Academy of Pediatrics continues to recommend inclusion of child passenger safety anticipatory guidance at every health-supervision visit. This technical report provides a summary of the evidence in support of 5 recommendations for best practices to optimize safety in passenger vehicles for children from birth through adolescence that all pediatricians should know and promote in their routine practice. These recommendations are presented in the revised policy statement on child passenger safety in the form of an algorithm that is intended to facilitate their implementation by pediatricians with their patients and families. The algorithm is designed to cover the majority of situations that pediatricians will encounter in practice. In addition, a summary of evidence on a number of additional issues that affect the safety of children in motor vehicles, including the proper use and installation of child restraints, exposure to air bags, travel in pickup trucks, children left in or around vehicles, and the importance of restraint laws, is provided. Finally, this technical report provides pediatricians with a number of resources for additional information to use when providing anticipatory guidance to families. *Pediatrics* 2011;127:e1050–e1066

INTRODUCTION: MAGNITUDE OF THE PROBLEM OF MOTOR VEHICLE CRASHES

Motor vehicle crashes represent the leading cause of death for children and youth older than 3 years in the United States.[1] Each year, more than 5000 children and adolescents under the age of 21 years die in crashes, which represents approximately 15% of people killed each year in crashes.[2] Fatalities represent only the tip of the motor vehicle crash problem for children and youth. For every fatality, approximately 18 children are hospitalized and more than 400 receive medical treatment for injuries sustained in a crash.[1] Current estimates of injuries and fatalities are updated annually and can be found in the Centers for Disease Control and Prevention Web-based Injury Statistics Query and Reporting System at www.cdc.gov/injury/wisqars.

In the United States, motor vehicle traffic-related mortality rates are highest for black and American Indian/Alaskan Native children, lowest among Asian/Pacific Islander children, and intermediate for Hispanic and white children.[3] Examining trends over a 20-year period through 2003 reveals significantly declining rates for child occupant deaths among all race and ethnic groups examined. However, among infants (aged 0–12 months), improvements in mortality rates among black children have slowed more recently. Occupant mortality rates among

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

children 1 to 4 years of age showed a tendency toward increased mortality in black, Hispanic, and American Indian/Alaskan Native children. Although there were significant declines in total motor vehicle mortality rates across all racial groups, improvement in occupant injury was greater for white children, and disparities actually widened for both black and American Indian/Alaskan Native children compared with white children.

The racial/ethnic disparities in motor vehicle occupant death rates are likely explained in large part by lower use of restraints, including child restraint systems, by people of racial minorities. Seat belt and child restraint use among black adults and children are lower than the national average.[4,5] Similarly, seat belt use among Hispanic (85%) and non-Hispanic black (80%) adults traveling with children was lower than that for white (96%) adults traveling with children.[6] The reasons for these disparities in restraint use are not completely known but may be related to a lack of knowledge as well as a lack of culturally appropriate messages from generalized public education intervention programs.[7] More culturally sensitive intervention programs designed to increase child restraint use among minority populations have resulted in significant increases in restraint use among target populations.[8]

Through the early 1990s, child occupant fatality rates remained relatively stagnant at approximately 3.5 deaths per 100 000 population.[9] Beginning in 1995, when children killed by deploying passenger air bags were first reported clinically, attention began to focus on the unique needs of children in automotive safety. Subsequently, in the United States, the number of motor vehicle fatalities and serious injuries has been reduced through a combination of increased attention to age-appropriate restraint use and rear seating position[10–15] as well as enhanced child restraint laws and enforcement of these laws.[16,17] In the 10 years from 1999 to 2008, the number of children younger than 15 years who died in motor vehicle crashes in the United States declined by 45%.[2] Annual updates on the number of children killed in motor vehicle crashes can be obtained from the National Highway Traffic Safety Administration (NHTSA) at www-fars.nhtsa.dot.gov/Main/index.aspx.

Although significant progress has been made in reducing the number of children killed in crashes, the exposure of children to motor vehicle travel and, thus, to potential crashes is great. Children younger than 16 years travel nearly as much as adults (average of 3.4 trips per day and 45 to 50 minutes/day spent in a vehicle), which emphasizes the importance of age-appropriate restraint on every trip.[18]

THE IMPORTANCE OF AGE-APPROPRIATE RESTRAINT USE

Mechanism of Action of Restraint Systems

Restraint systems are designed to reduce risk of ejection during a crash, better distribute the energy load of the crash through structurally stronger bones rather than soft tissues, limit the crash forces experienced by the vehicle occupant by prolonging the time of deceleration, and limit the contact of the occupant with interior vehicle structures. Optimal performance of restraint systems depends on an adequate fit between the restraint system and the occupant at the time of the crash. Restraint systems can be generally categorized as vehicle restraints—air bags and seat belts—or add-on restraints specifically made for children—child restraint systems. Child restraint systems include infant-only car safety seats (CSSs), convertible and combination CSSs, integrated seats, travel vests, and belt-positioning booster seats. A description of each type of restraint is provided below as well as in Table 1 of the accompanying policy statement.[19]

Age-Specific Prevalence of Restraint Use

In large part because of the increased attention paid to the needs of children in motor vehicle safety beginning in the mid-1990s, large increases in restraint use (including CSSs and booster seats) by children have been observed over the past decade. Data from the National Occupant Protection Use Survey and the National Survey of the Use of Booster Seats indicate that restraint use for children in the United States in 2008 stood at 99% among infants younger than 1 year, 92% among 1- to 3-year-olds, and 89% among 4- to 7-year-olds.[20] Restraint use for children driven by a belted driver was significantly higher (92%) than for those driven by an unbelted driver (54%). It is important to note that although child restraint use is high among the youngest children, improper use of the restraint may limit the effectiveness of the system. Among children either younger than 1 year or who weighed less than 20 lb, a group that has traditionally been recommended to ride in a rear-facing CSS, 21% were not compliant with these recommendations.[21] Similarly, although overall restraint use among older children is relatively high, nearly half of children 12 years and younger who are under 54 inches in height are not using a CSS or booster seat, which is their recommended form of optimal restraint.[21] Although the prevalence of use according to race and ethnicity varied somewhat among age groups, use rates tended to be higher among white and Asian non-Hispanic children (at least 90% for all age groups) and lower among black non-Hispanic children

(ranging from 72% for 8- to 12-year-olds to 94% for infants younger than 1 year).[22] It should be noted that child restraint use among black children 4 to 7 years of age increased from 73% in 2007 to 84% in 2008.

Among children 8 years and younger in crashes, overall reported use of child restraint systems has increased nearly threefold since 1999 to 80% of children in a large sample of children in crashes by 2007.[23] The largest relative increase in child restraint use among children in crashes was among 6- to 8-year-olds, yet 57% of these children continued to be inappropriately restrained in 2007. Forward-facing CSSs were primarily used by children 3 years and younger, whereas belt-positioning booster seats have become the most common restraints for 4- to 5-year-olds.[24]

Pediatric obesity has become a major public health concern in the United States as the prevalence of being overweight among children tripled over the past 2 decades.[25] Currently, 34% of children are categorized as being "overweight" (BMI $\geq$ 95th percentile) or "at risk for overweight" (BMI $\geq$ 85th to $<$95th percentile).[26] Childhood obesity has significant implications for child passenger safety, because young children who are overweight may not fit properly in CSSs or booster seats that would otherwise be appropriate for their age.[27] It is fortunate that, over the past several years, increasing numbers of CSSs and booster seats with higher weight and height limits have been introduced into the market in response to this challenge. Among currently available products listed in the American Academy of Pediatrics (AAP) pamphlet "2011 Car Safety Seats: A Guide for Families" (available at www.healthychildren.org/carseatlist), nearly half (14 of 29) of infant-only seats can accommodate children to 30 lb or more, which represents at least the 75th percentile for girls and boys at 24 months of age. Nearly all (30 of 35) currently available convertible CSSs can accommodate children to 35 lb or more when used rear-facing, a weight that exceeds the 95th percentile for boys and girls at 24 months of age. Similarly, for children 2 to 8 years of age, 34 of 53 currently available forward-facing seats used with a harness can accommodate children to at least 50 lb, which exceeds the 95th percentile for boys and girls younger than 5 years. Therefore, there are sufficient products available to consumers to accommodate larger children in the correct restraint. Limited data exist on the risk of injury to overweight children in motor vehicle crashes but suggest that overweight children may be at an increased risk of particular types of injuries, particularly lower-extremity fractures, compared with children of normal weight.[28–30] Further research is needed to establish motor vehicle safety as yet another public health burden imposed by childhood obesity and to ensure that overweight children are properly protected in motor vehicles.

Seat belt use among all front-seat occupants (drivers and front passenger-seat occupants) in the United States increased to 84% in 2009.[31] Among older children, restraint use in any seating location in the vehicle in 2008 was 85% among 8- to 12-year-olds and 83% among 13- to 15-year-olds.[6,20] Seat belt use anywhere in the vehicle among 13- to 15-year-olds varied according to race and ethnicity; white adolescents had higher seat belt use rates (89%) than either Hispanic (82%) or black non-Hispanic (46%) youth.

It is important to note that CSSs were designed as occupant safety devices in motor vehicles, not as general child seating devices. A recent study that used data from the National Electronic Injury Surveillance System operated by the US Consumer Product Safety Commission estimated that more than 8000 infants younger than 1 year are evaluated in hospital emergency departments each year for car seat–related (non–motor vehicle crash) injuries suffered when the car seats were used improperly or for unintended purposes.[32] The majority (85%) of injuries were related to falls, either infants falling out of car seats or car seats falling from elevated surfaces such as countertops and tables. Nearly half of the injuries occurred at home, and head and neck injuries accounted for 84% of the injuries to infants. Prolonged use of CSSs by young infants for positioning also contributes to the increased incidence of plagiocephaly, exacerbates gastroesophageal reflux, and increases risk of respiratory compromise.[33] Families should be encouraged to use CSSs only as occupant-protection devices for travel as they were intended.

Installation of Child Restraint Systems

CSSs must be installed tightly to derive the optimum benefit of both the crashworthiness of the vehicle (eg, crumple zones that dissipate the energy of the crash and prolong the time of deceleration of the vehicle) and the design of the seat itself. As a general rule, if a CSS can be moved more than 1 inch from side to side or front to back when grasped at the bottom of the seat near the belt or lower anchors and tethers for children (LATCH) attachment points, it is not installed tightly enough. Improper installation of a CSS may result in an increased likelihood of excessive movement of the child in the event of a crash, thus increasing the child's risk of injury.

The most recent estimates of CSS misuse are derived from an observational study of more than 5000 children in which 72.6% of CSSs were observed to have some form of misuse.[34,35] The

most common critical misuses were loose harness straps and a loose attachment of the CSS to the vehicle when using the seat belt. Results of several studies have indicated that misused CSSs may increase a child's risk of serious injury in a crash.[13,14,36,37]

An issue specific to installing rear-facing CSSs relates to the recline angle of the seat. Proper installation results in a semireclined angle of approximately 45°, which enables the infant's head to lie against the back of the CSS, as opposed to potentially falling forward, which compromises the infant's airway, if the seat is angled too upright. Preterm infants are particularly vulnerable to an increased risk of oxygen desaturation, apnea, and/or bradycardia, especially when placed in a semireclined position in CSSs.[38–41] Therefore, CSS monitoring in the infant's own CSS before discharge from the hospital should be considered for any infant who was less than 37 weeks' gestation at birth to determine if the infant is physiologically mature and has stable cardiorespiratory function. More specific information on car seat testing of preterm newborn infants and recommendations based on results of testing are available in an AAP clinical report on the subject.[33]

A relatively new way by which CSSs can be installed in passenger vehicles, known as LATCH, was designed to reduce the difficulty associated with installing CSSs. This system uses dedicated attachment points in the vehicle rather than using the vehicle seat belt for CSS installation. All vehicles and child restraints manufactured and sold in the United States after September 2002 are required to have this anchoring system. For rear-facing CSSs, there are 2 points of attachment at the base of the CSS. For forward-facing CSSs, a third dedicated attachment point near the top of the CSS is used for a top tether to attach to a separate anchor point in the vehicle (see Fig 1).

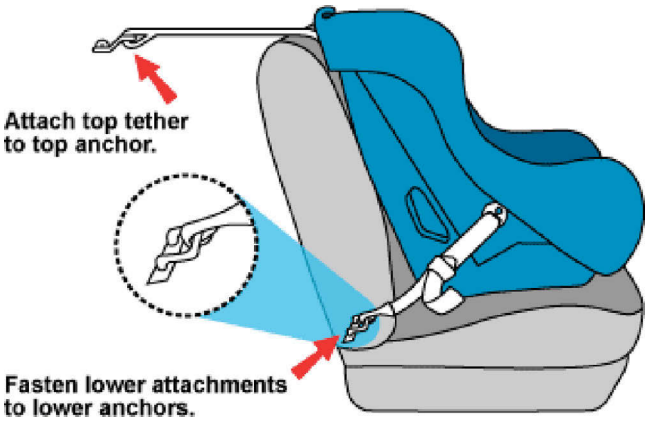

FIGURE 1
Schematic of the LATCH system.

Previous research has evaluated the performance of LATCH (or its European counterpart, ISOFIX) in laboratory sled-test environments[42–44] and demonstrated improved kinematics and reduced injury measures on crash test dummies, in particular with use of the top tether, when compared with using a seat belt to attach the CSS. To date, there are no real-world data from evaluations of the performance of LATCH, although its theoretical advantages in ensuring proper installation suggest that families should use it when available.

Arbogast and Jermakian have reviewed cases of CSSs attached by using LATCH and illustrated examples of LATCH misuse.[45] In 2005, a large-scale observation study that examined LATCH use and misuse in the United States was conducted at 66 sites across 7 states.[46] The study results indicated that many parents who purchased newer vehicles did not update their CSS to take advantage of the available LATCH attachment system. Approximately one-fifth of CSSs in vehicles equipped with LATCH did not have tether straps, and one-sixth did not have lower attachments. Even when their CSSs were LATCH equipped, approximately one-third of the drivers with LATCH-equipped vehicles stated that they could not use LATCH because there were no anchors in their vehicles. Much of the nonuse of lower anchors in this study related to the fact that the vehicle safety belt was the only method available in the center rear-seating position for installing a CSS. The rear seats of most passenger vehicles typically are equipped with lower LATCH anchors only in the outboard seating positions. When parents had experience attaching CSSs by using the safety belt and LATCH system, three-quarters reported a preference for LATCH, because they found it easier to use and obtained a tighter fit, and they felt that the child was more secure.

EVIDENCE FOR BEST-PRACTICE RECOMMENDATIONS

The following section of this technical report will provide a summary of the evidence in support of each of the best-practice recommendations included in the accompanying policy statement.

Children with certain physical and behavioral conditions may require specialized restraint systems and other considerations. Relevant conditions may include prematurity, cerebral palsy, the presence of a tracheostomy, muscle tone abnormalities, skeletal abnormalities, and certain behavioral or emotional conditions as well as

temporary conditions such as fractures that require spica casts. Therefore, the AAP has developed a separate policy statement that reviews important considerations for transporting children with special health care needs and provides current guidelines for the protection of children with specific health care needs, including those transported in wheelchairs.[47]

1. Best-Practice Recommendation: All Infants and Toddlers Should Ride in a Rear-Facing CSS Until They Are 2 Years of Age or Until They Reach the Highest Weight or Height Allowed by the Manufacturer of Their CSS

This best practice results from the need to support the young child's posterior torso, neck, head, and pelvis and to distribute crash forces over the entire body. Developmental considerations, including incomplete vertebral ossification, more horizontally oriented spinal facet joints, and excessive ligamentous laxity put young children at risk of head and spinal cord injury. Rear-facing CSSs address this risk by supporting the child's head and preventing the relatively large head from moving independently of the proportionately smaller neck.

In the United States, although the majority of children use rear-facing CSSs during the first year of life, 21% of infants who are either younger than 1 year or weigh less than 20 lb have been turned forward-facing.[21] In Sweden, many children remain rear-facing up to the age of 4 years and transition directly from the rear-facing CSS to a booster seat. Swedish researchers have reported that rear-facing CSSs reduce the risk of significant injuries (those with an Abbreviated Injury Scale score of $\geq$2) by 90% relative to unrestrained children, which reinforces their policy of children remaining in a rear-facing CSS up to the age of 4 years.[48,49]

Henary et al[50] reviewed US crash data to calculate the relative effectiveness of rear-facing CSSs compared with forward-facing CSSs for children 0 through 23 months of age in crashes from 1988 to 2003. The authors reported that children in forward-facing CSSs were significantly more likely to be seriously injured when compared with children restrained in rear-facing CSSs in all crash types (odds ratio [OR]: 1.76 [95% confidence interval [CI]: 1.40–2.20]). When considering frontal crashes alone, children in forward-facing CSSs were more likely to be seriously injured, although this finding was not statistically significant (OR: 1.23 [95% CI: 0.95–1.59]). In side-impact crashes, however, children in forward-facing CSSs were much more likely to be injured (OR: 5.53 [95% CI: 3.74–8.18]). When children 12 to 23 months of age were analyzed separately, those who were restrained in forward-facing CSSs were also more likely to be seriously injured (OR: 5.32 [95% CI: 3.43–8.24]). These authors concluded that for children through 23 months of age, rear-facing CSSs provided optimal protection. The lack of meaningful numbers of children 24 months or older in rear-facing CSSs in US databases has prevented extension of these analyses to even older age groups of children, such as those studied in Sweden.

2. Best-Practice Recommendation: All Children 2 Years or Older, or Those Younger Than 2 Years Who Have Outgrown the Rear-Facing Weight or Height Limit for Their CSS, Should Use a Forward-Facing CSS With a Harness for as Long as Possible, up to the Highest Weight or Height Allowed by the Manufacturer of Their CSS

The recommendation for forward-facing CSSs has been based, in part, on an analysis by Kahane[51] of laboratory sled tests, observational studies, and police-reported crash data from the early 1980s that estimated that correctly used forward-facing CSSs reduce the risk of death and injury by approximately 71% compared with unrestrained children. The engineering tests documented the biomechanical benefits of the CSS in spreading the crash forces over the shoulders and hips and controlling the excursion of the head during a crash. Kahane further estimated the effectiveness of a partially misused CSS as providing a 45% reduction in risk of fatality and serious injury. Using Fatality Analysis Reporting System (FARS) data from 1988 to 1994, NHTSA found that, among children between 1 and 4 years of age in passenger cars, those in forward-facing CSSs had a 54% reduction in risk of death compared with unrestrained children.[52] Given the currently high rates of restraint use among children in the United States, it is no longer meaningful to quote effectiveness estimates in comparison to unrestrained children.

Estimates of the effectiveness of forward-facing CSSs in comparison with children using seat belts, on the basis of real-world crash data, vary depending on the source of data used, the time period studied, and the analytical approach taken. Estimating effectiveness of child restraint systems through analysis of crash databases is challenging because of the association between how passengers are restrained in a given crash and whether that crash will be in a specific database. For example, the FARS, operated by the NHTSA, is a census of vehicle crashes in the United States in which at least 1 person died. The FARS has a sufficient number of outcomes of fatal child injuries for analyses but has a biased selection of crashes in that inclusion of crashes is associated with the outcome of interest (ie, mortality). Several different analytic techniques, de-

scribed hereafter, have been developed to minimize the effects of this bias.

The results of most studies to date have indicated that forward-facing CSSs are effective at preventing nonfatal injuries when compared with seat belts; effectiveness estimates have ranged from 71% to 82% reduction in serious injury risk.[13,53] Elliott et al[14] compared the effectiveness of child restraints to seat belts in preventing fatal injuries to 2- to 6-year-old children in crashes by combining data from the FARS with data from the National Automotive Sampling System–Crashworthiness Data System. The combined data set, in theory, overcame several of the known limitations of using either data source alone. Compared with seat belts, child restraints, when not seriously misused (eg, unattached restraint, child restraint system harness not used) were associated with a 28% reduction in risk of death (relative risk [RR]: 0.72 [95% CI: 0.54–0.97]) after adjusting for seating position, vehicle type, model year, driver and passenger ages, and driver survival status. When including cases of serious misuse, the effectiveness estimate was slightly lower (21%) and not statistically significant (RR: 0.79 [95% CI: 0.59–1.05]).

In a controversial analysis, Levitt[54] used FARS data from 1975 to 2003 and, by various methods, directly compared the mortality rates for child restraints and for seat belts for children aged 2 to 6 years and could not demonstrate a difference in effectiveness. Levitt restricted the FARS data set to 2-vehicle crashes in which someone in the other vehicle (ie, the vehicle without the index child occupant) died, under the assumption that the distribution of restraint use among children in potentially fatal crashes is independent of whether someone in the other vehicle dies, after adjusting for various crash-related characteristics. In a subsequent study in which a marginal-structural-model-type estimator was used in an attempt to explore the relationship between various biases inherent in data sources and the estimates of CSS restraint effectiveness, Elliott et al[55] suggested a 17% reduction in fatality risk for children 2 through 6 years of age in child restraint systems relative to seat belts. This reduction is estimated at 22% when severe misuse of the restraint is excluded.

3. Best-Practice Recommendation: All Children Whose Weight or Height Is Above the Forward-Facing Limit for Their CSS Should Use a Belt-Positioning Booster Seat Until the Vehicle Lap-and-Shoulder Seat Belt Fits Properly, Typically When They Have Reached 4 Feet 9 Inches in Height and Are Between 8 and 12 Years of Age

Children who have outgrown a forward-facing CSS (based on the height or weight limit of the seat) should be restrained in belt-positioning booster seats by using the lap-and-shoulder belts in the back seat of a vehicle. Booster seats position the child so that the lap-and-shoulder belt fits properly. Correct fit of the belt is defined as follows:

- The shoulder belt lies across the middle of the chest and shoulder, not the neck or face.
- The lap belt is low across the hips and pelvis, not the abdomen.
- The child is tall enough to sit against the vehicle seat back with his or her knees bent without slouching and can stay in this position comfortably throughout the trip.

Although seat belt geometry varies from vehicle to vehicle depending on the depth of the seat bottom and placement of the upper and lower anchor points of the belt, most vehicle seat belts will not fit correctly until a child reaches approximately 4 feet 9 inches in height and is between 8 and 12 years of age. This height threshold was derived from a study of 155 children 6 to 12 years of age who were assessed for the fit of the vehicle seat belt in 3 different types of vehicles in 1993.[56] The minimum height of a child who could fit properly in the vehicle seat belts was 148 cm (58 inches). It is important to note that this study is nearly 20 years old, and significant changes have been made to the vehicle fleet during this time.

Cases of serious cervical and lumbar spinal cord injury, as well as intraabdominal injuries, to children in motor vehicle crashes resulting from poorly fitting seat belts have been described for many years and are known as the "seat belt syndrome."[57] First described by Kulowski and Rost in 1956,[58] the term "seat belt syndrome" was coined by Garrett and Braunstein in 1962[59] to describe a distinctive pattern of injuries associated with lap seat belts in serious crashes. Two predominant factors have been hypothesized to explain this constellation of injuries: the immaturity of the pediatric pelvis to properly anchor the lap portion of the belt and the tendency of children to scoot forward in the seat so that their knees bend at the edge of the vehicle seat. From this position, in a rapid deceleration, the belt can directly compress abdominal organs against the spinal column, and the child's body may "jack-knife" around the belt, putting high tension forces on the lumbar spine, which may lead to distraction injuries of the posterior elements of the spine, such as Chance-type fractures.

Durbin et al[12] published results of the first real-world evaluation of the performance of booster seats compared with seat belts for young children. These authors determined that the risk of injury after adjusting for child, crash, driver, and vehicle characteristics was 59% lower for 4- to 7-year-olds in belt-positioning booster seats than those using only seat belts. Applying these results to Wisconsin state data

from 1998 to 2002, Corden[60] determined that there would be an approximate 57% reduction in deaths and hospitalizations if all 4- to 7-year-olds were in booster seats. A recent updated analysis of booster effectiveness in preventing nonfatal injuries was able to examine a greater percentage of older children using booster seats; 37% of the more recent study sample using booster seats were 6 to 8 years of age.[24] In this study, children 4 to 8 years of age using belt-positioning booster seats were 45% (95% CI: 4%–68%) less likely to sustain nonfatal injuries than children of similar ages using the vehicle seat belt. Among children restrained in belt-positioning booster seats, there was no detectable difference in the risk of injury between the children in backless versus high-back boosters.

Rice et al[61] extended the data on booster seat performance by estimating the effectiveness of booster seats in reducing the risk of fatal injuries to children 4 to 8 years of age. Using a matched cohort analysis of data from the FARS, Rice et al determined that booster seats reduced the risk of fatal injuries by 67% for 4- to 5-year-olds and 55% for 6- to 8-year-olds compared with unrestrained adults and children. They also determined that seat belts alone reduced the risk of fatal injury by approximately 62% for 4- to 8-year-olds compared with unrestrained adults and children. They did not demonstrate a significant difference in fatality risk reduction for booster seats when compared with seat belts (RR: 0.92 [95% CI: 0.79–1.08]). The authors postulated that although booster seats, which improve seat belt fit, may reduce the risk of nonfatal injuries (some of which may be attributable to improperly fitting seat belts), they may not improve the likelihood that children will survive a severe crash with major occupant compartment intrusion or during rollovers. It may be that properly fitting seat belts are no better than poorly fitting seat belts at preventing fatal injuries in these severe crashes.

Although most newer vehicles include lap-and-shoulder belts in all rear-seating positions, many older vehicles still in use may have only lap belts available in some seating positions, typically in the center of the rear seat. Laboratory tests have revealed increased head excursions when booster seats are used with lap belts compared with when only lap belts are used.[62,63] Other research results have indicated that booster-aged children using only lap belts are likely to strike their heads on vehicle seat backs or other interior components in front of them, even without booster seats.[64,65] Results of a recent study that used 2 real-world data sources suggested that children restrained in booster seats with lap belts had a lower injury risk when compared with children restrained in lap belts only, although the possibility of no difference could not be excluded.[66] For families faced with frequently transporting booster-aged children in lap-belt-only seating positions, there are other restraint options (eg, forward-facing CSSs with higher weight limits and safety vests) that, although typically more expensive than booster seats, are more likely to provide optimal protection if children ride regularly in these seating positions. It should be noted that the number of children in this scenario will decrease over time as vehicles equipped with lap-belt-only restraints in rear seats are phased out of the US vehicle fleet.

4. Best-Practice Recommendation: When Children Are Old Enough and Large Enough to Use the Vehicle Seat Belt Alone, They Should Always Use Lap-and-Shoulder Seat Belts for Optimal Protection

Lap-and-shoulder belts have been required in rear outboard positions of vehicles since 1989. However, it was not until 2005 that lap-and-shoulder belts were required in the center rear-seat position. Many manufacturers introduced center rear lap-and-shoulder belts in advance of this requirement, and by model year 2001, most vehicles provided them as standard equipment.[67] Arbogast et al[68] determined that the presence of a shoulder belt reduced the risk of injury by 81% for children seated in the center rear in seat belts, and the primary benefit is seen in reductions in abdominal injuries. Parenteau et al[69] had previously documented a similar shift in the pattern of injury to children in lap-only belt restraints to lap-and-shoulder belts. Their study, however, examined the rear seat as a whole and did not separate the rear seating positions.

Using data from the FARS, the NHTSA has evaluated the performance of lap-and-shoulder belts in the rear rows and found them to be effective (compared with unrestrained occupants) in all crash directions for children and adult occupants 5 years and older. The estimated fatality reduction, compared with unrestrained occupants, was 77% in rollover crashes, 42% in side impacts, 29% in frontal impacts, and 31% in rear impacts and other crashes.[70] Two studies have evaluated seat belt effectiveness specifically for children. Chipman et al,[71] using a database of fatal crashes in Ontario, Canada, estimated that seat belts reduced the risk of serious injury or death by 40% for children 4 to 14 years of age. Data from Wisconsin suggested that 100% seat belt use by children 8 to 15 years of age (compared with current 72% use) would result in reductions of 45% and 32% for deaths and hospitalizations, respectively.[60]

5. Best-Practice Recommendation: All Children Younger Than 13 Years Should Be Restrained in the Rear Seats of Vehicles for Optimal Protection

In large part because of the attention resulting from the tragedy of children killed by passenger air bags, significant declines in front seating of children in vehicles have occurred since the mid-1990s. By 2008, 95% of infants, 98% of children 1 to 3 years of age, and 88% of children 4 to 7 years of age rode in the rear seat.[20] These rates compare with rates of 85%, 90%, and 71%, respectively, in 2002, the first year from which these data were available from direct observation studies.[72] It should be noted that rear seating does not seem to vary on the basis of whether there is a state law requiring children to ride in the rear. In 2008, 92% of children who lived in states in which such a law existed rode in the rear, versus 93% of children from states in which no such law exists.[20] Children using child restraint systems were more likely to sit in the rear (≥93%) than were those in seat belts (89%) or riding unrestrained (84%). In a study of children involved in nonfatal crashes, children were more likely to be seated in the front if the vehicle was driven by a male or by someone other than the child's parent or if the vehicle was not equipped with a passenger air bag.[73] Among children younger than 4 years in CSSs who have been in crashes, there seems to be a preference for placing the CSS in the right outboard seating position in the rear row (41%) compared with the center rear (31%) or left outboard (28%),[74] which likely has to do with the increased ability for the driver to directly observe the child more easily when in the right outboard rear seating position.

Several studies have documented the benefits of rear seating for children. Estimates of the elevated risk of injury for children in the front seat compared with children in the rear have ranged from 40% to 70% depending on the time period and characteristics of the group studied.[10,75,76] The authors of 1 of these studies specifically noted that the beneficial effects of the rear seat were no longer seen for children 13 years and older.[10] Thus, the AAP continues to recommend that all children younger than 13 years ride in the rear seat. It is interesting to note that the benefits of rear seating for child occupants extend to side impacts as well; children seated in the rear are 62% less likely to sustain an injury.[77] Not only is the overall risk higher, but the severity of injury is also greater in the front seat. An analysis of crashes identified through the Crash Injury Research and Engineering Network (CIREN) revealed that child occupants in the front seat sustained more severe injuries than those seated in the rear rows as measured by an injury severity score higher than 16.[78]

Two recent studies specifically evaluated the potential incremental benefits of the center rear seating position compared with the rear outboard positions. Lund[79] used data from the National Automotive Sampling System–General Estimates System system from 1992 to 2000 to evaluate the effect of seating position on the risk of injury for children in child restraints. Lund reported that children in the center rear seat had a similar risk of injury to children in the outboard rear seats. In contrast, Kallan et al[74] used data from the Partners for Child Passenger Safety project, a large, child-focused crash-surveillance system, from 1998 to 2006 and found that children restrained in forward-facing CSSs and seated in the center rear had an injury risk 43% lower than similarly restrained children in either of the rear outboard positions (adjusted OR: 0.57 [95% CI: 0.38–0.86]). These contrasting findings are likely attributable to how injuries were defined in the 2 studies. Lund defined injury as any police-reported injury, which included those of a relatively minor nature. The threshold for injury was higher in the Kallan et al analysis, which included only injuries involving internal organs and fractures of the extremities.

CHILDREN AND AIR BAGS

In November 1995, an article in the *Morbidity and Mortality Weekly Report* of the Centers for Disease Control and Prevention described 8 deaths of child occupants involving air-bag deployment that were of special concern, because they involved low-speed crashes in which the children otherwise should have survived.[80] As passenger air bags diffused into the market, numerous case reports began appearing in the medical literature describing brain and skull injuries sustained by children in rear-facing CSSs and brain and cervical spine injuries sustained by older children who were often unrestrained or restrained in seat belts inappropriately for their age.[81–85]

Several researchers reviewed case series of children exposed to deploying passenger air bags to elucidate the mechanisms of injury.[86–90] For children killed in a rear-facing CSSs, the air bag typically deployed into the rear surface of the child restraint near the child's head and caused fatal skull and brain injuries. For older children who were either unrestrained or restrained in seat belts inappropriate for their age, braking before impact caused the child to pitch forward so that they were in the path of the air bag as it deployed. On deployment, the air bag caused a spectrum of injuries to the brain and cervical spine, including atlanto-occipital fractures, brainstem injuries, and diffuse axonal injury. Case series of other less serious injuries to child occupants associated with

air-bag deployment continue to appear in the literature, including injuries to the eye[91] and upper extremities[92] as well as respiratory and hearing problems related to the sound wave and cloud of fine particulate matter released during an air-bag deployment.[93]

Several population-based estimates of the effects of air bags on young children in crashes have consistently indicated an increased risk of fatal and nonfatal injuries to both restrained and unrestrained child occupants.[11,12,94–98] Exposure to passenger air bags increased the risk of both minor injuries, including facial and chest abrasions, and moderate and more serious injuries, particularly head injuries and upper-extremity fractures.

On the basis of this evidence, the NHTSA initiated a 2-pronged program of education and regulation in response to the initial reports of deaths and serious injuries to children from air bags. First, the NHTSA, joined by many national organizations including the AAP, recommended that all child passengers younger than 13 years sit in the rear seats of vehicles. Second, in 1997, the NHTSA enacted a substantial regulatory change to Federal Motor Vehicle Safety Standard (FMVSS) 208, the safety standard that governs the protection of motor vehicle occupants in frontal impact crashes. Because frontal air bags are designed to primarily protect occupants in frontal impact crashes, their performance is certified through FMVSS 208. The change provided automakers a choice in the type of test that could be used to certify frontal crash performance for unbelted adults.[99] This change in the standard resulted in the redesign of frontal air bags to reduce the force with which they deploy. These new air bags are often referred to as "second-generation air bags" and were generally present in all vehicles beginning with model year 1998.

Several studies have examined the effect of these design changes on child occupants in real-world crashes. Olson[100] found that second-generation air bags reduced the risk of death among right-front-seated children 6 to 12 years of age by 29% compared with no air bag. For children younger than 6 years, both first- and second-generation air bags increased the risk of death compared with no air bag; however, the increased risk of death was less for second-generation air bags (10%) compared with first-generation air bags (66%). Arbogast et al[101] quantified the risk of serious nonfatal injuries in frontal crashes among belted children in the front seat of vehicles in which second- versus first-generation passenger air bags deployed. Serious injuries were reported in 14.9% in the first-generation group versus 9.9% in the second-generation group. In particular, children in the second-generation group sustained fewer head injuries, including concussions and other serious brain injuries, than in the first-generation group.

Braver et al[102] examined federal crash data to determine the effect of second- versus first-generation air bags on the risk of fatal injuries to children in the right-front seat. Right-front passengers younger than 10 years in vehicles with second-generation air bags had statistically significant reductions in risk of dying in frontal collisions compared with children of similar ages in vehicles with first-generation air bags, including a 65% reduced risk among children 0 to 4 years of age (RR: 0.35 [95% CI: 0.21–0.60]). Nonsignificant decreases in risk of death were observed among children 10 to 14 years of age.

Kuppa et al[103] evaluated the influence of the air bag on the effectiveness of rear seating by using a double-pair comparison study of frontal impact crashes identified in the FARS. Two pairs were analyzed: the first group consisted of fatal crashes in which a driver and front outboard seat passenger were present and at least 1 of them was killed; the second group consisted of fatal crashes in which a driver and a rear outboard seat passenger were present and at least 1 of them was killed. This analysis examined vehicles with and without a passenger air bag separately. For restrained children 5 years or younger, the presence of a passenger air bag increased the benefit, in terms of reduced fatalities, associated with rear seating. For restrained child occupants older than 8 years, the rear seat was still associated with a lower risk of death than the front, but its benefit was less in vehicles with a passenger air bag than in vehicles without a passenger air bag.

Air bags continue to undergo significant redesigns in an effort to optimize their effectiveness in serious crashes while minimizing their risk of adverse injuries in minor crashes. In 2001, additional revisions were made to FMVSS 208, which now requires the testing of air-bag systems for all sizes of occupants, including children. At this time, no studies have evaluated the benefits of these designs, often termed "certified advanced compliant air bags," for child occupants.

There have been limited studies that have attempted to examine age-specific effects of air bags on risk of injury to children. Newgard and Lewis[97] used data from the National Automotive Sampling System–Crashworthiness Data System to evaluate specific cutoff points for age, height, and weight as effect modifiers of the association between the presence of a passenger air bag and serious injury among children involved in motor vehicle crashes. The time period studied (1995–2002) preceded the time when

second-generation air bags were generally available in the vehicle fleet. Newgard and Lewis found that children 0 to 14 years of age involved in frontal collisions seemed to be at increased risk of serious injury from air-bag presence (OR: 2.66 [95% CI: 0.23–30.9]) and deployment (OR: 6.13 [95% CI: 0.30–126]), although these values did not reach statistical significance. Among children 15 to 18 years of age involved in frontal collisions, there was a protective effect on injury from both air-bag presence (OR: 0.19 [95% CI: 0.05–0.75]) and deployment (OR: 0.31 [95% CI: 0.09–0.99]). A similar analysis has not been replicated to determine if different age cutoffs might be identified with children in vehicles equipped with second-generation air bags. Therefore, the AAP continues to strongly recommend that all children younger than 13 years sit in the rear seat. In vehicles with only a single row of seats, such as compact pickup trucks, the frontal air bag can be deactivated, or an on/off switch can be installed, to prevent its deployment in the event of a crash, thus allowing either the installation of a CSS in the front seat or the ability of a child younger than 13 years to ride in the front if necessary.[104]

Side air bags were introduced in the mid-1990s as a safety strategy to reduce serious injuries and fatalities occurring in side-impact crashes. Initial crash tests that involved vehicles equipped with so-called torso side air bags in the front seats revealed that the head was still at risk of serious injury in side-impact crashes.[105,106] To maximize protection of the head for adult front and rear-seat occupants of a variety of statures and seating postures, the roof-rail or head curtain air bag was developed and has become the preferred head-protection system for side-impact crashes. These systems, frequently accompanied by a separate torso side air bag, provide more extensive coverage of the upper vehicle side interior and often extend the entire length of the vehicle, including the rear rows. Side air bags have become a common safety technology in the vehicle; 79% of model-year 2006 vehicles have some type of side air bag either as standard or optional equipment.[107] The NHTSA recently conducted an analysis of side-impact protection with a focus on side air-bag technology[108] and determined that side air bags resulted in a reduction in struck-side fatality risk of 18% in multivehicle crashes and substantial improvement in a thoracic injury metric, the Thoracic Trauma Index, in laboratory assessments. Benefits were greater for head side air bags than those with torso side air bags alone. However, these analyses were primarily focused on protection of adult drivers and front-seat occupants. Arbogast and Kallan[109] used the Partners for Child Passenger Safety (PCPS) database to estimate the prevalence of side air-bag exposure to children in crashes and to provide estimates of injury risk among those exposed. In the study sample, 2.7% of children in crashes were exposed to a deployed side air bag. More than 75% of these children were seated in the rear seat, and 65% of those exposed were younger than 9 years. Of those exposed, 10.6% sustained an Abbreviated Injury Scale 2 injury to the head or upper extremity, a rate similar to that of children exposed to second-generation frontal air bags. These limited field data on the performance of side air bags with respect to child occupant protection suggest that, although a significant number of children are exposed to side air-bag deployments, there is no evidence that these air bags pose a particular risk of serious or fatal injuries to children.

SPECIAL CONSIDERATIONS

The Safety of Children Left in or Around Vehicles

Children should never be left unattended in or around parked cars. Among the safety risks that have been described, being backed over when the vehicle is set in motion, hyperthermia, and strangulation from entrapment in power windows are among the most serious and preventable injuries. In 2008, Kids and Cars, a safety advocacy group dedicated to the prevention of such injuries, amassed reports of a wide range of safety incidents that involved nearly 1000 children and resulted in more than 200 deaths.[110] In response to the Cameron Gulbransen Kids Transportation Safety Act of 2007 (Pub L No. 110-189), the NHTSA created a virtual database called the Not in Traffic Surveillance (NiTS) system to ascertain population-based estimates of the prevalence of noncrash deaths and injuries. NiTS data indicate that approximately 35 to 40 occupants (primarily children) die of hyperthermia and 5 die of power-window strangulation each year, which highlights the importance of never leaving children unsupervised in or around cars.[111]

The Safety of Children in Pickup Trucks

Pickup trucks are popular vehicles in the United States and accounted for approximately 13% of new vehicle sales in 2008.[112] Although many have only a single row of seats, extended-cab models have a second row of seats and may be viewed as family vehicles by parents who want to follow safety recommendations that children be placed in the rear seat. Compact extended-cab pickup trucks, which typically have a smaller rear-seat compartment, sometimes with side-facing, fold-down seats, present a particular safety hazard to children. Winston et al[113] found that children in the rear

seat of compact extended-cab pickup trucks were more than 4 times as likely to be injured (adjusted OR: 4.69 [95% CI: 2.44–9.01]) as were rear-row–seated children in other vehicles. A substantial portion of the increased risk was mediated by contact with the vehicle interior during the crash, because the rear-seat compartment in these trucks is typically not as well padded as in other vehicles. It is important to note that full-size extended-cab pickup trucks, which typically have a rear-seat compartment similar in size and configuration to other vehicles, were found to have injury risks similar to those of other passenger vehicles.

Of particular concern regarding the safety of pickup trucks for children is the use of the cargo area of pickup trucks for the transport of children and youth. Because the cargo area is not intended for passenger use, it is neither required nor designed to meet occupant safety standards applicable to passenger locations. The fatality risk to children in the cargo area of pickup trucks has been well described.[114,115] The most significant hazard of travel in the cargo area of a pickup truck is ejection of a passenger in a crash or noncrash event (eg, sudden stop, turn, swerve, or loss of balance, as well as intentional or unintentional jumps and falls). It is fortunate that the number of children and adolescents younger than 18 years killed as passengers in the cargo area of pickup trucks has declined by more than 50% over the past decade, from more than 40 per year to less than 20 per year more recently.[2] The most effective prevention strategies for reducing the number of deaths and injuries to children in pickup trucks are the prohibition of travel in the cargo area and age-appropriate restraint use in an appropriate rear-seat location in the cab.

The Safety of Children on Commercial Airlines

Currently, the Federal Aviation Administration (FAA) exempts children younger than 2 years from the requirement that all aircraft passengers occupy a seat with a separate safety belt.[116] The FAA and NHTSA agreed on a single government performance standard, FMVSS 213, that would satisfy both aviation and highway safety requirements for child restraint systems.[117] The FAA has also approved a harness-type restraint appropriate for children who weigh between 22 and 44 lb. This type of device provides an alternative to using a hard-backed seat and is approved only for use on aircraft. It is not approved for use in motor vehicles.[118] Newman et al[119] examined the potential impact and costs of a requirement for use of child restraint systems by young children on aircraft. The potential impact of such a regulation requires a number of assumptions, primarily regarding the effectiveness of child restraint systems in survivable aircraft crashes and the proportion of families who would switch from air to ground travel if required to assume the added cost of an additional aircraft seat and the child restraint system for their children younger than 2 years. Using available data on the risk of fatalities from air travel and the survivability of crashes and reasonable assumptions for RRs of death for restrained and unrestrained young children involved in crashes, Newman et al found that the number of deaths that could be prevented in the United States with mandatory child restraint system use in commercial aircraft is small: less than 1 per year. The number of deaths that could be prevented by mandatory child restraint system use is limited, because the number of deaths of unrestrained young children in survivable aircraft crashes is already low. Newman et al suggested that a policy of requiring child restraint system use for airplane travel is likely to lead to a net increase in deaths caused by increased motor vehicle travel if the proportion of families switching to automobile travel exceeds approximately 5% to 10%. This threshold varied with the estimated number of lives saved by child restraint system use on airplanes, the average length of the added round trips by car, and the risk profile of the drivers but was unlikely to exceed 15%. The National Transportation Safety Board disputed the "diversion" claim made by Newman et al and others and suggested that available data did not indicate that diversion to road travel has previously occurred when circumstances made it likely (eg, immediately after the terrorist attacks on September 11, 2001).[120]

An alternative approach supported by the FAA is to encourage families to inquire about the availability of open seats on less crowded flights so that parents could put their child in a child restraint system in a seat next to them without needing to buy a ticket and without revenue loss to the airline. This approach was also advocated by Bishai[121] in an editorial that accompanied the Newman et al study. If open seats are not available, families would be required to check the CSS as luggage. In 2008, the Department of Federal Affairs surveyed all major US airlines on their baggage policies and learned that with 1 exception, airlines have adopted policies that do not count CSSs toward checked baggage allowances.[122]

Data fundamental to creating an evidence-based policy, including information on the number of children younger than 2 years of age who currently fly unrestrained, as well as data on the number of children who sustain injuries in turbulence, are not available. Until data systems are created

and used to provide evidence to inform the policy debate and ticket-pricing policies and security screening procedures are enhanced to make it easier for families to follow best-practice recommendations for correct child restraint use during commercial airline travel, and to have their own CSS or booster seat available to them after airline travel, the current situation of allowing young children to travel in a manner inconsistent with best-practice recommendations is likely to continue.

CHILD RESTRAINT LAWS

The first state child occupant restraint law was passed in Tennessee in 1978, primarily attributable to the efforts of pediatrician Robert Sanders. By 1985, all 50 states and the District of Columbia had passed laws requiring child restraints for young children. However, these initial child passenger safety laws were generally inconsistent with best-practice recommendations at the time, which created several gaps in coverage of children and resulted in poor compliance with the provisions of the laws.[123] Recognizing the importance of laws in both changing restraint behavior and educating the public about recommended restraint practices, most states have recently enhanced their child occupant restraint laws through the enactment of booster seat use provisions for older children. Current information on all child restraint laws in the United States is updated by the Insurance Institute for Highway Safety and can be found at www.iihs.org/laws/ChildRestraint.aspx. Although the laws aim to ensure the appropriate use of all forms of child restraints (eg, CSSs and belt-positioning booster seats), the revised laws generally became known as "booster seat laws." Results of subsequent study of the association of a booster seat provision in a state child restraint law with changes in child restraint use in that state indicated that booster seat provisions that cover children from 4 through 7 years of age increase the use of child restraints by 39% among children in this age range.[16] Children 4 to 5 years of age in states with booster seat laws were 23% more likely to be reported as appropriately restrained than were children in other states, and those 6 to 7 years of age were twice as likely to be reported as appropriately restrained. For 6- to 7-year-olds, the effect was much stronger when the law included children through 7 years of age than when it included only those 4 to 5 years of age.

A focus-group study of violators of California's child restraint law revealed that multiple complex factors influence consistent use of a CSS.[124] At the time of the study, the California law required children younger than 4 years and weighing less than 40 lb to be properly secured in a CSS that meets federal standards. Parents who violated the law described a number of factors, including unreliable access to a vehicle, the trip circumstances, parenting style, and child refusal, that affected the use of a CSS at the time of the citation. Among parents who had been ticketed for not restraining their children, participation in a class in which child passenger safety information was provided demonstrated some benefit in their subsequent knowledge of child passenger safety issues, compared with a fine alone.

Seat belt laws have played a critical role in increasing seat belt use by 83% of front-seat occupants by 2008.[125] However, seat belt use continues to be lower—at 80% in 2008—among drivers and front-seat occupants 16 to 24 years of age. There are 2 different types of enforcement of seat belt laws: primary and secondary enforcement. Primary-enforcement laws allow a citation to be issued whenever a law enforcement officer observes an unbelted driver or passenger. Secondary enforcement seat belt laws require the officer to stop a violator for another traffic infraction before being able to issue a citation for not using a seat belt. Previous studies have demonstrated that, on average, the effects of primary-enforcement laws are larger and more consistent than secondary-enforcement laws in increasing seat belt use and decreasing injuries among adult drivers and passengers.[126–129]

Gaps between adult seat belt laws and child restraint laws result in lack of coverage for many older children (5–15 years of age) in all seating positions. For example, in some states, a 15-year-old can ride legally in the back seat without a restraint, because the laws in those states apply only to front-seat occupants. To gain insight on the potential effect of primary-enforcement safety belt laws on older child passengers, Durbin et al[130] compared reported use of seat belts among 13- to 15-year-old passengers in crashes in states with a primary-enforcement seat belt law versus states with a secondary-enforcement law. Restraint use was 7.2% (95% CI: 4.3%–10.1%) higher among 13- to 15-year-olds in primary-enforcement states versus those in secondary-enforcement states. Restraint use among 13- to 15-year-olds was significantly lower in secondary-enforcement versus primary-enforcement states, particularly when the driver was unrestrained. For 13- to 15-year-olds in a secondary state with an unrestrained driver, 65.8% were unrestrained compared with 22.8% in a primary-enforcement state (adjusted RR: 3.0 [95% CI: 1.5–15.7]). After adjusting for both driver age and restraint use, a 13- to 15-year-old was more than twice as likely to be unrestrained in a secondary-enforcement state com-

pared with a primary-enforcement state (RR: 2.2 [95% CI: 1.4–3.5]). The authors concluded that primary-enforcement laws were associated with higher rates of seat belt use compared with secondary-enforcement laws among children 13 to 15 years of age, a group not generally covered by restraint laws.

RESOURCES FOR PEDIATRICIANS AND FAMILIES

The NHTSA began a standardized child passenger safety training and certification program in 1998. Since then, tens of thousands of people have been certified as child passenger safety technicians.[131] These people participate in community-based child safety seat clinics and are a source of information for families on appropriate use and installation of all types of CSSs and booster seats. Although the algorithm to guide implementation of best-practice recommendations by pediatricians provided in the policy statement is designed to cover the majority of situations that pediatricians will encounter in practice, pediatricians should consider child passenger safety technicians as sources of information when atypical circumstances may be encountered that are not adequately managed by the algorithm. In most communities, technicians work at formal inspection stations; a list of these stations is available at www.seatcheck.org. If your community does not have an inspection station, you can find a technician in your area via the National Child Passenger Safety Certification Web site (http://cert.safekids.org) or the NHTSA child safety seat inspection station locator (www.nhtsa.dot.gov/cps/cpsfitting/index.cfm). Technicians with enhanced training in restraining children with special health needs, as well as those with Spanish-language proficiency, can be identified at these sites. Car seat checkup events are updated at www.safekidsweb.org/events/events.asp. In addition, additional resources for pediatricians and families can be found at www.aap.org and www.healthychildren.org.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Children, Adolescents, and Advertising

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Communications

ABSTRACT

Advertising is a pervasive influence on children and adolescents. Young people view more than 40 000 ads per year on television alone and increasingly are being exposed to advertising on the Internet, in magazines, and in schools. This exposure may contribute significantly to childhood and adolescent obesity, poor nutrition, and cigarette and alcohol use. Media education has been shown to be effective in mitigating some of the negative effects of advertising on children and adolescents.

INTRODUCTION

Several European countries forbid or severely curtail advertising to children; in the United States, on the other hand, selling to children is simply "business as usual."[1] The average young person views more than 3000 ads per day on television (TV), on the Internet, on billboards, and in magazines.[2] Increasingly, advertisers are targeting younger and younger children in an effort to establish "brand-name preference" at as early an age as possible.[3] This targeting occurs because advertising is a $250 billion/year industry with 900 000 brands to sell,[2] and children and adolescents are attractive consumers: teenagers spend $155 billion/year, children younger than 12 years spend another $25 billion, and both groups influence perhaps another $200 billion of their parents' spending per year.[4,5] Increasingly, advertisers are seeking to find new and creative ways of targeting young consumers via the Internet, in schools, and even in bathroom stalls.[1]

THE EFFECTS OF ADVERTISING ON CHILDREN AND ADOLESCENTS

Research has shown that young children—younger than 8 years—are cognitively and psychologically defenseless against advertising.[6–9] They do not understand the notion of intent to sell and frequently accept advertising claims at face value.[10] In fact, in the late 1970s, the Federal Trade Commission (FTC) held hearings, reviewed the existing research, and came to the conclusion that it was unfair and deceptive to advertise to children younger than 6 years.[11] What kept the FTC from banning such ads was that it was thought to be impractical to implement such a ban.[11] However, some Western countries have done exactly that: Sweden and Norway forbid all advertising directed at children younger than 12 years, Greece bans toy advertising until after 10 PM, and Denmark and Belgium severely restrict advertising aimed at children.[12]

ADVERTISING IN DIFFERENT MEDIA

Television

Children and adolescents view 40 000 ads per year on TV alone.[13] This occurs despite the fact that the Children's Television Act of 1990 (Pub L No. 101–437) limits advertising on children's programming to 10.5 minutes/hour on weekends and 12 minutes/hour on weekdays. However, much of children's viewing occurs during prime time, which features nearly 16 minutes/hour of advertising.[14] A 30-second ad during the Super Bowl now costs $2.3 million but reaches 80 million people.[15]

Movies

A 2000 FTC investigation found that violent movies, music, and video games have been intentionally marketed to children and adolescents.[16] Although movie theaters have agreed not to show trailers for R-rated movies before G-rated movies in response to the release of the FTC report, children continue to see advertising for violent media in other venues. For instance, M-rated video games, which according to the gaming industry's own rating system are not recommended for children younger than 17 years, are frequently advertised in movie theaters, video game magazines, and publications with high youth readership.[17] Also, movies targeted at children often prominently feature brand-name products and fast food restaurants.[18] In 1997–1998, 8 alcohol companies placed products in 233 motion pictures and in 1 episode or more of 181 TV series.[18]

Print Media

According to the Consumer's Union,[19] more than 160 magazines are now targeted at children. Young people see 45% more beer ads and 27% more ads for hard liquor in teen magazines than adults do in their magazines.[20] Despite the Master Settlement Agreement with the tobacco industry in 1998, tobacco advertising expenditures in 38 youth-oriented magazines amounted to $217 million in 2000.[21]

The Internet

An increasing number of Web sites try to entice children and teenagers to make direct sales. Teenagers account for more than $1 billion in e-commerce dollars,[22] and the industry spent $21.6 million on Internet banner ads alone in 2002.[23] More than 100 commercial Web sites promote alcohol products.[23] The content of these sites varies widely, from little more than basic brand information to chat rooms, "virtual bars," drink recipes, games, contests, and merchandise catalogues. Many of these sites use slick promotional techniques to target young people.[23,24] In 1998, the Children's Online Privacy Protection Act (Pub L No. 105–277) was passed, which mandates that commercial Web sites cannot knowingly collect information from children younger than 13 years. These sites are required to provide notice on the site to parents about their collection, use, and disclosure of children's personal information and must obtain "verifiable parental consent" before collecting, using, or disclosing this information.[25]

MARKETING TECHNIQUES

Advertisers have traditionally used techniques to which children and adolescents are more susceptible, such as product placements in movies and TV shows,[26] tie-ins between movies and fast food restaurants,[18] tie-ins between TV shows and toy action figures or other products,[7] kids' clubs that are linked to popular shows, and celebrity endorsements.[27] Cellular phones are currently being marketed to 6- to 12-year-olds, with the potential for directing specific advertisers to children and preteens. Coca-Cola reportedly paid Warner Bros. Studios $150 million for the global marketing rights to the movie "Harry Potter and the Sorcerer's Stone,"[28] and nearly 20% of fast food restaurant ads now mention a toy premium in their ads.[29] Certain tie-in products may be inappropriate for children (eg, action figures from the World Wrestling Federation or an action doll that mutters profanities from an R-rated *Austin Powers* movie).

Children's advertising protections will need to be updated for digital TV, which will be in place before 2010. In the near future, children watching a TV program will be able to click an on-screen link and go to a Web site during the program.[30] Interactive games and promotions on digital TV will have the ability to lure children away from regular programming, encouraging them to spend a long time in an environment that lacks clear separation between content and advertising. Interactive technology may also allow advertisers to collect vast amounts of information about children's viewing habits and preferences and target them on the basis of that information.[31]

SPECIFIC HEALTH-RELATED AREAS OF CONCERN

Tobacco Advertising

Tobacco manufacturers spend $30 million/day ($11.2 billion/year) on advertising and promotion.[32] Exposure to tobacco advertising may be a bigger risk factor than having family members and peers who smoke[33] and can even undermine the effect of strong parenting practices.[34] Two unique and large longitudinal studies have found that approximately one third of all adolescent smoking can be attributed to tobacco advertising and promotions.[35,36] In addition, more than 20 studies have found that children exposed to cigarette ads or promotions are more likely to become smokers themselves.[37,38] Recent evidence has emerged that tobacco companies have specifically targeted teenagers as young as 13 years of age.[39]

Alcohol Advertising

Alcohol manufacturers spend $5.7 billion/year on advertising and promotion.[40] Young people typically view 2000 beer and wine commercials annually,[41] with most of the ads concentrated in sports programming. During prime time, only 1 alcohol ad appears every 4 hours; yet, in sports programming, the frequency increases to 2.4 ads per hour.[42,43] Research has found that adolescent drinkers are more likely to have been exposed to alcohol advertising.[44–50] Given that children begin making decisions about alcohol at an early age—probably during grade school[50]—exposure to beer commercials represents a significant risk factor.[46,50] Minority children may be at particular risk.[51]

Drug Advertising

"Just Say No" as a message to teenagers about drugs seems doomed to failure given that $11 billion/year is spent on cigarette advertising, $5.7 billion/year is spent on alcohol advertising, and nearly $4 billion/year is spent on prescription drug advertising.[52] Drug companies now spend more than twice as much on marketing as they do on research and development. The top 10 drug companies made a total profit of $35.9 billion in 2002—more than the other 490 companies in the Fortune 500 combined.[53] Is such advertising effective? A recent survey of physicians found that 92% of patients had requested an advertised drug.[54,55] In addition, children and teenagers may get the message that there is a drug available to cure all ills and heal all pain, a drug for every occasion (including sexual intercourse).[41]

Food Advertising and Obesity

Advertisers spend more than $2.5 billion/year to promote restaurants and another $2 billion to promote food products.[56] On TV, of the estimated 40 000 ads per year that young people see, half are for food, especially sugared cereals and high-calorie snacks.[29,57] Healthy foods are advertised less than 3% of the time; children rarely see a food advertisement for broccoli.[58] Increasingly, fast food conglomerates are using toy tie-ins with major children's motion pictures to try to attract young people.[59] Nearly 20% of fast food ads now mention a toy premium in their commercials.[29] Several studies document that young children request more junk food (defined as foods with high-caloric density but very low nutrient density) after viewing commercials.[60–63] In 1 study, the amount of TV viewed per week correlated with requests for specific foods and with caloric intake.[61] At the same time, advertising healthy foods has been shown to increase wholesome eating in children as young as 3 to 6 years of age.[64]

Sex in Advertising

Sex is used in commercials to sell everything from beer to shampoo to cars.[65] New research is showing that teenagers' exposure to sexual content in the media may be responsible for earlier onset of sexual intercourse or other sexual activities.[66,67] What is increasingly apparent is the discrepancy between the abundance of advertising of products for erectile dysfunction (ED) (between January and October, 2004, drug companies spent $343 million advertising Viagra, Levitra, and Cialis)[68] and the lack of advertising for birth control products or emergency contraceptives on the major TV networks. This is despite the fact that 2 national polls have found that a majority of Americans favor the advertising of birth control on TV.[69,70] Ads for ED drugs give children and teens inappropriate messages about sex and sexuality at a time when they are not being taught well in school sex education programs.[71,72] Research has definitively found that giving teenagers increased access to birth control through advertising does not make them sexually active at a younger age.[73–80]

American advertising also frequently uses female models who are anorectic in appearance and, thus, may contribute to the development of a distorted body self-image and abnormal eating behaviors in young girls.[79,81,82]

ADVERTISING IN SCHOOLS

Advertisers have slowly but steadily infiltrated school systems around the country. The "3 Rs" have now become the "4 Rs," with the fourth R being "retail."[83,84] Ads are now appearing on school buses, in gymnasiums, on book covers, and even in bathroom stalls.[85] More than 200 school districts nationwide have signed exclusive contracts with soft drink companies.[86] These agreements specify the number and placement of soda-vending machines, which is ironic given that schools risk losing federal subsidies for their free breakfast and lunch programs if they serve soda in their cafeterias. In addition, there are more than 4500 Pizza Hut chains and 3000 Taco Bell chains in school cafeterias around the country.[87]

There is some good news, however. In May, 2006, the nation's largest beverage distributors agreed to halt nearly all sales of sodas to public schools and sell only water, unsweetened juice, and low-fat milk in elementary and middle schools. Diet sodas would be sold only in high schools.[88]

School advertising also appears under the guise of educational TV: Channel One. Currently available in 12 000 schools, Channel One consists of 10 minutes of current-events programming and 2 minutes of commercials. Advertisers pay $200 000 for advertising time and the opportunity to target 40% of the nation's teenagers for 30 seconds.[89] According to a recent government report, Channel One now plays in 25% of the nation's middle and high schools[81] and generates profits estimated at $100 million annually.[89]

CONCLUSIONS

Clearly, advertising represents "big business" in the United States and can have a significant effect on young people. Unlike free speech, commercial speech does not enjoy the same protections under the First Amendment of the Constitution.[90] Advertisements can be restricted or even banned if there is a significant public health risk. Cigarette advertising and alcohol advertising would seem to fall squarely into this category, and ads for junk food could easily be restricted.[91]

One solution that is noncontroversial and would be easy to implement is to educate children and teenagers about the effects of advertising—media literacy. Curricula have been developed that teach young people to become critical viewers of media in all of its forms, including advertising.[92–94] Media education seems to be protective in mitigating harmful effects of media, including the effects of cigarette, alcohol, and food advertising.[93–96]

RECOMMENDATIONS

1. Pediatricians should become familiar with the methods that advertisers use to target children and adolescents.
2. Pediatricians should only subscribe to magazines that are free of tobacco and alcohol advertisements for their waiting rooms (eg, *Good Housekeeping* has refused to carry tobacco ads since 1952).
3. Pediatricians should counsel their patients to limit total noneducational screen time to no more than 2 hours/day,[97] which will limit exposure to advertising of all kinds.
4. Pediatricians should write letters to advertisers if they see inappropriate ads and should encourage parents to do the same (letters can be addressed to the Children's Advertising Review Unit, Council of Better Business Bureaus, 845 Third Ave, New York, NY 10022).
5. Pediatricians should work with community groups and local school boards to implement media education programs that teach about the effects of advertising on children and adolescents. The federal government should help underwrite the cost of establishing and disseminating such programs.
6. Pediatricians should work with parents, schools, community groups, and others to ban or severely curtail school-based advertising in all forms.
7. Pediatricians should work with parent and public health groups to:
   a. ask Congress and the Federal Communications Commission to limit commercial advertising on children's programming to no more than 5 to 6 minutes/hour, which would decrease the current amount by 50%;
   b. ask Congress to implement a ban on cigarette and tobacco advertising in all media, including banners and logos in sports arenas;
   c. ask Congress to restrict alcohol advertising to what is known as "tombstone advertising," in which only the product is shown, not cartoon characters or attractive women;
   d. ask Congress to implement a ban on junk-food advertising during programming that is viewed predominantly by young children;
   e. ask Congress to increase funding for public TV—the sole source of high-quality, educational, noncommercial programming for children;
   f. advocate for confining ads for ED drugs to after 10 PM. The American Academy of Pediatrics has always strongly endorsed the advertising of birth control on TV. There is now considerable evidence that birth control advertising could lower teen pregnancy rates even further while having no impact on rates of teen sexual activity.[79] However, when birth control advertising is so rare on prime time TV, it makes no sense to allow ED drug advertising that may confuse children and teens about human sexuality and make sexual activity seem like a recreational sport.
   g. ask Congress and the Federal Communications Commission to prohibit interactive advertising to children in digital TV; and
   h. ask Congress to convene a national task force on advertising under the auspices of the Institute of Medicine, the National Institutes of Health, or the FTC. This task force would discuss the nature of the current problem and the current research and would propose solutions toward limiting children's exposure to unhealthy advertising, including the funding of future research. The task force would include representatives from the toy industry, the fast food industry, and the advertising community, as well as pediatricians, child psychiatrists and psychologists, and public health advocates.
8. Pediatricians, together with the American Academy of Pediatrics Media Resource Team, should work with the entertainment industry to ensure that the advertising of violent media to children does not occur, that product placements in movies and TV do not occur, that the dissemination and enforcement of the individual industries' own rating systems is facilitated, and that advertising for contraceptives is more widely disseminated on network TV.

abstract

Obesity has become a worldwide public health problem. Considerable research has shown that the media contribute to the development of child and adolescent obesity, although the exact mechanism remains unclear. Screen time may displace more active pursuits, advertising of junk food and fast food increases children's requests for those particular foods and products, snacking increases while watching TV or movies, and late-night screen time may interfere with getting adequate amounts of sleep, which is a known risk factor for obesity. Sufficient evidence exists to warrant a ban on junk-food or fast-food advertising in children's TV programming. Pediatricians need to ask 2 questions about media use at every well-child or well-adolescent visit: (1) How much screen time is being spent per day? and (2) Is there a TV set or Internet connection in the child's bedroom? *Pediatrics* 2011;128:201–208

INTRODUCTION

Obesity represents a clear and present danger to the health of children and adolescents. Its prevalence among American youth has doubled in the past 3 decades,[1] and there are now more overweight and obese adults in the United States than adults of normal weight.[2] However, obesity is also a worldwide problem; rates are increasing in nearly every country.[3,4] It is increasingly clear that the media, particularly TV, play an important role in the etiology of obesity.[5] As a result, many countries are now establishing new regulations for advertising to children on TV, and many government health agencies are now issuing recommendations for parents regarding the amount of time children spend watching TV.[6] Unfortunately, there are currently no data relating other media to obesity.

MEDIA AND OBESITY

There are a number of ways that watching TV could be contributing to obesity: (1) increased sedentary activity and displacement of more physical pursuits; (2) unhealthy eating practices learned from both the programming and the advertisements for unhealthy foods; (3) increased snacking behavior while viewing; and (4) interference with normal sleep patterns. However, most researchers now agree that the evidence linking excessive TV-viewing and obesity is persuasive.[7–9] There have been dozens of longitudinal and correlational studies documenting a connection.[9] An increasing number of these studies hold ethnicity and socioeconomic status—known to be key factors in obesity—constant and still reveal that TV-viewing is a significant con-

tributor to obesity.[7,10] Results of the longitudinal studies are particularly convincing. For example, a remarkable 30-year study in the United Kingdom found that a higher mean of daily hours of TV viewed on weekends predicted a higher BMI at the age of 30. For each additional hour of TV watched on weekends at age 5, the risk of adult obesity increased by 7%.[11] A group of researchers in Dunedin, New Zealand, followed 1000 subjects from birth to 26 years of age and found that average weeknight TV-viewing between the ages of 5 and 15 years was strongly predictive of adult BMI.[12] In a study of 8000 Scottish children, viewing more than 8 hours of TV per week at age 3 was associated with an increased risk of obesity at age 7.[13] Also, in 8000 Japanese children, more TV-viewing at age 3 resulted in a higher risk of being overweight at age 6.[14] Numerous American studies have had similar findings.[15–23]

The presence of a TV set in a child's bedroom seems to exacerbate the impact of TV-viewing on children's weight status.[24–28] A study of 2343 children aged 9 to 12 years revealed that having a bedroom TV set was a significant risk factor for obesity, independent of physical activity.[24] A cross-sectional study of 2761 parents with young children in New York found that 40% of the 1- to 5-year-olds had a bedroom TV, and those who did were more likely to be overweight or obese.[25] Teenagers with a bedroom TV spent more time watching TV, less time being physically active, ate fewer family meals, had greater consumption of sweetened beverages, and ate fewer vegetables than did teenagers without a bedroom TV.[26]

Recent correlational studies have also found a strong association between time spent watching TV and blood glucose level control in young people with diabetes,[29] type 2 diabetes mellitus,[30] insulin resistance,[31] metabolic syndrome,[32] hypertension,[33,34] and high cholesterol levels.[35–37] Furthermore, when TV time is diminished, so are measures of adiposity.[38,39]

MECHANISMS

How might time spent with media result in obesity? Contrary to popular opinion, overweight and obesity probably result from small, incremental increases in caloric intake (or increases in sedentary activities).[40] An excess intake of 50 kcal/day (eg, an extra pat of butter) produces a weight gain of 5 lb/year. Drinking a can of soda per day produces a weight gain of 15 lb/year.[41] Nearly 40% of children's caloric intake now comes from solid fat and added sugars, and soda or fruit drinks provide nearly 10% of total calories.[42] Because obesity is caused by an imbalance between energy intake and energy expenditure, screen time may contribute in several different ways.

Displacement of More Active Pursuits

Children spend more time with media than in any other activity except for sleeping—an average of more than 7 hours/day.[43] Many studies have found that physical activity decreases as screen time increases,[44–46]but many other studies have not.[47–49] Children and teenagers who use a lot of media may tend to be more sedentary in general,[7,50] or researchers' measures of physical activity may be too imprecise.[9] Nevertheless, increasing physical activity, decreasing media time, and improving nutritional practices have been shown to prevent the onset of obesity, if not decrease existing obesity as well.[51–55] Some of the newer interactive video games may be useful in this way.[56,57] For example, a study of preteens playing *Dance Revolution* and Nintendo's *Wii Sports* found that energy expenditure was equivalent to moderate-intensity walking.[58]

Unhealthy Eating Habits and Effects of Advertising

Children and teenagers who watch more TV tend to consume more calories or eat higher-fat diets,[59–64] drink more sodas,[65] and eat fewer fruits and vegetables.[66] Some researchers have argued that the viewing of TV while eating suppresses cues of satiety, which leads to overeating.[60] Others believe that viewers are primed to choose unhealthy foods as a consequence of viewing advertisements for foods high in fat, salt, and/or sugar and low in nutritional content ("junk food").[61] On any given day, 30% of American youngsters are eating fast food and consuming an additional 187 kcal (equaling 6 lb/year).[67,68] Fast food is big business: Americans spend more than $110 billion annually on it, which is more than that spent on higher education, computers, or cars.[69] A December 2010 study examined 3039 possible meal combinations at a dozen restaurant chains and found only 12 meals that met nutrition criteria for preschoolers. The same study found that 84% of parents had purchased fast food for their children in the previous week.[70] More than 80% of all advertisements in children's programming are for fast foods or snacks,[71–73] and for every hour that children watch TV, they see an estimated 11 food advertisements.[74] Although exposure to food ads has decreased in the past few years for young children,[73] it has increased for adolescents.[75]

In 2009, the fast-food industry alone spent $4.2 billion on advertising in all media.[70] A study of 50 000 ads from 2003–2004 on 170 top-rated shows found that 98% of food ads seen by children aged 2 to 11 years and nearly 90% of food ads seen by teenagers are for products that are high in fat, sugar, and/or sodium and low in nutritional content (junk food).[76] A newer study of 1638 hours of TV and nearly 9000 food

ads found that young people see an average of 12 to 21 food ads per day, for a total of 4400 to 7600 ads per year, yet they see fewer than 165 ads that promote fitness or good nutrition.[77] In 1 study, black children viewed 37% more ads than other youth.[78] New technology is enabling advertisers to reach young children and teenagers with a variety of online interactive techniques.[79–82] A study of the top 5 brands in 8 different food and beverage categories found that all of them had Internet Web sites: 63% had advergames (games used to advertise the product), 50% had cartoon characters, and 58% had a designated children's area.[79] Half of the Web sites urged children to ask their parents to buy the products, yet only 17% contained any nutritional information.[79] Teenagers' cell phones can be targeted by fast-food companies that can offer teenagers a discount on fast food as they walk by a particular restaurant.[81]

Available research results clearly indicate that advertising is effective in getting younger children to request more high-fat/low-nutrition food (junk food) and to attempt to influence their parents.[5,9,83–85] For example, a 2006 study of 827 third-grade children followed for 20 months found that total TV time and total screen media time predicted future requests for advertised foods and drinks.[86] Even brief exposures to TV food ads can influence children as young as preschool age in their food choices.[87] In 1 recent experiment, children consumed 45% more snacks when exposed to food advertising while watching cartoons than advertising for other products.[64] Similarly, children who played an online advergame that marketed healthy foods were more likely to eat healthy snacks than those who played an online advergame that advertised junk food.[82] Perhaps the most convincing study about the impact of advertising involved 63 children who tasted 5 pairs of identical foods (eg, French fries) and beverages (eg, milk) from unbranded packaging versus branded packaging. The results of the experiment revealed that the children strongly preferred the branded food and drinks to the unbranded foods.[88]

To illustrate the power of marketing, compare the commitment of the Robert Wood Johnson Foundation to spend $100 million per year to try to decrease childhood obesity with the fact that the food industry spends more than that every month marketing primarily junk food and fast food to young people.[84,89]

Food is also unhealthily portrayed in most TV programming and movies.[9,84,90,91] A study of the 30 highest-rated programs among 2- to 5-year-olds found that an average child would see more than 500 food references per week, half of which were to empty-calorie or high-fat/sugar/salt foods (D. L. G. Borzekowski, EdD, "Watching What They Eat: A Content Analysis of Televised Food References Reaching Preschool Children," unpublished manuscript, 2001). In an analysis of 100 films from 1991 through 2000, fats and sweets were the most common foods depicted.[91] Hollywood product placements are also being used to influence the food preferences and purchasing patterns of children and adolescents.[92,93] In the 200 movies examined from 1996 to 2005, a total of 1180 brand placements were identified. Candy (26%) and salty snacks (21%) were the most prevalent food brands, sugar-sweetened beverages (76%) were the most prevalent beverage brands, and fast food composed two-thirds of the food retail establishment brand placements.[93]

Effect of Media on Sleep Habits

TV and other media are known to displace or disturb young people's sleep patterns.[5,94,95] A longitudinal study of adolescents in New York found that viewing 3 or more hours/day of TV doubled the risk of difficulty falling asleep compared with adolescents who watch less than 1 hour/day.[96] There is also now evidence that later bedtimes and less sleep may be associated with a greater risk of obesity.[97–101] The mechanism may be that sleep loss leads to increased snacking and consumption of less healthy foods to maintain energy,[102,103] that sleep deprivation leads to fatigue and therefore greater sedentary behavior,[104] or that children who do not get enough sleep have metabolic changes as well.[105]

Stress may also play a role, although there are only a handful of studies that have studied this subject so far. For example, a Scottish study of nearly 1500 4- to 12-year-olds found that heavier TV use produced greater psychological stress in children and that this effect was independent of, but exacerbated by, decreases in exercise.[106]

CONCLUSIONS

Media clearly play an important role in the current epidemic of childhood and adolescent obesity. The sheer number of advertisements that children and adolescents see for junk food and fast food have an effect. So, too, does the shift away from good nutritional practices that increased media screen time seems to create. Any success in dealing with the current epidemic will require a major change in society's recognition of media exposure as a major risk factor for obesity and in young people's media habits and the advertisements to which they are exposed.[107,108]

RECOMMENDATIONS

1. Pediatricians should ask parents and patients 2 key questions about media use: (1) How much time per day does the child or teenager spend with screen media? and (2) Is there a TV set or unrestricted,

unmonitored Internet connection throughout the house, including in the child's bedroom?[109] This recommendation should be incorporated into every well-child visit, as outlined in *Bright Futures*.[110]

2. Pediatricians should encourage parents to discuss food advertising with their children as they monitor children's TV-viewing and teach their children about appropriate nutrition.[111–113]
3. Pediatricians should continue to counsel parents to limit total noneducational screen time to no more than 2 hours/day, to avoid putting TV sets and Internet connections in children's bedrooms, to coview with their children, to limit nighttime screen media use to improve children's sleep, and to try strongly to avoid screen exposure for infants under the age of 2 years. In a recent study of 709 7- to 12-year-olds, children who did not adhere to the American Academy of Pediatrics guidelines of less than 2 hours/day of screen time[114] and 11 000 to 13 000 pedometer steps per day were 3 to 4 times more likely to be overweight.[115] Conversely, preschool-aged children who ate dinner with their parents, got adequate sleep, and had limited screen-time hours had a 40% lower prevalence of obesity than those exposed to none of these routines.[116]
4. Pediatricians should work with community groups and schools to implement media education programs in child care centers, schools, and community-based programs such as the YMCA. Such programs that teach children how to understand and interpret advertisements may have the potential to immunize young people against harmful media effects.[117] In addition, programs that educate parents about limiting media use in general have already been shown to be highly effective.[8,38,39,118,119] Pediatricians should work with their state chapters, the AAP, parent and public health groups, and the White House[120] to do the following:

- Ask Congress, the Federal Trade Commission, and the Federal Communications Commission to implement a ban on junk-food advertising during programming that is viewed predominantly by young children.[84,121,122] Currently, several European countries restrict food advertising aimed at young children.[123] Several food manufacturers have already indicated a willingness to implement such a ban voluntarily,[124,125] but it remains to be seen whether they will follow through.[126–128] For example, children's cereals remain considerably unhealthier than adult cereals; they contain 85% more sugar, 65% less fiber, and 60% more sodium.[129] One-quarter of all food and beverage advertising originates from companies that do not participate in the initiative, and two-thirds of all advertising by companies that do participate is still for food and beverages of low nutritional value.[85] In addition, the food and beverage industry remains steadfastly opposed to any regulation. For example, in 2007, 1 soft drink company spent more than $1.7 million to lobby against marketing restrictions and school nutrition legislation.[130] Two recent studies showed that a ban on fast-food ads would reduce the number of overweight children and adolescents in the United States by an estimated 14% to 18%.[131,132] Just eliminating federal tax deductions for fast-food ads that target children would reduce childhood obesity by 5% to 7%.[131] On the other hand, advertisements and public service announcements for health foods and healthy nutritional practices should be encouraged. One recent experiment showed that children exposed to attractive advertisements for healthy foods develop significantly more positive attitudes than children shown junk-food ads.[133]
- Ask Congress and the Federal Communications Commission to prohibit interactive advertising involving junk food or fast food to children via digital TV, cell phones, and other media[79–81,121] and to ban payments for product placement in movies. Restoring power to the Federal Trade Commission to more tightly regulate children's advertising could be another way of accomplishing this goal.[84,134,135]
- Ask Congress to fund media research (eg, the Children Media Research and Advancement Act [CAMRA]). More research is specifically needed to determine (1) how heavy media use in children reflects or contributes to psychosocial elements of the child's life, such as stress in the home, (2) how new media technologies may be playing a role in exacerbating exposure to ads or encouraging more sedentary behavior, and (3) which of the above-mentioned mechanisms is most responsible for contributing to obesity and how such mechanisms can be ameliorated.[83,134]
- Encourage the production of more counteradvertising and more prosocial video games[136,137] and Web sites that encourage

children to choose healthy foods.[82]

6. Pediatricians should be aware that children with high levels of screen time have higher levels of childhood stress, which puts them at risk not only for obesity but also for a number of stress-associated morbidities (eg, mood disorders, substance abuse, diabetes, cardiovascular disease, asthma).[138] Consequently, displacing screen time with more prosocial or resilience-building activities (eg, exercise, imaginative or social play) is an important approach to addressing a wide array of societal ills including obesity.[139]

LEAD AUTHOR

Victor C. Strasburger, MD

COUNCIL ON COMMUNICATIONS AND MEDIA, 2010–2011

Deborah Ann Mulligan, MD, Chairperson
Tanya Remer Altmann, MD
Ari Brown, MD
Dimitri A. Christakis, MD
Kathleen Clarke-Pearson, MD
Holly Lee Falik, MD
David L. Hill, MD
Marjorie J. Hogan, MD
Alanna Estin Levine, MD
Kathleen G. Nelson, MD

abstract

The causes of adolescent substance use are multifactorial, but the media can play a key role. Tobacco and alcohol represent the 2 most significant drug threats to adolescents. More than $25 billion per year is spent on advertising for tobacco, alcohol, and prescription drugs, and such advertising has been shown to be effective. Digital media are increasingly being used to advertise drugs. In addition, exposure to PG-13– and R-rated movies at an early age may be a major factor in the onset of adolescent tobacco and alcohol use. The American Academy of Pediatrics recommends a ban on all tobacco advertising in all media, limitations on alcohol advertising, avoiding exposure of young children to substance-related (tobacco, alcohol, prescription drugs, illegal drugs) content on television and in PG-13– and R-rated movies, incorporating the topic of advertising and media into all substance abuse–prevention programs, and implementing media education programs in the classroom. *Pediatrics* 2010;126:791–799

INTRODUCTION

Although parents, schools, and the federal government are trying to get children and teenagers to "just say no" to drugs, more than $25 billion worth of cigarette, alcohol, and prescription drug advertising is effectively working to get them to "just say yes" to smoking, drinking, and other drugs.[1,2] In addition, television programs and movies contain appreciable amounts of substance use. Unlike traditional advertising, media depictions of legal drugs are generally positive and invite no criticism, because they are not viewed as advertising.[3] The result is that young people receive mixed messages about substance use, and the media contribute significantly to the risk that young people will engage in substance use.

ADOLESCENT DRUG USE

Although illegal drugs take their toll on American society, 2 legal drugs—alcohol and tobacco—pose perhaps the greatest danger to children and teenagers. Both represent significant gateway drugs and are among the earliest drugs used by children or teenagers. A preadolescent or adolescent who smokes tobacco or drinks alcohol is 65 times more likely to use marijuana, for example, than someone who abstains.[4] The younger the age at which experimentation occurs, the greater the risk of serious health problems.[5] Every year, more than 400 000 Americans die from illnesses directly related to cigarette use—more than from AIDS, car crashes, murder, and suicide combined.[6] More than 100 000 deaths annually can be attributed to exces-

sive alcohol consumption,[7] including the death of 5000 people younger than 21 years.[8] Drug use also represents one of many risky behaviors that occur during adolescence: teenagers who report that at least half of their friends are sexually active are 31 times more likely to drink, 5 times more likely to smoke, and 22 times more likely to try marijuana than are teenagers who do not report such a high prevalence of sexual activity among friends.[9]

EFFECTS OF ADVERTISING

The power of advertising to influence children and adolescents (and adults, for that matter) is incontrovertible.[1,10] Advertising works; otherwise, companies would not spend billions of dollars on it.[1] Many ads use celebrity endorsers, humor, rock music, or attractive young models, all of which have been shown to be effective with children and adolescents.[11] Advertising makes smoking and drinking seem like normative activities and may function as a "superpeer" in subtly pressuring teenagers to experiment.[12] Research has revealed that advertising may be responsible for up to 30% of adolescent tobacco and alcohol use.[13,14]

Cigarettes

More money is spent advertising tobacco than any drug—an estimated $15 billion per year,[15] almost half of what the National Institutes of Health spends each year to study all aspects of health (www.nih.gov/about/budget.htm). The tobacco industry (often referred to as "Big Tobacco") has engaged in a systematic campaign to attract underage smokers for decades and then lied to Congress about it.[16–19] Given the demographics of smoking (1200 deaths per day, half of which are of middle-aged adults; 50% of smokers begin by 13 years of age, and 90% of smokers begin by 19 years of age), the industry must recruit young people as smokers.[20] Recent statistics show that they continue to succeed. According to the 2009 Monitoring the Future study, nearly half of all teenagers have tried smoking, as have 20% of all 8th-graders.[21] Cigarette advertising seems to increase teenagers' risk of smoking by glamorizing smoking and smokers.[3,20] Smokers are depicted as young, independent, rebellious, healthy, and adventurous. By contrast, the adverse consequences of smoking are never shown. As a result, the US Surgeon General concluded in 1994 that cigarette advertising increases young people's risk of smoking.[20]

The most heavily advertised brands of cigarettes are also the most popular.[22] Tobacco advertising may even trump strong parenting practices.[23] Teen magazines have attracted an increasing number of cigarette ads since 1965.[24–26] Numerous studies have revealed that children or teenagers who pay closer attention to cigarette ads, who are able to recall such ads more easily, or who own promotional items are more likely to become smokers themselves.[27–31] Joe Camel single-handedly increased the market share for Camel cigarettes from 0.5% of adolescent smokers to 32%.[32] A recent meta-analysis of 51 separate studies revealed that exposure to tobacco marketing and advertising more than doubles the risk of a teenager beginning to smoke.[33]

Alcohol

Approximately $6 billion is spent annually on alcohol advertising and promotion.[34] Similar to tobacco ads, beer commercials are virtually custom-made to appeal to children and adolescents, using images of fun-loving, sexy, successful young people having the time of their lives.[3,35,36] Unlike tobacco advertising, alcohol advertising faces few restrictions. For example, whereas the tobacco industry gave up television advertising in the 1960s, beer, wine, and liquor ads are frequently featured on prime-time television, and young people view 1000 to 2000 alcohol ads annually.[12,37] Much of the advertising is concentrated during teen-oriented shows and sports programming. All of the top-15 teen-oriented shows contain alcohol ads.[38] Currently, teenagers are 400 times more likely to see an alcohol ad than to see a public service announcement (PSA) that discourages underage drinking.[39] Teen-oriented magazines contain 48% more advertising for beer, 20% more advertising for hard liquor, and 92% more advertising for sweet alcoholic drinks than do magazines aimed at adults of legal drinking age.[40,41]

According to the research, the effects of all of this advertising are increasingly clear.[3,42,43] A sample of 9- to 10-year-olds could identify the Budweiser frogs nearly as frequently as they could Bugs Bunny.[44] In a study of more than 3500 South Dakota students, 75% of 4th-graders and nearly 90% of 9th-graders recognized the Budweiser ferret ad.[45] Many studies have revealed that exposure to alcohol advertising results in more positive beliefs about drinking and is predictive of drinking during early adolescence and young adulthood.[46–52] The results of several longitudinal studies have shown a similar trend,[53,54] although they have sometimes been mixed.[48]

Prescription Drugs

Nearly $4 billion is spent annually on prescription drug advertising.[55] Drug companies now spend more than twice as much money on marketing as they do on research and development, and studies have revealed that the marketing efforts pay off[56]: results of a recent survey of physicians showed that 92% of patients had requested an advertised drug.[57] Children and teenagers get the message that there is a pill to cure all ills and a drug for every

occasion, including sexual intercourse. In the first 10 months of 2004, drugs companies spent nearly half a billion dollars advertising Viagra, Levitra, and Cialis.[58] Yet, the advertising of condoms, birth control pills, and emergency contraception is haphazard and rare and remains controversial.[1,59]

DRUGS IN ENTERTAINMENT MEDIA

Cigarettes

Scenes with smoking remain common in movies and, to a lesser extent, on prime-time television. Hollywood seems to use smoking as a shorthand for troubled or antiestablishment characters, but the smoking status of the actors themselves is also influential in whether their characters will smoke on-screen.[60] On prime-time television, 19% of shows portray tobacco use, and approximately one-fourth of them depict negative statements about smoking.[61] In addition, smoking is also found in nearly one-fourth of all music videos,[62] one-fourth of ads for R-rated movies, and 7.5% of ads for PG-13 and PG movies.[63]

Box-office movies and their subsequent video and pay-per-view distribution have become a major route of exposure to tobacco use. Although the most recent analyses show that smoking has decreased in popular movies,[64,65] the occurrence remains high. A content analysis of the top 100 box-office hits between 1996 and 2004 revealed that tobacco use was depicted in three-quarters of G-, PG-, and PG-13–rated movies and in 90% of R-rated movies.[66] Half of all G-rated animated films between 1937 and 1997 contained tobacco use.[67] Although the most recent content analysis of top-grossing movies between 1991 and 2009 showed that tobacco use peaked in 2003 and has since declined, in 2009, more than half of PG-13 movies still contained tobacco use.[65] But overall, the percentage of all top-grossing movies without smoking exceeded 50% for the first time in 2009.[65]

Unique longitudinal research has revealed that one of the most important factors in the onset of adolescent substance use is exposure to others who use drugs.[68] Nowhere is that exposure greater than on contemporary movie screens, and teenagers constitute 26% of the movie-going audience (but only 16% of the US population).[69] Results of a number of correlational and longitudinal studies have confirmed that exposure to television and movie smoking is now one of the key factors that prompt teenagers to smoke.[29,70–77] According to a new meta-analysis, it may account for nearly half of smoking initiation in young teenagers.[80] In fact, exposure to movie smoking may even trump parents' smoking status as being the key factor in adolescents' initiation of smoking.[73] A prospective study of more than 3500 teenagers revealed that exposure to R-rated movies doubles the risk of smoking, even when controlling for all other known factors.[79] Preadolescents whose parents forbid them from seeing R-rated movies are less likely to begin smoking (or drinking).[80] A study of 735 12- to 14-year-olds, with a 2-year follow-up, revealed that exposure to R-rated movies or having a television in the bedroom significantly increased the risk of smoking initiation for white teenagers.[81] The movie effect seems not to be confined to US teenagers but applies also to teenagers from other countries as well.[82,83]

Alcohol

Alcohol remains the number one drug portrayed on American television: 1 drinking scene is shown every 22 minutes, compared with 1 smoking scene every 57 minutes and 1 illicit drug use scene every 112 minutes.[84] On Music Television (MTV), teenagers can see alcohol use every 14 minutes. An analysis revealed that drugs were present in nearly half of 359 music videos—alcohol in 35%, tobacco in 10%, and illicit drugs in 13%.[85] On prime-time television, 70% of programs depict alcohol use.[61] More than one-third of the drinking scenes are humorous, and negative consequences are shown in only 23%. One study revealed that alcohol portrayals are as common on shows for 9- to 14-year-olds as on adult-oriented shows.[86] In popular music, the average teenager is exposed to nearly 85 drug references a day, the majority of which are for alcohol.[87] Popular movies are nearly equally rife with alcohol, with only 2 of the 40 highest-grossing movies not containing alcohol depictions.[88] Even G- and PG-rated movies contain frequent references to alcohol.[89,90] And, drinking is frequently depicted as normative behavior, even for teenagers.[91]

Again, the impact is increasingly clear from the research. A longitudinal study of more than 1500 California 9th-graders revealed that increased television and music video viewing was a risk factor for the onset of alcohol use among adolescents.[92] Results of a Columbia University study showed that teenagers who watch more than 3 R-rated films per month are 5 times more likely to drink alcohol compared with teenagers who watch none.[93] Also, in an intriguing study of 2- to 6-year-olds ($n = 120$) who were asked to role-play in a make-believe store, children were 5 times more likely to "buy" beer or wine if they had been allowed to see PG-13 or R-rated movies.[94] Finally, good longitudinal evidence is emerging to indicate that watching more movie depictions of alcohol is strongly predictive of drinking onset and binge drinking in US adolescents,[86,95,96] and the same results are being found for adolescents from other countries.[82,97]

Illegal Drugs

Illicit drugs are rarely seen on television,[61] with the exception of programs such as Showtime's *Weeds* and Fox's *That 70s Show*. Drug scenes are more common in movies (22% of the movies in 1 study contained drug scenes), and no harmful consequences are shown more than half of the time.[90] Marijuana is the most frequent drug seen in movies and seems to be making a comeback in R-rated movies such as *Harold and Kumar Go to White Castle* (2004) and *The Pineapple Express* (2008).[98] A Columbia study revealed that viewing R-rated movies was associated with a sixfold increased risk of trying marijuana.[93] Hollywood filmmakers do not seem to understand that humor tends to undermine normal adolescent defenses against drugs and legitimizes their use.[3] Increased consumption of popular music is also associated with marijuana use.[95,99]

NEW MEDIA

The new technologies—the Internet, social networking sites, and even cellular phones—offer new and problematic opportunities for adolescent drug exposure.[3,100] A variety of Web sites sell tobacco products, and few of them have effective age-verification procedures.[3,101] One national survey of more than 1000 youths 14 to 20 years of age revealed that 2% reported having purchased alcohol online, and 12% reported having a friend who did so.[102] Prescription drugs can also be purchased online with minimal difficulty. Popular beer brands use "advergames" online to entice a younger audience.[103] Teenagers also see considerable alcohol and drug content in online videos[104] and on social networking sites,[105] on which 1 study revealed that 40% of profiles referenced substance abuse.[106]

SUMMARY

The so-called war on drugs has been waged for decades, yet teenagers continue to use and abuse a variety of substances, especially tobacco and alcohol. The contribution of the media to adolescent substance use is only recently becoming fully recognized and appreciated. The Master Settlement Agreement has greatly restricted tobacco marketing by the tobacco companies that signed the agreement. However, tobacco continues to appear frequently in movies, and this fact contrasts markedly with US reality (approximately half of the US population lives in a community with restrictions on indoor smoking). Moreover, the case is strong for the argument that smoking shown in entertainment media plays a causal role in smoking onset. Certainly, it is time to eliminate all tobacco advertising and to decrease greatly the depiction of smoking in mainstream media. Because alcohol use is still condoned in many venues and use in moderation may be healthful for adults, such severe restrictions on alcohol advertising and programming may not be indicated. On the other hand, underage alcohol use does pose a clear and immediate threat to the teenagers who use it. Taken together, the evidence supports strong actions aimed at the entertainment industry about media depictions of tobacco use and strong actions aimed at motivating and assisting parents of children and young teenagers to restrict access to adult media venues with excessive substance use exposure.

Anticipatory Guidance by Pediatricians

1. Pediatricians should encourage parents to limit unsupervised media use and especially encourage removal of televisions from children's bedrooms. At every well-child visit, pediatricians should be asking at least 2 questions regarding media use: (*a*) How much entertainment media per day is the child or adolescent watching? and (*b*) Is there a television set or Internet access in the child's or adolescent's bedroom?[107] Research has revealed that having a television in the bedroom is associated with greater substance use and sexual activity in teenagers.[108]
2. Pediatricians should encourage parents to limit access by children and young adolescents to television venues with excessive substance use depictions (eg, MTV, HBO, Showtime, Comedy Central).
3. Pediatricians should encourage parents to limit younger children's exposure to PG-13 movies and avoid R-rated movies.[29,75–81,109]
4. Pediatricians should encourage parents to co-view media with their children and teenagers and discuss the content being viewed.
5. Pediatricians should encourage parents to turn off the television during evening meals.
6. Pediatricians should ensure that their waiting rooms are free of magazines that accept cigarette and alcohol advertising.

Community Advocacy by Pediatricians

7. Pediatricians should encourage their local school systems to incorporate media education into their curricula. In particular, drug-prevention programs should use basic principles of media literacy, designed to imbue skepticism toward media advertising. Currently, Drug Abuse Resistance Education (DARE) does not accomplish this goal, nor is there any evidence that DARE is effective.[12,110] More psychologically sophisticated drug-prevention cur-

ricula are available and should be used.[110–113]

Legislative Advocacy by Pediatricians

8. Pediatricians should encourage Congress to ban tobacco advertising in all media accessible to children, which several European countries have already done. Such a ban would seem to be constitutional, given that the US Supreme Court has already ruled that commercial speech does not enjoy the absolute First Amendment protections that free speech does.[114] Recently, Congress gave the Food and Drug Administration the authority to regulate tobacco products; however, the tobacco industry is expected to challenge any advertising bans.[115,116]
9. Pediatricians should encourage Congress to require the alcohol industry to report its annual expenditures to the Federal Trade Commission, including expenditures for media venues in which children and adolescents represent more than 10% of the market share (currently, voluntary advertising restrictions allow for venues in which up to 30% of the audience is children).
10. Pediatricians should encourage the alcohol industry to restrict advertising and product placement in venues in which more than 10% of the audience is children and adolescents.
11. Pediatricians should encourage the White House Office of National Drug Control Policy to begin conducting antismoking and anti–teen-drinking public service campaigns, including strong antismoking and antidrinking ads to be placed before television programming and movies that have youth ratings and contain alcohol and tobacco depictions.
12. Pediatricians should encourage allocation of more money in media research, given the importance of the media on the development and behavior of children and adolescents. Higher taxes on tobacco products and alcohol could be used to fund such research.
13. Pediatricians should encourage Congress to pass new strict laws regulating digital advertising that targets children and adolescents.[100,117]

Involvement of the Alcoholic Beverage, Tobacco, Drug, and Entertainment Industries in Encouraging Responsible Behavior

14. Pediatricians should encourage the advertising industry, drug companies, public health groups, and medical groups to have a full and open debate on the necessity of advertising prescription drugs. In addition, ads for erectile dysfunction drugs should be confined to after 10 PM in all time zones and should not be overly suggestive.[1]
15. Pediatricians should encourage the entertainment industry to have greater sensitivity about the effects of television and movies on children and adolescents and accept that the industry does, indeed, have a public health responsibility.[118] Cigarette smoking in movies should be avoided at all costs and should never be glamorized.[119,120] Disney has already promised to eliminate smoking in its movies.[121] Making film sets smoke-free zones would go far to diminish the portrayal of smoking in movies and would protect actors and actresses from secondhand smoke. Antismoking ads should precede the showing of any film that has tobacco use depicted.[119] Alcohol use should not be portrayed as normative behavior for teenagers, and the traditional depiction of the "funny drunk" should be retired. Television networks that have a large adolescent viewership should air public service ads about the dangers of smoking and drinking. Finally, the Motion Picture Association of America (MPAA) ratings need to be amended so that tobacco use will routinely garner an R rating in all new movies unless the risks and consequences of smoking are unambiguously shown or the depiction is necessary to represent a real historical figure who actually used tobacco.[119] So far, the MPAA has only agreed to consider smoking as a factor in assigning a rating.[122,123]
16. Pediatricians should encourage state and federal agencies, the entertainment industry, and the advertising industry to develop and maintain vigorous anti–drug-advertising campaigns that focus on the 2 drugs most dangerous to adolescents—tobacco and alcohol—in addition to illegal drugs. Antidrug ads have been shown to be highly effective at times (eg, the Truth campaign),[124–129] but the effectiveness of the National Youth Anti-Drug Media Campaign has been questioned.[130] Recently, and laudably, 6 major Hollywood studios have agreed to place antismoking ads on new movie DVDs that appeal to children.[131,132]
17. Pediatricians should work with and support the American Academy of Pediatrics Julius Richmond Center of Excellence (www.aap.org/richmondcenter), the mission of which is "to improve child health by eliminating children's exposure to tobacco and secondhand smoke," including through media exposure.[119]

AMERICAN ACADEMY OF PEDIATRICS

Committee on Public Education

Children, Adolescents, and Television

ABSTRACT. This statement describes the possible negative health effects of television viewing on children and adolescents, such as violent or aggressive behavior, substance use, sexual activity, obesity, poor body image, and decreased school performance. In addition to the television ratings system and the v-chip (electronic device to block programming), media education is an effective approach to mitigating these potential problems. The American Academy of Pediatrics offers a list of recommendations on this issue for pediatricians and for parents, the federal government, and the entertainment industry.

ABBREVIATIONS. AAP, American Academy of Pediatrics; MTV, Music Television; E/I, educational/informational.

For the past 15 years, the American Academy of Pediatrics (AAP) has expressed its concerns about the amount of time children and adolescents spend viewing television and the content of what they view.[1] According to recent Nielsen Media Research data, the average child or adolescent watches an average of nearly 3 hours of television per day.[2] This figure does not include time spent watching videotapes or playing video games[3] (a 1999 study found that children spend an average of 6 hours 32 minutes per day with various media combined).[4] By the time the average person reaches age 70, he or she will have spent the equivalent of 7 to 10 years watching television.[5] One recent study found that 32% of 2- to 7-year-olds and 65% of 8- to 18-year-olds have television sets in their bedrooms.[4] Time spent with various media may displace other more active and meaningful pursuits, such as reading, exercising, or playing with friends.

Although there are potential benefits from viewing some television shows, such as the promotion of positive aspects of social behavior (eg, sharing, manners, and cooperation), many negative health effects also can result. Children and adolescents are particularly vulnerable to the messages conveyed through television, which influence their perceptions and behaviors.[6] Many younger children cannot discriminate between what they see and what is real. Research has shown primary negative health effects on violence and aggressive behavior[7–12]; sexuality[7,13–15]; academic performance[16]; body concept and self-image[17–19]; nutrition, dieting, and obesity[17,20,21]; and substance use and abuse patterns.[7]

In the scientific literature on media violence, the connection of media violence to real-life aggressive behavior and violence has been substantiated.[8–12] As much as 10% to 20% of real-life violence may be attributable to media violence.[22] The recently completed 3-year National Television Violence Study found the following: 1) nearly two thirds of all programming contains violence; 2) children's shows contain the most violence; 3) portrayals of violence are usually glamorized; and 4) perpetrators often go unpunished.[23] A recent comprehensive analysis of music videos found that nearly one fourth of all Music Television (MTV) videos portray overt violence and depict weapon carrying.[24] Research has shown that even television news can traumatize children or lead to nightmares.[25] In a random survey of parents with children in kindergarten through sixth grade, 37% reported that their child had been frightened or upset by a television story in the preceding year.[26]

According to a recent content analysis, mainstream television programming contains large numbers of references to cigarettes, alcohol, and illicit drugs.[27] One fourth of all MTV videos contain alcohol or tobacco use.[28] A longitudinal study found a positive correlation between television and music video viewing and alcohol consumption among teens.[29] Finally, content analyses show that children and teenagers continue to be bombarded with sexual imagery and innuendoes in programming and advertising.[14,30,31] To date, there are no data available to substantiate the behavioral impact of this exposure.[31]

The new television ratings system and the v-chip are tools that can help protect children from potentially harmful content. All new television sets with screens measuring 13 inches or greater contain a v-chip that enables parents to program televisions to block out any shows that they deem inappropriate for their children.[32] To block out television shows, parents must use the television ratings system, which has age and content descriptors for violence, sexual situations, suggestive dialogue, and adult language. Although the ratings system and the v-chip can assist parents, ongoing evaluation is necessary to ensure that these tools are as effective as possible.[33–35] For example, the ratings should be applied uniformly and listed in television guides, newspapers, and journals so parents know what they mean.

Besides the v-chip, there are other means of protecting children from what is on television. Evidence

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

now shows that media education can help mitigate the harmful effects of media violence[36–40] and alcohol advertising[41,42] on children and adolescents. Media education programs have been included in the school curricula beginning in early elementary school in many states across the United States.[43]

Furthermore, continued support of the Children's Television Act of 1990[44] and additional regulations made in 1996[45] will help to ensure the airing of television programs specifically designated for children. The act requires broadcasters to air educational and informational programming for children at least 3 hours per week and to limit the amount of advertising time allowed during children's programming. The shows must be labeled E/I (for educational and informational) on the television screen.

RECOMMENDATIONS

The following recommendations are given for pediatricians and other health care professionals:

1. Remain knowledgeable about the effects of television, including violent and aggressive behavior, obesity, poor body concept and self-image, substance use, and early sexual activity, by becoming involved in the AAP *Media Matters* campaign.[46] Educate patients and their parents about these effects.
2. Use the AAP *Media History* form[46] to help parents recognize the extent of their children's media consumption.
3. Work with local schools to implement comprehensive media-education programs that deal with important public health issues.[36]
4. Serve as good role models by using television appropriately and by implementing reading programs using volunteer readers in waiting rooms and hospital inpatient units.
5. Become involved in the AAP's Media Resource Team (contact the Division of Public Education), and learn how to work effectively with writers, directors, and producers to make media more appropriate for children and adolescents. Contact networks and producers of television programs with concerns about the content of specific shows and episodes.
6. Ensure that appropriate entertainment options are available for hospitalized children and adolescents. Work with child life staff to assemble a screening committee that selects programs for closed circuit broadcast or a video library. Develop institution-specific, formal guidelines based on the established ratings system (which takes profanity, sex, and violence into account), and screen for content containing ethnic and sex role stereotyping. Considerations should also be made to avoid themes hospitalized children might find upsetting, and efforts should be made to enforce the ratings system in the hospital setting.
7. Support the Children's Television Act of 1990 and its 1996 rules by working to ensure that local television stations are in compliance with the act and by urging local newspapers to list ratings and E/I denotations of programs.
8. Monitor the television ratings system for appropriateness and advocate for substantive, content-based ratings in the future.

Pediatricians should recommend the following guidelines for parents:

1. Limit children's total media time (with entertainment media) to no more than 1 to 2 hours of quality programming per day.
2. Remove television sets from children's bedrooms.
3. Discourage television viewing for children younger than 2 years, and encourage more interactive activities that will promote proper brain development, such as talking, playing, singing, and reading together.
4. Monitor the shows children and adolescents are viewing. Most programs should be informational, educational, and nonviolent.
5. View television programs along with children, and discuss the content. Two recent surveys involving a total of nearly 1500 parents found that less than half of parents reported always watching television with their children.[5,47]
6. Use controversial programming as a stepping-off point to initiate discussions about family values, violence, sex and sexuality, and drugs.
7. Use the videocassette recorder wisely to show or record high-quality, educational programming for children.
8. Support efforts to establish comprehensive media-education programs in schools.
9. Encourage alternative entertainment for children, including reading, athletics, hobbies, and creative play.

Pediatricians should lead efforts in their communities to do the following:

1. Form coalitions including libraries, religious organizations, and other community groups to broaden media education beyond the schools.
2. Organize activities promoting media education, such as letter-writing campaigns to local television stations to advocate for better programming for children, and developing local TV turnoff week projects.[48]

Pediatricians should work with the Academy and local chapters to challenge the federal government to do the following:

1. Initiate legislation and rules that would ban alcohol advertising from television.
2. Fund ongoing annual research, such as the National Television Violence Study, and fund more research on the effects of television on children and adolescents, particularly in the area of sex and sexuality.
3. Assemble a *National Institutes of Health Comprehensive Report on Children, Adolescents, and Media* that would bring together all of the current relevant research.
4. Work with the US Department of Education to support the creation and implementation of media-education curricula for school children.

Pediatricians should work with the Academy and local chapters to challenge the entertainment industry to do the following:

1. Take responsibility for the programming it produces.
2. Adhere to the current television ratings system, and label programs conscientiously.
3. Collaborate with other public health advocates to convene a series of seminars with writers, directors, and producers to discuss ways to make media more appropriate for children and adolescents.
4. Produce more educational programming for children and adolescents, and ensure that the programming it produces is of higher quality, with less content that is gratuitously violent, sexually suggestive, or drug oriented.

ADDENDUM

A policy statement on "Developmental Anomalies of the External Genitalia in the Newborn" has recently been published (*Pediatrics*. 2000;106:138–142). The purpose of this review is to identify which newborns among those with abnormal genital development need to be screened for intersexuality, to outline the investigations necessary, and to suggest indications for referral to a center with experience in the diagnosis and management of these disorders.

The 1996 policy on Timing of Elective Surgery states that "children whose genetic sexes are not clearly reflected in external genitalia (ie, hermaphroditism) can be raised successfully as members of either sex if the process begins before the age of 2 years" [see the heading under Body Image and Sexual Development]. The 2000 policy on Developmental Anomalies of the External Genitalia acknowledges the considerable recent debate about the appropriate gender assignment of newborns with the most extreme forms of genital ambiguity, and notes that some have suggested that the current early surgical treatment be abandoned in favor of allowing the affected person to participate in gender assignment at a later time.

This controversy about gender reassignment does not invalidate the other recommendations about the timing of elective surgery on the genitalia of male children with particular reference to the risks, benefits, and psychological effects of surgery and anesthesia that are present in the 1996 statement.

Policy Statement—Children as Hematopoietic Stem Cell Donors

abstract

In the past half-century, hematopoietic stem cell transplantation has become standard treatment for a variety of diseases in children and adults, including selected hematologic malignancies, immunodeficiencies, hemoglobinopathies, bone marrow failure syndromes, and congenital metabolic disorders. There are 3 sources of allogeneic hematopoietic stem cells: bone marrow, peripheral blood, and umbilical cord blood; each has its own benefits and risks. Children often serve as hematopoietic stem cell donors, most commonly for their siblings. HLA-matched biological siblings are generally preferred as donors because of reduced risks of transplant-related complications as compared with unrelated donors. This statement includes a discussion of the ethical considerations regarding minors serving as stem cell donors, using the traditional benefit/burden calculation from the perspectives of both the donor and the recipient. The statement also includes an examination of the circumstances under which a minor may ethically participate as a hematopoietic stem cell donor, how the risks can be minimized, what the informed-consent process should entail, the role for a donor advocate (or some similar mechanism), and other ethical concerns. The American Academy of Pediatrics holds that minors can ethically serve as stem cell donors when specific criteria are fulfilled. *Pediatrics* 2010;125:392–404

INTRODUCTION

In the past half-century, allogeneic hematopoietic stem cell transplantation (HSCT) has become standard treatment for a variety of conditions in children and adults, including selected hematologic malignancies, immunodeficiencies, hemoglobinopathies, bone marrow failure syndromes, and congenital metabolic disorders. There are 3 sources of allogeneic hematopoietic stem cells: bone marrow, peripheral blood, and umbilical cord blood.

The ideal allogeneic hematopoietic donor matches the recipient at the major HLA sites; that is, the donor and recipient are identical at the major histocompatibility complex sites. HLA-matched biological siblings are generally preferred as donors by physicians who perform transplants because of reduced risks of graft-versus-host disease (GVHD) and other transplant-related complications as compared with unrelated donors.[1–3]

When an HLA-matched sibling is not available, those in need of HSCT sometimes cannot find an HLA-matched donor despite the listing of more than 7 million living adult persons on the National Marrow Donor

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Program registry and 6 million additional donors and cord blood units in other registries around the world.[4] This is particularly true for members of ethnic minority groups.[5–7]

When the potential recipient is a child, potential sibling donors may be children themselves. In rare cases, children may also be considered as potential donors for an adult sibling, parent, or other family member.

The American Academy of Pediatrics (AAP) believes that minors can ethically participate as hematopoietic stem cell donors. This statement includes a discussion of the ethical considerations regarding minors serving as stem cell donors using the traditional benefit/burden calculation from the perspectives of both the donor and the recipient. This statement also includes an examination of the circumstances under which a minor can ethically participate as a hematopoietic stem cell donor, how the risks can be minimized, what the informed-consent process should entail, and other ethical concerns.

SOURCES OF HEMATOPOIETIC STEM CELLS

The first successful bone marrow transplant occurred in 1963.[8] The patient was a 26-year-old physician with relapsed acute lymphoblastic leukemia that was refractory to chemotherapy. He received bone marrow from 6 family members, although it was shown that his bone marrow was mainly repopulated by cells from 1 brother, with some female cells present. The first successful pediatric bone marrow transplants occurred 5 years later in 1968 for children with severe combined immunodeficiency (SCID) and Wiskott-Aldrich diseases.[9,10] In 1973, the first successful unrelated bone marrow transplant for a 5-year-old with SCID was performed in the United States with an adult European donor.[11]

Gianni et al[12] described the collection of peripheral blood stem cells using granulocyte colony-stimulating factor (G-CSF), a growth factor that stimulates mobilization of bone marrow stem cells into the peripheral blood, in 1989. G-CSF–mobilized peripheral blood stem cells were first used for autologous transplantation; their use was subsequently expanded to include allogeneic transplantation.[13] More recently, some adult bone marrow donors have received G-CSF because stimulated bone marrow is richer in stem cells and, therefore, induces a quicker engraftment.[14–16] Experience with G-CSF–mobilized bone marrow in pediatrics is limited, although a phase 3 trial is in process.[17]

The use of cord blood for allogeneic stem cell transplantation began in 1988 with the successful umbilical cord blood transplantation from an HLA-matched sibling to a patient with Fanconi anemia.[18] In 1998, the Children's Hospital of Oakland, with the support of the National Heart, Lung, and Blood Institute, created a sibling-donor cord blood program that collects, characterizes, stores, and releases cord blood units from families with children who are affected by conditions that may require HSCT.[19] Today, that program continues in collaboration with Viacord.[20]

Even before the establishment of the sibling-donor cord blood program, families have gone to great measures to conceive an HLA-matched child when an HLA-matched sibling did not exist to obtain umbilical cord blood for transplantation. In 1990, Abe and Mary Ayala became the first successful publicized case in which a family sought to conceive a child (Marissa) to save another child (Anissa).[21] Marissa's cord blood was stored for more than 1 year when additional stem cells were procured from her bone marrow to ensure an adequate number of cells.[22]

The movement to create siblings who can serve as HLA-matched donors has been aided by the development of in vitro fertilization (IVF) and preimplantation genetic diagnosis (PGD). In the first such reported case, cord blood was collected at the birth of Adam Nash, who was conceived using IVF and PGD for his sister Molly Nash, a 5-year-old with Fanconi anemia.[23]

The more common umbilical cord blood transplant, however, occurs not within families but between strangers through public cord blood banks. Public cord blood banks collect blood from the umbilical cords of newborn infants to be used as a source of hematopoietic stem cells for unknown pediatric and adult patients.[24] The National Marrow Donor Program lists 90 000 cord blood units donated by parents after their infant's birth,[4] and there are more than 359 000 cord blood units stored internationally,[25] with ongoing attempts to expand collection and storage and enhance ethnic diversity.[26] These public cord blood banks contrast with private cord blood registries that advertise to pregnant women and couples to encourage prospective parents to store their newborn infant's cord blood as a form of insurance in case their own child (or his or her siblings) will need a transplant.[27] To date, at least 1 child has benefited from her parents' decision,[28] but the likelihood of this occurring is quite low, and the collection and storage in private stem cell banks for families at low risk is discouraged by the AAP, the American Medical Association, the American College of Obstetrics and Gynecology, and the American Society for Blood and Marrow Transplantation.[29–32]

ETHICAL CONSIDERATIONS

Most pediatric physicians who perform transplants believe it is acceptable to expose minors to the risks of a

stem cell donation when that donation offers a substantial prospect of benefit to a close family member and when proper consent is obtained.[33] As detailed later in this statement, the risks to the minors who serve as stem cell donors can be characterized as more than minimal, but they are nonetheless generally modest, with few serious complications.[17,34–40] Although healthy children are restricted to a minimal risk threshold in research,[41] parents expose their children to greater risks in selected activities, such as when they permit their children to participate in certain athletic activities or in the workforce.[42–44] Furthermore, family members are often asked to assist each other, at times at personal cost to themselves.[45–47] Ethically, then, to determine if a stem cell donation by a minor is permissible, one must examine the risks and benefits from the perspective of the donor as well as the risks and benefits to the recipient and to his or her family.[45,48]

Risks and Benefits of Serving as a Hematopoietic Stem Cell Donor

Medical Risks and Benefits

There is no direct medical benefit from serving as a stem cell donor. The benefit is always stated as the psychosocial benefit of helping a sibling or other close family member[36] (discussed in the next section).

The medical risks of stem cell collection depend, in part, on its source and how it is collected. The medical risks of bone marrow collection from children and adults are similar, with the major risk being that of anesthesia, but other serious complications include nerve, bone, or tissue injury.[36] Between 9 and 11 deaths have been reported worldwide, for an estimated incidence of 1 death per 10 000 donations.[37] Two of these deaths were cardiac arrests before donation. Postdonation deaths were caused by cardiac events, respiratory arrest, pulmonary emboli, sickle cell crisis, and stroke.[37] Morbidity risks include blood loss and the potential need for transfusions, wound infection, and pain at the site of marrow aspiration.[35] Common short-term adverse effects associated with bone marrow donation include fatigue, pain at donation site, low back pain, headaches, nausea, difficulty walking, problems sleeping, and, less commonly, bleeding problems.[34,36] Long-term adverse effects are rare, but some donors experience chronic pain at the donation site.[34] Many donors are placed on iron supplementation after marrow collection, although smaller children who donate for larger recipients may require a blood transfusion after the donation procedure.[38]

To collect peripheral blood stem cells for hematopoietic donation, the donors receive G-CSF to increase the number of circulating stem cells. Preparation begins with 4 to 5 daily injections of G-CSF and is usually associated with bone pain. Although the bone pain is often described as the most uncomfortable part of the procedure in adults, the pain appears to be less in children. Stem cells are then collected through a process known as apheresis, which requires 2 large venous catheters. Most children younger than 12 years require central vascular access for apheresis; line placement may require either general anesthesia or conscious sedation.[39] Although complications are uncommon (1.1% overall for adults and children), many of the complications arise from the central venous catheter.[17]

Priming of the apheresis circuit with heterologous packed red blood cells is virtually universal for donors who weigh less than 20 kg.[39] This exposes the healthy donors to the risks of heterologous blood products. The donors may also develop thrombocytopenia, although the platelet count is rarely so low that it puts them at risk of bleeding. More than 5% of child donors receive platelet concentrates, particularly when the donor's platelet count decreases and subsequent days of collection are planned.[39]

To ensure that there is an adequate number of stem cells in the peripheral blood, donors require G-CSF mobilization. Some evidence suggests that the effects of G-CSF in healthy subjects may be more complex than originally thought. Although most G-CSF effects are thought to be transient and self-limited, preliminary data suggest that G-CSF affects not only myeloid cells but also chromosomal integrity and gene expression.[49] There is also the theoretic risk of potentially increasing the long-term risk of leukemia,[36,49] but to date, no clinical data support this concern.[50] Peripheral blood stem cell donors complain in the short-term of fatigue, low back pain, sleeping problems, lightheadedness, and difficulty walking.[34] Recovery time, however, is shorter than that for bone marrow donors.[36] Serious adverse events, including splenic rupture after G-CSF administration, have been reported[17,50]; however, to date, splenic rupture has not been described in children.[17]

A review by Pulsipher et al[51] of 2408 adult patients who donated peripheral blood stem cells through the National Marrow Donor Program revealed that severe events occurred in 15 donors (0.6%), the majority of whom required hospitalization for such medical issues as severe symptoms (nausea, chills, bone pain), severe chest pain, bleeding, and thrombocytopenia. In addition, 25 nonhematologic cancers and 1 case of chronic lymphocytic leukemia were reported. When compared with the expected cancer rates according to the National Cancer Institute's Surveillance Epidemiology and End Results database, there was no evidence of increased risk in the donor cohort.[51]

Although G-CSF is not approved for use in healthy children, data from the Pediatric Blood and Marrow Consortium have shown that approximately 23% of all matched sibling transplants use peripheral blood stem cells primed with G-CSF.[36] The most common adverse effects reported in children include pain and arthralgia, which increase with donor age.[36]

An analysis that compared the amount of pain from bone marrow aspiration with that from peripheral blood stem cell collection revealed that the severity of the pain was similar in adult siblings, although the type of pain differed. For bone marrow donors, the pain was at the site of aspiration, whereas for peripheral blood, the pain was bone pain attributable to marrow expansion related to G-CSF.

Finally, stem cells may be collected from cord blood. The collection of umbilical cord blood for hematopoietic stem cell donation occurs in the delivery room. Although one can modify the delivery to maximize the number of cells collected,[52] the Institute of Medicine and the American College of Obstetrics and Gynecology strongly discourage this practice.[52,53] If the mode of delivery is not modified, the collection poses no risks to the infant.[53] The number of umbilical cord stem cells that can be obtained may not be adequate if the recipient is large, and decisions may need to be made about collecting additional hematopoietic stem cells from the cord blood–donating child at a later date.

A major advantage of umbilical cord blood is that HLA-matching is less critical, because lymphocytes in cord blood are less immunologically reactive than are lymphocytes from older donors. This increases the utility of cord blood for unrelated donations, particularly for minority recipients, for whom identifying a fully matched unrelated donor may be difficult.[54] Even within related donor-recipient pairs, however, there is the advantage of a reduced likelihood of acute and chronic GVHD with umbilical cord blood transplants, compared with recipients of bone marrow transplants, even when in both cases the donors are HLA-identical siblings.[55] However, slower immunologic recovery and delayed engraftment may counterbalance some of the benefits of decreased GVHD.

Psychosocial Risks and Benefits

The primary benefit to the donor is the psychosocial benefit of helping a sibling or other close family member. This benefit may accrue even if the transplant is unsuccessful, because the donor and family can at least be reassured that the stem cell transplant was tried.

There is a small but growing literature on the psychosocial risks and harms caused by hematopoietic stem cell donation by children. Data show that many children experience distress related to their role as a donor. Many pediatric donors believe that they did not have a choice about whether to serve as a marrow donor, report being poorly prepared for the procedures, and describe feeling responsible for the recipient's course after transplantation.[56,57]

An important period of psychosocial risk follows the donation and the infusion of the stem cells into the recipient, because the recipient must then go into isolation for weeks to months, and 1 or both parents may be at the hospital for extended periods of time. Data show that many donors feel that they were inadequately prepared for what to expect after the infusion.[58–60] In addition, until engraftment occurs, donors often feel neglected, but this is also true of nondonor siblings. Careful psychological research, then, is necessary to separate the confounding effect of being a donor from that of having a sibling with a life-threatening illness.[36,61–63] That is, part of the distress may be attributable to having a very sick sibling who is the focus of the parents' attention,[62,63] regardless of whether one serves as a donor. Research is needed to compare the harms and benefits of being a sibling donor versus a sibling nondonor. The data that exist were based on small samples. A small study of donor and nondonor siblings revealed a trend toward increased behavioral problems exhibited by donor children when compared with nondonor siblings, which the authors speculated could have been the result of unmet emotional needs in donor siblings.[64] Nondonors, however, felt some envy toward donors who could contribute to the care of the ill sibling.[57] In 2 studies that compared experiences of nondonor siblings and successful donor siblings, one third of the siblings in each group reported a moderate level of posttraumatic stress.[65,66] In addition, donor siblings experienced higher levels of anxiety and lower self-esteem than did nondonor siblings, but donor siblings had more adaptive skills in school, whereas nondonor siblings had more school problems.[65,66] Both donors and nondonors reported loneliness and a lack of attention from parents.[65,66] It is not surprising that siblings of recipients who underwent unsuccessful transplants reported greater negative effects and feelings of guilt than those of recipients whose transplants were successful.[56,58,62] However, all siblings agreed that the psychological benefits and harms of serving as a donor outweighed the physical harms.[62,65,66]

Risks and Benefits to the Hematopoietic Stem Cell Recipient

The main risks and benefits to the recipient are clinical, and they vary depending on the source of stem cells. In general, there is quicker engraftment

after transplantation with primed peripheral blood stem cells. However, there is also greater T-lymphocyte infusion with peripheral blood stem cell transplantation and, therefore, greater risk of chronic GVHD without improvement in survival.[16,67] Transplantation using umbilical cord stem cells is associated with a decreased risk of GVHD, perhaps because fewer lymphocytes accompany the stem cell graft or because those lymphocytes are less immunocompetent.

Recent data suggest that pediatric patients with leukemia have better outcomes when they receive bone marrow rather than peripheral blood stem cell transplants, although bone marrow transplants are associated with slower engraftment.[36,68] This has led to a reemphasis on bone marrow collection. There has also been some research on the use of G-CSF with bone marrow collection to promote more rapid engraftment and reduce risks to the recipient, thus prompting consideration of the use of primed bone marrow. The latter may increase the risks to the donor both short-term (ie, pain from G-CSF for 4–5 days before collection) and long-term (ie, uncertain long-term risks of exposure to G-CSF).

CONDITIONS UNDER WHICH A MINOR MAY PARTICIPATE AS A HEMATOPOIETIC STEM CELL DONOR

Currently, there are no guidelines regarding participation of minors as hematopoietic stem cell donors. The AAP believes it is ethically permissible for minors to participate as donors if 5 criteria are fulfilled. The criteria are: (1) there is no medically equivalent histocompatible adult relative who is willing and able to donate; (2) there is a strong personal and emotionally positive relationship between the donor and recipient; (3) there is some likelihood that the recipient will benefit from transplantation; (4) the clinical, emotional, and psychosocial risks to the donor are minimized and are reasonable in relation to the benefits expected to accrue to the donor and to the recipient; and (5) parental permission and, where appropriate, child assent have been obtained.

Condition 1

The first criterion requires that there be no medically equivalent histocompatible adult relative who is willing and able to donate. Given the relatively modest medical risks of hematopoietic stem cell donation and the great need for histocompatibility, the AAP supports family decisions to screen both adult and child family members in the initial donor search. However, when multiple siblings are histocompatible with a recipient, and donor characteristics that lead to the choice of the best donor are equivalent, a donor above or closest to the age of consent should be approached first about donation, because he or she can better understand the risks, benefits, purpose, and procedures of donation. Likewise, siblings with normal cognitive function should be preferred to siblings with significant cognitive disabilities because of their greater ability to understand the risks and benefits of donation. In the earliest reports of bone marrow donation by children, 1 family explicitly requested the donor to be a sibling with mental retardation, although other siblings may have been available.[69] Although all children are vulnerable, younger children who cannot understand what is happening and children with cognitive disabilities cannot actively assent, and they are considered more vulnerable than cognitively intact or older children.

Although some might argue that a search of adult family members and even the international bone marrow donor registry should be undertaken before children are screened, there are reasons to permit sibling pediatric donors to undergo screening earlier in the process. A sequential search of adults or a requirement to search the international registries takes additional time and is frequently unsuccessful. To require a family to undertake a search for an unrelated donor ignores the fact that authorization of a stem cell donation by a minor is within the proper realm of parental decision-making.[45,48] It also ignores the fact that transplants from HLA-matched siblings are associated with similar or better outcomes and fewer complications for the recipients than transplants from HLA-matched unrelated donors. In particular, although some studies have suggested no difference,[1,70] relative risks of acute and chronic GVHD are generally 1.5 to 3.5 times more frequent after unrelated-donor transplants compared with sibling-donor transplants.[2,3,67,70–72] Finally, a search of the unrelated donor registries will incur costs that may become the responsibility of the family. Therefore, although parents may choose to defer testing their minor children, it is morally permissible to seek stem cells from all sources simultaneously and not to require a sequential search.

Condition 2

The second condition requires that there be a strong personal and positive relationship between the donor and recipient or, in the case of directed cord blood, that a strong personal and positive emotional relationship be anticipated. This is important, in part, to increase the likelihood that the donor will experience some psychological benefit. Case reports in the literature help clarify this point. Marissa Ayala, for example, served as a donor for her older sister by combining her cord blood with additional hematopoietic stem cells procured under anesthesia when she was 14

months of age. She then served as a flower girl at her sister's wedding at 2.5 years of age[73] and, at 18 years of age, positively described her participation in an interview while vacationing with her sister in Hawaii.[74] Although one cannot expect nor require most donor-recipient sibling relationships to be this emotionally strong, it would be morally problematic to ask a minor to serve as a donor to an unknown, emotionally distant, or emotionally abusive relative. In *Cruzan v Bosze*, a father sought to have his twin children tested as potential bone marrow donors for their half-brother.[75] The twins' mother objected, in part because the children did not know their stepbrother. In its decision, the court agreed with the mother. In the case of A. R., a younger sister was asked to serve as the bone marrow donor for her teenaged brother, who had sexually assaulted her.[76] Despite an inadequate psychosocial evaluation, A. R. was declared fit to serve as a stem cell donor. Authors of a commentary argued that the sister should never have been evaluated for donor compatibility and that the donation should have been prohibited.[77] Most recently, an adopted child developed acute lymphoblastic leukemia, and his 3 biological siblings with whom he had no relationship were tested for HLA compatibility.[78] None were HLA compatible, but the case raised the question of why the children were HLA-tested in the first place, given the lack of an intimate relationship with the ill child.[79] These cases reveal how parents may be so focused on the ill child that they do not adequately consider the needs and interests of the potential minor donor siblings. Rather, minors should only serve as hematopoietic stem cell donors for family members when there is a strong personal and emotionally positive relationship between the donor and recipient. Exceptions should only be considered with judicial review. Minors should never be considered as potential donors for strangers or listed on an international bone marrow registry except as cord blood donors.

Condition 3

The third condition requires that there be some likelihood that the recipient will benefit from transplantation. It is hard to define what the threshold of likelihood of success for the recipient should be to justify the procurement of donor stem cells, and this is further complicated by the inexactness of the recipient's prognosis. However, the fact that a histocompatible sibling is available does not mean that a transplant should be attempted without regard to the likelihood of success. Although the medical risks of serving as a hematopoietic stem cell donor do not change regardless of the transplant outcome, the psychosocial risks should not be underestimated. This is particularly true for the donor whose sibling dies.[80] Therefore, although the transplant team may be willing to attempt a transplant regardless of likelihood of success, there should be some minimum threshold of anticipated success below which the potential minor donor should not be exposed to the risks of stem cell collection.[33,81] The threshold likelihood of success may be less stringent for donors who are competent older teenagers or adults and who can, therefore, consent for themselves. The donor advocate (or some similar mechanism as befits an individual program as discussed for condition 5) should ensure that the likelihood of success is above some threshold to justify imposing the risks of donation on the minor sibling.

Condition 4

The fourth condition requires that the clinical, emotional, and psychosocial risks to the donor be minimized and be reasonable in relation to the benefits expected to accrue to the donor and the recipient. The transplant team should help ensure that the parents consider the risks and benefits of a sibling donation from the independent perspectives of the recipient and of the donor.

One way to minimize risks is to carefully select the method of stem cell collection. Each method of obtaining stem cells has distinct risks and benefits. Numerous factors should be considered in this decision, including the preferences of the minor and parents and the potential benefit to the recipient. For example, one may want to avoid peripheral blood stem cell donation by young children to minimize the need for central venous catheters and to avoid exposing the donor to third-party blood products. Central venous lines in children have a low risk of harm, but the harms can be serious and include the risks of anesthesia as well as the risks from the catheter placement (eg, pneumothorax, hemothorax).[39,40] Some of the psychological and emotional risks to child donors can be minimized by preparing them through medical play-acting, by allowing them to ask questions, and by including them in the decision-making process, to the extent of their ability.[56–60]

Finally, in some situations, it may be appropriate for the transplant team to educate the family about alternative therapies that may be tried that offer a reasonable likelihood of success. For example, for children with malignancies, chemotherapeutic trials may offer an alternative to HSCT. For children with enzyme deficiencies secondary to genetic conditions, some enzyme-replacement therapies exist, and others are in development. For children with bone marrow failure or hemoglobinopathies, nontransplant alternatives may include chronic transfusion or growth-factor support, and gene transfer is on the horizon.

Condition 5

The fifth condition requires that parental permission and donor assent be obtained. Legally, in pediatrics, parental permission is sufficient for proceeding with clinical treatment (with a few exceptions), whereas parental permission and the child's assent (when possible) is necessary for research purposes.[82] However, stem cell donation by minor siblings is unusual in that it is often performed as a clinical procedure, yet the direct benefits of the clinical procedure accrue to a third party (the recipient) rather than to the donor child. Even in the research setting, the risks and benefits may or may not accrue to the donor (discussed further in the next section). In seeking parental permission, it is important to acknowledge the tension that parents experience when 1 of their children is ill and to appreciate the conflict of interest created if they consider authorizing 1 of their healthy children to serve as a hematopoietic stem cell donor.

Transplant teams also face a conflict of interest in that their primary responsibility is to the potential recipient; yet, the same physicians may advise, consent, and possibly take the potential donor to the operating room for stem cell procurement. The Advisory Committee on Organ Transplantation of the US Department of Health and Human Services recommends that all living solid-organ donors have a donor advocate,[83] and this recommendation was incorporated into the AAP statement "Minors as Living Solid-Organ Donors."[84] The AAP proposes a similar requirement for all minors who are potential hematopoietic stem cell donors, a mechanism first implemented at the M. D. Anderson Cancer Center in 1994.[36] The primary obligation of the donor advocate (or some similar mechanism as befits an individual program) is to help the donor (and parents) understand the process and procedures and to protect and promote the interests and well-being of the donor. As such, the donor advocate (for the rest of this statement, "donor advocate" will be used to indicate either a specific donor advocate or some similar mechanism) should not be involved in direct patient care of the potential transplant recipient.[85] The donor advocate or, if necessary, a donor advocate team should have (1) training and education in child development and child psychology, (2) skills in communicating with children and understanding children's verbal and nonverbal communication, and (3) working knowledge of hematopoietic stem cell donation and transplantation.[84] The donor advocate should help to ensure that the risks to the child are reasonable and minimized, that the siblings' relationship is a personal and emotionally positive relationship (ie, that there is a healthy emotional relationship between them), that the donation has a reasonable likelihood of success, and that there is no other medically equivalent histocompatible adult relative who is able and willing to serve as a source of stem cells.

The donor advocate should help the parents weigh the risks and benefits for the healthy child to serve as a hematopoietic donor for an ill family member and not just weigh the risks and benefits from the perspective of the potential recipient or from that of the family as a unit. The donor advocate should be involved from the onset, starting with the decision about whether the minor should undergo HLA testing. When older children and adolescents are being considered as hematopoietic stem cell donors, they should be included in all stages of the decision-making process to the extent that they are capable.[82,86] Discussions that involve the potential minor donor must be developmentally appropriate.[86] The psychological as well as medical aspects of the donation should be discussed in language that is understandable to the potential donor. Consistent with his or her capacity, the minor needs to be aware that the donated stem cells may not engraft or may fail after engraftment, the recipient may develop severe or even fatal complications of the transplant (eg, GVHD), or the original disease may recur. The minor needs to be aware that the outcome is beyond his or her control. The literature shows that many donors feel neglected after donation as the focus returns to the ill recipient.[58,62,87] Parents and other family members should be reminded that they need to be attentive to the needs of both the donor and recipient.

Research on minors who served as stem cell donors has revealed that most siblings felt they had no choice about whether to serve as a stem cell donor, but most also agreed that they would do it again.[56] Nevertheless, in some cases, a minor may object to participation. Although the parents' consent alone may be sufficient, unless state law or institutional policy requires the minor's active assent,[88] a donor advocate should explore the reasons for the refusal and determine if further education and discussion can modify the minor's refusal. A child mental health professional and/or an ethics consultant/ethics committee may also need to be involved to help clarify the child's concerns. The donor advocate, child mental health professional, ethics consultant, or ethics committee must have the authority to suspend or prohibit a donation if it is determined that the donation is likely to have a serious and sustained long-term adverse effect on the donor. The recipient should not begin myeloablative preparation for bone marrow infusion (conditioning) unless there is a clear decision to proceed with the do-

nation. Once the recipient has begun conditioning, the child donor should not be offered the opportunity to renege, because this would be lethal to the recipient.

RESEARCH ON HSCT

To advance the effectiveness of HSCT, research will need to be performed on both donors and recipients. When the participants are minors, the research must conform to Subpart D of the federal regulations that govern pediatric research.[41]

Subpart D distinguishes between research that does and does not offer the prospect of direct benefit. Children are permitted to participate in research that offers the prospect of direct benefit, provided the "risk is justified by the anticipated benefit to the subjects" and "the relation of the anticipated benefit to the risk is at least as favorable to the subjects as that presented by available alternative approaches."[41] For most research on HSCT, the research offers the prospect of direct benefit to the recipient, but the donor is a healthy child. As such, the research does not offer the prospect of direct benefit to the donor child. Although some have tried to argue that the donor and recipient should be viewed as a dyad, this would permit greater risk taking on the part of a healthy child than most interpretations of the regulations permit.[36]

When research does not provide the prospect of direct benefit, children are permitted to participate in minimal-risk research (eg, surveys of pain experience). What counts as minimal risk, however, is ambiguous.[89–91] Children with a disorder or condition are permitted to participate in research that poses a minor increase over minimal risk. Healthy siblings do not have a disorder or condition. This restriction has raised 3 objections. First, it is not clear what it means to have a "disorder or condition," that is, whether one must have a disease or condition or whether it is adequate to be at risk of having a disease or condition.[92–95] Some have even argued that having an ill sibling constitutes a "condition."[36,92] A second objection is that the regulations are overly restrictive in that the minor increase over the minimal-risk standard is adequate protection for all children.[91] The third objection is that the regulations are unjust in providing greater protection to healthy than to ill children.[96]

If the proposed research pertains to adequate pain control and the standard therapies are used, then one might state that survey research to quantify the degree of pain entails minimal risk. However, if the research entails the use of a drug (eg, the original expansion of G-CSF from adult volunteer donors to sibling donors), the research is always classified as posing at least a minor increase over minimal risk. Such research can only be performed if the responsible institutional review board (IRB) determines that the donor's participation involves a prospect of direct benefit to the donor himself or herself (45 CFR 46.405 approval) or if the IRB determines that being a donor constitutes a condition and the incremental risks of the research involve no greater than a minor increase over minimal risk (45 CFR 46.406 approval). Either of these determinations by an IRB is likely to be controversial. Otherwise, the research requires national review under 45 CFR 46.407.[97,98] Although this will increase the regulatory burden for performing research on healthy donors, it may also increase the oversight that research that exposes a healthy child to significant risk without prospect of direct benefit deserves.[36,97] In December 2008, the US Food and Drug Administration (FDA) Pediatric Advisory Committee's Pediatric Ethics Subcommittee convened to review a proposed pediatric study under the provisions of 45 CFR 46.407 and the corresponding regulations that govern clinical investigations regulated by the FDA, 21 CFR 50.54. The protocol involved a phase 3 trial in which donors would be randomly assigned to receive G-CSF to determine its effect on engraftment and GVHD.[99] The National Cancer Institute Central Institutional Review Board (CIRB) acknowledged the pressure that normal siblings would experience with respect to participation and "that it would be difficult or impossible to separate this influence from the pressure to act as a bone marrow donor independent of the research."[100] The CIRB elaborated: "the CIRB suggests but does not require the use of a third party informed assent monitor to minimize potential influence, as well as the use of different doctors for the recipients and the donors. The board notes that the latter suggestion is already standard practice in many allogeneic stem cell transplant programs."[100] The FDA approved the protocol under 45 CFR 46.407 but mandated use of a donor advocate as a stipulation of 407 approval. The donor advocate or assent monitor is analogous to the donor advocate proposed in our condition 5 as a mandatory component for all HSCT when the donor is a minor.

Subpart D also gives significant respect to the child's preferences regarding research participation. The regulations are clear that, when the child is "capable of assenting," the child must provide "affirmative agreement" to participate.[41] The regulations also give IRBs the authority to decide from which children assent should be sought.[41] Although no age is provided in the regulations, many studies seek assent of children as young as 6 or 7 years of age. However, given the complexities involved in stem cell transplant research, it would be reasonable for the IRB to restrict the assent requirement to donors older than 9 years.[101]

When an IRB finds that assent is necessary and the child donor refuses to assent, transplant teams, families, and donor advocates should try to understand the reason for a refusal and try to address the objections. However, under current regulations, if the child is determined to have sufficient capacity to assent, then his or her refusal to participate in research is definitive.

CHILDREN CONCEIVED TO SAVE A SIBLING

In some families, parents intentionally conceive a child to serve as an umbilical cord blood stem cell donor for an older sibling. Often, these children are conceived through IVF and PGD to ensure an HLA match.[102] PGD may be performed either to ensure that the embryo is HLA-identical while simultaneously avoiding the birth of a child with a severe heritable condition (eg, Fanconi anemia) or purely to ensure that the embryo is HLA-identical. As of 2005, 5 PGD centers in 4 countries have performed HLA-genotyping in 180 IVF cycles. In 122 cycles, the goal was to avoid a genetic condition (thalassemia being the most common) and to create an HLA-matched sibling. In 58 cycles, PGD was used solely for HLA-typing.[102]

Some people have moral or religious objections to the use of IVF and PGD because they can result in excess embryos, many of which are discarded. Even those who accept IVF and PGD to avoid the birth of a child with a severe heritable condition and simultaneously to ensure a specific HLA identity may be troubled by the use of PGD when it is used only to ensure an HLA-identical sibling.[103–107] When PGD is used purely for HLA-matching, the objection is that the child is used solely as a means (donor) for the sibling-recipient and that all children should be treated as ends in themselves.[108] This is a misunderstanding of the Kantian ethical principle. There is no absolute moral prohibition against using a person as a means, provided that the person is not used solely as a means. Available evidence is anecdotal but reveals that children conceived to save siblings are loved both for their role in saving their sibling's life (means) and as another member of the family (end-in-itself) which is consistent with the moral permissibility of children as hematopoietic stem cell donors.[103–107]

Pediatricians may be asked about PGD by parents who are willing to attempt to conceive an HLA-matched sibling. Pediatricians should educate these parents about the risks and benefits of attempting to conceive a child who will serve as a hematopoietic stem cell donor and should support them emotionally throughout the process or refer them to a colleague who has the competency and expertise to do so. The willingness of health care professionals to collect cord blood for stem cells in the delivery room must be ensured before delivery, although the pregnant woman and couple must also understand that the health of both the newborn infant and the pregnant woman have priority and that peripartum events may preclude collection.[29] To avoid exposing the newborn infant to any risks from the donation, the delivery should not be modified to maximize the number of cells collected. If delivery is not modified, the procedure poses no risk to the newborn infant, and there is no need for a donor advocate.

COURT REVIEW

The earliest cases of bone marrow transplant with a minor donor often involved judicial review.[109] Given that legal precedent for stem cell donation by incompetent adults and children is firmly established, as a general matter, donation by a minor should not require court review or approval. Historically, the primary value of the judicial review process was to ensure an independent advocate for the incompetent potential donor.[69] In solid-organ transplantation, there is now a requirement to provide an independent donor advocate for living donors.[83] The AAP supports the appointment of a donor advocate in any HSCT that involves a donor younger than 18 years (except for cord blood stem cell donation). The donor advocate should assess whether the recipient for whom the minor is being asked to donate is an appropriate candidate (eg, a child sibling who has a reasonable chance of benefit from the transplant procedure), should ensure that the donor and recipient have a strong personal and emotionally positive relationship, and should verify that no adult family members are appropriate and willing donors. The donor advocate should also work with the child to provide developmentally appropriate education and support and to ensure that the family attends to the needs and interests of the donor. In cases for which there is concern regarding parental motives or what is in the donor's best interest, ethics consultation with either an ethics consult service or ethics committee may be an appropriate next step.[32,84] Judicial review should be reserved as a last resort or to permit exceptions to any of the conditions listed above. For example, a court may be asked to adjudicate the permissibility of a stem cell donation by a minor when no strong personal relationship exists between the minor donor and recipient.

LONG-TERM FOLLOW-UP

There is an urgent need for improved understanding of the long-term effects, both medical and psychosocial, of minors who serve as hematopoietic stem cell donors. Ideally, national donor registries would be established that would collect short-term and long-term medical and psychological data that would allow for more accurate assessment of the risks, benefits, and

outcomes of hematopoietic stem cell donation. Currently, there is 1 such project titled RDSafe (related donor safety initiative) that is evaluating approximately 10 000 related and unrelated donors over the next 5 years. The researchers plan to examine both psychological and medical issues for 1 year. This project is laudable, although when the donors are children, follow-up will be needed for a much longer time frame. In this vein, the AAP supports health care professionals who seek authorization from minor donors and their parents for long-term collection and storage of donor health data. Parents should be responsible for authorizing the child's registration, but the child should be asked to give his or her own consent when he or she reaches the age of majority.

RECOMMENDATIONS

1. Children who are medically appropriate potential donors may ethically serve as hematopoietic stem cell donors if 5 criteria are fulfilled: (1) there is no medically equivalent histocompatible adult relative who is willing and able to donate; (2) there is a strong personal and emotionally positive relationship between the donor and recipient; (3) there is a reasonable likelihood that the recipient will benefit; (4) the clinical, emotional, and psychosocial risks to the donor are minimized and are reasonable in relation to the benefits expected to accrue to the donor and to the recipient; and (5) parental permission and, when appropriate, child assent are obtained (see recommendation 3).
2. A donor advocate (or some similar mechanism as befits an individual program) with expertise in pediatric development should be appointed for all individuals who have not reached the age of majority and who are being considered as hematopoietic stem cell donors. The donor advocate must be independent of the team responsible for direct care of the recipient and should be involved from the onset, starting with the decision about whether the minor should undergo HLA-testing. A donor advocate is not necessary in cord blood donation. Donor advocates should ensure that the criteria in recommendation 1 are met.
3. When children and adolescents are being considered as hematopoietic stem cell donors, they should be included in all stages of the decision-making process to the extent that they are capable. The donor advocate should facilitate their inclusion. Parents may authorize their child's participation as a hematopoietic stem cell donor. A minor's dissent should lead to further discussion and involvement of the donor advocate, child mental health professional, and ethics consultants and/or ethics committee if necessary. The donor advocate, with the assistance of child mental health professionals and ethics consultants and/or ethics committee as needed, should have the authority to prevent or delay the donation if the donation is likely to have a serious and sustained long-term adverse impact on the donor. The recipient should not begin conditioning unless there is a clear decision to go ahead with the donation. Once the recipient has begun myeloablative preparation for bone marrow infusion (conditioning), the child donor cannot renege, because this would be lethal to the recipient.
4. Pediatricians should be aware that they may be asked about IVF with PGD to ensure the conception of an HLA-matched sibling for cord blood donation. If delivery is not modified, umbilical cord blood procurement poses no risk to the newborn infant. In some cases, it will be necessary to collect additional hematopoietic stem cells from this child at a later date. In those cases, the other criteria enumerated in recommendation 1 regarding pediatric donors must be met.
5. To advance the effectiveness of different hematopoietic stem cell transplants, research will need to be performed on donors and recipients. When the donor is a minor, the research must conform to the federal regulations governing pediatric research. This may require national review when the research imposes more than minimal risk without prospect of direct benefit to donor subjects.
6. Long-term follow-up data should be collected to help determine the actual medical and psychological benefits and risks for child donors. These data should then be used to modify future recommendations regarding the permissibility of minors serving as hematopoietic stem cell donors.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Injury and Poison Prevention

Children in Pickup Trucks

ABSTRACT. Pickup trucks have become increasingly popular in the United States. A recent study found that in crashes involving fatalities, cargo area passengers were 3 times more likely to die than were occupants in the cab. Compared with restrained cab occupants, the risk of death for those in the cargo area was 8 times higher. Furthermore, the increased use of extended-cab pickup trucks and air bag-equipped front passenger compartments creates concerns about the safe transport of children. The most effective preventive strategies are the legislative prohibition of travel in the cargo area and requirements for age-appropriate restraint use and seat selection in the cab. Parents should select vehicles that are appropriate for the safe transportation needs of the family. Physicians have an important role in counseling families and advocating public policy measures to reduce the number of deaths and injuries to occupants of pickup trucks.

Motor vehicle trauma remains a leading cause of death of children. Occupants in pickup trucks should receive the same level of protection provided in other vehicles according to national policies that address protection of motor vehicle occupants. The safety issues relevant for pickup trucks include the following: 1) prohibition of cargo area travel; 2) age-appropriate restraint use; 3) appropriate seat location in the cab; 4) appropriate use of rear seating positions in various models of extended cab vehicles; and 5) risk of air bag-related injuries.

Pickup trucks have become increasingly popular vehicles for passenger transportation. Pickup truck registrations numbered 36.2 million in 1998, representing 17% of registered motor vehicles in the United States.[1] Census data for 1992 indicated that 73% of pickup trucks were used for personal transportation.[2] Restraint use in the cab of pickup trucks has been reported to be lower than restraint use in other passenger vehicles.[3]

TRAVEL IN THE CARGO AREA

Travel in the cargo area of the pickup truck is a major occupant protection issue that disproportionately involves youth. Because the cargo area is not intended for passenger use, it is neither required nor designed to meet occupant safety standards applicable to passenger locations. Nevertheless, the cargo area is used for transporting passengers. In 1997, 161 deaths of occupants riding in the cargo area were reported; 77 (48%) were children and adolescents younger than 20 years. Of these occupants, 7 (9%) were younger than 5 years; 15 (19%) were 5 through 9 years of age; 14 (18%) were 10 through 14 years of age; and 41 (53%) were 15 through 19 years of age.[4]

Persons who are injured when traveling in cargo areas of pickup trucks are more likely to sustain multiple injuries and injuries of greater severity and have a greater likelihood of death than do occupants in the cab. The most significant hazard of travel in the cargo area of a pickup truck is ejection of a passenger in a crash or noncrash event (eg, sudden stop, turn, swerve, or loss of balance, as well as intentional or unintentional jumps and falls). Studies have demonstrated that the proportion of occupants ejected from the cargo area markedly exceeds the proportion ejected from the cab.[5–11]

In a recent study of fatalities in pickup trucks from 1987 through 1996, nearly one third of the deaths among occupants of the cargo area were a result of noncrash events. Of the deaths that occurred as a result of cargo area occupants being ejected, 40% were children and adolescents 17 years or younger. Cargo area passengers were 3 times more likely to die than were occupants in the cab. Compared with restrained cab occupants, the risk of death for those in the cargo area was 8 times higher.[12]

Enclosed cargo areas (camper shells) do not provide adequate protection against injury to occupants. In 1997, 14% of cargo area deaths of children and adolescents younger than 20 years were in enclosed cargo areas.[4] Carbon monoxide poisoning, which may result in death, is an additional hazard to those traveling in the enclosed cargo area of a pickup truck.[13]

Fewer than 50% of the states restrict transport of passengers in the cargo area. No 2 states have identical laws, and only 1 state fully prohibits travel in cargo areas. Restrictions in other states vary according to the age groups to which they apply, conditions of travel (eg, if restrained), and presence of an enclosed cargo area.[14] The application of seat belt and child passenger safety laws to travel in pickup truck cargo areas may be an option in some states; however, in certain states, even occupant area seat belt laws do not apply to pickup trucks. Many Native American nations have adopted occupant restraint laws that apply to pickup trucks as well as passenger cars; other nations use the laws of the state.[15]

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

EXTENDED CABS

With increased sales and use of pickup trucks for personal and family transportation, manufacturers have produced vehicles that can accommodate an increased number of occupants. A variety of extended cab vehicles are available with additional seating capacity that may include a rear bench seat, side-facing back seats, a full back seat with lap/shoulder belts, and/or a middle front seat position with a lap belt (also available in standard pickup trucks). Crash data for occupants in these seats are limited. Compatibility issues exist between vehicle seats and safety seats, including booster seats in some pickup truck seating positions. Car safety seats can only fit and be properly secured in a full-size rear or front seat. Many rear-facing car safety seats do not fit in pickup seats with limited space in front of them, and this limited space may not provide adequate head excursion distance for children in untethered forward-facing car safety seats. For older children, booster seats must be used with lap/shoulder belts to provide adequate protection; however, lap/shoulder belts may not be available in pickup rear seats.

AIR BAGS

Concerns about the safety of children in front passenger seats equipped with an air bag are the same as those for other passenger vehicles. Infants must always ride in rear-facing car safety seats in the back seat until they are at least 1 year old and weigh at least 20 pounds. Infants must never ride in the front passenger seat when it is equipped with an air bag. All children should be properly restrained in car safety seats, booster seats, or lap/shoulder belts appropriate for their size and age. The safest place for children is in the back seat in vehicles with a full-size rear seat. However, if there is no rear seat, the rear seat is not full-size, or the rear seat is incompatible with use of a car safety seat or booster seat, the front passenger air bag should be equipped with an on/off switch to accommodate the safe transport of children. The switch should be off when transporting children in the front seat.

Hospital Record Keeping

A need for data exists about injuries in extended cabs, use and nonuse of occupant protection systems, and comparisons of injuries and injury mechanisms between enclosed and unenclosed cargo areas. Documentation of the circumstances of injuries that occur in pickup trucks is needed to contribute to epidemiologic data and to develop preventive counseling guidelines.

RECOMMENDATIONS

1. The most effective prevention strategies to reduce the number of deaths and injuries to children in pickup trucks are the prohibition of travel in the cargo area and age-appropriate restraint use in an appropriate seat location in the cab.
2. Parents should be counseled about the following considerations for selecting or using vehicles to meet the safe transportation needs of the family:
   - No passengers should be transported in the cargo area of a pickup truck or a nonpassenger section of any vehicle.
   - Trips should be planned in advance so that an appropriate seat position and restraint device are used for each passenger.
   - Compatibility should be checked between the vehicle seat (front and back seats) and the car safety seat before purchasing a vehicle or a child safety seat.
   - Infants in rear-facing car safety seats should not be placed in front passenger seats when an airbag is present and activated. If no appropriate rear seating position is available, only place the infant in the front passenger seat if an airbag on/off switch is installed and turned off.
   - Car safety seats should fit completely on the rear seat of the pickup truck and can be properly secured facing the rear for infants younger than 1 year and weighing <20 pounds, and facing forward for older children. The addition of a tether may improve the security of a car safety seat.
   - All forward-facing car safety seats should be installed using a top tether in addition to the vehicle belt.
   - Teenagers should agree that they will not ride or transport others in the cargo area of a pickup truck.
3. The who, what, when, where, why, and how of the injury event should be recorded.[16]
4. Physicians should serve as educators and public policy advocates for measures that will decrease the number of deaths and injuries to children and youth who travel in pickup trucks.
5. Physicians need to be effective advocates for more stringent and comprehensive state legislation that would prohibit any occupant from traveling in the cargo area of a pickup truck. If the state exempts pickup trucks from seat belt laws, efforts should be made to modify these laws to include all passengers in all seat locations. The American Academy of Pediatrics has developed a model state legislation packet related to travel in pickup trucks.[17]
6. Law enforcement agencies should be strongly urged to enforce laws relating to occupant travel, including restraint and seat belt use laws, as well as laws prohibiting travel in cargo areas of pickup trucks.

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Subcommittee on Chronic Abdominal Pain

Chronic Abdominal Pain in Children

ABSTRACT. Children and adolescents with chronic abdominal pain pose unique challenges to their caregivers. Affected children and their families experience distress and anxiety that can interfere with their ability to perform regular daily activities. Although chronic abdominal pain in children is usually attributable to a functional disorder rather than organic disease, numerous misconceptions, insufficient knowledge among health care professionals, and inadequate application of knowledge may contribute to a lack of effective management. This clinical report accompanies a technical report (see page e370 in this issue) on childhood chronic abdominal pain and provides guidance for the clinician in the evaluation and treatment of children with chronic abdominal pain. The recommendations are based on the evidence reviewed in the technical report and on consensus achieved among subcommittee members. ***Pediatrics*** **2005;115:812–815;** ***abdominal pain, irritable bowel syndrome, functional bowel disorders.***

ABBREVIATION. ENS, enteric nervous system.

BACKGROUND

Despite decades of clinical observations resulting in numerous articles, books, and monographs, the subject of long-lasting constant or intermittent abdominal pain in childhood remains one of ambiguity and concern for most pediatric health care professionals. The definition of chronic abdominal pain used clinically and in research over the last 40 years has used the criterion of at least 3 pain episodes over at least 3 months interfering with function.[1] In clinical practice, it is generally believed that pain that exceeds 1 or 2 months in duration can be considered chronic. A child who chronically complains of abdominal pain is often a formidable challenge; although the symptom usually indicates a benign problem, the parents may be terribly worried, the child may be in distress, the practitioner may be concerned about ordering tests to avoid missing serious occult disease, and the family may be enmeshed in psychosocial complexities. Management of this problem can be time consuming and frustrating. Yet, in only a small number of such children is the abdominal pain caused by an underlying organic disease. In most children, the pain is functional, that is, without demonstrable evidence of a pathologic condition such as an anatomic, metabolic, infectious, inflammatory, or neoplastic disorder.

The pathophysiology of functional abdominal pain is thought to involve abnormalities in the enteric nervous system (ENS), a rich and complex nervous system that envelops the entire gastrointestinal tract. The ENS is also known as the "gut brain" or the "little brain in the gut."[2] The ENS interacts with the central nervous system, allowing bidirectional communication. A dysregulation of this brain-gut communication plays an important role in the pathogenesis of functional abdominal pain. Most of the research on childhood visceral pain in the 1980s and early 1990s focused on the role of motility disorders and psychiatric abnormalities. Recently, however, more sophisticated diagnostic techniques have failed to identify motor abnormalities severe enough to account for these patients' symptoms. It is now believed that adults and children with functional bowel disorders, rather than having a baseline motility disturbance, may have an abnormal bowel reactivity to physiologic stimuli (meal, gut distension, hormonal changes), noxious stressful stimuli (inflammatory processes), or psychological stressful stimuli (parental separation, anxiety).[3] Additionally, adult patients with functional bowel disorders attending gastrointestinal clinics were often found to have psychological disturbances regardless of the final diagnosis. It was concluded that psychological factors may have been more important in determining health-seeking behavior than the cause of the symptom.[4]

There is growing evidence to suggest that functional abdominal pain disorders may be associated with visceral hyperalgesia, a decreased threshold for pain in response to changes in intraluminal pressure.[5,6] Mucosal inflammatory processes attributable to infections, allergies, or primary inflammatory diseases may cause sensitization of afferent nerves and

PEDIATRICS (ISSN 0031 4005).

have been associated with the onset of visceral hyperalgesia.[7] The concept of visceral hyperalgesia may be explained to the patients and family members comparing gut hyperalgesia to what happens when one experiences a burn or a scar: the skin may remain sensitive for prolonged periods of time and perceive as noxious even stimuli that are normally not uncomfortable (such as contact with clothes). There is also an increasing body of evidence in adults suggesting that an abnormal central processing of afferent signals at the level of the central nervous system may play a role in the pathophysiology of this condition.[8,9]

Functional abdominal pain is the subject of many misconceptions in both the health care and lay communities. A recent survey by the American Academy of Pediatrics and the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition completed by more than 300 general pediatricians showed that functional abdominal pain was considered an unclear or wastebasket diagnosis by 16% of responders and a specific diagnosis with clear criteria for diagnosis by only 11% of responders (unpublished data). There is ambiguity and confusion with nomenclature as well, with many clinicians using the term "recurrent abdominal pain" to mean functional, psychological, or stress-related abdominal pain. Furthermore, many clinicians are unaware of the different symptom patterns with which functional abdominal pain can present.

The systematic review of the medical literature on chronic abdominal pain in children summarized in the technical report[10] has identified findings that may be surprising to many clinicians. For example, although children with chronic abdominal pain and their parents are more often anxious or depressed than are children without chronic abdominal pain, the presence of anxiety, depression, behavior problems, or recent negative life events does not seem to be useful in distinguishing between functional abdominal pain and abdominal pain attributable to organic disease. Similarly, although children with chronic abdominal pain are more likely than children without chronic abdominal pain to have headache, joint pain, anorexia, vomiting, nausea, excessive gas, and altered bowel symptoms, the presence of these associated symptoms is unlikely to help the physician discriminate between functional and organic disorders. In contrast, the presence of alarm symptoms or signs (see recommendation 3 below for a list) may suggest a higher likelihood of organic disease and is an indication for the performance of diagnostic tests, whereas in the absence of alarm symptoms, diagnostic studies are unlikely to have a significant yield of organic disease. Furthermore, there is no evidence that emotional or behavioral symptoms predict the clinical course or that families of children with chronic abdominal pain differ in broad areas of family functioning. Although clinicians prescribe a range of treatments, there are only limited or inconclusive studies of pharmacologic or behavioral therapy in children.

RECOMMENDATIONS

1. The term "recurrent abdominal pain" as currently used clinically and in the literature should be retired. Functional abdominal pain is the most common cause of chronic abdominal pain. It is a specific diagnosis that needs to be distinguished from anatomic, infectious, inflammatory, or metabolic causes of abdominal pain. Functional abdominal pain may be categorized as one or a combination of: functional dyspepsia, irritable bowel syndrome, abdominal migraine, or functional abdominal pain syndrome (see Table 1).
2. Functional abdominal pain generally can be diagnosed correctly by the primary care clinician in children 4 to 18 years of age with chronic abdominal pain when there are no alarm symptoms or signs, the physical examination is normal, and the stool sample tests are negative for occult blood, without the requirement of additional diagnostic evaluation.

TABLE 1. Recommended Clinical Definitions of Long-Lasting Intermittent or Constant Abdominal Pain in Children

Chronic abdominal pain	Long-lasting intermittent or constant abdominal pain that is functional or organic (disease-based)
Functional abdominal pain	Abdominal pain without demonstrable evidence of a pathologic condition, such as an anatomic, metabolic, infectious, inflammatory, or neoplastic disorder; functional abdominal pain may present with symptoms typical of functional dyspepsia, irritable bowel syndrome, abdominal migraine, or functional abdominal pain syndrome
Functional dyspepsia	Functional abdominal pain or discomfort in the upper abdomen
Irritable bowel syndrome	Functional abdominal pain associated with alteration in bowel movements
Abdominal migraine	Functional abdominal pain with features of migraine (paroxysmal abdominal pain associated with anorexia, nausea, vomiting, or pallor as well as a maternal history of migraine headaches)
Functional abdominal pain syndrome	Functional abdominal pain without the characteristics of dyspepsia, irritable bowel syndrome, or abdominal migraine

3. The presence of alarm symptoms or signs, including but not limited to involuntary weight loss, deceleration of linear growth, gastrointestinal blood loss, significant vomiting, chronic severe diarrhea, persistent right upper or right lower quadrant pain, unexplained fever, family history of inflammatory bowel disease, or abnormal or unexplained physical findings, is generally an indication to pursue diagnostic testing for specific anatomic, infectious, inflammatory, or metabolic etiologies on the basis of specific symptoms in an individual case. Significant vomiting includes bilious emesis, protracted vomiting, cyclical vomiting, or a pattern worrisome to the physician. Alarm signs on abdominal examination include localized tenderness in the right upper or right lower quadrants, a localized fullness or mass effect, hepatomegaly, splenomegaly, costovertebral angle tenderness, tenderness over the spine, and perianal abnormalities.
4. Testing may also be performed to reassure the patient, parent, and physician of the absence of organic disease, particularly if the pain significantly diminishes the quality of life of the patient.
5. The child with functional abdominal pain is best evaluated and treated in the context of a biopsychosocial model of care. Although psychological factors do not help the clinician distinguish between organic (disease-based) and functional pain, it is important to address these factors in the diagnostic evaluation and management of these children.
6. Education of the family is an important part of treatment of the child with functional abdominal pain. It is often helpful to summarize the child's symptoms and explain in simple language that although the pain is real, there is most likely no underlying serious or chronic disease. It may be helpful to explain that chronic abdominal pain is a common symptom in children and adolescents, yet few have a disease. Functional abdominal pain can be likened to a headache, a functional disorder experienced at some time by most adults, which very rarely is associated with serious disease. It is important to provide clear and age-appropriate examples of conditions associated with hyperalgesia, such as a healing scar, and manifestations of the interaction between brain and gut, such as the diarrhea or vomiting children may experience during stressful situations (eg, before school examinations or important sports competitions).
7. It is recommended that reasonable treatment goals be established, with the main aim being the return to normal function rather than the complete disappearance of pain. Return to school can be encouraged by identifying and addressing obstacles to school attendance.
8. Medications for functional abdominal pain are best prescribed judiciously as part of a multifaceted, individualized approach to relieve symptoms and disability. It is reasonable to consider the time-limited use of medications that might help to decrease the frequency or severity of symptoms. Treatment might include acid-reduction therapy for pain associated with dyspepsia; antispasmodic agents, smooth muscle relaxants, or low doses of psychotropic agents for pain or nonstimulating laxatives or antidiarrheals for pain associated with altered bowel pattern.
9. Additional research is needed to fill the large gaps of knowledge on chronic abdominal pain in children.

FUTURE RESEARCH

Research on chronic abdominal pain in children should incorporate several methodologic features to generate higher-quality evidence for future clinical practice guidelines. The following specific suggestions are made:

1. Symptom phenotypes of study patients should be described in detail, including not only abdominal pain (intensity, frequency, duration, location) but also associated gastrointestinal and other symptoms.
2. Investigators should specify how eligibility criteria were assessed for research participation.
3. Investigators should specify the work-up performed and provide details of the organic conditions found as part of the diagnostic investigation.
4. Validated outcome measures should be used to assess global improvement and changes in individual symptoms.
5. Potential differences in illness course and treatment response should be examined for patients with different symptom phenotypes.
6. Diverse populations should be investigated, including patients in primary care, community controls, and children from different cultural and ethnic groups.
7. The Rome II criteria[11] (see Table 6 of the technical report[10]) should be validated in a range of clinical settings and populations to determine the utility of the criteria in making clinically useful distinctions between individuals and groups of patients.

In view of the paucity of published literature on therapeutic approaches to this condition, there is an urgent need for trials of all currently used interventions in children with functional abdominal pain. We support the statement of the Functional Bowel Disorders Working Group Report of the First World Congress of Pediatric Gastroenterology, Hepatology, and Nutrition meeting that "there is a need to develop drugs to modulate abnormalities in sensorimotor function of the enteric nervous system in functional disorders to relieve specific symptoms and to assess the proper role of these drugs in the treatment of children and adolescents" and "the role of antidepressants (tricyclics, selective serotonin reuptake inhibitors) in the treatment of functional gastrointestinal disorders associated with abdominal pain needs to be assessed."[12(pS113)] The Rome II working teams also agreed with this need, recommending guidelines for clinical trial research.[13]

TECHNICAL REPORT

Subcommittee on Chronic Abdominal Pain

Chronic Abdominal Pain in Children

ABSTRACT. Chronic abdominal pain, defined as long-lasting intermittent or constant abdominal pain, is a common pediatric problem encountered by primary care physicians, medical subspecialists, and surgical specialists. Chronic abdominal pain in children is usually functional, that is, without objective evidence of an underlying organic disorder. The Subcommittee on Chronic Abdominal Pain of the American Academy of Pediatrics and the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition has prepared this report based on a comprehensive, systematic review and rating of the medical literature. This report accompanies a clinical report based on the literature review and expert opinion.

The subcommittee examined the diagnostic and therapeutic value of a medical and psychological history, diagnostic tests, and pharmacologic and behavioral therapy. The presence of alarm symptoms or signs (such as weight loss, gastrointestinal bleeding, persistent fever, chronic severe diarrhea, and significant vomiting) is associated with a higher prevalence of organic disease. There was insufficient evidence to state that the nature of the abdominal pain or the presence of associated symptoms (such as anorexia, nausea, headache, and joint pain) can discriminate between functional and organic disorders. Although children with chronic abdominal pain and their parents are more often anxious or depressed, the presence of anxiety, depression, behavior problems, or recent negative life events does not distinguish between functional and organic abdominal pain. Most children who are brought to the primary care physician's office for chronic abdominal pain are unlikely to require diagnostic testing. Pediatric studies of therapeutic interventions were examined and found to be limited or inconclusive. *Pediatrics* **2005;115:e370–e381. INTRODUCTION

The exact prevalence of chronic abdominal pain in children is not known. It seems to account for 2% to 4% of all pediatric office visits.[1] One study suggested that 13% of middle-school students and 17% of high-school students experience weekly abdominal pain.[2] In the latter study, it was also noted that approximately 8% of all students had seen a physician for evaluation of abdominal pain in the previous year. Quality of life in adult patients with chronic abdominal pain is substantially poorer than that of the general population.[3] The economic cost related to this condition in children is not known but is likely to be substantial, considering that expenses associated with irritable bowel syndrome (IBS) in adults have been estimated to be $8 billion to $30 billion per year.[4–6] The long-term outcome of this condition has not been determined, but preliminary data indicate that young adults with a history of recurrent abdominal pain that began in childhood who are treated by a subspecialist are significantly more likely than their peers without recurrent abdominal pain to have lifelong psychiatric problems and migraine headaches.[7] Despite the high prevalence and effects of this condition, no evidence-based guidelines for its evaluation and treatment exist.

With this background in mind, the American Academy of Pediatrics and the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition established a subcommittee charged with developing evidence-based guidelines for the evaluation and treatment of chronic abdominal pain in children. A major problem in reviewing the literature arose in defining criteria for recurrent or chronic abdominal pain. For many years, the term "recurrent abdominal pain" has been used to describe all cases without an organic etiology. It was first introduced in the pediatric literature by Apley and Naish[8] in the late 1950s, an era in which some organic gastrointestinal disorders had not been fully appreciated. Children were considered to have recurrent abdominal pain if they had experienced at least 3 bouts of pain, severe enough to affect activities, over a period of at least 3 months. This definition had initially constituted the entry criteria for their descriptive studies, but recurrent abdominal pain later became a term used clinically to describe

all children with abdominal pain without an organic etiology. It is now agreed that recurrent abdominal pain is a description, not a diagnosis. Recurrent abdominal pain, as a case definition, includes children with a variety of functional gastrointestinal disorders causing abdominal pain, such as nonulcer dyspepsia, IBS, or abdominal migraine. It also may include children with organic disease (see questions 2–6 later in this report). In this article we avoid use of the term "recurrent abdominal pain" whenever possible to lessen the confusion that the term engenders. Table 1 summarizes terms currently used to describe long-lasting constant or intermittent childhood abdominal pain.

The preponderance of the available pediatric literature on this subject is still based on the Apley and Naish criteria.[8] Thus, evidence was sought in articles that were selected based on the presence of Apley and Naish criteria as entry criteria unless the subcommittee felt that other strong qualities (for example, large epidemiologic study or double-blind, randomized, controlled trial [RCT]) justified their evaluation and inclusion as part of the evidence, which meant that some articles including children with abdominal pain of <3 months' duration were excluded from consideration.

After a careful evaluation of the published literature, no evidence-based procedural algorithm could be produced; instead, questions of interest to clinicians were posed and clinical guidance was generated linked to the standard clinical approach of history, physical examination, diagnostic testing, and treatment. This article is organized in 3 parts: (1) the methodology used to review the evidence and generate the statements is described; (2) questions are answered regarding subgroups of disorders, the role of diagnostic evaluation (history, laboratory tests, radiologic and invasive techniques, and psychosocial evaluation), and the efficacy of pharmacologic, behavioral, and surgical interventions; and (3) a summary of the quality of the evidence is provided (Appendix 1).

TABLE 2. Literature-Search Strategy

Search Terms	No. of Articles Returned
([("abdominal pain"[MeSH terms] OR abdominal pain[text word]) AND notpubref[sb]] AND "child"[MeSH terms])	6662

MeSH indicates medical subject heading (PubMed's controlled vocabulary); notpubref[sb] limits the search to the biomedical literature.

METHODOLOGY

The guideline-development process of Woolf[9] was used with a subcommittee of experts and community physicians guiding the work of the methodologist (H.P.L.) to assemble the evidence, reviewing the results of the methodologist and using the nominal group technique[10] to arrive at conclusions based on the evidence.

After initial discussions, 15 questions were defined and collapsed into the 8 questions in this review. An initial search (see Table 2) was performed on PubMed (www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed) on October 27, 2000, searching for "abdominal pain" in the broadest possible way but limited to pediatric studies; 1498 titles were retrieved. The search was repeated on June 19, 2002, providing another 158 references, for a total of 1656.

In the review process, the following were exclusion criteria: non-English, nonpediatric, nonrecurrent/nonfunctional/nonchronic abdominal pain, small study (sample size ≤5), no original data, letter to the editor, study on *Helicobacter pylori*, and study subjects not baseline-healthy (eg, patients with sickle cell disease). The studies regarding *H pylori* were excluded because the literature regarding *H pylori* had been reviewed recently by a North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition committee and a practice guideline had been published.[11] All titles were reviewed by a single reader (H.P.L.); 10% of the excluded articles were reviewed by 2 committee members (C.D.L. and R.B.C.), with 100% agreement regarding exclusion criteria. Of nonrejected titles, abstracts were read by a single reader (H.P.L.), and additional exclusions were made. Articles

TABLE 1. Currently Used Definitions to Describe Childhood Abdominal Pain

Recurrent abdominal pain as defined by Apley and Naish8	≥3 episodes of abdominal pain, over a period of ≥3 mo, severe enough to affect activities
RAP	A common abbreviation for recurrent abdominal pain that has been used in the literature to depict recurrent abdominal pain as defined by Apley and Naish; many physicians incorrectly use this term to imply functional abdominal pain
Chronic abdominal pain	Abdominal pain with a minimum duration of 3 mo; some clinicians believe that pain lasting >1–2 mo is chronic
Rome II criteria for abdominal pain	Abdominal pain for at least 12 wk, which need not be consecutive, in the preceding 12 mo; these criteria apply to IBS, functional dyspepsia, and functional abdominal pain
Functional abdominal pain	Abdominal pain that occurs in the absence of anatomic abnormality, inflammation, or tissue damage
Nonorganic abdominal pain	A term that is often used interchangeably with functional abdominal pain
Psychogenic abdominal pain	A term that is often used interchangeably with functional abdominal pain

TABLE 3. Articles and Studies Processed in the Review

Reason	Title	Abstract	Article	Total

Study detailed review				83

CAP indicates chronic abdominal pain. Non-CAP includes articles on *Helicobacter* and abdominal pain.
* These totals reflect the following overlaps: 45 rejected as abstracts and titles; 9 articles rejected as abstracts and articles; 7 rejected as titles and articles; and 1 rejected as abstract, title, and article.

were read by at least 2 readers (medical student and H.P.L.). Ten articles were abstracted in parallel, with similar results, demonstrating a reliable procedure. Data were abstracted regarding the study as a whole, design and quality, patient groups, and outcomes and their values. Efforts were made to standardize the vocabulary used in recording the methodology and results, resulting in a controlled vocabulary of 1262 terms. After review, 94 articles were included in the evidence review.

The definitions of the study designs were as follows: uncontrolled experiment, an unspecified group of participants received intervention and follow-up data were provided; case-series cross section, data were provided on a single group of participants; case-series follow-up, baseline and follow-up data were provided on a single group of participants; cohort cross section, a single group of participants was divided into 2 or more groups on the basis of a specified feature (eg, history or laboratory tests) and described; cohort follow-up, baseline and follow-up data were provided on a single group of participants who were divided into 2 or more groups; case control, 2 or more groups were assembled and retrospective or current data are provided; and RCT, participants were randomly assigned to intervention, and follow-up data are provided. Because the questions were all comparative, only studies with 2 arms or more were included in this review (thereby excluding case series).

Table 3 shows the type of articles and studies as processed in the review. Most articles were rejected on the basis of title review. Some articles were rejected at more than 1 point in the process, as indicated by the overlaps. Ninety-four articles were left for review. Sixty-four articles had full data investigation, which included separating articles into 1 or more studies in case there was, for example, a baseline case-control study with a cohort follow-up; hence, the 64 articles translated into 83 studies.

An article might have more than 1 study in it if, for instance, there was an initial cohort cross-section with a subsequent cohort follow-up reported in the same article. Of the 83 studies for which methodology was reviewed, 46 were case control, 20 were cohort cross section, 10 were cohort follow-up, and 7 were RCTs. A recent systematic review of treatments in recurrent abdominal pain identified the same RCTs,[12] providing validation for our approach.

Data abstracted for each study as a whole included study city; study country; single or multiple site; site type (community, physician office, academic pediatric setting, gastroenterologist office); funding source; age range, mean, and SD; sample size; number of groups; number of outcomes; and number of time points.

A methodology review was performed for each study, based on the Newcastle-Ottawa Scale for assessing the quality of nonrandomized studies in meta-analyses.[13] Inclusion and exclusion criteria were noted by using the controlled vocabulary. The evidence was characterized in terms of outcome type (based on the controlled vocabulary), outcome name (specific to this study), outcome units (for continuous outcomes), outcome time point (baseline or later), method (how outcome was assessed), sample size at outset, and sample size at termination (a difference from sample size at outset indicated loss to follow-up). Data for continuous outcomes (in which a quantity was measured within a participant) were usually characterized by the mean and SD. For categorical data (in which participants were counted once), the category was labeled by using the controlled vocabulary, test statistic name, *P* value (and comments), and data source (page/figure/table).

Figure 1 summarizes the geographic distribution of the studies for which the country was provided. Of 89 articles for which data were provided, 62 (70%) were performed at a single site, 30 (34%) were based on research at an academic pediatric center, 27 (31%) were performed at a gastroenterology clinic, 17 (19%) were performed at the community level, and 9 (10%) were performed at general pediatric offices.

We calculated a quality score for each study as the ratio of quality items attained to the total number of items. The average, SD, and confidence intervals are given for each design in Table 4. Although the quality scores seem to increase for the more preferred designs, the confidence intervals all overlap.

Evidence tables for each of the 8 questions were generated across studies and grouped according to arm type, method, or outcome, as pertinent to the question. There were 685 outcomes across the studies, categorized as history outcomes (550 [80%]), tissue/physiologic outcomes (115 [17%]), physical examination outcomes (15 [2%]), and use of medications (5 [1%]). Among the 685 outcomes, 161 of the *P* values (23%) were not statistically significant, and an additional 316 (46%) were not provided by investigators. Each subcommittee member took responsibility for 1 or more questions. Each reviewed the evidence tables and the

TABLE 4. Quality Scores by Design

	No. of Studies	Average Score, %	SD, %	Confidence Interval, %
RCT	7	70	15	(58–82)
Cohort follow-up	9	64	21	(50–78)
Cohort cross section	18	58	18	(50–67)
Case control	46	53	26	(45–60)

TABLE 5. Rating of Evidence Quality

Level	Criteria
A	Well-designed RCTs or diagnostic studies on relevant populations: ≥2 studies that compared the test with a criterion standard in an independent, blind manner in an unselected population of children similar to those addressed in the report
B	RCTs or diagnostic studies with minor limitations and overwhelmingly consistent evidence from observational studies: a single study that compared the test with a criterion standard in an independent, blind manner in an unselected population of children similar to those addressed in the report
C	Observational studies (case-control and cohort design)
D	Expert opinion, case reports, reasoning from first principles

primary articles and generated a summary of the research. The scale for rating evidence is given in Table 5.

The reviews were discussed by the subcommittee, and the nominal group technique[10] was used to achieve consensus.

QUESTIONS

Question 1: Is there evidence that children with chronic abdominal pain have symptom patterns that can be categorized as functional dyspepsia, IBS, or abdominal migraine?

There is limited but credible evidence of the existence of functional dyspepsia, IBS, and abdominal migraine in children (evidence quality C).

Although often discussed as a homogeneous group of patients, there are different phenotypic manifestations of functional abdominal pain. The wide variety of descriptive terms applied to these patients' symptoms, including irritable bowel of childhood, spastic colon of childhood, nonorganic recurrent abdominal pain, and psychogenic recurrent abdominal pain, reflects both the heterogeneity of the group and the limited understanding of the pathogenesis of symptoms.

The sensitivity and specificity of the Apley and Naish criteria have been questioned, and some investigators have proposed the "Rome" criteria,[14] which suggest that many children and adolescents with recurrent or chronic abdominal pain manifest symptom clusters that facilitate the diagnosis of disorders on the basis of symptoms alone. In 1999, a group of investigators (Rome II committee) was charged with identifying and then developing diagnostic criteria for childhood functional disorders including recurrent abdominal pain. They developed a symptom-based classification of functional disorders

TABLE 6. Rome II Criteria for Functional Bowel Disorders Associated With Abdominal Pain or Discomfort in Children[14]

Functional dyspepsia: in children mature enough to provide an accurate pain history (at least 12 wk, which need not be consecutive) within the preceding 12 mo of:
- Persistent or recurrent pain or discomfort centered in the upper abdomen (above the umbilicus); and
- No evidence (including upper endoscopy) that organic disease is likely to explain the symptoms; and
- No evidence that dyspepsia is exclusively relieved by defecation or associated with the onset of a change in stool frequency or stool form

IBS: in children old enough to provide an accurate pain history (at least 12 wk, which need not be consecutive) in the preceding 12 mo of:
- Abdominal discomfort or pain that has 2 of the following 3 features:
  - Relieved with defecation
  - Onset associated with a change in frequency of stool
  - Onset associated with a change in form (appearance) of stool
  - and
- There are no structural or metabolic abnormalities to explain the symptoms
- The following symptoms also support a diagnosis of IBS:
  - Abnormal stool frequency defined as >3 bowel movements per day or <3 bowel movements per week
  - Abnormal stool form (lumpy/hard or loose/watery)
  - Abnormal stool passage (straining, urgency, or feeling of incomplete evacuation)
  - Passage of mucus with stool
  - Bloating or feeling of abdominal distention

Functional abdominal pain: at least 12 wk of:
- Nearly continuous abdominal pain in a school-aged child or adolescent;
- No, or only occasional, relation of pain with physiologic events (eg, eating, menses, or defecation);
- Some loss of daily functioning;
- Pain that is not feigned (eg, malingering); and
- Insufficient criteria for other functional gastrointestinal disorders that would explain the abdominal pain

Abdominal migraine: in the preceding 12 mo:
- Three or more paroxysmal episodes of intense, acute midline, abdominal pain lasting 2 h to several days, with intervening symptom-free intervals lasting weeks to months;
- Evidence of absence of metabolic, gastrointestinal, and central nervous system structural or biochemical diseases is absent; and
- Two of the following features:
  - Headache during episodes
  - Photophobia during episodes
  - Family history of migraines
  - Headache confined to 1 side only
  - An aura or warning period consisting of visual disturbances, sensory symptoms, or motor abnormalities

associated with abdominal pain (Table 6). The goal for these criteria was to decrease cost and suffering for the patients by encouraging a defined-criteria diagnosis of the disorder rather than one obtained after excluding organic diseases. The group felt that the classic Apley and Naish criteria of recurrent abdominal pain were too general and failed to recognize that recurrent abdominal pain was not a final diagnosis. It was also apparent to the group that children and adolescents often displayed a symptom complex similar to previously described functional disorders in adults, such as IBS and functional dyspepsia. Clinical experience also suggested that a symptom complex called abdominal migraine existed.

A prospective study of 257 children 5 years of age or older presenting with abdominal pain or discomfort, nausea, or vomiting for 1 month or more identified 127 subjects meeting the Rome II criteria for dyspepsia (before evaluation for disease).[15] Symptoms were ulcer-like in 26% and dyspepsia-like in 15% of the subjects. Fifty six of these subjects underwent esophagogastroduodenoscopy, and 35 were found to have no evidence of disease. These 35 subjects were believed to fulfill strict criteria for functional dyspepsia. Symptoms of IBS were present in approximately one fourth of the patients with functional dyspepsia.

Questionnaires administered during a population-based study of middle- and high-school students revealed a symptom complex consistent with IBS in 6% of middle-school students and 14% of high-school students.[2] None of these subjects were tested for organic disease. A prospective study of 227 children 5 years of age or older referred to a pediatric gastroenterology clinic for evaluation of chronic abdominal pain showed that 117 had symptoms consistent with IBS.[16] Diagnostic testing failed to reveal underlying disease. Concomitant upper abdominal discomfort or nausea was present in one third of these subjects.

A well-designed and implemented epidemiologic study[17] of a general population demonstrated an increased prevalence of a lifetime maternal history of migraine in children with recurrent abdominal pain, migraine headache, and abdominal migraine. Abdominal migraine was defined as recurrent abdominal pain associated with nausea and/or vomiting of sufficient severity to stop normal activity plus 3 of the following: pallor, fever, limb pain, dizziness, or headache. Among study patients, 2.4% had abdominal migraine. Children with abdominal migraine were 2.6 times more likely to have a maternal history of migraine. Another prospective cross-sectional questionnaire study[18] of a large random sample of school children 5 to 15 years old compared children with migraine headaches and children with abdominal migraine. Abdominal migraine was defined as (1) pain severe enough to interfere with normal daily activities; (2) pain dull or colicky in nature; (3) periumbilical or poorly localized pain; (4) any 2 of anorexia, nausea, vomiting, or pallor; (5) attacks lasting for at least 1 hour; and (6) complete resolution of symptoms between attacks. Approximately 4.1% had abdominal migraine. Children with migraine headaches were twice as likely to have abdominal migraine, and children with abdominal migraine were twice as likely to have migraine headaches as the general population.

Question 2: What is the predictive value of history items?

There are no studies of unselected patients showing that pain frequency, severity, location, or effects on lifestyle are able to distinguish between functional and organic disorders (evidence quality C).

Children with recurrent abdominal pain are more likely than children without recurrent abdominal pain to have headache, joint pain, anorexia, vomiting, nausea, excessive gas, and altered bowel symptoms. There are insufficient data to determine if the presence of associated symptoms can help the physician distinguish between functional and organic disorders (evidence quality C).

The presence of alarm symptoms or signs suggests a higher pretest probability or prevalence of organic disease and may justify the performance of diagnostic tests. Alarm symptoms or signs include but are not limited to involuntary weight loss, deceleration of linear growth, gastrointestinal blood loss, significant vomiting, chronic severe diarrhea, persistent right upper or right lower quadrant pain, unexplained fever, and family history of inflammatory bowel disease (evidence quality D).

Functional abdominal pain lacks a diagnostic marker. Because no prospective studies on natural history or incidence compare the history of children with and without recurrent episodes of abdominal pain, it cannot be stated that duration of pain itself supports a diagnosis of functional pain. The committee was able to identify 25 peer-reviewed studies of patients with chronic abdominal pain of >3 months' duration in which symptom description was included in the results and patient-selection criteria were most likely to exclude author bias (survey, questionnaire, or consecutive patients prospectively or retrospectively enrolled for study).[2,8,19–41] One quarter of these studies were performed in North America, one quarter were performed in the Far East, and half were performed in Europe. The available studies provide evidence that frequency, severity, location, and timing (postprandial, waking during night) of abdominal pain do not help distinguish between organic and functional abdominal pain. Children with recurrent episodes of abdominal pain are more likely than children without abdominal pain or children with behavior disorders to have anorexia, nausea, episodic vomiting, constipation, diarrhea, headache, arthralgia, or eye problems. Yet, none of these associated symptoms have been reported to help distinguish between organic and functional abdominal pain. Younger age of onset of pain and inability to attend school because of pain were associated with a decision to consult a physician.[37]

Physical examination of children with recurrent or chronic abdominal pain has been described rarely. The presence of tenderness on abdominal palpation has been reported to be characteristic of children with recurrent episodes of abdominal pain without

evidence of organic disease when compared with control children.[28]

Question 3: What is the predictive value of laboratory tests?

There is no evidence to evaluate the predictive value of blood tests (evidence quality D).

There is no evidence to determine the predictive value of blood tests in the face of alarm signals (evidence quality D).

Because researchers have used results of laboratory testing as inclusion or exclusion criteria for functional abdominal pain, there are no studies that have evaluated the usefulness of common laboratory tests (complete blood cell count, erythrocyte sedimentation rate, comprehensive metabolic panel, urinalysis, stool parasite analysis) to distinguish between organic and functional abdominal pain. Investigations of specific biological markers have described significant differences between patients with recurrent episodes of abdominal pain and control subjects (such as increased plasma cholecystokinin concentrations and decreased plasma oxytocin and cortisol concentrations in children with pain).[29,42] However, the number of patients in these studies is small, and the value of such measurements to clinical practice remains to be determined. The coexistence of abdominal pain and an abnormal test result for a common gastrointestinal disorder such as lactose malabsorption or *H pylori* infection does not necessarily indicate a causal relationship between the 2. Treatment of lactose malabsorption often does not result in resolution of abdominal pain, and children with *H pylori* infection are not more likely to have abdominal pain than children without *H pylori*. Children with lactose malabsorption may have a phenotype overlapping with diarrhea-predominant IBS.

Question 4: What are the predictive values of other diagnostic tests?

There is no evidence to suggest that the use of ultrasonographic examination of the abdomen and pelvis in the absence of alarm symptoms has a significant yield of organic disease (evidence quality C).

There is little evidence to suggest that the use of endoscopy and biopsy in the absence of alarm symptoms has a significant yield of organic disease (evidence quality C).

There is insufficient evidence to suggest that the use of esophageal pH monitoring in the absence of alarm symptoms has a significant yield of organic disease (evidence quality C).

Ultrasonographic examination of the abdomen and pelvis is a painless, noninvasive, and inexpensive test that can detect abnormalities of the kidneys, gallbladder, liver, pancreas, appendix, intestines, ovaries, and uterus. When abdominal and pelvic ultrasonography has been performed in children with recurrent episodes of abdominal pain without alarm symptoms, abnormalities have been found in fewer than 1%.[43] Abnormalities detected on ultrasonography may not be causally related to the patient's abdominal pain. When atypical symptoms are present, such as jaundice, urinary symptoms, back or flank pain, vomiting, or abnormal findings on physical examination, an abdominal and pelvic ultrasonography is more likely to detect an abnormality (approximately 10%).

Endoscopy and biopsy of the esophagus, stomach, and duodenum, an invasive and expensive procedure, can detect esophagitis, gastritis, duodenitis, and ulceration. Esophageal pH monitoring, also an invasive and expensive test, measures the frequency and duration of exposure of the esophagus to gastric acid as a means of diagnosing gastroesophageal reflux. Studies of endoscopy, biopsy, and/or esophageal pH monitoring performed in children with recurrent abdominal pain have demonstrated abnormalities in 25% to 56%, but reports have been limited by small sample size, sample bias, variability of findings, and questionable specificity and generalizability.[40,44–46] Endoscopic or histopathologic abnormalities such as esophagitis, gastritis, or duodenitis do not predict the prognosis, which is generally favorable in children with recurrent abdominal pain, including those with dyspepsia.[15]

Question 5: What is the diagnostic value of the psychosocial history?

The literature was reviewed with respect to 3 domains of psychosocial history: life-event stress, child emotional/behavioral symptoms, and family functioning.

Life-Event Stress

There is a small amount of evidence suggesting that the presence of recent negative life events is not useful in distinguishing between functional abdominal pain and abdominal pain of other causes (evidence quality B). There is limited evidence suggesting that daily stressors are associated with the occurrence of pain episodes and that higher levels of negative life events are associated with increased likelihood of symptom persistence (evidence quality C). There is no evidence on whether life stress influences symptom severity, course, or response to treatment (evidence quality D).

Studies including comparison groups of other patients are relevant in assessing the value of the psychosocial history in the differential diagnosis of chronic abdominal pain. One study[47] compared 30 pediatric patients with recurrent episodes of abdominal pain with 30 patients referred for acute minor illness or injury. Life-event change in the previous year did not differ significantly between the 2 groups. Another study found no difference between patients with recurrent abdominal pain and patients with minor organic disease (eg, gastritis, esophagitis) on measures of patients' personal life events or mothers' reports of family life events.[48] No studies have found that the presence of life-event stress significantly differentiates patients with functional abdominal pain from other patient groups.

Nonetheless, several investigations have reported higher levels of life stress in children with chronic abdominal pain compared with children without abdominal pain. Two studies compared pediatric patients with abdominal pain with healthy school children and found significantly higher levels of life-event stress in patients with pain.[23,49] A diary study

found that patients with recurrent episodes of abdominal pain reported significantly more daily stressors than healthy school children; moreover, the relation between daily stressors and somatic complaints was significantly stronger for patients with abdominal pain than for healthy school children.[41] Thus, although there is no evidence that life stress helps distinguish between patients with functional abdominal pain and patients with organic disease, children with functional abdominal pain may experience stressors that warrant attention. Additional research is needed to evaluate whether these stressors contribute to symptom severity, course, or response to treatment.

Emotional/Behavioral Symptoms

There is evidence suggesting that the presence of anxiety, depression, or behavior problems is not useful in distinguishing between functional abdominal pain and abdominal pain of other causes (evidence quality B). There is evidence that patients with recurrent abdominal pain have more symptoms of anxiety and depression (internalizing emotional symptoms) than do healthy community controls (evidence quality B). In contrast, there is evidence that children with recurrent abdominal pain do not have higher levels of conduct disorder and oppositional behavior (externalizing emotional symptoms) compared with healthy community controls (evidence quality B). There are no data on whether emotional/behavioral symptoms predict symptom severity, course, or response to treatment (evidence quality D). There is evidence suggesting that children with recurrent abdominal pain are at risk of later emotional symptoms and psychiatric disorders (evidence quality B).

Several studies have used standardized measures to assess emotional/behavioral symptoms in patients with chronic abdominal pain and other patient groups. In a study comparing 30 patients with abdominal pain with 30 patients with acute minor illness or injury, no significant differences were found between the patient groups when depression was assessed by interview or a child self-report measure.[47] Another study comparing 19 patients with functional abdominal pain with 19 patients with an organic etiology of abdominal pain found no significant differences between the groups on the Child Behavior Checklist completed by the mother or on the Rutter B2 Behavioral Scale completed by the teacher.[50] Similarly, no significant differences were found between patients with and without organic findings in 2 studies that included pediatric patients whose abdominal pain ranged in duration from 1 month to several years.[48,51] Thus, no studies have found a significant difference between patients with abdominal pain that is functional or organic in etiology with respect to emotional/behavioral symptoms.

Considerable evidence suggests that patients with chronic abdominal pain have more symptoms of anxiety and depression than do community controls. In a study of 31 children with recurrent abdominal pain and 31 matched classroom control children, mothers' reports indicated significantly higher scores for internalizing emotional symptoms (anxiety, depression) in children with abdominal pain.[52] Teachers' reports did not show significant group differences. However, a structured diagnostic interview indicated that 26 of the 31 children with abdominal pain met the criteria for a psychiatric diagnosis. In most cases, these diagnoses were anxiety related. Others also have observed higher levels of anxiety and depression in patients with recurrent episodes of abdominal pain compared with community controls,[48,51] although 1 study found that patients with abdominal pain were within the normal range for anxiety and depression on the basis of published normative data,[53] and another found no difference between patients with abdominal pain and controls on self-report or interview measures of depression.[25] A community-based study of students in middle and high school found that those with IBS-like symptoms had significantly higher scores than their peers without IBS on self-report questionnaire measures of anxiety and depression.[2] In contrast to the positive findings for anxiety and depression, no studies have found significant differences between children with recurrent episodes of abdominal pain and community controls on measures of conduct disorder or oppositional behavior.

Finally, results of 3 studies suggest that children with recurrent abdominal pain may be at risk of later anxiety and depression. A recent study compared 28 young adults evaluated for functional abdominal pain between the ages of 6 and 17 years with 28 matched former childhood participants of a study of tonsillectomy and adenoidectomy (controls).[7] An average of 11 years after the target visit, a structured psychiatric diagnostic interview was administered to identify psychiatric disorders based on *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*[54] criteria. Compared with controls, those with persistent abdominal pain were significantly more likely to meet criteria for a lifetime or current history of anxiety disorder. In another study, children with abdominal pain and controls were identified in data from a national longitudinal birth cohort study.[34] At 36 years of age, participants were administered a semistructured psychiatric interview that generated scores representing thresholds for psychiatric disorder. Persistent abdominal pain in childhood was significantly associated with psychiatric disorder in adulthood. In a prospective study of 31 patients with recurrent abdominal pain and 31 control children, mothers' reports of depressive symptoms and anxiety in their children 5 years after baseline assessment were significantly higher for patients with abdominal pain than for control children.[55]

Family Functioning

There is evidence that parents of patients with recurrent abdominal pain have more symptoms of anxiety, depression, and somatization than do parents of community controls or parents of other pediatric patients (evidence quality C). There is some evidence that families of patients with recurrent abdominal pain do not differ from families of control children or families of patients with acute illness in broad areas of family functioning, such as family cohesion, conflict, and marital satisfaction (evidence quality C).

Two studies used structured diagnostic interviews to assess family history of psychiatric disorders in patients with recurrent episodes of abdominal pain compared with other patient groups. In 1 study, 28 adults with a childhood history of recurrent episodes of abdominal pain were compared with 28 adults who had undergone minor surgery as children (controls).[7] Participants with a history of childhood abdominal pain were significantly more likely than controls to report having a first-degree relative with generalized anxiety disorder, and there was a trend suggesting group differences on family history of major depression. In another study, on the basis of interviews with 20 mothers of children with functional abdominal pain and 20 mothers of children with an organic etiology for abdominal pain, the mean number of psychiatric disorders per relative was found to be significantly higher in the functional-pain group than in the organic-pain group.[56] With respect to particular types of disorders, a significant difference was found only for somatization disorder, with the functional-pain group having a higher proportion of affected relatives. A third study[51] found that, compared with control parents, mothers (but not fathers) of children with recurrent episodes of abdominal pain had significantly higher levels of anxiety, depression, and somatization symptoms. Studies also have reported higher levels of emotional distress in parents of children with recurrent episodes of abdominal pain compared with parents of children without abdominal pain.[24,25,34]

Finally, a few studies have examined broad areas of family functioning. These studies found no difference between patients with abdominal pain and other patient groups or controls on measures of parent marital satisfaction[47,48] or family cohesion and conflict.[48] In 1 study, children with recurrent episodes of abdominal pain reported greater parental encouragement of illness behavior than did children without abdominal pain.[48]

Question 6: What is the effectiveness of pharmacologic treatment?

A thorough review of the literature with a focus on RCTs revealed a paucity of studies examining pharmacologic and dietary interventions. Therefore, definitive statements concerning therapeutic efficacy are quite limited.

There is evidence that treatment for 2 weeks with peppermint oil may provide benefit in children with IBS (evidence quality B).

In a randomized, double-blind, controlled trial, 42 children with IBS were given pH-dependent, enteric-coated peppermint-oil capsules or placebo. After 2 weeks, 75% of those receiving peppermint oil had decreased severity of pain associated with IBS.[57] It was concluded that peppermint oil can be used as a therapeutic agent during the symptomatic phase of IBS. This was a short study of an agent not commonly used in the treatment of IBS. Entry criteria were not well described, other symptoms were not affected, and the safety and palatability of the drug were not described. Despite these shortcomings, the study represents an important proof-of-concept study supporting a beneficial effect of a medication with possible smooth muscle–relaxing properties in children with IBS.

There is inconclusive evidence of the benefit of H_2-receptor antagonists to treat children with dyspepsia (evidence quality B).

A double-blind, placebo-controlled trial of famotidine was conducted in 25 children with abdominal pain and dyspepsia.[58] Among the different variables evaluated, only the global evaluation suggested that there was a benefit of famotidine over placebo. Using the quantitative assessment, however, the mean improvement of the score using famotidine versus placebo was not statistically significant. There was also a significant improvement in symptoms during the first treatment period regardless of the medication used. A subset of patients with dyspeptic symptoms demonstrated a significant benefit from the drug. In this study, enrolled children had to meet Apley and Naish criteria and had to have dyspeptic symptoms. The study population was heterogeneous, with some patients having positive *H pylori* titers and others having an abnormal lactose breath hydrogen test. It is the opinion of the subcommittee that H_2-receptor antagonists may be beneficial for children with severe dyspeptic symptoms (including heartburn), but the results were difficult to generalize to children with functional abdominal pain.

There is inconclusive evidence that fiber supplement intake decreases the frequency of pain attacks for patients with recurrent abdominal pain (evidence quality B).

A randomized, double-blind, placebo-controlled study in 52 children with recurrent episodes of abdominal pain recruited from primary care practices[59] demonstrated a statistically significant decrease in pain attacks in children who were given additional fiber, compared with those receiving placebo. The study involved small groups (26 each), and improvement was marginal (7 improved with placebo and 13 with fiber).

There is inconclusive evidence that a lactose-free diet decreases symptoms in children with recurrent abdominal pain (evidence quality B).

In a study of 103 children 6 to 14 years of age with nonlocalized abdominal pain for 4 months, a similar prevalence of lactase deficiency was found in the control and abdominal-pain groups.[60] Thirty-eight patients completed 3 successive 6-week diet trials conducted in a double-blind fashion. The patients then were placed on a 12-month milk-elimination diet. The results suggested that the elimination of lactose did not affect the overall rate of improvement in abdominal pain. In addition, the recovery rate was similar in both lactose absorbers and nonabsorbers, independent of dietary restrictions. This study suggested that lactose intolerance and recurrent abdominal pain are 2 separate entities, and a lactose-free diet has no effect on outcome of abdominal pain in lactose absorbers and nonabsorbers.

There are limited data to suggest that pizotifen is efficacious in the treatment of abdominal migraine (evidence quality B).

Pizotifen is a potent antagonist of the serotonin 2A (5-HT2A) receptor, which is not approved for use in

the United States. A placebo-controlled crossover study used pizotifen for the treatment of 14 children with abdominal migraine.[61] Patients received either pizotifen (0.25 mg, twice daily) or placebo syrup for 2 months, then the alternate treatment for 2 months. While being treated with pizotifen, the study children had fewer days of abdominal pain and lower indices of severity and misery. The medication was well tolerated. These results may not be generalizable to children with milder symptoms. Common adverse effects include drowsiness, dizziness, increased appetite, and weight gain.

Question 7: What is the effectiveness of cognitive-behavioral therapy?

There is evidence that cognitive-behavioral therapy may be useful in improving pain and disability outcome in the short term (evidence quality B).

Two RCTs[62,63] evaluated the efficacy of a cognitive-behavioral program and a cognitive-behavioral family intervention for the treatment of nonspecific abdominal pain. In the first study, results showed that both the experimental and the control groups had decreased levels of pain. However, the treated group improved more quickly, the effects generalized to the school setting, and a larger proportion of subjects were completely pain-free by 3 months' follow-up. In the second study, the children and mothers who were taught coping skills had a higher rate of complete elimination of pain, lower levels of relapse at 6 and 12 months' follow-up, and lower levels of interference with their activities as a result of pain, and parents reported a higher level of satisfaction with the treatment. After controlling for pretreatment levels of pain, children's active self-coping and mothers' caregiving strategies were significant independent predictors of pain behavior after treatment.

Question 8: What is the effectiveness of surgery?

There is no evidence of the possible beneficial role of surgery in the evaluation or management of children with recurrent abdominal pain (evidence quality D).

There are no studies comparing diagnostic or therapeutic surgery with other approaches (evidence quality D).

The literature search identified a study[64] aimed at evaluating the results of diagnostic laparoscopy in children with chronic recurrent abdominal pain. It was a series of 13 children with chronic severe episodes of abdominal pain who were subjected to diagnostic laparoscopy. Extensive laboratory and imaging studies did not contribute to the diagnosis. Laparoscopic findings that identified the cause of abdominal pain were obtained in 12 of 13 patients. Laparoscopic appendectomy was performed in all patients. Follow-up varied from 6 months to 3 years. Abdominal pain resolved in 10 patients. It was concluded that diagnostic laparoscopy is a valuable procedure in the management of children with chronic recurrent abdominal pain. The study patients represented a subgroup of children with very severe symptoms of abdominal pain, all having required hospitalization and multiple imaging studies. Although they all were found to have an organic etiology for their pain, some of the etiologies may actually be debatable as causes of disease (for example, cecal adhesion or fibrosed appendix). Two patients required a second laparoscopy for complications related to the first one. No other study addresses laparoscopy or other procedures as treatments of recurrent abdominal pain.

SUMMARY

Chronic abdominal pain (long-standing intermittent or constant abdominal pain) is common in children and adolescents. In most children, chronic abdominal pain is functional, that is, without objective evidence of an underlying organic disorder. Yet, an important part of the physician's job is to determine which children have an organic disorder. A review of the current evidence, however, indicates that there are no studies showing that pain frequency, severity, location, or effects on lifestyle help to discriminate between functional and organic disorders. Children with chronic abdominal pain are more likely than children without chronic abdominal pain to have headache, joint pain, anorexia, vomiting, nausea, excessive gas, and altered bowel symptoms, but there is insufficient evidence that the presence of the associated symptoms can help the physician discriminate between functional and organic disorders. Although children with chronic abdominal pain and their parents are more often anxious or depressed, the presence of anxiety, depression, behavior problems, or recent negative life events does not seem to be useful in distinguishing between functional and organic abdominal pain.

There is evidence that children with functional abdominal pain can have symptom clusters characterized as functional dyspepsia, IBS, or abdominal migraine as well as isolated abdominal pain. Some patients have features of more than 1 type of functional abdominal pain.

The physician also must decide whether to order diagnostic tests and, if so, which tests. The presence of alarm symptoms or signs suggests a higher pretest probability or prevalence of organic disease and may justify the performance of diagnostic tests. Alarm symptoms or signs include but are not limited to weight loss, deceleration of linear growth velocity, significant vomiting, chronic severe diarrhea, evidence of gastrointestinal blood loss, persistent right upper or right lower quadrant pain, unexplained fever, family history of inflammatory bowel disease, or abnormal or unexplained physical findings. The predictive value of blood tests, with or without alarm signals, has not been studied adequately. There is no evidence to suggest that the use of ultrasonographic examination of the abdomen and pelvis in the absence of alarm symptoms has a significant yield of organic disease. There is little evidence to suggest that the use of endoscopy with biopsy or esophageal pH monitoring has a significant yield of organic disease in the absence of alarm symptoms.

There is limited evidence suggesting that daily stressors are associated with the occurrence of pain episodes and that higher levels of negative life events are associated with increased likelihood of symptom persistence. Some evidence suggests that patients

with chronic abdominal pain have more symptoms of anxiety and depression than do community controls and are at greater risk of later emotional symptoms and psychiatric disorders. However, there are no data on whether emotional or behavioral symptoms predict symptom severity, course, or response to treatment. Parents of patients with chronic abdominal pain seem to have more symptoms of anxiety, depression, and somatization than do parents of community controls or parents of other pediatric patients. However, families of children with chronic abdominal pain do not seem to differ from families of children without abdominal pain or families of patients with acute illness in broad areas of family functioning.

There have been few studies of the treatment of chronic abdominal pain in children. There is inconclusive evidence that a lactose-free diet decreases symptoms or that a fiber supplement decreases the frequency of pain attacks. There is inconclusive evidence of the benefit of acid suppression with H_2-receptor antagonists to treat children with dyspepsia. There is evidence that treatment for 2 weeks with peppermint oil may provide benefit in children with IBS. There is also evidence that cognitive-behavioral therapy may be useful in improving pain and disability outcome in the short term.

APPENDIX 1. Summary of the Quality of the Evidence

Question	Evidence	Quality of Evidence
1	There is limited but credible evidence of the existence of functional dyspepsia, IBS, and abdominal migraine in children.	C
2	There are no studies of unselected patients showing that pain frequency, severity, location, or effects on lifestyle are able to distinguish between functional and organic disorders.	C
2	Children with recurrent abdominal pain are more likely than children without recurrent abdominal pain to have headache, joint pain, anorexia, vomiting, nausea, excessive gas, and altered bowel symptoms. There are insufficient data to determine whether the presence of associated symptoms can help the physician to distinguish between functional and organic disorders.	C
2	The presence of alarm symptoms or signs suggests a higher pretest probability or prevalence of organic disease and may justify the performance of diagnostic tests. Alarm symptoms or signs include but are not limited to involuntary weight loss, deceleration of linear growth, gastrointestinal blood loss, significant vomiting, chronic severe diarrhea, persistent right upper or right lower quadrant pain, unexplained fever, and family history of inflammatory bowel disease.	D
3	There is no evidence to evaluate the predictive value of blood tests.	D
3	There is no evidence to determine the predictive value of blood tests in the face of alarm signals.	D
4	There is no evidence to suggest that the use of ultrasonographic examination of the abdomen and pelvis in the absence of alarm symptoms has a significant yield of organic disease.	C
4	There is little evidence to suggest that the use of endoscopy and biopsy in the absence of alarm symptoms has a significant yield of organic disease.	C
4	There is insufficient evidence to suggest that the use of esophageal pH monitoring in the absence of alarm symptoms has a significant yield of organic disease.	C
5	There is a small amount of evidence suggesting that the presence of recent negative life events is not useful in distinguishing between functional abdominal pain and abdominal pain of other causes.	B
5	There is limited evidence suggesting that daily stressors are associated with the occurrence of pain episodes and that higher levels of negative life events are associated with increased likelihood of symptom persistence.	C
5	There is no evidence on whether life stress influences symptom severity, course, or response to treatment.	D
5	There is evidence suggesting that the presence of anxiety, depression, or behavior problems is not useful in distinguishing between functional abdominal pain and abdominal pain of other causes.	B
5	There is evidence that patients with recurrent abdominal pain have more symptoms of anxiety and depression (internalizing emotional symptoms) than do healthy community controls.	B
5	In contrast, there is evidence that children with recurrent abdominal pain do not have higher levels of conduct disorder and oppositional behavior (externalizing emotional symptoms) compared with healthy community controls.	B
5	There are no data on whether emotional/behavioral symptoms predict symptom severity, course, or response to treatment.	D
5	There is evidence suggesting that children with recurrent abdominal pain are at risk of later emotional symptoms and psychiatric disorders.	B
5	There is evidence that parents of patients with recurrent abdominal pain have more symptoms of anxiety, depression, and somatization than do parents of community controls or parents of other pediatric patients.	C
5	There is some evidence that families of patients with recurrent abdominal pain do not differ from families of community controls or families of patients with acute illness in broad areas of family functioning, such as family cohesion, conflict, and marital satisfaction.	C
6	There is evidence that treatment for 2 wk with peppermint oil may provide benefit in children with IBS.	B
