that may be for forensic purposes or done in consultation with child protective services, consider obtaining the caregiver's consent and/or obtaining legal advice before making such contact. The medical record of the siblings should be reviewed in the same thorough fashion.

If a child with the possible fabricated illness is verbal, the child should be interviewed separately from the caregiver for his or her recollection of any symptoms, including where and when they occurred. It is also important to take a careful family and social history, including information about any unusual or frequent illnesses in the extended family and siblings.

Fabricated illness in a child, like other forms of child maltreatment, is not a diagnosis of exclusion. The pediatrician should evaluate the child for illness fabrication while simultaneously searching for other medical explanations for the illness: for example, unusual and rare medical problems, such as cyclic vomiting or mitochondrial disease. Some parents are overanxious or difficult, and others perceive their child as vulnerable because of some earlier traumatic event, such as extreme prematurity, and may "shop around" for a physician.[43] When parental behaviors result in harm to the child, the child has been maltreated, whatever the caregiver's motivation.[37]

The specific features of an evaluation for fabricated illness in a child depend on the type of fabrication suspected. The pediatrician may need to perform toxicology tests if poisoning is suspected or may need to request blood group typing or subtyping if blood contamination is a concern. If testing is needed to confirm the diagnosis, the child must be protected from any additional or ongoing harm while the evaluation is underway. Although the hospital is generally considered an appropriate setting to complete this testing, the offending caregiver often continues the illness fabrication in the hospital.[7] Consequently, the caregiver's contact with the child may need to be supervised to protect the child from further harm.

If there are concerns that a child may be a victim of fabricated illness, physicians should defer procedures and prescriptions. The physician's responsibility is to protect the child.

COVERT VIDEO SURVEILLANCE

Covert video surveillance (CVS) has been proposed as a method of ensuring the child's safety during the hospitalization, as well as to expose and document the offending caregiver's fabricating behavior toward the child while in the hospital.[44,45] The use of CVS has been controversial.[46] Some argue that it is an invasion of the parent's right to privacy or that it represents entrapment.[47] Others respond that privacy is not guaranteed in a hospital setting, because health care providers, such as nurses, may walk into patient rooms at any time unannounced. Also, for some conditions, monitors are attached to a child and sound at the nurses' station. Some consider CVS to be a diagnostic tool,[48] but others argue that the recordings can be difficult to interpret and that a caregiver may be falsely accused of harm.[47] Because it can be difficult to prove to child protective services and in legal proceedings that illness has been fabricated, some children will not be protected from further harm without the use of CVS to document the abuse. Some of the disadvantages of the use of CVS include its cost, the need for real-time monitoring to interrupt any harm to a child, and the risk of additional harm to the child even with close monitoring.[44,45]

In 1 series, CVS was required to make the diagnosis of fabricated illness in a child in more than half of the cases. In 10% of the cases, however, it proved helpful because it showed that the child had a medical problem.[45] CVS has been used to detect caregivers suffocating infants, intentionally causing fractures, administering poison, and injecting harmful substances into intravenous lines. Some offending caregivers, who were previously thought to be very attentive to the child, were shown to ignore the child when no one was watching. CVS can also disprove a caregiver's falsified claim, such as showing that apnea did not occur when a caregiver has reported it. Furthermore, CVS has the potential to show that the abuse was premeditated and occurred without provocation.

If CVS is to be implemented, the hospital should develop protocols that guide its use. The protocols should include provision for continuous monitoring, training for the observers or monitors, and a plan that ensures rapid intervention if the child is observed to be at risk.

An approach that can be considered instead of CVS is separation of the child from the suspected offending caregiver and subsequent observation of the child's condition. The child must be separated for sufficient time to determine whether there is any change in the child's condition while, as much as possible, maintaining constant all other management, such as medication use. During this trial period, the suspected offending caregiver must not be allowed any contact with the child unless strict third-party supervision is maintained. Intervention by child protective services will likely be required to establish and maintain this separation. If symptoms do not disappear, this is strong indication that the symptoms were not fabricated, providing the child has been adequately protected during the separation. The association between the trial separation and any improvement in a child's condition may be difficult to prove in a legal setting, especially because improvement in a child's condition may be attributed to a spontaneous remission or resolution of the underlying medical problem.

MANAGEMENT AND PROGNOSIS

Reporting Suspected Maltreatment

Physicians should report any reasonable suspicions of child abuse promptly to child protective services authorities. All states have laws that mandate physicians report suspected child maltreatment if they have reasonable cause to suspect. In a review by Sheridan,[10] only approximately one-third of the cases of suspected fabricated illness in a child had been reported. Another study found that pediatricians do not report unless they are almost certain of the diagnosis of fabricated illness. In this study, the pediatricians estimated the probability that their diagnosis was correct as greater than 90%.[24] Although the laws do not require this level of certainty for reporting, physicians may be concerned that a caregiver will escalate the illness induction to "prove" the child's illness. Also, pediatricians may be reluctant to report suspicions of illness fabrication because of previous experience with child protective services and the legal system failing to protect a child without additional corroborating evidence.

Many state child protective services systems do not list fabricated illness or any of its various names as a specific form of child maltreatment. When reporting suspected fabricated illness in these states, the pediatrician should focus on how the child was affected: for example, the pediatrician may report suspected physical abuse, emotional abuse, risk of harm, and all the categories that apply to the particular situation. Pediatricians should collaborate with child protective services and law enforcement to ensure the best outcome for the child.

Outcome if Reported

Even when fabricated illness is reported to child protective services, many children are not protected from further harm. In the 2-year surveillance study in the United Kingdom and the Republic of Ireland referred to previously,[24] approximately one-third of the children (46 of 119) were allowed to return home.[28] Approximately one-quarter of the children (27) still had signs or symptoms of abuse at follow-up. Only one-third of the children were placed in caregiving arrangements outside the control of the alleged offending parent. Child protective services and the courts were more likely to intervene and protect children who were young and who had been physically abused as opposed to older children who suffered other harm.

If children who have been victims of fabricated illness are returned home to the care of the offending caregiver, reabuse is common.[28,49] Approximately 40% suffer further abuse, including other forms of maltreatment, such as physical and emotional abuse.[49] On the basis of Rosenberg's review,[7] in 20% of the fatal cases the child had been returned home after the parents had been confronted about the suspicion of fabricated illness, and the child subsequently died. In a study in 54 children with a diagnosis of fabricated illness followed for 1 to 14 years, many of the children manifested other problems, including emotional and behavioral conditions, such as conduct disorders. Criminal conviction of the offending caregiver was found in only 8% of the cases in the Rosenberg series.[7]

In a cohort study that had several methodologic limitations, including follow-up of only approximately 50% of the original sample identified, the factors associated with better outcomes for children who had been victimized included the following: (1) continuous positive input from the spouse and/or grandparents, (2) successful short-term foster care before returning to live with the offending caregiver, (3) the offender's long-term therapeutic relationship with a social worker, (4) successful remarriage for the offending caregiver, (5) early adoption of the victim, and (6) long-term foster care placement.[49] It was not possible to determine the relative benefits for children of remaining with the abusing caregiver versus being separated. Among those children who were with the fabricator of the illness at the time of this study, children placed away from their mother, even temporarily, appeared to have a better outcome than those who did not experience this separation.

Caregiver Treatment and Reunification

When confronted with the suspicion that the illness has been fabricated,

15% to 45% of offenders admitted to causing or fabricating the child's illness, although many denied any deception.[7,45] In general, the prognosis has been poor for offenders, but there are some reports of apparent successful treatment.[50] Identifying an offender's motivation may not be critical to making a diagnosis of fabricated illness in a child, but understanding the motivation is important for determining the course of treatment.[34,51] Schreier[11] outlines the following indicators of successful treatment: (1) the abuser admits to the abuse and has been able to describe specifically how he or she abused the child, (2) the abuser has experienced an appropriate emotional response to his or her behaviors and the harm he or she has caused the child, (3) the abuser has developed strategies to better identify and manage his or her needs to avoid abusing the child in the future, and (4) the abuser has demonstrated these skills, with monitoring, over a significant period of time. Schreier also asserts that the partners of offending caregivers should participate in treatment, because they have frequently colluded in the abuse of the child. The partner's lack of nurture for the offending caregiver may also be 1 motivation for the child's abuse.

SUMMARY

Caregiver-fabricated illness in a child is a relatively rare but very serious form of child maltreatment. The pediatrician who suspects that signs or symptoms of a disease are being fabricated should focus on the harm or potential harm to the child caused by the actions of that caregiver and by the efforts of medical personnel to diagnose and treat a nonexistent disease. Pediatricians need to have a high index of suspicion and be alert to the possibility when signs and symptoms do not fit a particular illness, when they appear resistant to treatment, or when they evolve into another or additional illnesses. Proper diagnosis of fabricated disease involves a thorough evaluation of medical records, clear communication among medical professionals, and often, a multidisciplinary approach. If the child protective services system's response seems inadequate, the pediatrician should ask a local specialist in child abuse pediatrics for advice and assistance. A focus on the motives of the caregiver, although useful in therapy, is not necessary for a diagnosis of this form of child maltreatment.

Children, Adolescents, and the Media

- *Policy Statement*

POLICY STATEMENT

Children, Adolescents, and the Media

abstract

FREE

Media, from television to the "new media" (including cell phones, iPads, and social media), are a dominant force in children's lives. Although television is still the predominant medium for children and adolescents, new technologies are increasingly popular. The American Academy of Pediatrics continues to be concerned by evidence about the potential harmful effects of media messages and images; however, important positive and prosocial effects of media use should also be recognized. Pediatricians are encouraged to take a media history and ask 2 media questions at every well-child visit: How much recreational screen time does your child or teenager consume daily? Is there a television set or Internet-connected device in the child's bedroom? Parents are encouraged to establish a family home use plan for all media. Media influences on children and teenagers should be recognized by schools, policymakers, product advertisers, and entertainment producers. *Pediatrics* 2013;132:958–961

INTRODUCTION

Media, from traditional television to the "new media" (including cell phones, iPads, and social media), are a dominant force in children's lives. Although media are not the leading cause of any major health problem in the United States, the evidence is now clear that they can and do contribute substantially to many different risks and health problems and that children and teenagers learn from, and may be negatively influenced by, the media. However, media literacy and prosocial uses of media may enhance knowledge, connectedness, and health. The overwhelming penetration of media into children's and teenagers' lives necessitates a renewed commitment to changing the way pediatricians, parents, teachers, and society address the use of media to mitigate potential health risks and foster appropriate media use.

According to a recent study, the average 8- to 10-year-old spends nearly 8 hours a day with a variety of different media, and older children and teenagers spend >11 hours per day.[1] Presence of a television (TV) set in a child's bedroom increases these figures even more, and 71% of children and teenagers report having a TV in their bedroom.[1] Young people now spend more time with media than they do in school—it is the leading activity for children and teenagers other than sleeping.[1,2]

In addition to time spent with media, what has changed dramatically is the media landscape.[3,4] TV remains the predominant medium (>4 hours per day) but nearly one-third of TV programming is viewed on alternative platforms (computers, iPads, or cell phones). Nearly all children and teenagers have Internet access (84%), often high-speed, and one-third have

access in their own bedroom. Computer time accounts for up to 1.5 hours per day; half of this is spent in social networking, playing games, or viewing videos. New technology has arrived in a big way: some 75% of 12- to 17-year-olds now own cell phones, up from 45% in 2004. Nearly all teenagers (88%) use text messaging. Teenagers actually talk less on their phones than any other age group except for senior citizens,[5,6] but in the first 3 months of 2011, teenagers 13 through 17 years of age sent an average of 3364 texts per month.[5] Half of teenagers send 50 or more text messages per day, and one-third send more than 100 per day.[5] Teenagers access social media sites from cell phones,[6] and as reviewed in a recent clinical report from the American Academy of Pediatrics (AAP), social media, mainly Facebook, offers opportunities and potential risks to young wired users.[7] They are also avid multitaskers, often using several technologies simultaneously,[1] but multitasking teenagers are inefficient.[8] For example, using a mobile phone while driving may result in both poor communication and dangerous driving.[9]

Despite all of this media time and new technology, many parents seem to have few rules about use of media by their children and adolescents. In a recent study, two-thirds of children and teenagers report that their parents have "no rules" about time spent with media.[1] Many young children see PG-13 and R-rated movies—either online, on TV, or in movie theaters—that contain problematic content and are clearly inappropriate for them.[10,11] Few parents have rules about cell phone use for their children or adolescents. More than 60% of teenagers send and/or receive text messages after "lights out," and they report increased levels of tiredness, including at school.[12] One study found that 20% of adolescents either sent or received a sexually explicit image by cell phone or Internet.[13]

For nearly 3 decades, the AAP has expressed concerns about the amount of time that children and teenagers spend with media and about some of the content they view. In a series of policy statements, the AAP has delineated its concerns about media violence,[14] sex in the media,[10] substance use,[11] music and music videos,[15] obesity and the media,[16] and infant media use.[17] At the same time, existing AAP policy discusses the positive, prosocial uses of media and the need for media education in schools and at home.[18] Shows like "Sesame Street" can help children learn numbers and letters, and the media can also teach empathy, racial and ethnic tolerance, and a whole variety of interpersonal skills.[19] Prosocial media may also influence teenagers. Helping behaviors can increase after listening to prosocial (rather than neutral) song lyrics, and positive information about adolescent health is increasingly available through new media, including YouTube videos and campaigns that incorporate cell phone text messages.[20]

RECOMMENDATIONS FOR PEDIATRICIANS AND OTHER HEALTH CARE PROVIDERS

- Become educated about critical media topics (media use, violence, sex, obesity, substance use, new technology) via continuing medical education programs.
- Ask 2 media questions and provide age-appropriate counseling for families at every well-child visit: How much recreational screen time does your child or teenager consume daily? Is there a TV set or an Internet-connected electronic device (computer, iPad, cell phone) in the child's or teenager's bedroom? In a busy clinic or office, these 2 targeted questions are key. There is considerable evidence that a bedroom TV increases the risk for obesity, substance use, and exposure to sexual content.[1,21–26]
- Take a more detailed media history with children or teenagers who demonstrate aggressive behavior; are overweight or obese; use tobacco, alcohol, or other drugs; or have difficulties in school.
- Examine your own media use habits; pediatricians who watch more TV are less likely to advise families to follow AAP recommendations.[27]

PEDIATRICIANS SHOULD RECOMMEND THE FOLLOWING TO PARENTS

- Limit the amount of total entertainment screen time to <1 to 2 hours per day.
- Discourage screen media exposure for children <2 years of age.
- Keep the TV set and Internet-connected electronic devices out of the child's bedroom.
- Monitor what media their children are using and accessing, including any Web sites they are visiting and social media sites they may be using.
- Coview TV, movies, and videos with children and teenagers, and use this as a way of discussing important family values.
- Model active parenting by establishing a family home use plan for all media. As part of the plan, enforce a mealtime and bedtime "curfew" for media devices, including cell phones. Establish reasonable but firm rules about cell phones, texting, Internet, and social media use.

RECOMMENDATIONS FOR SCHOOLS

Community-based pediatricians, especially those serving in an advisory role to schools, are influential voices in school and neighborhood forums and can work to encourage a team approach among the medical home, the school home, and the family home. So pediatricians, especially

those serving as school physicians or school medical advisors should:

- Educate school boards and school administrators about evidence-based health risks associated with unsupervised, unlimited media access and use by children and adolescents, as well as ways to mitigate those risks, such as violence prevention, sex education, and drug use-prevention programs.
- Encourage the continuation and expansion of media education programs, or initiate implementation of media education programs in settings where they are currently lacking.
- Encourage innovative use of technology where it is not already being used, such as online education programs for children with extended but medically justified school absences.
- Work collaboratively with parent-teacher associations to encourage parental guidance in limiting or monitoring age-appropriate screen times. In addition, schools that do use new technology like iPads need to have strict rules about what students can access.

PEDIATRICIANS SHOULD WORK WITH THE AAP AND LOCAL CHAPTERS TO CHALLENGE THE ENTERTAINMENT INDUSTRY TO DO THE FOLLOWING

- Establish an ongoing dialogue with health organizations like the AAP, the American Medical Association, the American Psychological Association, and the American Public Health Association to maximize prosocial content in media and minimize harmful effects (eg, portrayals of smoking, violence, etc).
- Make movies smoke-free, without characters smoking or product placement.[11]

PEDIATRICIANS SHOULD WORK WITH THE AAP AND LOCAL CHAPTERS TO CHALLENGE MANUFACTURERS OF PRODUCTS WITH PUBLIC HEALTH IMPLICATIONS (TOBACCO, ALCOHOL, FOOD) TO DO THE FOLLOWING

- Make socially responsible decisions on marketing products to youth; betterment of their health is the ultimate goal.

PEDIATRICIANS SHOULD WORK WITH THE AAP AND LOCAL CHAPTERS TO CHALLENGE THE FEDERAL GOVERNMENT TO DO THE FOLLOWING

- Advocate for a federal report within either the National Institutes of Health or the Institute of Medicine on the impact of media on children and adolescents that would establish a baseline of what is currently known and what new research needs to be conducted.
- Encourage the entertainment industry and the advertising industry to create more prosocial programming and to reassess the effects of their current programming.
- Issue strong regulations—self-regulation is not likely to work—that would restrict the advertising of junk food and fast food to children and adolescents.
- Establish an ongoing funding mechanism for new media research.
- Initiate legislation and rules that would ban alcohol advertising from television.[11]
- Work with the Department of Education to support the creation and implementation of media education curricula for schoolchildren and teenagers.

abstract

FREE

This policy statement provides a framework for the pediatrician's role in promoting the health and well-being of all children in the context of their families and communities. It offers pediatricians a definition of community pediatrics, emphasizes the importance of recognizing social determinants of health, and delineates the need to partner with public health to address population-based child health issues. It also recognizes the importance of pediatric involvement in child advocacy at local, state, and federal levels to ensure all children have access to a high-quality medical home and to eliminate child health disparities. This statement provides a set of specific recommendations that underscore the critical nature of this dimension of pediatric practice, teaching, and research. *Pediatrics* 2013;131:623–628

Environmental and social factors contribute significantly to the health and well-being of children in the contexts of families, schools, and communities. Over the past decade, the Institute of Medicine recognized and quantified the effects of external factors on early brain development and the health of children in 2 seminal reports, *Neurons to Neighborhoods*[1] in 2000 and *Children's Health, the Nation's Wealth*[2] in 2004. As understanding of the mechanisms and impact of biological, behavioral, cultural, social, and physical environments on healthy development deepens and expands, the long-standing role of pediatricians in promoting the physical, mental, and social health and well-being of all children must also evolve.[3] The field of pediatrics must address the problems facing children in the 21st century by influencing these critical determinants of child health and well-being.[4] To do so, pediatricians must successfully merge their traditional clinical skills with public health, population-based approaches to practice, and advocacy.

DEFINITION OF COMMUNITY PEDIATRICS

The American Academy of Pediatrics (AAP) offers a definition of community pediatrics to remind all pediatricians, pediatric medical subspecialists, and pediatric surgical specialists alike of the profound importance of the community dimension in pediatric practice. Community pediatrics is the practice of promoting and integrating the

positive social, cultural, and environmental influences on children's health as well as addressing potential negative effects that deter optimal child health and development within a community. Community pediatrics includes all of the following:

- A perspective that expands the pediatrician's focus from one child to the well-being of all children in the community;
- A recognition that family, educational, social, cultural, spiritual, economic, environmental, and political forces affect the health and functioning of children;
- A synthesis of clinical practice and public health principles to promote the health of all children within the context of the family, school, and community[5]; and
- A commitment to collaborate with community partners to advocate for and provide quality services equitably for all children.[6,7]

Participating in community activities to improve the health and welfare of all children is considered an integral part of the professional role and ethical obligation of all pediatricians. For many pediatricians, efforts to promote the health of children have been directed at attending to the needs of particular children in a practice setting, on an individual basis, and providing them with a medical home[8] in concert with pediatricians' own community interests and commitments. Increasingly, however, the major threats to the healthy development of America's children stem from problems that cannot be addressed adequately by the practice model alone.[9] These problems include infant mortality; preventable infectious diseases; dental caries; sedentary lifestyles; chronic health care needs; obesity, metabolic syndrome, and other historically adult-onset chronic diseases; high levels of intentional and unintentional injuries; exposure to violence in all forms; risks of neurodevelopmental disabilities and illnesses from exposure to environmental tobacco smoke, lead, and other environmental hazards; substance abuse; mental health conditions; poor school readiness[10]; family dysfunction; sexual health, unwanted pregnancies, and sexually transmitted diseases; relatively low rates of breastfeeding; social, medical, behavioral, economic, and environmental effects of disasters[11]; and inequitable access to medical homes[12] and basic material resources and poverty.[13] Whether the pediatrician is communicating with patients and families or with a community, it is critical to remember that this must be done in a culturally and linguistically effective manner to be successful. On the part of pediatricians, culturally effective communication includes behaviors and attitudes that are appropriate to care for patients and families with a wide variety of cultural attributes.

SOCIAL DETERMINANTS OF HEALTH

In the past decade, increasing attention has been paid toward recognizing the social determinants of children's physical, mental, and behavioral health. Briefly, social determinants are the economic and social conditions that shape the health of individuals and communities. In 2005, the World Health Organization established a Commission on the Social Determinants of Health to examine the evidence of the effects of social determinants on health outcomes, specifically for the purpose of promoting health equity globally. With the description of the life course health development model[14] and the recognition of the life course health development perspective by agencies serving children and families, including the US Maternal and Child Health Bureau, the effects of poor social and economic factors in childhood on the quality of adult health have become increasingly clear. For example, authors of studies have examined the link between childhood obesity and cardiovascular disease in adulthood, lack of adequate calcium and vitamin D intake in childhood on adult osteoporosis, and childhood maltreatment and family dysfunction on adult mental and physical health problems.[13,15,16]

Childhood obesity, dental caries, asthma, and early mental health issues are prevalent in today's child population and interact reciprocally with family dysfunction or school stress. Pediatricians must have the knowledge, skills, and willingness to address these issues in addition to more traditional clinical solutions. An integral approach to doing so incorporates interdisciplinary practice. As former AAP president Robert Haggerty, MD, reminded us in 1995, "we must become partners with others, or we will become increasingly irrelevant to the health of children."[17] Pediatricians should recognize that health care is merely 1 influential component of overall health and well-being for children and families, and children often move through other systems, such as education, child welfare, mental health/social services, and juvenile justice. Interdisciplinary communication and coordination are crucial for successfully addressing all factors that contribute to a child's health and well-being.

THE NATURAL AND BUILT ENVIRONMENTS

The physical environment is an important part of a community. Health hazards from toxic environmental exposures (such as mold, heavy metals, and fluorocarbons) are routinely recognized and brought to the attention of pediatricians. Less consideration has been given to the potential for adverse effects on health from "built environments," such as poor-quality housing, lack of access to

opportunities for safe gross motor play, inadequate transportation, especially for children with limited mobility, and lack of coordinated community planning, although awareness has grown over the past decade of the effects of the built environment on the childhood obesity epidemic.[18] Accessible housing and transportation options that meet the needs of all children and families, including those with mobility, sensory, and health impairments, to travel safely and making all community and leisure environments accessible to all children, especially those with special needs, has the potential to decrease the risk of obesity and metabolic syndrome.

Because the design of a child's physical environment can cause or prevent illness or injury, a high-quality environment is essential for children to achieve optimal health and development. Community planning and building and land-use policies can either undermine or promote safety, health, and optimal development while simultaneously preserving future resources. Children in low-income families are more likely to be exposed to structural hazards in the home and are more likely to have diseases such as lead poisoning and asthma. Although environmental risks are more prevalent in low-income families, children from any income level may be exposed. For all children, examining the quality of a child's physical environment is crucial when assessing children's health. Pediatrician advocates are needed to speak out for children's needs in the physical environment.

PARTNERING WITH PUBLIC HEALTH

One could argue that pediatricians have always been a part of the public health system. As trusted sources of information for parents and front-line providers of preventive health care for children, pediatricians have fulfilled the role of addressing the needs of populations of children, whether they are in an early education and child care setting, school, or local community. Pediatricians often contribute to the public health system by recognizing and reporting illnesses, hazards, and trends to public health departments.

Because of this responsibility, pediatricians should know where to get accurate information regarding the latest public and school health issues facing children in their communities, as well as how to communicate this information effectively either individually to families or to groups in public forums or through the media. The Institute of Medicine has recently provided a framework for primary care and public health professions to work together.[19] Pediatricians should partner with local health departments and school districts and child welfare agencies to be aware of programs for children and families that address certain needs, such as injury prevention, child maltreatment prevention, lead poisoning, environmental tobacco smoke control, breastfeeding promotion, overweight/obesity prevention, asthma, perinatal care, trauma, child abuse prevention, and disaster preparedness.[20–23] One example of a pediatric/public health approach would be to ensure that children's issues are addressed in disaster planning/response.

LOCAL, STATE, AND FEDERAL ADVOCACY

The passage of the Patient Protection and Affordable Care Act in 2010 was a milestone in health care in the United States that could not have been achieved without advocacy on multiple levels by many groups of people, including pediatricians. Pediatricians have always advocated on behalf of the nation's youngest citizens, whether on the individual level for necessary services or more widely at the community, state, or federal level in legislative avenues. Because children do not have a voice in government, others must speak up on behalf of the nation's most vulnerable population of citizens.

In recent years, pediatric medical education has promoted the formal training of residents in legislative advocacy. The AAP Community Pediatrics Training Initiative has developed advocacy training modules for use in pediatric residency training programs and is supporting individual programs to implement advocacy rotations in their curricula. Statewide collaboratives, such as in California and more recently in New Jersey, have been established to serve as networks for residency programs to share advocacy curricula and support implementation of new curricular experiences in legislative advocacy. These efforts are in direct response to the recognition that, to influence policies and laws affecting children and families, pediatricians need specialized skill sets to be effective advocates on multiple levels.

With the passage of the 2010 Patient Protection and Affordable Care Act, pediatric leadership and advocacy will be crucial to ensure some just reward for the activities described in this policy statement. To counter the growing financial and productivity pressures on practicing pediatricians, some recognition of the importance of addressing the social determinants of children's health will be necessary in the financing models for accountable care organizations.[24]

RECOMMENDATIONS

With the shifting epidemiology of problems facing children and growing recognition that social determinants play a major role in children's health, pediatricians must have a second

"bag of tools" in addition to the clinical "doctor's bag" that addresses more traditional agents of childhood disease. This second bag of tools includes skills such as being able to function in an interdisciplinary fashion; partnering with public health and child welfare entities; recognizing root sources of health and pathology from children's social, economic, physical, and educational environments; and advocating on multiple levels. The following recommendations offer guidelines for pediatricians to optimize their effectiveness as clinical practitioners and advocates in the community. To accomplish these recommendations, payment and financing systems must be appropriately aligned and recognize clinicians who provide population-based prevention.[25]

1. Pediatricians should use community data (epidemiologic, demographic, and economic) to increase their understanding of the effects that social determinants have on child health outcomes.
2. Pediatricians should work together with public health departments, school districts,[21–23] child welfare agencies, community and children's hospitals, and colleagues in related professions to identify and decrease barriers to the health and well-being of children in the communities they serve.[26,27] In addition, pediatricians should have access to information about community programs and resources that could affect the health and well-being of the children in their community.
3. Pediatricians should routinely, and in a culturally effective manner, promote preventive health strategies for common childhood issues (ie, immunization, injury prevention, oral health, sexual health, nutrition, obesity prevention, breastfeeding, positive parenting, and abuse and neglect) in both individual well-child visits as well as on a population level within a community. Pediatricians can play an important role in coordinating and focusing new and existing services to realize maximum benefit for all children.[28,29]
4. Pediatricians and other members of the community should interact with and advocate to improve all settings and organizations in which children spend time (eg, early education and child care facilities, schools, school-based health centers, family support and resource centers, youth programs, recreation venues, and transportation systems). Together with families, schools and community resources should be considered as primary assets in promoting children's health, safety, and development.
5. Pediatricians should advocate for universal access to health care in a medical home and for the social, economic, educational, and environmental resources essential for every child's healthy development, including those in foster care who may have no other natural advocates.
6. Pediatricians should be able to interface with the media and be able to be trusted sources of information for parents and the general public about public health issues pertaining to children, such as vaccine safety and emergency/disaster/crisis medical issues.
7. Pediatric medical education (both undergraduate and graduate) should include specific curricula on community and public health topics pertaining to child health, including social determinants of health, how to identify and access community resources, school health, health care systems and financing, and child advocacy, including interactions with the public child welfare system and legislative advocacy skills.
8. Continuing medical education programs should consider and periodically review basic community pediatric competencies to be included in maintenance of certification efforts for pediatricians.[30] Maintenance of certification and quality improvement activities should include options to address child health issues in community settings.
9. AAP chapters and their members should provide leadership for further understanding of community pediatrics and encourage participation in creative, community-based, integrated models such as those supported through the Community Access to Child Health program and the Healthy Tomorrows Partnership for Children program.
10. The AAP is committed to continued recognition and provision of leadership and support to pediatricians to develop and exercise advocacy skills at the local, state, and national levels to ensure that children have access to care, to resources, and to conditions that promote healthy development. This includes support for the following:
    - Federal and state programs that reduce the burden of debt on medical students in pediatric primary care and pediatric medical subspecialty and surgical specialty fellowships, including but not limited to the National Health Service Corps.
    - Incorporation into the curricula for residency programs and for young physicians' discussion of different strategies

for engaging in community activities no matter the practice setting.

- Expectation of community engagement as an explicit part of comprehensive clinical payment models currently under development, including the patient-centered medical home and accountable care organizations.

11. The AAP is committed to continuing to strategically address the lack of payment for the work pediatricians do in the community, which addresses social determinants of health and population-based health issues, much of which is currently uncompensated. Not only should these services be recognized as a crucial part of child health, but also, payment for these services should be at a reasonable and fair level so that pediatricians can afford to pursue these activities in their communities.

By caring for children in the context of their families and communities, pediatricians play an important role in promoting the health and well-being of the nation's youngest citizens. Pediatricians who work with schools, early education and child care programs, community agencies and organizations, and local public health departments and child welfare agencies equip themselves to be effective child advocates in the community. Pediatricians can also play a crucial role in public health by communicating important facts about issues facing children's health; ensuring children's issues are addressed in disaster planning and response efforts[11]; and advocating at the local, state, and federal legislative levels for universal access for all children to high-quality medical homes and for social policies that promote equal opportunities for the development of children, families, and communities. The recommendations in this policy statement are meant to provide a framework for guiding the development of relevant curricula in pediatric medical education and supporting the practice of high-quality and effective pediatric care.

abstract

FREE

Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). This policy statement has been developed to assist the pediatrician in understanding and supporting the use of condoms by their patients to prevent unintended pregnancies and STIs and address barriers to their use. When used consistently and correctly, male latex condoms reduce the risk of pregnancy and many STIs, including HIV. Since the last policy statement published 12 years ago, there is an increased evidence base supporting the protection provided by condoms against STIs. Rates of acquisition of STIs/HIV among adolescents remain unacceptably high. Interventions that increase availability or accessibility to condoms are most efficacious when combined with additional individual, small-group, or community-level activities that include messages about safer sex. Continued research is needed to inform public health interventions for adolescents that increase the consistent and correct use of condoms and promote dual protection of condoms for STI prevention with other effective methods of contraception. *Pediatrics* 2013;132:973–981

INTRODUCTION

This policy statement updates a previous statement from the American Academy of Pediatrics published in 2001.[1] The medical and societal consequences of adolescent sexual activity, including sexually transmitted infections (STIs) and unintended pregnancies, remain a significant public health problem. Although abstinence of sexual activity is the most effective method for prevention of pregnancy and STIs, young people should be prepared for the time when they will become sexually active. Prevention of STIs in adolescents involves safer sexual practices by those who are sexually active or who no longer plan to be abstinent. Since publication of the previous statement, there has been increasing evidence supporting the effectiveness of condoms to prevent many STIs, including HIV. Increased availability of condoms has been shown to increase use, and widespread distribution programs have been recommended by the Centers for Disease Control and Prevention (CDC).[2]

In this policy statement, the use of condoms as a method of preventing STIs, including HIV and pregnancy will be reviewed including effectiveness, factors that influence use, and the roles that schools, communities,

and parents can play in improving use of condoms and increased availability of condoms.

TRENDS IN ADOLESCENT SEXUAL ACTIVITY AND CONSEQUENCES

Despite recent data indicating that sexual activity has declined among adolescents, the current rates of sexual activity and health consequences of STIs and pregnancy remain a significant public health concern. The CDC, through its Youth Risk Behavior Survey (YRBS), reports sexual risk behaviors in a nationally representative sample of high school students surveyed biannually. In the most recently available YRBS (2011), 47.4% of students reported that they had ever had sexual intercourse, 33.7% reported that they were currently sexually active, and 15.3% had had sexual intercourse with four or more partners in their lifetime. Among sexually active students, 60.2% reported condom use during their last sexual encounter. Of additional concern, by 12th grade, nearly two-thirds (63.1%) of students reported ever being sexually active but reported lower use of condoms than did sexually active 9th- and 10th-graders.[3]

In 2011, approximately 330 000 teenagers gave birth,[4] and in 2008, the most recently available estimates are that 750 000 teenagers became pregnant.[5] Despite the fact that US teen birth rates are at the lowest level in the past 70 years,[6] the birth rate for US teenagers remains higher than other developed nations, and marked disparities by race/ethnicity and geographic area persist.[7]

Rates of STIs remain highest among adolescents and young adults, with estimates suggesting that 15- to 24-year-olds, who represent 25% of the sexually experienced population, acquire nearly half of all new STIs.[8] Rates of *Chlamydia*, gonorrhea, and syphilis have all continued to increase in adolescent and young adults.[9] A study that examined the prevalence of STIs among female adolescents 14 to 19 years of age in the United States from the 2003–2004 NHANES reported a 24.1% prevalence of any of 5 STIs (*Neisseria gonorrhea, Chlamydia trachomatis*, *Trichomonas vaginalis*, herpes simplex virus type 2, and human papilloma virus [HPV] infections) among all female adolescents and a prevalence of 37.7% among sexually experienced females. Importantly, even among those whose sexual partner was the same age or 1 year older, the prevalence was high (25.6%), and among those with only 1 lifetime partner, the prevalence was 19.7%.[10]

For specific infections, in 2011 the highest *Chlamydia* rates were seen in 15- to 19-year-old (3.4%) and 20- to 24-year-old women (3.7%). Of concern, during 2010–2011, rates increased 4% for those aged 15 to 19 years and 11% for those aged 20 to 24 years. Reported rates of *Chlamydia* are lower among young men, likely because of decreased screening efforts, but have increased 6% for those 15 to 19 years of age and 12% for those 20 to 24 years of age between 2010 and 2011. In studies of higher-risk populations (for example, the National Job Training Program, an educational program for disadvantaged youth) at entry, rates of *Chlamydia* for women and men 16 to 24 years of age were 10.3% and 8%, respectively. Similarly, in juvenile correctional facilities, 13.5% of women and 6.5% of men screened positively for *Chlamydia*.[9]

Adolescent and young adult women also have the highest rates of gonorrhea compared with any other age and gender group and increased 1.4% in 15- to 19-year-old women during 2009–2010 (unchanged in 2011), and increased 5.4% in 20- to 24-year-old women during 2010–2011. Adolescent and young adult men have also had increasing rates of gonorrhea, increasing 6% in those aged 20 to 24 years during 2010–2011.[9]

Syphilis rates in both men and women are highest in the 15- to 24-year old age group and increased most dramatically during 2010–2011 in 20- to 24-year-old men (5.2–21.9 cases/100 000), particularly in men who have sex with men (MSM).[9]

An estimated 10 065 young people aged 13 to 24 years received a diagnosis of HIV infection in 2011, accounting for 20% of all new infections in the United States. Among adolescent/young adult males living with and diagnosed with HIV, 77% acquired infection from MSM, 4% from heterosexual transmission, and 13% were perinatally acquired. Among females, 56% acquired infection by heterosexual transmission, and 34% were perinatally acquired.[11,12] Anonymous HIV screening in locations where youth 12 to 24 years of age congregate in communities surrounding the Adolescent Trials Network for HIV/AIDS interventions found a prevalence of HIV of 15.3% in 611 MSM tested, 60% of whom did not know they were infected.[13] In addition to patients with behaviorally acquired HIV infections, an estimated 9038 people with perinatally acquired HIV are now in adolescence and young adulthood. These youth are generally receiving highly active antiretroviral therapy, and concern exists for extensive drug-resistant strains.[14] In a prospective cohort study of the reproductive health of sexually active adolescent girls perinatally infected with HIV, the cumulative incidence of pregnancy at 19 years of age was 24%, and incidence of STIs was 26%, stressing the need for comprehensive HIV/STI-prevention strategies.[15]

CONDOM USE

Recent Trends in Adolescent Condom Use

The condom remains the most popularly used contraceptive method among teenagers.[3] An increased proportion of sexually active adolescents report using a condom at last intercourse, according to 2 CDC surveys. In the YRBS, condom use increased from 46.2% in 1991 to 60.2% in 2011.[3] The prevalence of condom use was higher among male (68.6%) than female (53.9%) students and higher among white (63.3%) and African American (62.4%) than Hispanic students (54.9%).[3] In the National Survey of Family Growth, condom use at last intercourse increased among females from 31% in 1988 to 52% in 2006–2010 and males from 53% to 75%.[16] Rates of actual condom use in both surveys may also be lower than thought because of the uncertain/questionable validity of self-report of this and other sexual behaviors that are prone to bias. For example, in a clinic-based sample of African American females 15 to 21 years of age in Atlanta, Georgia, 186 young women reported 100% condom use via an audio computer-assisted self-interviewing technique. In these young women, 34% had a positive biologic marker for unprotected vaginal sex in the past 14 days (a Y-chromosome polymerase chain reaction assay). As a possible explanation of these findings, condoms may have been used inconsistently or incorrectly, or youth might have provided socially desirable answers.[17]

Factors That Influence Condom Use

A number of factors, including individual, family, sociodemographic, attitude, education, relationship, and partner-related factors, influence condom use. For example, in a national study of adolescent males,[18] factors associated with greater consistency of condom use included African American race/ethnicity, more positive condom attitudes, and more discussion of health topics with parents. Adolescents who did not have formal sex education were half as likely to use a condom at first intercourse and even less likely to use condoms consistently. Lower condom use at first sex was associated with older age, an older or casual first sexual partner, and a partner using another method of contraception. These factors were also associated with lower condom use at last sex, except for having a casual sexual partner, which was associated with higher condom use.[18]

Higher rates of condom use are noted in youth who perceive their partners as wanting to use condoms and in those able to communicate their desire to use condoms with their partners.[19] Motivations for young people to have sex include the pursuit of fulfilling sexual experiences in addition to other motivations such as intimacy, procreation, or in response to peer or partner pressure. However, adolescents' lack of condom use is associated with perceptions that condoms reduce sexual pleasure and/or that partners disapprove of condom use.[20] Condom-promotion campaigns that include linking condom use to enhanced sensitivity and sensuality, and, thus, a more positive experience as a motivating factor, have found increased uptake of condoms and safer sex behaviors.[21–23]

The influence of social networks that encourage condom use is becoming increasingly recognized.[24,25] However, increased relationship intimacy and closeness to the partner's family can be associated with less condom use.[26] Condom use rates are higher in new relationships compared with established relationships.[27] Other factors associated with increased condom use include receiving comprehensive sex and HIV education programs,[28] attending schools where condoms are available,[29] and perceiving a risk of STIs.[30]

The effect of the media on adolescent sexual behavior has been reviewed in a recent American Academy of Pediatrics policy statement.[31] Adolescents are exposed to an increasing amount of sexual content in music, movies, magazines, television, and the Internet, and this exposure plays an important role in adolescent initiation of sexual activity. Despite the increasingly sexually explicit material in media and programming, there are rare messages promoting responsible sexual activity, such as contraception, including condom use.[31] On primetime television, 77% of programs have sexual content but only 14% reference risks or responsibility of sexual behavior.[32]

Adults, especially parents, play an important role in promoting the sexual health of adolescents. Bright Futures outlines how pediatricians and other health care providers can support parents in promoting healthy sexual development and sexuality, including the use of condoms to protect against STIs including HIV.[33] A number of studies have examined the role of parent-adolescent communication about sexual risk and association with increased adolescent use of condoms.[34–38] Parental communication about sexual risk and condom use are associated with increases in adolescents' use of condoms.[34–36,38] Timing of the discussion is important; in 1 study, the highest rates of condom use at first and last sex, as well as for regular use, were found among adolescent girls who communicated with their mothers about condom use before onset of sexual activity compared with after initiation.[34] In a recent longitudinal study of parents and their

children regarding the timing of parent and child communication about sexual behaviors, more than 40% of the children had intercourse before there were discussions about STI symptoms, condom use, birth control, or partner condom refusal.[39] This suggests increased efforts are needed by pediatricians, educators, and those in public health to encourage parents to talk about these issues.

In a large study of African American and Puerto Rican teens aged 14 to 17 years, separate face-to-face interviews were conducted with 907 mother-adolescent pairs to examine factors that predicted mother-adolescent discussions about condoms. Those mothers who communicated effectively about condoms had greater knowledge of sexuality and HIV, perceived that they had enough information to discuss condoms, had received information from a health-related source, were comfortable in discussing condoms and sexuality, and believed that condom use prevents HIV. The implication for pediatricians is that providing parents with accurate information about adolescent sexual behavior, risks, and use and effectiveness of condoms can improve communication with their adolescents.[40]

Other opportunities for parents to become comfortable speaking with their adolescents about sexual health was demonstrated in a novel work site–based trial. In weekly small-group sessions, parent training with a standardized prevention curriculum, designed to help parents of 11- to 16-year-old children communicate about sexual health, found significant differences compared with a control group in discussions of these topics, including condom education. At baseline, 4% of adolescents reported that a parent had discussed with them how to use a condom, and by the 9-month follow-up survey, 36% reported receipt of instruction.[41]

EFFECTIVENESS OF CONDOM USE

Materials used for male condoms are of 3 types: most (>80%) are composed of latex (natural rubber), and a small proportion (<5%) are natural membrane (lamb cecum) or synthetic (eg, polyurethane; approximately 15%).[42] Only latex and synthetic condoms are recommended for prevention of STIs and HIV because natural membrane condoms contain small pores that may allow passage of viruses, including HIV, hepatitis B virus, and herpes simplex virus.[43,44] Synthetic condoms, when compared with latex condoms, are generally more resistant to deterioration and are compatible with both oil- and water-based lubricants. Synthetic condoms have similar failure rates to latex condoms in prevention of pregnancy.[45] Although not extensively studied, synthetic condoms are believed to provide STI protection similar to male latex condoms; however, US Food and Drug Administration (FDA) labeling currently restricts their recommended use for latex-sensitive or -allergic people.[42,45] Condoms lubricated with the spermicide nonoxynol-9 are no longer recommended, because they have a shorter shelf life, increased cost, and lack of added benefit compared with other lubricated condoms[46] and may increase likelihood of HIV transmission as a result of increased genital mucosal irritation.[47] In the United States, condoms are regulated as medical devices by the FDA, and stringent manufacturing standards exist such that each condom is tested for holes or weak spots before sale.[48]

Condoms can be highly effective against unintended pregnancy when used consistently and correctly. Method failure of the male condom for unintended pregnancy is estimated to be 2% in 12 months of use (ie, 2 pregnancies per 100 woman-years with perfect use), although with typical use, the failure rate (accounting for inconsistent and incorrect use) is 18%.[49] The most important noncontraceptive benefit of condom use is the additional protection against acquisition and transmission of STIs, including HIV. Evidence supporting the protection provided by condoms against acquisition of most STIs, including HIV, has increased markedly over the past decade.[50] If placed on the penis before genital contact and used throughout intercourse, condoms should prevent contact with semen, genital lesions, and infectious discharges in both males and females. Condoms greatly reduce the risk of STIs that are transmitted to or from the penile urethra, including gonorrhea, *Chlamydia*, trichomoniasis, hepatitis B virus, and HIV. Condoms also provide protection against STIs transmitted via skin-to-skin contact or contact with mucosal surfaces, including genital herpes simplex virus, HPV, syphilis, and chancroid in those affected areas covered by the condom.[51–54] Passage of the smallest sexually transmitted pathogen, hepatitis B virus, is effectively blocked by latex condoms, according to in vitro studies.[55–59] Most of the studies on condom effectiveness evaluate vaginal penile sexual activity. Latex and synthetic condoms also can be used during anogenital and orogenital intercourse to reduce the risk of STI.[42]

Well-designed epidemiologic studies and those of discordant couples have shown that condoms are highly effective against heterosexual transmission of HIV infection.[60] The most recent Cochrane review estimated the effectiveness of condom use at 80%.[61]

Inconsistency of the estimates of the effectiveness of condoms against

other STIs can be attributed to limitations in study design, because the quality of studies historically tended to be weaker than for studies of HIV.[54] Recent studies have empirically documented that the effectiveness of condom use against many STIs is underestimated because of limitations of study design.[62–68] Even with these limitations, these and more recent studies with improved methodologies have found that condoms provide protection against a variety of STIs, including gonorrhea, *Chlamydia*, trichomoniasis, genital herpes, and HPV.[53,54,65,69–74]

Given the coital-dependent nature of condoms, effectiveness against both unintended pregnancy and STIs is closely tied to the degree of consistency or correctness of use. Factors associated with decreased condom effectiveness include failure to use a condom with every act of intercourse; failure to use condoms throughout intercourse, such as placing condoms on after initiating intercourse or removing before ejaculation; condom breakage and slippage; and improper lubricant use with latex condoms (oil-based lubricants, such as petroleum jelly, baby oil, hand lotions, and some vaginal medications), which can reduce condom integrity and may result in breakage.[51]

Five key condom instructions reached by consensus at a World Health Organization Experts Meeting[51] are as follows:

1. Use a new condom for each act of sexual intercourse.
2. Before any genital contact, place the condom on the tip of the erect penis with the rolled side out.
3. Unroll the condom all the way to the base of the erect penis.
4. Immediately after ejaculation, hold the rim of the condom and withdraw the penis while it is still erect.
5. Throw away the used condom safely.

FEMALE CONDOM

The female condom 1 (FC1; Reality, Femy, Care Contraceptive Sheath, Femidom), a loose-fitting polyurethane sheath with 2 flexible polyurethane rings, introduced in 1994, was the first condom marketed to women but is no longer in production in the United States. The FC2 (similarly designed to the FC1 but made of nitrile and without a seam) was approved for use in 2009 by the US FDA and is the only female-initiated barrier method for STI prevention currently available in the United States. Data regarding contraceptive effectiveness of female condoms suggest estimated rates of pregnancy during the first 12 months of perfect use and typical use for FC1 were 5% and 21%; these pregnancy rates are slightly higher than those associated with use of the male condom.[75]

Although laboratory and clinical studies suggest that the female condom might be as effective as the male condom in preventing STIs, data are much more limited. Continued research is needed to evaluate the effectiveness and acceptability of female condoms, which currently account for less than 1% of US condom use overall.[75,76]

DUAL PROTECTION

Hormonal contraceptives and intrauterine devices offer pregnancy protection but no protection against STIs. Use of "dual methods" (the combined use of condoms and hormonal contraceptives or an intrauterine device) may be the optimal approach for protection against both pregnancy and STIs for adolescents. Although dual method use has been increasing over time, studies find that fewer than 25% of adolescents use dual methods[77–79] According to data from the National Survey of Family Growth, condom use is lower in women who use "highly effective user-independent methods of contraception" defined as injectables, intrauterine devices, and implants, even lower than those who use oral contraceptives.[80]

Adolescents with main and regular partners tend to discontinue condom use quickly, especially if other pregnancy prevention methods are used.[27] Studies that have examined dual method use among adolescents have found that increased use is associated with perceived risks of pregnancy and STIs, communication with parents about sexual risk, parental approval of birth control, positive attitudes toward condoms, increased use with casual partners versus main partners, partner support for condom use, and self-efficacy of condom negotiation.[77,78,81–84] In 1 clinic-based study of African American and Hispanic female adolescents who received counseling and watched a video incorporating themes of condom use and nonuse, researchers found that at 3-month follow-up, those who had the intervention were more than twice as likely to have used a condom at last intercourse than in the usual care group. However, differences did not persist at the 12-month follow-up.[85]

EFFORTS AIMED AT INCREASING CONDOM USE

Eighty-three studies of curriculum-based sex- and HIV-education programs among people younger than 25 years from all countries were reviewed, finding that two-thirds of the programs significantly improved one or more sexual behaviors. Of the 54 studies that evaluated effects on condom use, nearly half (48%) demonstrated an increase in condom use, and no studies found decreased condom use. Concern that these programs might hasten the initiation of sex appears unfounded. In the 52 studies that measured timing of initiation of

sex, 42% found that sexual initiation was significantly delayed for at least 6 months, and 55% found no effect.[28]

Condom availability programs have been evaluated in a variety of settings. In a study of programs in Massachusetts high schools, adolescents in schools where condoms were available were more likely to receive condom use instruction and less likely to report lifetime or recent sexual intercourse, and adolescents who were sexually active were twice as likely to use condoms at most recent sexual encounter.[29] Likewise, clinic-based interventions have been shown to be effective in increasing condom use and decreasing STIs.[86,87] Clinic-based safer sex interventions are endorsed by the CDC.[88]

A recent meta-analysis of high-quality US and international studies of structural-level condom distribution interventions found significant effects on increased condom use, condom acquisition, condom carrying, delayed sexual initiation of youth, and reduced incidence of STIs. The interventions that increase availability or accessibility to condoms are most efficacious when combined with additional individual, small-group, or community-level activities. The intervention effects were significant across target participant characteristics (youth, adults, commercial sex workers, STI clinic populations, or males).[89]

RECOMMENDATIONS

1. Abstaining from sexual intercourse should be encouraged for adolescents as the most effective way to prevent STIs, including HIV infection, and unintended pregnancy.
2. Pediatricians and other clinicians should actively support and encourage the consistent and correct use of condoms as well as other reliable contraception as part of anticipatory guidance with adolescents who are sexually active or contemplating sexual activity. The responsibility of males as well as females in preventing unintended pregnancies and STIs should be emphasized.
3. Pediatricians and other clinicians are encouraged to implement the recommendations in Bright Futures promoting communication between parents and adolescents about healthy sexual development and sexuality including the use and effectiveness of condoms.
4. Restrictions and barriers to condom availability should be removed, given the research that demonstrates that increased availability of condoms facilitates use. Beyond retail distribution of condoms, sexually active adolescents should have ready access to condoms at free or low cost where possible. Pediatricians and other clinicians are encouraged to provide condoms within their offices and to support availability within their communities.
5. Condom availability programs should be developed through a collaborative community process and accompanied by comprehensive sequential sexuality education to be most effective. This is ideally part of a K–12 health education program, with parental involvement, counseling, and positive peer support.
6. Schools should be considered appropriate sites for the availability of condoms because they contain large adolescent populations and may potentially provide a comprehensive array of related educational and health care resources. Training of youth to improve communication skills around condom negotiation with partners can occur in school-based settings.
7. Pediatricians and other clinicians should actively help raise awareness among parents and communities that making condoms available to adolescents does not increase the onset or frequency of adolescent sexual activity and that use of condoms can help decrease rates of unintended pregnancy and acquisition of STIs.
8. Pediatricians and other clinicians should provide and support parental education programs that help parents develop communications skills with their adolescent children around prevention of STIs and proper use of condoms.
9. The American Academy of Pediatrics should encourage additional research to identify strategies to increase continued condom use in established relationships and strategies for use of dual protection with condoms aimed at prevention of STIs and a second contraceptive method for the most effective prevention of pregnancy.

POLICY STATEMENT

Conflicts Between Religious or Spiritual Beliefs and Pediatric Care: Informed Refusal, Exemptions, and Public Funding

abstract

FREE

Although respect for parents' decision-making authority is an important principle, pediatricians should report suspected cases of medical neglect, and the state should, at times, intervene to require medical treatment of children. Some parents' reasons for refusing medical treatment are based on their religious or spiritual beliefs. In cases in which treatment is likely to prevent death or serious disability or relieve severe pain, children's health and future autonomy should be protected. Because religious exemptions to child abuse and neglect laws do not equally protect all children and may harm some children by causing confusion about the duty to provide medical treatment, these exemptions should be repealed. Furthermore, public health care funds should not cover alternative unproven religious or spiritual healing practices. Such payments may inappropriately legitimize these practices as appropriate medical treatment. *Pediatrics* 2013;132:962–965

INTRODUCTION

Religion plays an important role in the lives of many individuals. Fifty-eight percent of respondents to a recent poll reported that religion is very important in their lives, and 23% reported that it is fairly important.[1] The relationship between religion and medicine is complex. Some studies suggest "greater involvement in religion conveys more health-related benefits."[2] There are, however, times when religion and medicine conflict. The current policy statement addresses 3 related issues: (1) parents' refusal of medical treatment of their children; (2) religious exemptions to child abuse and neglect laws; and (3) public funding of alternative unproven religious or spiritual healing practices. The statement situates religious refusals within the scope of parental authority and argues that children's future autonomy should be protected. Religious exemption statutes do not protect all children equally and create uncertainty and, to protect children's health, should be repealed. Public health care funding should focus on established, effective therapies, and paying for spiritual healing practices may inadvertently engender medical neglect. The discussion of these specific topics should not be interpreted as a broader criticism of the interaction between religion and medicine.

RELIGIOUS OBJECTIONS TO MEDICAL CARE

Although parents have broad authority, they have less discretion in making medical decisions for their children than for themselves. On the basis of the ethical principles of autonomy and respect for persons, capacitated adults should have wide license in making medical decisions for themselves, including the refusal of potentially life-saving medical treatment. Their liberty should only be limited in cases of direct harm to third parties, such as the risk of transmitting serious infectious diseases. Infants and children lack the ability to make autonomous medical decisions; therefore, the law generally authorizes their parents or guardians to make such decisions on their behalf. These decisions should primarily focus on the child's best interests.[3,4] Clinicians should afford parents and guardians significant discretion in their interpretation of these interests and collaborate with them to develop treatment plans that promote their children's health. Although family autonomy and privacy are important social values, parents' choices may be limited when they rise to the level of abuse or neglect.[5]

Failure to provide children with essential medical care has been increasingly recognized as a form of neglect. In 1983, the US Department of Health and Human Services (HHS) amended its definition of negligent treatment to include failure to provide adequate medical care.[6] A number of factors are relevant to the evaluation of suspected medical neglect, including likelihood and magnitude of the harm of foregoing medical treatment and the benefits, risks, and burdens of the proposed treatment.[7–9] For example, the risk of an individual unimmunized child contracting a communicable vaccine-preventable disease may be low if immunization rates in the community are high and disease prevalence is low.[10] Serious harms include death, severe disability, or severe pain. The American Academy of Pediatrics (AAP) Committee on Child Abuse and Neglect identifies a variety of factors that can lead to children not receiving appropriate medical care and corresponding graduated management options for pediatricians. For example, lack of awareness, knowledge, or skills can be addressed by counseling and education.[7] Ethics consultation is an additional management option.[7,11] If less-restrictive alternatives are not available or successful, pediatricians should refer families to child protective services agencies. In emergencies, providers may be ethically justified in administering treatment immediately necessary to preserve life, prevent serious disability, or treat severe pain. They should notify child protective services as soon as possible.

The basis for some parents' rejection of medical treatment is religious or spiritual. Traditions vary in the scope of medical treatments they refuse. For example, members of the Followers of Christ refuse all medical treatment in favor of prayer, anointing with oil, and the laying on of hands.[12] Christian Scientists may use dentists and physicians for "mechanical" procedures, such as setting bones or childbirth, but consider most illnesses to be the result of the individual's mental attitude and seek healing through spiritual means, such as prayer. They consider these healing practices incompatible with concurrent medical treatment.[13] Other religious groups prohibit only specific medical interventions. On the basis of their interpretation of scripture, Jehovah's Witnesses only prohibit the use of blood and its major fractions.[14] Understanding these differences is important in identifying whether there are mutually acceptable alternatives.

Some religious refusals have, tragically, led to children's deaths from readily treatable conditions, such as pneumonia, appendicitis, or diabetes.[12,15] Although the free exercise of religion, including parents teaching their children their religious beliefs, is an important societal value, it must be balanced against other important societal values, such as protecting children from serious harm.[16] In some situations, the issue is primarily an empirical one —the relative efficacy of medical and spiritual interventions. Although systematic empirical evidence of the efficacy of religious interventions is often lacking, the courts can judge efficacy by using criteria generally accepted by both parents and health care providers. In other situations, the issue involves differing conceptions of benefit and harm. Parents and guardians should have significant discretion in weighing the risks and benefits of a proposed treatment. At times, the primary benefit of refusing medical treatment or seeking alternative nonmedical treatment is religious or spiritual, such as the implications of the treatment on the patient's eternal salvation. In such cases, the potential benefit cannot be evaluated by using generally accepted criteria. In such situations, the child's future ability to decide this contested issue for himself or herself should be protected.[17] Some adolescents may possess adequate decision-making capacity to comprehend and evaluate the risks and benefits of medical treatment. The possibility of coercion should also be considered in the evaluation of whether a capacitated adolescent's dissent is autonomous.[18]

The courts have consistently ordered life-saving medical treatment over parental religious objections.[8,9] In passages frequently quoted in subsequent rulings, the US Supreme Court famously stated, "The right to practice religion freely does not include liberty to expose the community or the child to communicable disease or the latter to

ill health or death" and "Parents may be free to become martyrs themselves. But it does not follow they are free, in identical circumstances, to make martyrs of their children before they have reached the age of full and legal discretion when they can make that choice for themselves."[19] There is less unanimity in judicial decisions if the condition is not life-threatening, the treatment has significant adverse effects, or the treatment has limited efficacy.[7–9] Courts may also consider the negative psychological effects of court-ordered treatment or medical foster care in their decisions.

RELIGIOUS EXEMPTIONS TO CHILD ABUSE AND NEGLECT LAWS

Most states have "religious exemptions" to their child abuse and neglect laws. These exemptions proliferated in response to the Child Abuse Prevention and Treatment Act of 1974. The act stated, "Provided, however, that a parent or guardian legitimately practicing his religious beliefs who thereby does not provide specified medical treatment for a child, for that reason alone shall not be considered a negligent parent or guardian."[20] Enacting exemptions was a condition for states to receive federal child abuse grants. More than 40 states adopted exemptions, which vary in their location within each state's code and wording.[8] Some apply to child protective services agencies' ability to intervene, and others apply to parents' criminal liability. The HHS revised its position, taking a neutral stance, when the act was reauthorized in 1983: "Nothing in this part should be construed as requiring or prohibiting a finding of negligent treatment or maltreatment when a parent practicing his or her religious beliefs does not, for that reason alone, provide medical treatment for a child."[21] After reauthorization of the act in 1987, HHS clarified that reports of medical neglect should only be made if there is harm or a substantial risk of harm, and religious exemptions should be a matter of state discretion rather than federal imposition.[18] A number of states subsequently amended or repealed their religious exemption statutes.[8,16] Most recently, after the deaths of 2 children, Oregon repealed its exemption.[22]

The AAP believes that religious exemptions to state child abuse and neglect laws should be repealed. These exemptions fail to provide an equivalent level of protection to children whose parents practice spiritual healing and children whose parents do not.[16] In addition, they may create confusion that results in harm to children; parents may be unclear about their duty to provide medical treatment, child protective services agencies may falsely believe that they cannot intervene until after a child suffers serious injury or dies, and prosecutors and courts may be uncertain whether parents are subject to criminal liability if their child dies of medical neglect.[5,16] Although the exemptions could be revised to make it explicit that seeking medical care is required when a child is seriously ill,[5,8] repeal is preferable because it provides greater clarity.[16] For example, parents and spiritual healers who are members of groups that refuse all medical treatment may not be able to differentiate moderate from severe illnesses and, therefore, fail to seek medical attention in a timely manner.[14,16]

PUBLIC FUNDING OF SPIRITUAL HEALING PRACTICES

In addition to efforts to create religious exemptions, some churches and legislators have sought to provide public funds to pay for religious or spiritual healing practices. For example, Medicare and Medicaid cover care provided at Christian Science sanatoria and other religious nonmedical health care institutions and exempt these institutions from medical oversight requirements.[23] In addition, there were unsuccessful efforts to include coverage of Christian Science practitioners in the 2009 federal health care reform bills[24] and ongoing efforts to include their services in the essential health benefits package. These efforts should be distinguished from both health care services provided by religious organizations, such as Roman Catholic and Seventh-day Adventist hospitals, and pastoral care provided as a bundled service.

Coverage for unproven care by unlicensed practitioners is poor public policy for several reasons. Fundamentally, public funds should be spent on established, effective therapies.[25] In addition, religious nonmedical health care institutions provide custodial rather than skilled nursing care, a benefit not covered in other institutions. Given patients' exemptions from undergoing medical examinations, it is not possible to determine whether patients of religious nonmedical health care institutions would otherwise qualify for benefits.[23,26] Because providing public funding for unproven alternative spiritual healing practices may be perceived as legitimating these services, parents may not believe that they have an obligation to seek medical treatment. Although the AAP recognizes the importance of addressing children's spiritual needs as part of the comprehensive care of children, it opposes public funding of religious or spiritual healing practices.

RECOMMENDATIONS

1. Pediatricians, pediatric medical subspecialists, and pediatric surgical specialists should respect families and their religious or spiritual beliefs and collaborate with them to develop treatment plans to promote their children's health.
2. Pediatricians, pediatric medical subspecialists, and pediatric surgical specialists should report

suspected cases of medical neglect to state child protective services agencies, regardless of whether the parents' decision is based on religious beliefs.

3. Pediatricians, pediatric medical subspecialists, pediatric surgical specialists, and the AAP and its chapters should work to repeal religious exemptions to child abuse and neglect laws and to prevent public payment for religious or spiritual healing practices.

abstract

FREE

Sales of raw or unpasteurized milk and milk products are still legal in at least 30 states in the United States. Raw milk and milk products from cows, goats, and sheep continue to be a source of bacterial infections attributable to a number of virulent pathogens, including *Listeria monocytogenes, Campylobacter jejuni, Salmonella* species, *Brucella* species, and *Escherichia coli* 0157. These infections can occur in both healthy and immunocompromised individuals, including older adults, infants, young children, and pregnant women and their unborn fetuses, in whom life-threatening infections and fetal miscarriage can occur. Efforts to limit the sale of raw milk products have met with opposition from those who are proponents of the purported health benefits of consuming raw milk products, which contain natural or unprocessed factors not inactivated by pasteurization. However, the benefits of these natural factors have not been clearly demonstrated in evidence-based studies and, therefore, do not outweigh the risks of raw milk consumption. Substantial data suggest that pasteurized milk confers equivalent health benefits compared with raw milk, without the additional risk of bacterial infections. The purpose of this policy statement was to review the risks of raw milk consumption in the United States and to provide evidence of the risks of infectious complications associated with consumption of unpasteurized milk and milk products, especially among pregnant women, infants, and children. *Pediatrics* 2014;133:175–179

INTRODUCTION

Foodborne illness accounts for substantial morbidity and mortality in the United States. Estimates suggest that each year, as many as 48 million Americans experience foodborne illness, accounting for 128 000 hospitalizations and 3000 deaths.[1] In addition, surveillance estimates by the Centers for Disease Control and Prevention demonstrated no overall improvement in the incidence of foodborne illness in the United States from 2006 to 2009.[2] Among the most preventable of these foodborne illnesses are infections related to ingestion of raw or unpasteurized milk and milk products because of ubiquitous access to healthy, pasteurized milk and milk products, as well as legislation prohibiting the sale of raw dairy products in much of the United States. Reasons for the continued burden of disease related to raw or unpasteurized milk or milk products are primarily related to

misinformation regarding the purported benefits of these raw dairy products. Consumption of raw dairy products is especially risky among populations such as pregnant women, infants, the elderly, and immunocompromised individuals, who are most susceptible to infection with pathogens ingested in raw milk or milk products. Evidence demonstrates the overwhelming benefits to food safety conferred by pasteurization and consumption of pasteurized dairy products.

EPIDEMIOLOGY OF DISEASES CAUSED BY RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS IN THE UNITED STATES

Before pasteurization of milk began in the United States in the 1920s, consumption of raw dairy products accounted for a significant proportion of foodborne illnesses among Americans and resulted in hundreds of outbreaks of tuberculosis and infections caused by bacteria, such as *Brucella abortus*, streptococcal species, and enteric pathogens.[3] Although most milk and milk products consumed today in the United States are pasteurized, an estimated 1% to 3% of all dairy products consumed are not pasteurized. From 1998 through 2009 alone, consumption of raw milk or milk products in the United States resulted in 93 illness outbreaks, 1837 illnesses, 195 hospitalizations, and 2 deaths.[4] These foodborne illnesses were caused primarily by ingestion of raw milk or milk products contaminated with *Escherichia coli* 0157, *Campylobacter* species, or *Salmonella* species. Seventy-nine percent of the outbreaks involved at least 1 person younger than 20 years.[4] In a second study, 121 dairy-associated foodborne illness outbreaks were identified in the United States from 1993 to 2006. Of these, 73 (60%) were associated with unpasteurized dairy products, resulting in 1571 cases, 202 hospitalizations, and 2 deaths; 60% of the patients were younger than 20 years. Thirteen percent of patients involved in raw milk or milk product foodborne illness outbreaks were hospitalized, compared with 1% of patients involved in outbreaks associated with pasteurized products. In addition, 55 (75%) of all 121 outbreaks occurred in 21 states that permitted the sale of unpasteurized dairy products.[5] Immigrant groups are another population at risk for illness from consumption of traditional foods made with raw milk.[6,7]

A number of pathogenic and opportunistic bacteria, parasites, and viruses (see Organisms Detected in Raw or Unpasteurized Milk or Milk Products) have been detected in raw milk or milk products.[4–22] In addition, patterns of dairy consumption appear to have affected the prevalence of illnesses associated with different dairy products. Among milk- or milk product–associated foodborne illness outbreaks reported to the Centers for Disease Control and Prevention between 1973 and 2009, 82% were attributable to raw milk or cheese. However, increasingly, recent illnesses associated with raw or unpasteurized cheese have been reported. This underscores the importance of all raw milk products as potential sources of illness.

Populations at highest risk of morbidity and mortality from foodborne illnesses include older adults, immunocompromised individuals, young infants, and children. The risks involved with infections attributable to consumption of raw milk and milk products are particularly high among pregnant women and their fetuses, as well as young children. For example, consumption of raw milk or milk products has been associated with a fivefold increase in toxoplasmosis among pregnant women[23]; listeriosis associated with high rates of stillbirths, preterm delivery, and neonatal infections, such as sepsis and meningitis[6]; and *E coli* 0157–associated diarrheal disease and hemolytic-uremic syndrome, primarily among young children.[24] Between 17% and 33% of all cases of invasive disease attributable to *Listeria monocytogenes* in the United States occur among pregnant women, unborn fetuses, or newborn infants, a 13- to 17-fold increase compared with the general population.[25–27] Complications include a 20% risk of spontaneous abortion or stillbirth, with two-thirds of infants developing neonatal infection, including pneumonia, sepsis, or meningitis.[28]

GUIDELINES FOR SALES OF RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS BY THE FOOD AND DRUG ADMINISTRATION AND INDIVIDUAL STATES

The modern pasteurization process consists of raising the temperature of milk to at least 161°F for more than 15 seconds, followed by rapid cooling. Since 1924, the Food and Drug Administration (FDA) has regulated the production, handling, transportation, processing, testing, and sale of milk in all 50 states in the United States. In 1987, the FDA prohibited the interstate shipment of raw milk for human consumption, effectively banning interstate commerce of raw milk or milk products. No federal agencies, however, including the FDA, have jurisdiction in the regulation and enforcement of milk sanitation within individual states. In 2011, the National Association of State Departments of Agriculture conducted a review demonstrating that 30 states allow raw milk sales, but only a few of these allow sales in grocery stores. In addition, the 1987 FDA ban on interstate raw dairy transport allows for an exception of cheese made from raw milk, provided the cheese has been aged a minimum of 60 days and is clearly labeled as unpasteurized. However, there is evidence that *E coli* can survive in cheese products even

after a 60-day aging period,[29] and recent outbreaks of *E coli* O157 illness associated with such unpasteurized, aged cheese have been documented in Arizona, California, Colorado, and New Mexico.[30]

RISKS AND BENEFITS OF RAW VERSUS PASTEURIZED MILK AND MILK PRODUCTS

Infections associated with consumption of raw and unpasteurized milk and milk products are related to contamination with pathogenic and opportunistic organisms from a variety of sources. Contamination of raw milk occurs by a number of mechanisms, including direct contact with bovine fecal matter; transmission of organisms from bovine skin or hide; clinical or subclinical mastitis; primary bovine diseases, such as tuberculosis; environmental contamination; and contact with insects, animals, and humans, for example, by contamination from soiled clothing.

Proponents of the health benefits of raw or unpasteurized milk and milk products claim that pasteurization destroys or neutralizes important nutrients in milks, such as proteins, carbohydrates, calcium, vitamins, and enzymes.[31–33] For example, claims that consumption of raw milk is not associated with lactose intolerance and that destruction of lactase by pasteurization of milk leads to lactose intolerance have not been substantiated by independent studies.[34–37] Other claims purporting links between pasteurized milk and autism, allergic reactions, and asthma have largely been based on testimonials or anecdotes and have not been demonstrated based on scientific data. In contrast, numerous scientific analyses have demonstrated that pasteurized milk and milk products contain equivalent levels of such nutrients compared with raw, unpasteurized milk and milk products.[31–39]

RECOMMENDATIONS FROM NATIONAL AND INTERNATIONAL ORGANIZATIONS REGARDING CONSUMPTION OF RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS

Virtually all national and international advisory and regulatory committees related to food safety have strongly endorsed the principles of consuming only pasteurized milk and milk products. These include the American Medical Association, the American Veterinary Medical Association, the International Association for Food Protection, the National Environmental Health Association, the FDA, and the World Health Association. In January 2012, the US federal government denied a petition requesting federal-level legalization of all raw milk sales on the basis of its analysis of the scientific basis for the food safety benefits of pasteurization.[40]

The American Academy of Pediatrics (AAP) has strongly endorsed the use of pasteurized milk in its 2012 *Red Book*.[41]

CONCLUSIONS

In summary, the AAP strongly supports the position of the FDA and other national and international associations in endorsing the consumption of only pasteurized milk and milk products for pregnant women, infants, and children. The AAP also endorses a ban on the sale of raw or unpasteurized milk and milk products throughout the United States, including the sale of certain raw milk cheeses, such as fresh cheeses, soft cheeses, and soft-ripened cheeses. This recommendation is based on the multiplicity of data regarding the burden of illness associated with consumption of raw and unpasteurized milk and milk products, especially among pregnant women, fetuses and newborn infants, and infants and young children, as well as the strong scientific evidence that pasteurization does not alter the nutritional value of milk. The AAP also encourages pediatricians to contact their state representatives to support a ban on sale of raw milk and milk products. Additional resources containing information regarding the safety of pasteurization and the risks of consuming raw or unpasteurized milk or milk products are provided in this statement.

ORGANISMS DETECTED IN RAW OR UNPASTEURIZED MILK OR MILK PRODUCTS

Bacteria

Brucella species
Campylobacter jejuni
Coxiella burnetii
Cryptosporidium species
Enterotoxigenic *Staphylococcus aureus*
Listeria monocytogenes
Mycobacterium bovis
Salmonella species
Escherichia coli
- Shiga toxin-producing *E coli* (STEC [eg, *E coli* O157])
- Enterohemorrhagic *E coli* (EHEC)
- Enterotoxigenic *E coli* (ETEC)

Shigella species
Yersinia entercolitica

Parasites

Giardia species

Viruses

Norovirus
Rabies
Vaccinia

abstract

FREE

The medical home and the Individuals With Disabilities Education Act Part C Early Intervention Program share many common purposes for infants and children ages 0 to 3 years, not the least of which is a family-centered focus. Professionals in pediatric medical home practices see substantial numbers of infants and toddlers with developmental delays and/or complex chronic conditions. Economic, health, and family-focused data each underscore the critical role of timely referral for relationship-based, individualized, accessible early intervention services and the need for collaborative partnerships in care. The medical home process and Individuals With Disabilities Education Act Part C policy both support nurturing relationships and family-centered care; both offer clear value in terms of economic and health outcomes. Best practice models for early intervention services incorporate learning in the natural environment and coaching models. Proactive medical homes provide strategies for effective developmental surveillance, family-centered resources, and tools to support high-risk groups, and comanagement of infants with special health care needs, including the monitoring of services provided and outcomes achieved. *Pediatrics* 2013;132:e1073–e1088

In decades past, debate centered on the question: "does early childhood intervention work?" Time and extensive research clearly reveal an affirmative answer.[1] In the new millennium, the focus of discussion has turned to distinct conceptual matters and specific questions:

- What roles and actions are best assumed by collaborative professionals in providing a system of early intervention (EI) shared by pediatricians in the medical home and EI programs?
- What models of intervention are optimal when considering infants/toddlers, families, agencies, pediatricians, and best use of resources for optimal outcomes?
- What systematic barriers to optimal intervention are present and what supports are available to overcome them?

Given the ever-growing body of evidence demonstrating the value of EI services for infants with special needs and their families, there remains a necessity for close collaboration between the infants'

medical home and their respective Individuals With Disabilities Education Act (IDEA) Part C state programs. This clinical report, reflecting the work of diverse stakeholders (clinicians, policy makers, academicians, family members, and governmental staffs), will:

1. Review the common core components of IDEA Part C and the medical home;
2. Review evidence of the value of medical home and EI programs for infants/toddlers with special needs;
3. Provide pediatricians with information on evidence-based best-practice models for effective EI;
4. Highlight systematic barriers to identification/integration of infants in EI services; and
5. Offer resources for medical home personnel and families to support this collaboration.

CORE COMPONENTS OF IDEA PART C AND THE MEDICAL HOME

IDEA Part C Programs

For more than half a century, the field of early childhood intervention has emphasized factors impacting an infant's overall function. These encompass both biologic (epigenetic, infectious, etc) and experiential variables (quality of relationships; exposure to, or lack of, opportunities for exploration and learning).[2] The importance of these early experiences was a compelling concept in the 1975 creation of the Education for All Handicapped Children Act (Pub L No. 94-142), which provided "special education" services for children 5 to 21 years of age. Eleven years later, the law was extended and broadened to incorporate the concept of support to infants 0 to 3 years old and their families. This 0 to 3 component, now called Part C of IDEA, addressed "an urgent and substantial need" in several areas: (1) enhancing the development of infants and toddlers with special needs; (2) reducing downstream governmental costs of special education and/or institutionalization by intervening earlier; and (3) supporting the ability of families to interact with and meet the needs of the infant/toddler.[3–6]

The long-standing charge to each state's Part C program is to create and sustain a statewide, comprehensive, coordinated, family-centered, multidisciplinary, and interagency system of EI services for delivery in the local or regional area. In doing so, each state is required to establish eligibility criteria for serving, at a minimum, 2 cohorts of children: (1) those with a diagnosed physical or mental condition with a high likelihood of developmental delays; or (2) a developmental delay in 1 or more of 5 domains (cognitive, motor, communication, social/emotional, adaptive).[3,5] States may also elect to serve infants at risk for delay because of biological or environment risk factors and/or children who have been in Part C but are now eligible for preschool education (if the family desires to stay in the Part C system).

Because each state is charged with developing these eligibility criteria and is subject to legislative and budgetary constraints, notable variations in eligibility and services occur from state to state. Historically, federal monies for Part C are relatively small. Thus, states rely on systems of coordination with state, local, other public, and private funding sources, serving as payers of last resort rather than as primary payers for intervention services.

This model has demonstrated success on several levels. By 1992, 143 000 children and their families were receiving services via Part C. In 2009, that number had risen to 349 000, or 2.67% of the US population 3 years or younger. With variables related to eligibility criteria and budgets, the percentage of the 0- to 3-year-old population being served in 2009 ranged from 1.24% (Georgia) to 6.5% (Massachusetts). Despite fiscal challenges at the federal and state level, at the time of this publication, all 50 states continue to participate in the Part C program.[3,7]

The most recent reauthorization of IDEA Part C in 2004 placed increasing importance on quality measures of outcome, provision of services in the child's natural environment, and identification efforts for eligible infants ("child find"). There was also a strengthening of the relationship between EI and services being rendered in each state according to the Child Abuse Prevention and Treatment Act Reauthorization Act of 2010 (Pub L No. 111-320).[8]

Because of state-to-state variations regarding eligibility criteria, definitions of "developmental delay," and state budgetary priorities, the nature of EI services can seem heterogeneous when viewed through a national lens. Nonetheless, 2 core concepts remain stable across Part C programs across the country:

- Nurturing relationships are the fundamental elements for optimal early development; and
- IDEA Part C is dedicated to helping families better understand their infants and to coordinating the various regional systems and services available to the family and child.

The Medical Home

By definition, a "medical home" for children is a process of care. The American Academy of Pediatrics (AAP) has described the medical home as

the provision of primary care to children that is accessible, family-centered, continuous, comprehensive, coordinated, compassionate, and culturally effective. Historically, the medical home was commonly discussed in the context of children with special health care needs, but increasingly, its value has been seen across the full spectrum of infants, children, and adolescents.[9–11]

Clearly, the core components of care that define a medical home match closely those specified legislatively in IDEA Part C. As child find is mandated in Part C, there is recognition that the pediatric medical home is an integral part of that process.[11] Emerging evidence supports the medical home process regarding its value to children's ultimate development and well-being.[12–18] The Healthy People 2020 goals and those of the Patient Protection and Affordable Care Act cite the promotion of the patient-centered medical home.[19,20] When considering the intersection of EI and the medical home, a key component of the medical home process is that of identifying infants and toddlers with developmental disorders.[21–25] A natural next step is timely and appropriate referral to EI services for coordinated, culturally effective, and family-centered developmental intervention.

Over the past decade, the medical home concept has extended beyond pediatric practices into those of family/community physicians and internal medicine. A recent workforce study by the AAP described a robust pediatric workforce for the population of US children but noted a significant problem of distribution (regional shortages and oversupplies).[26] Family physicians provide a medical home opportunity for approximately one-third of the US pediatric population. Historically, these services have been in rural communities; estimates suggest up to 5 million children/adolescents live in counties with no pediatrician. Supporting both family physician medical homes and Part C agencies serving rural and/or frontier areas of the country should be a focus at both the preservice and in-service levels.[27]

As the model of the pediatric medical home has gained support over recent years, the number of recommended or expected tasks/screening procedures for the primary pediatrician has also increased.[14] Acknowledging potential time and budgetary constraints within pediatric practices, methods to streamline identification of infant developmental delays have been developed and are critical to meeting family needs and successful referral to EI services for the child.[4,28]

EVIDENCE-BASED OUTCOMES AND BEST PRACTICE CONSIDERATIONS

Over the past half century, research in the neurosciences and in child development have placed an increasing priority on the support needed in the first few years of life as brain growth and function are being shaped for future "scaffolding" of skills and knowledge. Program development and methods of program evaluation have since been generated and demonstrated to assist in this neurodevelopmental process. From this body of work have emerged several global principles related to early childhood development and intervention for optimal development.[29] Brains are built over time and are modulated by the interactive influences of genes and experience that literally affect the architecture of the developing brain.

- Access to basic medical care (prenatal and during early childhood) prevents threats to healthy development through early diagnosis/identification of problems with subsequent EI and ongoing care management.
- When parents, community programs, and professionals who provide early childhood services (including the pediatrician in the medical home) promote supportive relationships and rich learning experiences for infants and young children, a stronger foundation is created for higher achievement in school and, eventually, the community.
- The economic cost of creating and applying supportive conditions for early childhood development is less than the alternative "down the road" costs of addressing problems later in childhood or adolescence.
- From a legislative and policy perspective, a strong investment in early childhood intervention is foundational for community and economic development on multiple levels.

Although these global incentives derive from studies across various medical and nonmedical fields, it is instructive to consider, more specifically, the benefits stemming from the 2 entities being considered: the medical home and EI services for infants and toddlers.

Benefits From Participation in a Medical Home

The primary care medical home, with core attributes including being family centered; community based; and accessible, coordinated, and continuous in support, has increasingly been endorsed by the AAP and other child-oriented agencies as highly valuable.[30] The core concepts of these processes of care seem intuitive for physicians charged with providing preventive and timely care to infants/toddlers.

The benefits of a medical home in providing efficient, high-quality, comprehensive primary care are well documented. For example, the medical home has been linked to improved health status, more timely care, increased family-centeredness, improved family functioning, and more appropriate health-care utilization.[9,10,13,17,31,32] The National Survey of Early Childhood Health reports that nearly half of parents have concerns about their child's development,[33] yet few parents report that their concerns are elicited during outpatient clinic visits.[34] In addition, children at high-risk of developmental delay have been associated with lower odds of having a medical home compared with children at low or no developmental risk.[35] Thus, a growing consensus recognizes the ability of a medical home process to provide developmental health services and promote a comprehensive system of community services for early childhood development,[33,36,37] a process altogether consistent with and supportive of the core elements of EI services under IDEA Part C.

Benefits From EI

When evaluating benefits derived from early identification and intervention, there are 2 major streams for measuring outcomes: (1) benefits to the child and the family; and (2) economic advantages derived from EI programs.[38]

An increasing number of well-constructed longitudinal studies have emerged over the past decade. The indicators measured reflect positive and sustainable outcomes. The Infant Health and Development Program tracked outcomes in low birth weight and preterm infants who received EI services. At 8 years of age, improvements were noted in verbal abilities, receptive language scores, and overall cognitive performance.[39] At the 18-year follow-up, there were notable improvements in academic performance and endorsement of less risky behaviors, fewer arrests, and a lower dropout rate.[40] Other studies have generated similar positive data as long as 15 to 40 years beyond early childhood.[41,42]

Equally important to communities and agencies are the studies demonstrating the fiscal advantages of providing quality EI services. A 2003 report from the Federal Reserve Bank of Minneapolis reveals EI programs as "economic development initiatives" that should be at the top of economic lists for local and state governments. The authors found that 1 program demonstrated an $8 return for every dollar invested in EI and estimated that 80% of the benefits were directly applicable to society in general (because of more efficient use of school services and less use of criminal justice and other public systems).[43–46] In the 2008 study, The Economics of Early Childhood Policy,[47–49] Kilburn and Karoly provide the foundation for support of EI from strictly an economic perspective and conclude: "The costs savings for government could be large enough to not only repay the initial costs of the program but also to possibly generate savings to government or society as a whole multiple times greater than the costs."

The benefits reflected in these studies and other studies expand the concept of EI from one of solely a social-service/educational policy to one of critical economic-development and conservative fiscal responsibility.[50] Availability of these data should support advocacy efforts of the medical home on behalf of infants (Fig 1).

MEDICAL HOMES, EI PROGRAMS, AND BEST PRACTICE MODELS

Given the evidence-based data regarding the value of medical homes and EI services, the continuing challenge is to identify which models of intervention are consistent with best practice consensus, and which demonstrate greatest outcomes with best stewardship of professional and fiscal resources. The medical home can be essential in helping families and

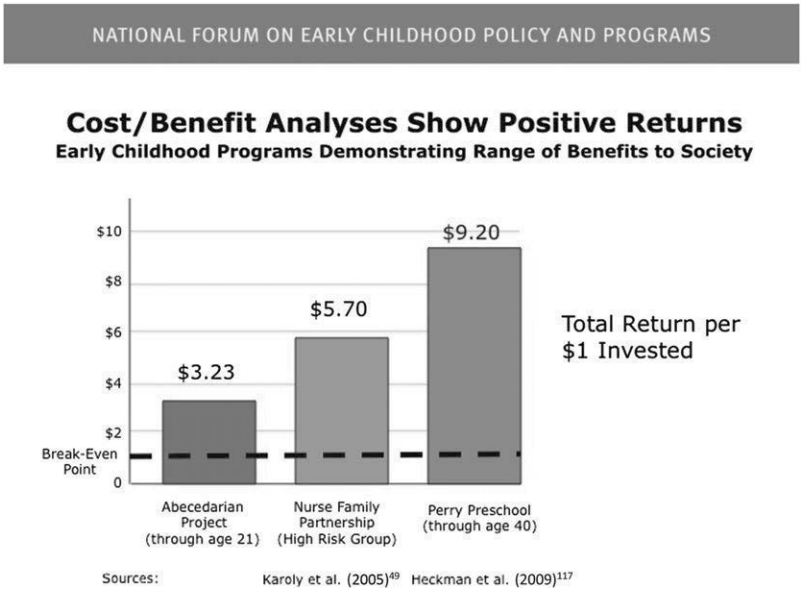

FIGURE 1
Cost/benefit analysis of benefits to society of early childhood programs. (Reprinted with permission from the Center on the Developing Child at Harvard University, www.developingchild.harvard.edu.).

diverse providers better understand the roles played by professionals involved in the infant's overall intervention program.

Two concepts are increasingly prioritized when translating evidence-based neuroscience into functional application for "best practice" provision of EI services:

1. Creating frequent opportunities that allow for "learning in the natural environment" rather than in simulated "treatment" situations; and
2. Utilizing methods of "coaching" as a model for families, medical homes, and EI programs providing services to infants.

The concept of providing intervention services within the context of a natural learning environment has been a legal and conceptual component of IDEA Part C intervention since its inception. Part C considers "natural environments" as meaning settings that are natural or typical for similarly aged and nondisabled peers. The broader concept of learning in the natural environment encompasses several key elements:

- There is base acknowledgment that learning takes place in the context of relationships, and as such, intervention strategies should enhance rather than disrupt typical activities unique to a family.
- There is endorsement of parents, siblings, extended family, and others as key agents for the infant's developmental learning.
- Thus, emphasis is on supporting those change agents and their abilities during everyday activities, rather than attempting to teach new skills outside of natural contexts.
- Focus is on function and development of personal-social skills in the infant while promoting awareness and confidence in parents to guide their infant with special needs.

Rather than a "medical model" wherein a specific treatment is applied directly to the child for a specific malady, the paradigm is shifted to a contextual and consultation-based delivery of supports and services to the family and the infant.[51,52] Similar to the concept of the medical home being a process, rather than an address, the concept of natural environment describes process rather than a physical address.[53] These concepts have been endorsed by national stakeholder organizations, including those of speech, physical, and occupational therapies.[54–56]

Increasingly, a best practice method, endorsed across diverse disciplines, provides coaching strategies to families for use in the child's natural learning environments. This method has been shown to build the capacities of a parent or other caretaker as new skills (both in the family member and the child) are acquired.[57,58] Coaching techniques to support parents are used by therapists in the natural learning environment and can be modified and applied by the pediatrician in the medical home process.[59–62] Key elements in the coaching process are shown in Table 1.

There is a more complex subset of infants who might benefit periodically from adjunctive traditional "hands-on" (direct) medical therapy. This is generally for specific goals and often for limited periods of time. These complex health care needs may include severe visual or hearing impairments, tracheotomies, and congenital malformations with inherent limitations to daily activities or needs, etc. Referrals for supportive direct services should be based on specific and measurable outcome goals. Preferably, such goals should be written in concert with the global goals of the family (also reflected in the individualized family service plan as a component of "care coordination").

Unfortunately, confusion is too often experienced by families when the infant is dually served by therapists applying direct medical therapy and professionals in the medical home and/or EI program by using transdisciplinary coaching within the natural learning environment. Unless these services are explained and

TABLE 1 Elements in the Coaching Process

Element	Examples for Application
Joint planning	Agreement by coach and parent on actions assumed by coach and subsequent opportunities for the parent to practice between coaching visits.
Observations	Consider the family's actions/practices/routines to better develop new skill sets, strategies, and ideas for use in the natural learning environment.
Action	Spontaneous or scheduled events, occurring in real-life situations, that allow the family member to practice, refine, or analyze new skills.
Reflections	The coach revisits the existing strategies to ensure they are in keeping with evidence-based practices and consider if/when modifications are needed.
Feedback	After the family member is allowed to reflect on strategies employed, actions being applied, and opportunities to practice new skills in the natural learning environment, the coach provides information affirming the parent's understanding or adds information to deepen the parent's understanding.

Modified from Rush DD, Shelden ML. *Evidence-Based Definition of Coaching Practices*. Morganton, NC: Center for the Advanced Study of Excellence in Early Childhood; 2005.[114]

closely coordinated, a mistrust of one professional or the other can develop.[57]

FOUR DEVELOPMENTALLY HIGH-RISK GROUPS COMMON TO MEDICAL HOMES AND EI PROGRAMS

Among all the children seen in the medical home, several subgroups involve particularly high risks, specific opportunities for EI services, and ongoing collaboration with the pediatrician:

Infants and Toddlers From Environments of Abuse or Neglect

Data from the US Department of Health and Human Services (2011) revealed ~825 000 substantiated cases of abuse/neglect resulting in 1770 child deaths.[63] Infants younger than 1 year remained the highest risk group for fatalities. Among children 0 to 3 years of age who are maltreated but survive, negative effects (social/emotional, cognitive, and/or physical) have been described in up to 47%.[64] Given the astounding cost of child protective services (provision of educational, judicial, and health-related services are estimated at $94 to $103 billion per year), the ability to identify and prevent conditions leading to maltreatment warrant serious consideration and action.[15]

A gap exists in the provision of EI services to maltreated infants and toddlers. Of the ~35% with a need, only 12.7% actually receive services.[65] The Child Abuse and Prevention Treatment Act of 2010 acknowledged this and sought to advance "effective practices and programs to improve activities that promote collaboration between the child protective services system and the medical community, including providers of mental health and developmental disability services, and providers of early childhood intervention services."

Social and emotional development is most vulnerable to previous maltreatment, with attachment issues, severe feeding differences, and sleep disorders being especially prominent among infants.[66] Given research evidence that (1) early brain development affects lifelong capacity to regulate emotions and learn; (2) the "active ingredient" for brain development is the quality of relationships between the infant and those providing care and nurturing; and (3) infants/toddlers exposed to persistent multiple risk factors are in need of EI as early as possible, the close, collaborative interaction of the medical home and the regional Part C program is vital to infant outcome and community cost containment.[67,68]

Infants and Toddlers With Mental Health Issues

Closely related to the issues of maltreatment, but by no means limited to this group, are infants and toddlers experiencing mental health issues (either primary to the child or among their caregivers).[69] Coexisting conditions can act as "red flags" for developing infant mental health concerns (Table 2).[70,71] Likewise, mental health issues affecting the infant/toddler can result in additional developmental delay or dysfunction.[15] As awareness of infant mental health issues increases and as more focus is placed on providing needed services for this group, the medical home and the Part C programs together remain at the forefront of identification, intervention, and surveillance over time.[72–75]

Elements of support for infant mental health include: (1) easy accessibility for diverse families; (2) a system for early identification of concerns and timely application of screening/referral; (3) provision of full access to an array of supportive resources; (4) promotion of family knowledge of conditions and of service delivery systems; and (5) ensuring family-centered care with family satisfaction as an outcome of interventions.[76,77] These elements are provided when the medical home process and the regional Part C program perform collaboratively. The focus of intervention to support infant mental health remains on the infant-caregiver relationship rather than on solely the child or adult.[78] Instruments such as the Ages and Stages, Third Edition,[79,80] the Ages and Stages: Social/Emotional screener,[81] Mental Health Screening Tool Zero to 5 Years,[82] and the AAP "Addressing Mental Health Concerns in Primary Care: A Clinician's Toolkit,"[83] among others, offer functional options for use with families.

TABLE 2 Risk Factors Potentially Impacting Infant Mental Health

Family and Associated Environmental Factors	Child Factors
Low socioeconomic status/poverty	Premature birth
Low maternal education	Low birth weight
History of domestic violence	"Difficult" temperament and/or poor "goodness of fit" with primary caregivers
Maternal/paternal depression	Exposure to "toxic stressors" (alcohol, illicit drugs, traumatic events, environmental exposures, such as lead, etc)
History of parental criminality	Cognitive dysfunction
Parental health problems	Genetic conditions with associated behavioral disorders
Parental mental health disorders	
Family history of mental health disorders	

Modified from Brauner CB, Stephens BC. Estimating the prevalence of early childhood serious emotional/behavioral disorders: challenges and recommendations. *Public Health Rep.* 2006;121(3):303–310.[70]

Infants and Toddlers From Culturally Diverse Backgrounds

Linguistic and/or cultural differences between families and professionals in the medical home or EI program create barriers to both appropriate screening and, potentially, to enrollment and provision of services. Families' beliefs and understanding of child development and differences in developmental progression reflect cultural perspectives. Their views of "community" and the child may differ from a professional's "deficit-oriented" interpretation of the child's functioning capacity.[84]

Numerous factors and variables affect the process of screening, referral, and service provision, including: socioeconomic status, religious differences, regional demographics, English proficiency or literacy, immigration status, family support systems, and access to services. When 1 or more of these potential barriers exist, the results may include families' feelings of being insulted or treated rudely, fear of the medical community in general, confusion about appointments/referrals, or being discounted in the decision process.[85–89]

The disparities noted previously can negatively affect the processes of care in the medical home and the regional Part C program.[90] Feinberg et al[91] discussed the effect of race on effective participation in EI programs. African American children with developmental delay(s) were 5 times less likely than were white children to receive EI services. Garcia and Ortiz[84] have described similar differences in the Latino population and have offered suggestions for prereferral interventions to support culturally and linguistically different populations. As medical home personnel consider quality improvement efforts, areas for consideration might include lack of awareness of racial privilege, assumptions of the value of science over spirituality (in reference to developmental differences), importance of individual over the family group, and logistics required for higher frequency interactions with the developmental or medical community[91,92] (Table 3).

Infants and Toddlers From Economically Deprived Backgrounds

Robust data from economically at-risk populations describe (1) disparities in referral and provision of services for EI and developmental support; and (2) variations in policy commitment to low-income young children and families. Some of these disparities remain at the institutional/policy level within each state (eligibility criteria, coordination efforts, etc). For example, among states with narrow EI eligibility criteria, poor children are 18% less likely to receive EI services.[93] Some are the result of barriers discussed above relative to cultural differences and to mental health issues.[94–98]

The effects of poverty and comorbid conditions, such as food insecurity, have been linked not only to health and ultimate educational performance but also to mental health and behavior in young children and their mothers.[99,100] It is critical for professionals in both medical homes and Part C programs to integrate quick and effective methods of surveillance for poverty-related issues, such as food insecurity, as a component of early childhood intervention[101] (Table 4).

TOOLS FOR THE MEDICAL HOME: MEETING THE CHALLENGES OF COLLABORATION

The medical home process is highly valued by families as they perceive "added value" benefits of more predictable care and less unplanned emergent care, especially among families of children with special needs.[12] As the value placed on the medical home continues to rise, so too are the seemingly unending expectations. But as screening procedures and protocols are encouraged, time and reimbursements remain significant limiting factors.[102,103] Thus, it is imperative that the professionals in the medical home have ready access to tools to provide efficient screening, surveillance, referral, and ongoing collaboration in support of infants/toddlers and EI services.[104]

In 2006, the AAP published a policy statement, "Identifying infants and

TABLE 3 Cultural Barriers to Medical Home Screening and Referral for EI Services

Families
Limited proficiency in English (parent and/or child); differences in speech or dialect
Limited reading skills
Acculturation level and knowledge of/comfort with agencies
Attitudes toward child development and disabilities
Conflicts: work, child care, transportation, or financial
Extended family expectations different from parents/professionals
Medical homes
Sensitivity to cultural diversity within medical home staff
Sensitivity to religious preferences and differing family traditions
Paternalistic approaches to parents of infants from different cultures
Use of medical jargon
EI programs
Lack of language-appropriate information materials
Shortage of available bilingual personnel
Inflexible scheduling practices
Sensitivity to cultural diversity among families served

Modified from Zhang C, Bennett T. Facilitating the meaningful participation of culturally and linguistically diverse families in the IFSP and IEP process. *Focus Autism Other Dev Disabil.* 2003;18(1):51–59.[115]

TABLE 4 Potential Questions for Social History in Families of Infants/Toddlers by Using the *IHELLP* Mnemonic

Area of Interest	Example Questions
Income	
General	Do you have fear of running short of money by the end of the month?
Food security	Do you or anyone in the family ever skip meals because there is not enough money for food? Do you receive assistance (food stamps, etc)?
Housing	Is housing or payment for housing a problem for you?
Associated utilities	Do you have trouble or concern about paying electric/gas/water bills?
Education and development	Do you have concerns about how your infant is developing?
Early childhood programs	Is your child in a program to assist you in supporting her development?
	Do you feel the need for such a program?
Legal status	Do you have questions about your immigration status or about benefits/services for you and your infant/toddler?
Literacy	Do you have trouble reading forms given from our office or agencies?
	Do have difficulty in reading generally?
	Do you read to your child each day? (Based on above answers)
Personal safety	Do you feel that you and your infant/toddler are safe in your present situation/relationship?
	Have you or your spouse ever been the subject of domestic violence?

Modified from Kenyon C, Sandel M, Silverstein M, Shakir A, Zuckerman B. Revisiting the social history for child health. *Pediatrics*. 2007;120(3). Available at: www.pediatrics.org/cgi/content/full/120/3/e734.[101]

young children with developmental disorders in the medical home: an algorithm for developmental surveillance and screening"[105] (http://pediatrics.aappublications.org/content/118/1/405.full.html), which offers a roadmap and valuable resources to the pediatrician seeking to identify and refer eligible infants for EI services. Since its publication, Earls et al[23] reported a longitudinal study of developmental and behavioral screening in a North Carolina project containing insightful ideas and suggestions for practical applications in practice.

King et al[24] conducted a quality improvement follow-up study on developmental screening and surveillance. Attempting to apply the algorithm suggested in the 2006 AAP policy statement, clear gains were made in identifying and referring young children to EI programs. But many practices described struggles in implementing the processes in particularly busy seasons, with staff turnover, and regarding certain time-sensitive screens. Tracking of referrals made was difficult. King et al's[24] review (http://pediatrics.aappublications.org/content/125/2/350.full.html) offers insights for other medical homes attempting to optimize identification and referrals for EI.

Marks et al[106] in 2011 published suggestions for enhancing the algorithm for developmental and behavioral surveillance in children ages 0 to 5 years (http://cpj.sagepub.com/content/50/9/853). In addition to further data supporting the use of specific screening tools, the review offers practitioners specific guidance in the following components of care:

- Eliciting and addressing parents' concerns;
- Milestone and behavioral skill monitoring;
- Identifying developmental/behavioral risk and protective factors;
- Making accurate and informed observations about child-parent interactions; and
- Child referral resources.

Three other resources available to the medical home offer guidance and efficiency in approaching at-risk infants/toddler who have potential need for EI services. The 2006 clinical report from the AAP,[107] "Clinical genetic evaluation of the child with mental retardation or developmental delays," remains a useful tool for the practitioner in which decision trees, clinical guidelines, and resources for clinical application are outlined (http://pediatrics.aappublications.org/content/117/6/2304.full.html). Michaud's[108] overview of prescribing therapy services for children with motor disabilities (http://pediatrics.aappublications.org/content/113/6/1836.full.html) and Sneed et al's[109] review of the differences in prescribing therapies and medical equipment in medical versus educational settings (http://pediatrics.aappublications.org/content/114/5/e612.full.html) are both practical and insightful guides for the busy medical home.

Once the practitioner has identified an eligible infant/toddler in need of services, the family benefits from open and effective lines of collaboration between the medical home and the Part C program. A summary of suggestions for better communication between medical homes and EI programs is provided in Table 5.[110,111] A representative sample of the numerous resources available to the medical home and to families is outlined in Table 6.

Despite the barriers and challenges inherent to practitioners and programs, there remains strong potential for collaboration between medical homes and EI programs at the policy

and programmatic levels.[89,112] Kozlowski et al[113] described an investigation comparing parents of toddlers with autism to those of children with other developmental disorders. The data, generated through the Louisiana Part C Program, described time delays between when parents first perceived differences in their children's communication styles and when referrals from physicians were made to the EI program. Collaborative model ventures such as this will continue to inform families, medical home professionals, EI service programs, and state agencies.

SUGGESTIONS FOR COLLABORATION BETWEEN THE MEDICAL HOME AND EI PROGRAMS

- Improving child-find and optimizing the referral process

Practitioners should incorporate the AAP recommendations for developmental surveillance, which allows for enhanced identification and timely referral for EI services.

The referral should set the stage for collaboration with EI programs. The AAP referral form is available (http://www.medicalhomeinfo.org/downloads/pdfs/EIReferralForm_1.pdf) and can help streamline the process, and individual states may have referral forms that are specific for the individual state Part C program. Such forms can be used in referrals to adjunctive service programs.

The referral provides an opportunity for education about appropriate developmental milestones, as well as eliciting family goals and expectations, which should inform supervision of the individualized family service plan and clinical approval for EI and other developmental services.

The medical home should incorporate a system for referral tracking. An example referral form (Appendix) provides a template to obtain family permission at the time of the referral so that EI programs can communicate the results of the initial evaluation with the medical home. Modifications for individual states/programs may be needed (Appendix).

- Efficient evaluation and coordination of services

Practitioners should not wait for a specific diagnosis before initiating an appropriate referral to EI. Early referral should request:

- assistance with multidisciplinary assessment;
- provision of support to parents in addition to the child;
- provision of knowledge about and integration with community resources; and
- a preferred mechanism for information return from the intervention program.

Various protocols are available to guide a stepwise developmental evaluation of infants and young children (see above). Included among these resources is the AAP "Caring for Children With Autism Spectrum Disorders: A Resource Toolkit for Clinicians."

As practices enhance their capacity for care coordination, consideration should be given to develop mechanisms for identifying families who need assistance with the referral process or who have complex psychosocial or medical issues. These strategies might include:

- closer follow-up;
- linkage to a care coordinator; and
- incorporation of health information technology to assist in identification, clinical decision support, and tracking.

Families should be encouraged to partner with the professionals in the medical home to recognize and monitor appropriate consultation and service options. These may include:

- monitoring of the child's progress being made related to services being purchased;
- informing families of appropriate treatment models;
- being available to programs and school systems for clarification of medical issues that affect development and learning; and
- proactively planning the transition from Part C (birth to 3 years) to Part B of IDEA, and the 3- to 5-year-old programs in their local school system.
- Advocacy roles for physicians in the medical home

TABLE 5 Ideas for Communication/Collaboration Between Medical Homes and Part C

Channels for concise bidirectional, "minimum effort" communication needs to be in place and familiar to both the medical home and the regional Part C Program. Tools such as the AAP Referral Form for Early Intervention should be deemed acceptable (with modifications as needed) and readily available (http://www.medicalhomeinfo.org/downloads/pdfs/EIReferralForm_1.pdf).[113]

Professionals at both the medical home and the Part C program need continual update in medical records as the child is seen and changes are noted.

To best sustain the process of information sharing, the individuals at each program should know who one another are and how to contact directly when needed.

Information from the medical home should be available to the Part C assessment team before its evaluation and information, and recommendations on intervention should be forwarded to the medical home as the individualized family service plan is developed and modified.

When the child is seen by subspecialists, their input to both the medical home and the Part C program is valuable.

Timely and ongoing flow of information between the medical home and the Part C program reassures the family of coordinated, family-centered care; it relieves the family of the burden of having to interpret and transport the information.

Modified from Stille CJ. Communication, comanagement, and collaborative care for children and youth with special healthcare needs. *Pediatr Ann.* 2009;38(9):498–504.[110]

TABLE 6 Resources for Medical Homes and Families

Resource	Comments
American Academy of Pediatrics www.HealthyChildren.org	At the American Academy of Pediatrics Web site. Includes developmental milestones for infants/toddlers 0–5 y of age. Information about infants born preterm and about early childhood delays in all areas, including language and social skills, is available.
Zero To Three www.zerotothree.org	Includes information and resources on a number of topics, including early development, language, and behavior.
Learn the Sign, Act Early Center for Disease Control and Prevention, The National Center on Birth Defects and Developmental Disabilities www.cdc.gov/actearly	Provides an array of checklists, fact sheets, positive parenting tip sheets, and links to useful sites for specific issues.
National Dissemination Center for Children With Disabilities http://nichcy.org/babies 1-800-695-0285	Funded by the US Office of Special Education and Rehabilitative Services. This site provides information about services in one's state and local region. Information is guided for families, medical professionals, and school personnel.
Family Voices www.familyvoices.org	Family Voices aims to achieve family-centered care for all children and youth with special health care needs and/or disabilities. The site provides families with tools to make informed decisions, advocate for improved public and private policies, build partnerships among professionals and families, and serve as a partner in the child's health care. National and state sites and organizations are available.
Child and Family WebGuide: Expert Reviewed Sites on Children and Families www.cfw.tufts.edu	The WebGuide is a directory that evaluates, describes, and provides links to hundreds of sites containing information about child development research and practical advice for professionals and families.
Your Child: Development and Behavior Resources: A Guide to Information and Support for Parents www.med.umich.edu/yourchild/index.htm	The site provides: evidence-based information for families and professionals; links to support groups, agencies, and organizations; recommended books and other tools; links to sites for "timely topics"; and a guide for families on using the Internet to find reliable parenting information.
National Association for the Education of Young Children (NAEYC) http://www.naeyc.org/	Founded in 1926, NAEYC is the world's largest organization (80 000 members) working on behalf of young children. Resources and publications for medical homes, families, and agency programs for infants and toddlers are available.

Realize state-to-state differences in eligibility criteria, assessment policies, and services provided under Part C; be aware of updated changes in aspects of service for your state.

Be aware of potential costs to the family (public funding, private insurance, private pay).

Be cognizant of resources (fiscal and professional) available within the state and their local Part C programs and support efforts to optimize services to infants/toddlers.

Maintain an updated resource list of local and regional services/resources, including both subspecialty consultants and supportive programs.

Assign time to meet with staff from local and regional programs (in office, over telephone, or through local continuing education or hospital staff meetings).

Work within AAP Chapter structures to monitor and encourage state governmental services to infants and children; interaction at the legislative and the agency levels is critical to support fiscal, policy, and quality assurances of outcomes. Fiscal considerations include both monies to operate quality programs and a system of proper reimbursements for primary physicians and specialists caring for children with special needs. Policy considerations include ensuring that families have timely access to primary and subspecialty services.

Explore opportunities to participate on statewide or regional boards tasked with oversight of the early childhood programs.

CONCLUSIONS

The positive economic effect of front-end EI services has been clearly demonstrated. Short-term and longitudinal data (even into young adulthood) demonstrate the value of early childhood intervention focusing on family-centered, coordinated services that support parent-child relationships as the core element of intervention. Likewise, the economic and health-related values (long-term) derived from being a child supported by the medical home process continue to emerge.

Seeking to enhance collaboration between the sister systems and to minimize systematic barriers is clearly in the best interest of infants, toddlers, their families, and the larger community. Such collaboration serves families in their critical roles as coaches to their children (living, playing, and growing in the infant's natural learning environment).

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management

- *Policy Statement*

POLICY STATEMENT

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management

abstract

FREE

This policy statement identifies the potential value of electronic prescribing (e-prescribing) systems in improving quality and reducing harm in pediatric health care. On the basis of limited but positive pediatric data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. The American Academy of Pediatrics also recommends a set of functions that technology vendors should provide when e-prescribing systems are used in environments in which children receive care. *Pediatrics* 2013;131:824–826

COUNCIL ON CLINICAL INFORMATION TECHNOLOGY EXECUTIVE COMMITTEE, 2011–2012

KEY WORDS

electronic prescribing, health information technology, medication, pediatrics, prescription, quality improvement

BACKGROUND

The American Academy of Pediatrics (AAP) is committed to providing the best and safest health care system possible for children.

Medication prescribing or ordering in pediatrics is an error-prone process that can lead to adverse medication events and patient harm.[1,2] Electronic prescribing (e-prescribing) is widely recognized as a component of the care process that improves quality and reduces costs by facilitating handoffs, improving clinical decision-making, and potentially improving medication adherence.

NEW INFORMATION

Prescribing error rates in children were estimated to be between 5% and 27% in a recent systematic review.[3] Prescribing errors are most prevalent with antibiotic agents but may occur even with medications that do not require weight-based dosing.[4] Medication errors in children may lead to more severe complications because of narrow therapeutic profiles and the inability of some children to communicate adverse effects. Many existing e-prescribing systems are not well designed for use in pediatric patients and lack the required features outlined in this statement. Parental health and English literacy have been shown to play important roles in the correct medication administration in children.[5,6]

From a legislative viewpoint, the past decade has been an active one for the national medication-prescribing landscape. In particular, 2 major statutes specifically addressed the goal of 100% adoption of e-prescribing through both time-dependent incentives and penalties.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

The Medicare Improvements for Patients and Providers Act (Pub L No. 110-275 [2008]) provided for incentive payments to Medicare-participating providers that use e-prescribing software to generate prescriptions. The Health Information Technology for Economic and Clinical Health Act (Pub L No. 111-5 [2009]) established a program of incentive payments for Medicare and Medicaid providers who adopt, implement, and demonstrate meaningful use of health information technology. One of the key requirements of meaningful use is to generate and transmit prescriptions electronically to the pharmacy. The meaningful use requirements also encourage the routine use of medication lists, medication allergy lists, drug–drug interaction and drug-allergy checking, and drug formulary checking.

CONCLUSIONS

E-prescribing systems can improve the quality and safety of medication administration by reducing preventable adverse drug events,[7–9] reducing dosing errors,[10] improving communication,[11,12] avoiding adverse effects,[13,14] and improving efficiency.[15] The benefits of e-prescribing systems in pediatrics can only be achieved by systems with appropriate functionality and may be hampered by poorly developed systems[16] or implementation strategies.[17] At present, many e-prescribing systems fall short of providing expert-recommended functional characteristics.[18] Specific challenges in pediatric e-prescribing include age- and indication-specific, weight-based dosing requirements, rounding based on formulary (liquid or solid), the conversion of doses from an ingredient amount to a volume for liquids, the desire to provide easily administered home doses, and, when necessary, extemporaneously compounded dosage forms. Although these systems already confer numerous advantages over the paper-based alternative, they will need to evolve to be an ideal platform for safe and effective pediatric medication prescribing. The features listed in Table 1, derived in part from previous work by the AAP,[19] will help address these challenges to safe and effective pediatric prescribing.

RECOMMENDATIONS

1. Because safety for children is paramount, e-prescribing systems used for the care of children should include, at a minimum, pediatric-specific medication catalogs; pediatric-specific decision support, such as weight-based dose calculations and individual and daily dose alerts; rounding; ingredient amount-to-volume conversions for liquid medications; metric-only labeling instructions; and pediatric drug information and formulation options. This recommendation may be implemented by sharing reports, such as the accompanying technical report,[20] with standards development organizations and the Office of the National Coordinator for Health Information Technology–Authorized Testing and Certification Bodies to encourage the inclusion of minimum requirements into the development of standards and certification criteria.
2. When possible, e-prescribing systems should be implemented as part of a robust electronic health record and include drug–drug interaction and allergy checking. When implementing a stand-alone e-prescribing system, consideration should be given to a solid design (including correct field length and standard vocabulary) and the potential future need to generate reports with, transfer data to, or interface the e-prescribing system with an electronic health record. E-prescribing systems must be

TABLE 1 Pediatric Requirements for Safe and Effective e-Prescribing

Category	Pediatric Requirements
Patient information	Date of birth or age in units more specific than years
	Weight in kilograms
	Height in centimeters
	Any history of intolerable adverse effects or allergy to medications
Medication information	Indication-based dosing and individual and daily dose alerts, using a mg/kg per day or mg/m^2 per day formula, unless inappropriate
	Weight-based dosing calculations
	All available formulations, including liquid formulations that may be specific brands
	Common formulations requiring extemporaneous compounding or combinations of active ingredients
Cognitive support	Dose-range checking (minimum and maximum amount per dose, amount per day based on weight, surface area, and total dose)
	Automatic strength-to-volume conversions for liquid medications
	Adverse effect warnings specific to pediatric populations
	Alternative therapies based on ameliorable adverse effects
	Tall Man lettering to reduce medication selection errors
	Medication-specific indications to reduce ordering of sound-alike drugs
Pharmacy information	Pharmacies that will create extemporaneous compounds
Data transmission	Use of messaging standards for data transmission to pharmacies that include the patient's weight and notes pertaining to weight-based calculations
	Transmission of strength, concentration, and dose volume labeled in metric units for liquid medications

efficient for use in pediatric offices and must integrate well with existing office workflow. Recommendation 2 may be implemented by educating providers on the required elements of pediatric-appropriate e-prescribing systems through published reports, such as the accompanying technical report.[20]

3. E-prescribing systems should be able to provide patients and their parents with administration instructions based on their level of health literacy and their preferred language. Recommendation 3 may be implemented by educating e-prescribing vendors and providers of the need for this feature.
4. Pharmacies should work to enhance their technology infrastructure and workflows to enable efficient acceptance and processing of electronic prescriptions generated and transmitted by certified health information technology. Furthermore, pharmacies should be capable of performing the dose-range checks to provide independent redundancy.
5. Private and public insurers and other third-party payers should offer financial incentives to health care providers and pharmacies to use e-prescribing systems with appropriate decision support.
6. States should work to harmonize their respective legislation to the US Drug Enforcement Agency's interim final rule on e-prescribing of controlled substances. Recommendations 4, 5, and 6 may be implemented by continued advocacy activities at the local, state, and national levels.

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management

- *Technical Report*

TECHNICAL REPORT

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management

abstract

FREE

This technical report discusses recent advances in electronic prescribing (e-prescribing) systems, including the evidence base supporting their limitations and potential benefits. Specifically, this report acknowledges that there are limited but positive pediatric data supporting the role of e-prescribing in mitigating medication errors, improving communication with dispensing pharmacists, and improving medication adherence. On the basis of these data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. This report supports the accompanying policy statement from the American Academy of Pediatrics recommending the adoption of e-prescribing by pediatric health care providers. *Pediatrics* 2013;131:e1350–e1356

The US health care system has the distinction of being the world's most expensive delivery system while also having among the lowest levels of quality, as judged by many metrics, including infant mortality, life expectancy, and potential years of life lost.[1,2] More specifically, despite US leadership in establishing many standards of care that correlate with improved quality, the US health care system is able to deliver, at best, 60% of the recommended care in most practices.[3,4] Reasons for this inefficiency include the voluminous information resources to consult and the experts' parallel processing and modeling skills (including integrating considerations of the patient's other illnesses, lifestyle, and genome) required to make an optimal decision.[5] Other challenges include the health care system's existing methods of payment, which lead to fragmented care.[6] Difficult-to-resolve health disparities also occur when there are suboptimal interactions between a person's preferences, the regulatory/operational health care system, and internalized biases, stereotypes, or knowledge deficits. All of these challenges to information management affect the delivery of care.[7] For these reasons, health information technology (HIT) has become recognized as a set of tools that complement the provision of care.[8] Electronic prescribing (e-prescribing) is widely recognized as a component of the prescribing process that facilitates handoffs, improves clinical decision-making, and may improve medication adherence. E-prescribing was defined in 2008 by the Centers for Medicare and Medicaid Services as a system providing prescribers with

the ability to generate and "electronically send an accurate, error-free and understandable prescription directly to a pharmacy from the point-of-care."

RATIONALE FOR ADOPTING E-PRESCRIBING

Adoption of e-prescribing has been strongly endorsed by a variety of professional societies and federal agencies for more than a decade.[9-13] The reason for almost unanimous support for e-prescribing tools is the mounting evidence in adult populations that e-prescribing can improve prescribing quality and provide better pharmacovigilance. Monitoring pharmaceuticals requires collecting, observing, researching, assessing, and evaluating data and derivative information related to safe, effective, and consistent medication use. Pharmacy data management successes reveal a path for transforming medication communication throughout the health care system. The Institute of Medicine summarized this literature in its publication *Preventing Medication Errors*[14] and recommended national mandates for this technology. There is less literature specific to pediatric populations; however, the literature that is specific to this population has been encouraging.

Quality Challenges for E-Prescribing in Pediatrics

By far, the strongest rationale for adopting e-prescribing recognizes the inherent challenges with pediatric prescribing, which are responsible for an error rate in children of between 5% and 27% in a recent systematic review.[15] Physiologic factors, such as the nearly universal need for weight or body surface area considerations in dosing, make medication ordering more prone to errors in children than in adults.[14,16,17] In addition to these physiologic factors, the therapeutic window for many drugs is smaller for children than adults. Pharmacologic factors, including age-based variability in absorption, metabolism, and excretion of drugs in children as compared with adults, as well as the age-specific contraindications of certain medications, pose special vulnerabilities to the adverse effects of overdosing. The conversion of doses from ingredient amounts to volumes for liquids labeled for home use is also problematic.[18-20] Prescribing errors are most prevalent with antibiotic agents but may occur even in medications that do not require weight-based dosing or ingredient-to-volume conversion.[21] Medication errors in children may lead to more severe complications because of the inability of children to communicate some adverse effects.

Decreased Preventable Adverse Drug Events

Adverse drug events are defined as injuries "resulting from medical intervention related to a drug" and are the leading cause of iatrogenic harm to patients.[22] The Institute of Medicine conservatively estimated that each year, more than 1.5 million preventable adverse drug events occur in the United States.[14] In an ambulatory study in adults, 25% of patients experienced 1 or more adverse drug events (27 events per 100 patients).[23] Estimates in 1995 placed the cost of drug related morbidity and mortality between $20 billion and $130 billion, with most of the cost stemming from drug-related hospital admissions.[24]

The rate of adverse drug events attributable to ambulatory drug administration has been estimated at 3% to 4% in 1 study.[25] This rate is highest in children taking multiple prescription medications.[26] Pediatric patients, although less likely to suffer harm from an adverse event, are susceptible to more types of adverse events, but the quality of the evidence is variable.[27,28] Studies evaluating e-prescribing systems reveal consistent reductions in potential adverse drug events in systems that organize and coherently report medication summaries.[29-31]

Reducing Dosing Errors

Dosing errors represent the most common medication error in pediatrics.[32] Although seemingly easy to catch, dosing error-checking is complicated by the fact that children's weights vary from as little as 500 g for micro premature infants to well over 100 kg for some obese adolescents, differing by a factor of more than 200. To illustrate the challenge, 2 patients (1 weighing 2 kg and the other 100 kg) discharged with a prescription for 5 mg/kg per day of ranitidine could receive a dose of between 10 mg and 300 mg a day and still not catch the attention of a pharmacist, because all doses between these amounts are reasonable for children, depending on their weight.

E-prescribing systems are able to present standardized dosing formulae, to use the patient's weight to calculate a dose, to convert that dose to a volume for liquids, and to present that dose in a format that is least likely to be confusing to the prescriber, pharmacist, nurse, or parent. Truly sophisticated prescribing systems use individual dose limits and total daily dose limits, compared with weight- or body surface area-based normal values.[33] Some particularly sophisticated systems write out the final dose (ie, "ten [10]") to further improve clarity and to reduce the risk of prescription tampering.[34] Finally, a recent article demonstrated the power of annotating electronic prescriptions with the actual calculation leading up to the dose.[35]

Improved Communication

After dosing errors, missing information and illegible prescriptions cause

the majority of prescribing errors in children[36] and significantly impede the ability for these errors to be caught by pharmacists or other health care providers. Illegible handwriting may be at fault for at least 20% of all errors.[26,37] Groups such as the Pediatric Pharmacy Advocacy Group, the Institute for Safe Medication Practices, and the American Society of Health System Pharmacists[38] have espoused requirements for safe pediatric prescribing, recognizing that these prescriptions should include information about the child's age, weight, and indication for therapy and should adhere to a format (eg, no trailing zero) that minimizes miscommunication. The Institute for Safe Medication Practices, the American Academy of Pediatrics, and other groups support the labeling of all prescriptions for liquid medication with volume in milliliters (mL).[39-41]

Parental health and English literacy has been shown to play an important role in the correct medication administration in children.[42,43] E-prescribing systems may provide administration instructions that are appropriate for the parents' or child's health literacy and can be provided in the patient's or her family's primary language.

Software can default or force entry of specific information. For example, a date may be automatically populated, a weight may be pulled from an existing electronic health record (EHR), and a user may be prevented from completing the prescription until essential information has been completed. Pharmacists view the net effect of e-prescribing as positive in the areas of patient safety, effectiveness of care, and efficiency of care.[44,45] In pediatrics, e-prescribing can improve communication through both improving clarity of prescriptions and providing standardized information about indications for therapy, rationales for overriding allergy alerts, and the weight-based calculations leading to a specific dose.[35] For all patients, e-prescribing systems can improve communication about provider willingness to allow generic substitution,[46-48] which, by avoiding higher copayments, can improve medication adherence.[49]

A study on prescriptions[35] demonstrated the value of including body weight and the process associated with calculating a dose. In this study, pharmacies stated that prescribing safety was improved by "showing your work" related to the cognitive processes associated with prescribing and found it especially beneficial in pediatric prescribing.

Avoiding Adverse Effects

Medication adverse effects may be related to interactions between a medication and the host (allergies or unintended effects) or may be related to other patient medications, dietary choices, or other diagnoses. These unintended consequences may be life-threatening or, more commonly, may lead to poor therapeutic adherence by children and families. Often, these consequences can be ameliorated by choosing an equally efficacious alternative therapy at the time of the initial prescription or after onset of the unintended effect. E-prescribing systems can display results of past therapy and help avoid prescribing medications that may not be tolerated. Systems that are more sophisticated warn about potential unintended effects, thereby decreasing the burden on the family and potentially having a beneficial effect on the economics of health care.[50,51]

Improving Efficiency

The process of prescribing and ensuring adherence is 1 of the most time consuming in practice settings. Both new and refilled prescriptions require attention to the 5 rights: making sure the right patient receives the right medication in the right dose, using the right route, and at the right time. E-prescribing is able to help with many of these issues by providing early warnings for duplicate therapies, contraindications for use (such as in pregnancy or for lactating mothers), and other prescribing risks mentioned previously.

As a component of an efficient practice, e-prescribing may decrease delays in renewing chronic medications or in flagging renewals as inappropriate. In pediatrics, there is an additional challenge of modifying a dose for some medication refills as the child grows, which can be facilitated by information technology. Perhaps the most pervasive way that e-prescribing can boost practice efficiency is by recognizing the distributed nature of work in the ambulatory setting. For example, a well-designed e-prescribing system might allow a refill or new prescription to be drafted by 1 provider or designee and completed by an authorized prescriber either in the office or any location by using Web-enabled information technology.[34]

E-PRESCRIBING SYSTEM FUNCTIONAL REQUIREMENTS

The theoretical benefits of e-prescribing systems in pediatrics can only be achieved by systems with appropriate functionality and may be hampered by poorly developed systems[52] or implementation strategies.[49] At present, many e-prescribing systems fall short of providing expert recommended functional characteristics.[53] These features broadly cover patient identification and data access, current medication/medication history availability, medication selection, alerts and reminders, medication information, data transmission/storage, monitoring and renewals, prescribing practice feedback, and system security/confidentiality.

The use of e-prescribing systems in children will require overcoming some unique challenges inherent in pediatrics. Paramount among these challenges is the question about the relevance and sensitivity of drug interaction or adverse-effect alerts.[54,55] The existing insensitivity results in many false-positive alerts and subsequently in override rates ranging from 89% to 91%.[25,56-58] Although few studies have been published that assess this phenomenon in children, children tend to be on fewer chronic medications and, because of generally good renal and hepatic function, may be less at risk for severe adverse reactions,[59] thereby magnifying this concern in pediatrics.

Age- and indication-specific weight-based dosing requirements, coupled with the fact that home administration may be associated with a high potential for errors,[21] place additional requirements on the pediatric e-prescribing system (dose rounding, minimum/maximum dosing checks, etc) that may not be as important for adult prescribing. E-prescribing systems need to modify both dosing guidelines and dose-screening parameters to support pediatric dosing for every indication that warrants modified dosing regimens. Furthermore, they need to support the desire to provide easily administered home doses (in mL for liquids) and, when necessary, extemporaneously compounded dosage forms. In short, these systems will need to evolve to be an ideal platform for safe and effective pediatric medication prescribing, although they already confer numerous advantages over the paper-based alternative. The features listed in Table 1, derived in part from previous work by the American Academy of Pediatrics,[16] will help address these challenges to safe and effective pediatric e-prescribing.

TABLE 1 Pediatric Requirements for Safe and Effective Electronic Prescribing

Category	Pediatric Requirements
Patient information	Date of birth or age in units more specific than years
	Weight in kg
	Height in cm
	Any history of intolerable adverse effects or allergy to medications
Medication information	Indication-based dosing and individual and daily dose alerts, using mg/kg per day or mg/m^2 per day formula, unless inappropriate
	Weight-based dosing calculations
	All available formulations, including liquid formulations that may be specific brands
	Common formulations requiring extemporaneous compounding or combinations of active ingredients
Cognitive support	Dose range checking (minimum and maximum amount per dose, amount per day based on weight, surface area, and total dose)
	Automatic strength to volume conversions for liquid medications
	Adverse-effect warnings specific to pediatric populations
	Alternative therapies based on ameliorable adverse effects
	Tall-man lettering to reduce medication selection errors
	Medication-specific indications to reduce ordering of sound-alike drugs
Pharmacy information	Pharmacies that will create extemporaneous compounds
Data transmission	Use of messaging standards for data transmission to pharmacies that include the patient's weight and notes pertaining to weight-based calculations
	Transmission of strength, concentration, and dose volume labeled in metric units for liquid medications

FEDERAL INITIATIVES TO IMPROVE E-PRESCRIBING ADOPTION

The past decade has been an active one for the national medication prescribing landscape. In particular, 2 major statutes specifically address the goal of 100% e-prescribing adoption through both time-dependent incentives and penalties. Each of these statutes will be described below.

Medicare Improvements for Patients and Providers Act

The Medicare Improvements for Patients and Providers Act (MIPPA) became law on July 15, 2008 (Pub L No. 110-275). MIPPA was designed to avert a statutory Medicare reduction in payments for physicians and implement other changes. In addition to its effect on physician fees, MIPPA addressed the chasm between literature describing improved quality of care related to e-prescribing and the current state of poor adoption (especially among health care providers caring for older and sicker populations). It addressed this chasm by incentivizing the adoption of e-prescribing by authorized prescribers. MIPPA created new financial incentives to encourage physicians who provide services to Medicare patients to adopt technology that will allow them to order prescriptions electronically. Use of this technology is meant to reduce medical errors and help physicians consider cost issues as they make prescribing decisions. Under MIPPA, beginning in 2009, physicians received a 2% increase in payments, phasing down to 0.5% in 2013. However, in 2014 and afterward, physicians who have not implemented the technology will lose 2% of their payments. The incentives and penalties under MIPPA may have less of an effect on pediatric patients, because not all pediatricians see a sufficient number of Medicare-eligible patients.

The Health Information Technology for Economic and Clinical Health Act

The Health Information Technology for Economic and Clinical Health (HITECH) Act was incorporated as part of the American Recovery and Reinvestment Act of 2009 (H.R. 1), the economic stimulus bill signed into law on February 17, 2009 (Pub L No. 111-5). The HITECH Act is intended to promote the widespread adoption of HIT to support the electronic sharing of clinical data among hospitals, physicians, and other health care stakeholders. According to a 2009 report by Surescripts (http://www.surescripts.com/downloads/npr/national-progress-report.pdf), the number of prescribers sending prescriptions electronically more than doubled from 2008 to the end of 2009 to 156 000, which corresponds to only 25% of all office-based prescribers. The same report stated that 85% of community pharmacies, as well as the 6 largest mail-order pharmacies, were able to receive electronic prescriptions. Therefore, the infrastructure for e-prescribing is nearly ready, but prescribers have not yet fully adopted this technology. The HITECH Act builds on existing federal efforts to encourage e-prescribing/HIT adoption and use. The Congressional Budget Office (CBO) estimates that Medicare and Medicaid spending under the HITECH Act will total $32.7 billion over the 2009–2019 period. CBO hypothesizes, however, that widespread HIT adoption will reduce total spending on health care. Through 2019, CBO estimates that the HITECH Act will save the Medicare and Medicaid programs a total of approximately $12.5 billion. Under current law, CBO predicts that approximately 45% of hospitals and 65% of physicians will have adopted HIT by 2019. CBO estimates that the incentive mechanisms in the HITECH Act will boost those adoption rates to approximately 70% for hospitals and 90% for physicians.

The HITECH Act provides financial incentives for HIT use among health care practitioners. It establishes several grant programs to provide funding for investing in HIT infrastructure, purchasing certified EHRs, training, and the dissemination of best practices. E-prescribing functionality is a required component of these EHRs. Important to pediatricians, the legislation further authorizes a 100% federal match for payments to certain qualifying Medicaid service providers who acquire and use certified EHR technology.

E-Prescribing of Controlled Substances

In March 2010, the US Drug Enforcement Agency published the interim final rule on e-prescribing of controlled substances. Before the interim final rule, controlled substances were excluded from e-prescribing through a prohibition by the Drug Enforcement Agency. Even though this ruling will close the gap in e-prescribing, the rules require recertification of systems by outside auditors, new credentialing and auditing processes for prescribers, and a new level of authentication by prescribers before prescriptions are able to be routed electronically. Physicians must apply to federally approved credential service providers or certification authorities to verify their identity and obtain the necessary credentials to engage in e-prescribing of controlled substances. Once a provider is authorized by a third person in the practice to prescribe controlled substances, providers must provide 2 modes of identification, including a user identification/password, a token (like a smart card), or a biometric factor (like a thumbprint) (http://www.deadiversion.usdoj.gov/fed_regs/rules/2010/fr0331.htm). Because of the complexity required to prevent drug diversion (forgeries), vendor compliance and provider adoption is expected to take 1 to 2 years.

abstract

FREE

This policy statement serves to combine and update 2 previously independent but overlapping statements from the American Academy of Pediatrics (AAP) on culturally effective health care (CEHC) and workforce diversity. The AAP has long recognized that with the ever-increasing diversity of the pediatric population in the United States, the health of all children depends on the ability of all pediatricians to practice culturally effective care. CEHC can be defined as the delivery of care within the context of appropriate physician knowledge, understanding, and appreciation of all cultural distinctions, leading to optimal health outcomes. The AAP believes that CEHC is a critical social value and that the knowledge and skills necessary for providing CEHC can be taught and acquired through focused curricula across the spectrum of lifelong learning.

This statement also addresses workforce diversity, health disparities, and affirmative action. The discussion of diversity is broadened to include not only race, ethnicity, and language but also cultural attributes such as gender, religious beliefs, sexual orientation, and disability, which may affect the quality of health care. The AAP believes that efforts must be supported through health policy and advocacy initiatives to promote the delivery of CEHC and to overcome educational, organizational, and other barriers to improving workforce diversity. *Pediatrics* 2013;132:e1105–e1116

INTRODUCTION

This policy statement serves to combine and update 2 previous statements from the American Academy of Pediatrics (AAP) on culturally effective health care (CEHC)[1] and workforce diversity.[2] The impetus to combine these independent policy statements comes from the recognition that the provision of culturally effective care and enhancing the diversity of the pediatrician workforce represent parallel and often overlapping initiatives to improve care for pediatric patients. This policy statement provides guidance for policy makers, advocacy groups, medical educators, and physicians on the provision of CEHC and enhancing the diversity of the pediatrician workforce.

CEHC can be defined as the delivery of care within the context of appropriate physician knowledge, understanding, and appreciation of all cultural distinctions, leading to optimal health outcomes, quality of life,

and family satisfaction.[1] For the purposes of this policy statement, the term "culture" is used to signify the full spectrum of values, behaviors, customs, language, race, ethnicity, gender, sexual orientation, religious beliefs, disabilities, and other distinct attributes of population groups. The AAP believes that "culturally effective care" is a more inclusive term than "cultural competence" because it encompasses the values of competence and, more important, focuses on the outcomes of the physician-patient or physician-family interaction.

The AAP has a distinguished history of promoting diversity within the pediatrician workforce. Of particular note is the 1994 *Report of the AAP Task Force on Minority Children's Access to Pediatric Care*,[3] which promulgated 66 recommendations covering a wide range of topics, from the health status of minority children, to barriers to accessing pediatric care, to workforce needs. Racial and ethnic diversity was also a major issue addressed by the report of the Task Force on the Future of Pediatric Education II,[4] which called for increases in the percentage of underrepresented in medicine (URM) pediatricians in practice and academic medicine to meet the needs of the ever-growing population of children from racial/ethnic minority groups.

Over the past decade, the discussion of patient diversity by the medical community has increasingly expanded beyond the traditional attributes of race and ethnicity to include cultural characteristics such as language, race, ethnicity, ancestry, national origin, immigration status, religion, age, marital status, gender, sexual orientation, gender identity or expression, and disability.[5] A broader and more inclusive definition of patient diversity consequently requires an expansion of diversity beyond race and ethnicity within the pediatrician workforce as well. The AAP believes that it has an important leading role in applying this expanded definition of patient diversity to improve the provision of CEHC for all populations.

This statement makes the case for a diverse pediatrician workforce; explores the impact that patient attributes have on their health care; investigates CEHC education and training; and addresses health policy and implementation. These issues are complex and nuanced, and a forceful commitment from an educated leadership will be needed to fully achieve the statement's recommendations.

CASE FOR A DIVERSE WORKFORCE

The Association of American Medical Colleges' description of URM encompasses "those racial and ethnic populations that are underrepresented in the medical profession relative to their numbers in the general population."[6] URM groups in the United States currently include black and African American, American Indian and Alaska Native, Native Hawaiian and other Pacific Islander, Hispanic and Latino, as well as any Asian other than Chinese, Filipino, Japanese, Korean, Asian Indian, Thai, or Vietnamese/Southeast Asian.[7] Some of the most compelling evidence in support of increased workforce diversity is that physicians from URM groups disproportionately practice in underserved communities and treat a greater number of underrepresented minority, Medicaid, and uninsured patients.[5,8–10] Whatever the reason for these practice patterns, the contributions of the minority physician workforce to the care of these groups of patients are therefore significant.

Numerous studies have demonstrated that minority patients suffer from significant health disparities and experience more barriers to accessing health care services than do other nonminority patients, but access to care for minority patients is improved when the physician and the patient are racially or ethnically consentient.[5,11,12] Such congruence between patient and physician is, however, relatively infrequent.[12] This is perhaps why a 2006 study by the Health Resources and Services Administration noted that "although studies in our review suggested that interpersonal care was on balance better in race concordant patient-practitioner relationships, and that patients tended to prefer practitioners of their own race, these findings did not apply to all patients and practitioners."[13]

A study examining patient-physician social concordance using 4 social characteristics (race, gender, age, and education) showed that lower patient-physician social correspondence was associated with less favorable patient perceptions of care and lower global satisfaction ratings; conversely, stepwise patient-physician similarities were shown to improve patient perceptions of care in an additive fashion.[14] A large study looking at patient-physician congruence in adult patients with diabetes mellitus who were at high risk of cardiovascular disease concluded that African American patients who received treatment from African American physicians were significantly more adherent to taking their medications and that Spanish-speaking patients were significantly more adherent to taking their medications when their physicians were linguistically concordant.[15] Consequently, there is an ongoing need to increase racial and ethnic diversity among the pediatrician workforce in part because minority pediatricians continue to be more likely to provide care to minority children and their families in a disproportionate manner.[2]

PATIENT ATTRIBUTES AND IMPACT ON HEALTH CARE

Data from the US Census Bureau project that by 2020, 44.5% of American

children 0 to 19 years of age will belong to a racial or ethnic minority group.[16] Consideration of cultural attributes in addition to race and ethnicity would greatly increase this projection of diversity. For example, in 2010, there were 646 000 same-sex unmarried couple households in the United States, and a number of these households reported having children.[17] Data from 2008 indicate that 23% of US citizens were living in rural locations, 12% of US citizens who were living outside of residential facilities or nursing homes had a disability, and 4% identified themselves as lesbian, gay, bisexual, or transgender.[18]

According to the US Census Bureau, approximately 20% of the US population older than 5 years speaks a language other than English at home. Although the majority of these people report that they also speak English well, it is estimated that approximately 24.5 million people in the United States need some assistance with English. Approximately 62% of these people speak Spanish at home.[19]

Census data confirm the growing numbers of foreign-born immigrants residing in the United States. The US Census Bureau uses this term to refer to anyone who is not a US citizen at birth. This includes naturalized US citizens, lawful permanent residents (immigrants), temporary migrants (such as foreign students), humanitarian migrants (such as refugees and asylees), and persons illegally present in the United States.[16,20] However, obtaining accurate estimates of numbers of US foreign-born immigrants is difficult because of respondents' concerns regarding potential legal difficulties arising from participating in census activities. In addition, census data may not accurately provide information on migrant workers' children and the growing numbers of homeless children.

The pool of foreign-born immigrant children includes both legal and undocumented children as well as international adoptees. Foreign-born immigrant children often face multiple challenges, including language barriers, and in addition to the common illnesses typical of other US children, they may suffer from other diseases rarely diagnosed in the United States. Furthermore, the diversity of the US foreign-born immigrant population, manifested even in individuals from the same country of origin, is such that health needs and health literacy are extremely varied, making the delivery of care for this population still more challenging. Homeless children face higher rates of trauma-related injuries, developmental delays, neurologic problems, and asthma, among other conditions.[21] Migrant workers' children face similar health and linguistic challenges and, because of unstable living conditions, poverty, and other social constraints, are often unable to access comprehensive health care.[21]

Significant and pervasive racial and ethnic health and health care inequities persist among children with chronic health conditions, such as attention-deficit/hyperactivity disorder, asthma, autism spectrum disorder, Down syndrome, cerebral palsy, cystic fibrosis, diabetes, sickle cell anemia, obesity, traumatic brain injury, and HIV/AIDS.[22] Black and Hispanic parents of children with special health care needs report higher dissatisfaction with care and more difficulties navigating services for their children compared with their white counterparts.[23] Although *Healthy People 2020* has listed "cultural sensitivity in health care provision" as 1 of 7 key determinants of health under the heading of health disparities,[18] addressing disparities in cultural attributes and attitudes between physicians and their patients, patients' families, and/or guardians requires educational interventions to ensure that pediatricians and other health care professionals are able to provide CEHC to a diverse patient population.[24] To better understand and overcome long-standing and minimally improving health care disparities, the Institute of Medicine in 2009 formed a Subcommittee on Standardized Collection of Race/Ethnicity Data for Healthcare Quality Improvement.[25]

Certain patient populations and communities suffer from poorer health compared with other populations. Reliable data have shown that patients who belong to racial, ethnic, linguistic, or other minority groups tend to have greater morbidity than do white, English-speaking patients.[12,26–32] Research has shown that early life events influence one's health over an entire lifetime and that there is a stepwise health gradient that is defined distinctly by socioeconomic status.[33,34] *Healthy People 2020* has outlined much broader examples of health disparities beyond race and ethnicity, with disparate health outcomes noted to be associated with gender, sexual identity and orientation, age, disability, socioeconomic status, and geographic location.[18] Although some studies have suggested that, compared with heterosexual people, lesbian, gay, bisexual, and transgender (LGBT)*[35] people face greater mental health challenges,[36] other studies have not found such mental health differences but instead simply disparities in accessing routine health care services.[37,38] LGBT patients may be reticent

*Some support groups, community organizations, and researchers are now using the acronym LGBTQ or GLBTQ instead of LGBT. The "Q" may represent questioning or queer (in a nonpejorative way) and includes individuals who are uncertain of their sexual orientation but may still be considered a sexual minority or who self-identify as queer. However, according to the Gay & Lesbian Alliance Against Defamation, the use of the term "queer" is not universally accepted within the LGBT community, and care should be taken to avoid its use unless quoting or describing someone who self-identifies as queer.

to disclose their sexual or gender identity in a medical encounter for fear of being judged and also may believe that their physician is unfamiliar with LGBT health concerns.[39] LGBT youth face additional challenges as they navigate middle school and high school, where they may experience varying degrees of harassment, discrimination, exclusion, and isolation,[40] which may lead to increased depressive symptomatology as well as increased risk of suicidal ideation and self-harm compared with their heterosexual peers.[41,42]

CEHC: EDUCATION AND TRAINING

The AAP maintains that CEHC should be promoted through health policy and education at all levels, from premedical education and medical school through residency training and continuing medical education (CME). This task is complex; multiple languages and dialects must be addressed, requiring significant resources ranging from translation services to community linkages as well as commitment from both the learner and the educator. Nevertheless, the AAP maintains that at every level of education, pediatricians must be able to interact effectively and respectfully with patients and their families regardless of the cultural differences that may exist between them. These educational efforts should enhance the knowledge and understanding of pediatricians and other child health care professionals about the cultures of their patients and their families and increase their ability to provide care in a manner that is responsive to the individual needs of each patient. Educational programs must focus on the enhancement of interpersonal and communication skills, which are essential to nurturing the pediatrician-patient or pediatrician-family relationship and optimizing the health status of patients.

In addition, programs to enhance student, trainee, and physician awareness about their own preconceptions and cultural attributes will likely translate into more open communication with and greater appreciation of the cultural backgrounds of all patients.[43] Educational programs such as those developed through the National Center for Cultural Competence can be effective in training of students, house officers, and faculty.[44]

The literature pertaining to teaching multicultural issues to medical students is robust. Many medical educators believe that training physicians to provide CEHC should begin earlier, as part of undergraduate premedical curricula. Some medical educators have suggested that these educational endeavors should focus less on individual attitudes and the characteristics of minority groups and more on discussions pertaining to social barriers and inequities at the institutional or systems level.[45,46] Others have raised concerns about the model of addressing multiculturalism and cultural competence through lectures and occasional workshops and have argued for the incorporation of these topics as a continuum throughout medical school. Some medical schools, in an effort to better integrate these skills, have opted to identify space for these activities within existing courses on patient-physician relationships and medical interviewing and develop "thoughtfully prepared instructional material throughout the four-year curriculum."[46,47] Efforts to weave CEHC education into core pediatric clerkships in the third year of medical school have demonstrated success in increasing knowledge, enhancing attitudes, and improving clinical skills.[48]

Medical schools should choose to focus at least some of their recruitment efforts on encouraging students from underserved areas, including rural locations, to apply, and should also consider proficiency in a second language an asset in evaluating prospective medical students. Educational endeavors that merit institutional and program support are instructional sessions for students and residents on how to use to their best advantage (and how to evaluate) professional medical interpreters and translation services. At a minimum, medical school curricula and pediatric residency education programs should include educational components that elucidate the impact of low English proficiency, low literacy, and low health literacy on pediatric health care and offer strategies for remediating these problems. Furthermore, increasing the number of bilingual educational opportunities in the US at all educational levels would increase the likelihood that future physicians would be more likely to speak the same language as their patients.

Program requirements for residency education in pediatrics developed by the Pediatric Residency Review Committee call for structured educational experiences that prepare residents for the role of child health advocate within the community and inclusion of the multicultural dimensions of health care in the curriculum.[49] The Residency Review and Redesign in Pediatrics (R^3P) Committee of the American Board of Pediatrics recognizes that there is a need for some flexibility in training to allow for a variety of career choices, acknowledging that residency education is merely a segment of an educational continuum that starts in medical school and is sustained throughout the years of clinical practice.[50] Immersion experiences for pediatric trainees have used community-academic partnerships to move CEHC training into underserved communities, enhancing educational experiences and creating classrooms without walls.[51,52] A curriculum designed to foster cultural humility asks physicians to engage in self-reflection and self-critique as lifelong learners and requires the physician to

bring humility to the power balance in the physician-patient relationship.[53] This curriculum, piloted by 1 family practice program, resulted in increased patient engagement during the office visits as well as high levels of satisfaction reported by participating residents.[54] Such a curriculum could be adapted for appropriate pediatric resident outpatient practices.

Beyond residency training, pediatricians and other child health care professionals can benefit from CME to enhance the provision of CEHC. The AAP regularly incorporates CEHC into its CME programming. Other resources exist that may be helpful in identifying important components for educational activities. For example, the Culturally Effective Care Toolkit on the AAP Web site can provide guidance and resources for enhancing CEHC in practice.[55]

Educational programs may include a component that allows individual participants to analyze personal beliefs and values. Programs may focus on the communication aspects of providing CEHC by exploring how assumptions and stereotypes influence interactions between physicians and patients or their families, as well as between physicians and other clinicians. Because people are influenced by their own personal experiences and may or may not subscribe to group-assumed norms, people who share the same cultural background may think and act differently. For this reason, it is important that programs intended to address the cultural values and practices of specific groups not perpetuate stereotypes. Physicians must also be aware that the culture of medicine itself promotes certain attitudes and biases that may interfere at times with the physician-patient or physician-parent relationship.

Culture is not static; changes can and do occur over time. An appreciation of cultural change and the significance of intracultural diversity (variation among individuals within the same culture) can help to prevent cultural stereotyping.[56] Programs aimed at enhancing the provision of CEHC should be tailored to the demographics of the pediatric population or community where the pediatrician serves.

CEHC: BARRIERS AND OPPORTUNITIES

Cultural variations in verbal and nonverbal communication can be a major barrier to effective pediatric care. Although the role of culturally linked behaviors that may influence the physician-patient interaction, including eye contact, body language, and communication styles, has not been fully explored,[57] language barriers have been shown to have a major effect on health care. Parents and their children in the United States increasingly speak a language other than English at home and/or have limited English proficiency. When the pediatrician and his or her patient and the patient's family do not speak the same language with fluency, there is a potential for problems to occur, such as obtaining an inaccurate history, misunderstanding of therapies, and/or deferred medical visits.[58,59]

Pediatricians continue to struggle with recommendations to use trained interpreters and provision of appropriate language services.[60] These barriers could be addressed through the use of certified medical interpreters (or bilingual pediatricians and other pediatric health care professionals) to meet the needs of pediatric patients whose parents are not proficient enough in English to interact with members of the health care system.[61] These services, however, remain beyond the reach of many pediatricians because of their cost. In 2009, Medicaid or State Children's Health Insurance Programs in only 13 states and the District of Columbia provided reimbursement for language services, and many insurance carriers do not reimburse for such services because they expect medical practices to absorb the cost as part of their overall business expense.[62] Despite the difficulties associated with identifying and accessing appropriate language services, however, the AAP opposes the use of children and adolescents as medical interpreters for their parents and family members.

Another facet of the relationship between language and CEHC is health literacy. The Institute of Medicine defined health literacy as "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions."[63] Although this is a particular problem for individuals with low or marginal literacy skills, health literacy can also affect patients and families with adequate language literacy. Many individuals, even those with high health literacy and for whom English is their native language, find the complex wording of insurance statements, benefits coverage, hospital admissions forms, prescription drug information sheets, and similar documents to be confusing. Low health literacy for pediatric patients and their families, similar to limited English proficiency, is a barrier to the provision of optimal pediatric health care. Whereas health literacy may not be a distinct cultural attribute, language and health literacy are greatly affected by cultural distinctions and, if low, directly contribute to unfavorable patient outcomes. A provision in the Patient Protection and Affordable Care Act of 2010 now requires that any summary of benefits and coverage be presented "in a culturally and linguistically appropriate manner."[64] Commonsense innovations such as these may alleviate some of the challenging implications of low health literacy across the patient population.

At the level of the individual pediatrician, CEHC requires acquisition of knowledge, development of skills, and demonstration of behaviors and attitudes that are appropriate to care for patients and families with a wide variety of cultural attributes. Physician demographics, gender, and religious beliefs are but a few of the factors that influence (often subconsciously) medical recommendations for patients from all backgrounds.[43] As such, physician self-reflection, self-knowledge, and self-critique have been identified as critical components of competence, which can be expanded further to encompass the concept of cultural humility. Practiced over time, these specific skills, in addition to conscious realignment of inherent imbalances in power that often undermine provider-patient communications and fostering of mutually respectful and dynamic partnerships within the community in which one practices, form the foundation for practicing with cultural humility.[53] Although using these knowledge bases, skills, behaviors, and attitudes is commonly referred to as cultural competence and cultural sensitivity, these terms focus on process. CEHC focuses on outcomes and emphasizes the need for continued monitoring and documentation.

Clearly, reasons for health disparities are numerous and may also include patients' cultural beliefs about health care and healing, dietary deficiencies, insufficient exercise, barriers to access to health care resources, financial indigence, inadequate insurance coverage, and inability to communicate with English-speaking physicians and other health care professionals. Trying to communicate effectively with parents who are deaf or hard of hearing also can pose significant barriers and may lead to suboptimal health care even when the child/patient is able to hear; this may direct the pediatrician to seek creative solutions to provide family-centered care.[65] One study evaluated 3 community-based, culturally and linguistically sensitive initiatives that demonstrated that it is possible to reduce or eliminate racial/ethnic disparities in the child health arena by engaging patients and reinforcing participant collaboration.[66] A paper on quality improvement initiatives highlighted how a patient-centered medical home serves to reduce disparities and demonstrated that family involvement and partnering with others in the community not directly involved in patient care are key components of a successful program.[67] The National Committee for Quality Assurance's Patient-Centered Medical Home 2011 Standards ask practices to assess the language needs and characteristics of their patient populations; the standards also expect practice-based care teams to be trained on effective patient communication, particularly with vulnerable populations.[68] The growing number of practices achieving Patient-Centered Medical Home recognition translates into a greater number of pediatricians who understand and appreciate the importance of CEHC.

Pediatricians should become knowledgeable about the resources available to their patients and families within their institutions (offices, hospitals), health maintenance organizations, and communities. Pediatricians who seek out opportunities to partner with institutions, such as third-party payers, hospitals, health departments, and education departments, will be better able to advocate for the specific cultural needs of their patients and thereby increase patient satisfaction and quality of health care.

WORKFORCE DIVERSITY: BARRIERS AND OPPORTUNITIES

The ethnic and racial gap between pediatricians (as well as other physicians) and their patients persists despite efforts to increase the diversity of the pediatrician workforce. Data from the AAP Annual Survey of Graduating Residents show that the percentage of underrepresented minorities (African American, Hispanic, and Native American) who graduated from US medical schools increased from 9% in 2003 to 15% in 2009, but this increase but was not statistically significant. Approximately a third of graduating residents report having grown up in a bilingual or multilingual family (34% in 2009; 29% in 2010).[69] Although these levels of URM pediatric trainees are encouraging, the percentages are far below the current estimates of the pediatric population, and these trends are unlikely to change drastically in the near future. Also, unlike most other medical specialties (except perhaps obstetrics and gynecology), the numbers of women entering pediatric training continue to increase and currently exceed the numbers of men in pediatric training.[70] Over time, it will be important to evaluate how this trend affects the availability of male pediatricians to treat patients who have this preference, which could, among other factors, be influenced by patient gender and specific cultural norms.

Literature in support of the Supreme Court decisions related to the University of Michigan's affirmative action policies has strongly stated the case for diversity at all levels of medical education. A more diverse faculty and student body is viewed as an indispensable component of quality medical education. Nevertheless, gains in enhancing diversity may be derailed by legislative actions, such as the passage of proposition 209 in 1996 in the state of California, which eliminated race-conscious admissions at public institutions. Since then, there has been a decline in the percentage of in-state minority students accepted

to and matriculating in California medical schools, with no appreciable rebound over time.[71] Institutional diversity will increase the cultural exposure of all faculty and students, which will help to dispel stereotypes and improve cultural competence by virtue of everyday interactions. A more diverse workforce will likely lead to a more diverse medical research agenda for improving health and the delivery of health care services among racial, ethnic, and cultural minority patients. Creating such a workforce, it is argued, begins with the diversity of those admitted to doctor of medicine and doctor of philosophy educational programs. Indeed, in a modern multicultural society, promoting diversity within the medical profession to better reflect the diversity of the patient population while maintaining the high quality of the health care workforce is in keeping with the societal obligation of medical schools to produce well-trained professionals to meet the future health care needs of the country.[8,13,72] The Association of American Medical Colleges published its flagship statement in 2008 to serve as a tool for medical schools for the development of diversity-related policies and, in doing so, implored those in academic medicine to be "serious about creating and sustaining diversity in medical education, biomedical research, and the physician workforce."[73]

Financial incentives to encourage URM students to enter medical training continue to grow nationally through organizations such as the National Institute on Minority Health and Health Disparities, and through state and regional programs. These incentives, including loan forgiveness/repayment and tuition reimbursement, may help to address many financial barriers such as low family income and educational debt. Institutional programs, such as the Center of Excellence in Diversity at Stanford University, reach out to promising premedical students to help prepare them for careers in medicine.[74] Diversity programs, along with educational institutions, acknowledge the importance of minority faculty concomitantly serving as mentors to minority students, serving on admissions committees, overseeing diversity initiatives, and serving in leadership positions at all levels. To support all of these activities, there must be a simultaneous commitment to increase diversity at the highest organizational and institutional levels.

Another approach to increasing the recruitment of minority students into the health professions is to focus on reaching out to individuals in earlier educational stages, such as elementary and high school. To maximize the effectiveness of these programs, appropriate support structures for these individuals within their communities, schools, postsecondary institutions, health care organizations, medical societies, and other entities need to be established. These support structures include financial incentives, mentoring and shadowing programs, adequate staffing for diversity programs, and educational and other initiatives related to cultural effectiveness and diversity. Holistic review of college and medical school applications may further bolster the numbers of URM students admitted to institutions of higher learning. Giving weight not only to the applicant's academic credentials but also to leadership potential, ability to work within a team, and interpersonal and communications skills, while taking into account personal circumstances, may provide more opportunities for outstanding students with essential nonacademic qualifications to succeed. There is clearly a need to pursue active recruitment of minority candidates for health-professions education programs. To increase the small number of minority individuals entering pediatrics without negatively affecting the number entering other specialties, the total number of minority individuals entering medical school must first be increased.

Workforce diversity and CEHC may also be enhanced by increasing minority representation in hospital governance and leadership positions, which can heighten the institution's efforts to reduce health care disparities and promote diversity in management and leadership. For example, minorities comprise 29% of the patient population nationally, yet they represent only 14% of hospital board members, 14% of executive leadership positions, and 15% of first- and mid-level management positions.[75] Such data illustrate an opportunity to foster programs that promote minority representation in hospital decision-making roles.

HEALTH POLICY AND IMPLEMENTATION

Although mandates from government agencies and regulatory bodies have served as important policy leverage or motivation to promote the provision of CEHC, these mandates have been largely unfunded, implying that academic institutions, hospitals, pediatricians, and other physicians must defray the costs of their implementation.[76] Decreasing payment to physician practices for clinical care and decreasing hospital operating margins have rendered these mandates largely impractical. Additionally, financial and other incentives from insurers, government agencies, and other payers to reward physicians and hospitals for delivering CEHC have been meager and, hence, have not supplied the impetus and support to encourage fundamental systemic changes, which are often costly.

In an era when cost containment is an urgent priority for the health care

community, research plays a pivotal role in changing the societal value of CEHC. The AAP regards CEHC as vital and a critical social value. However, many health care payers, employers, institutions, and others fear exacerbating current financial pressures and hardship when trying to provide such care. Many estimates of costs associated with poor child health do not take into account lifetime costs resulting from loss of productivity and earning potential; those who would contend that improving eligibility for health insurance will adequately address child health disparities need also to consider barriers such as insurance enrollment and access to care while recognizing the burden of certain chronic health conditions that disproportionately impact underserved children.[77] Reliable and timely data to demonstrate long-term decreases in health care costs, appropriate use of health care services, and improved patient health outcome measures would provide a solid foundation for addressing valid concerns about the financial implications of providing CEHC. To this end, culturally effective knowledge and skills need to be applied to research development and implementation. From a quality-of-care perspective, moreover, this research would allow policy makers to identify at-risk patient populations and to develop strategies to address health disparities on national, regional, state, and local levels.

Although Medicaid and other public insurers are placing increased emphasis on "cultural competence" and quality care,[78] few tools exist for health care payers to measure the outcomes of processes implemented to ensure CEHC. The use of patient-satisfaction scoring systems that assess shared decision-making, mutual respect, trust, and other culturally sensitive parameters should be encouraged. Survey instruments should use quality measures that are within the scope of responsibility of the health care professional, and the results of these surveys should be used to identify priorities for continuing education. When carefully designed to reflect the health and wellness values of the specific community being surveyed, such outcomes-driven efforts will allow greater focus on the effectiveness of interventions designed to monitor and ensure quality care.

Sponsors of diversity initiatives must likewise be able to track their progress in reaching specific targets and goals through research and data-driven outcome measures. For instance, institutional goals and metrics that are established for the purpose of recruiting and retaining minority trainees and faculty could be used to assess effectiveness. It is difficult to improve what we cannot measure. Limited data on cultural minorities in medicine hamper the ability of the profession to evaluate the current status of diversity, implement activities to enhance it, and measure the outcomes of these activities. The AAP has begun to address this concern by compiling more data regarding better tracking of attributes other than race and ethnicity through research generated by its Annual Survey of Graduating Residents, its new Pediatrician Life and Career Experience Study, its membership surveys, and collaborations with external organizations. However, more must be done to measure progress in improving diversity within medicine and pediatrics.

CONCLUSIONS

Since adoption of the *Report of the AAP Task Force on Minority Children's Access to Pediatric Care*,[3] the AAP has strengthened its commitment to ensure that all infants, children, adolescents, and young adults have access to optimal CEHC, ideally through a medical home.[80] Additionally, the AAP acknowledges that CEHC is multifaceted, complex, and often costly. The AAP believes that the education of pediatricians about cultural attributes and about the importance of implementing culturally effective practices and policies is essential. Because pediatricians are committed to lifelong learning, education that will enhance the provision of such care must be available at all levels, from premedical education and medical school through residency training and CME.

The medical community has made insufficient progress in diversifying its workforce. Improving diversity within the pediatrician workforce will require proactive leadership from the medical community in a number of areas, including recruitment, mentoring, education, organizational support systems, and financial incentives. Success will also depend on the collaboration and cooperation of many stakeholders, including the AAP, with respect to initiatives designed to promote diversity within the health professions. Pediatricians are not alone in seeking solutions to improve the delivery of pediatric health care to the neediest patients. Pediatricians, other health care professionals, hospitals, universities, community groups, health care payers and insurers, regulatory and accrediting bodies, legislators, and others have significant roles to play in ensuring CEHC and will have to participate in health policy deliberations on this topic. Broad-based participation will ensure that a pediatric focus and perspective are brought to bear on decisions that have a direct effect on the quality of care that is delivered to children. In particular, stakeholders will have to advocate for necessary financial, regulatory, and other support among decision-makers to implement appropriate changes to the US health care delivery system.

Individual pediatricians need educational tools; the pediatric community needs the results of outcomes research to bolster, validate, and sustain its effort; institutions need support and encouragement to provide appropriate and effective education and training; foundations and other organizations need to have a pediatric perspective in all health care and policy development considerations; and legislative bodies, including federal and state agencies, need to provide the funding and infrastructure necessary to implement and evaluate mandates. The AAP has played, and must continue to play, a pivotal role in all of these important health policy deliberations.

RECOMMENDATIONS

The AAP believes that increasing the diversity of the pediatrician workforce and enhancing the provision of culturally effective care to the pediatric population will help achieve the AAP mission of promoting optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. Thus, the AAP is committed to working in collaboration with AAP chapters and other groups, including but not limited to medical societies, hospitals, universities, health care payers and insurers, federal agencies, and policy makers, to achieve greater workforce diversity and promote the provision of culturally effective pediatric care and recommends the following:

1. Pediatricians should assume a leadership role in advocating for a diverse workforce. Diversity in this context includes a wide spectrum of racial, ethnic, and cultural attributes, which include values, behaviors, customs, language, sexual orientation, religious beliefs, socioeconomic status, and other distinct population attributes. Many individuals exhibiting such a broad range of perspectives and attributes are URM compared with their presence in the general population.
2. The AAP should support the development of sequentially staged programs that prepare URM students to pursue careers in health professions, including pediatrics. URM medical student, resident, or physician groups would encompass those individuals from ethnic and racial populations that are underrepresented in the medical profession relative to their numbers in the general population as a whole.
3. Medical student, resident, and faculty recruitment activities should support and advocate for the full spectrum of diversity as described in Recommendation 1.
4. Affirmative-action programs should be supported because they promote the entry of URM students into medical school.
5. Financial assistance should be broadened for URM students, including federal funding for diversity programs, Title VII funding, loan-forgiveness/repayment programs, and tuition reimbursement.
6. Educational and health care institutions and organizations must employ individuals who are primarily responsible for the implementation, management, and evaluation of diversity programs that address the full spectrum of diversity as described in Recommendation 1.
7. Institutional commitment to improve workforce diversity must include formal programs or mechanisms to ensure that individuals of diverse backgrounds can rise to leadership positions. Furthermore, commitment from a number of groups (including institutions, the AAP, AAP chapters, medical societies, federal agencies, and policy makers) is necessary to ensure the provision of CEHC.
8. Pediatricians should assume a leadership role in advocating for CEHC for all infants, children, adolescents, and young adults.
9. The AAP, along with health care organizations at all levels, should continue to participate in the development and assessment of effectiveness of educational programs that promote CEHC. The curricula should address issues including but not limited to the patient's and one's own cultural beliefs, values, behaviors, customs, language, sexual orientation, religious beliefs, disabilities, and other distinct attributes.
10. Pediatricians must continue to work locally with hospitals, offices, and managed care organizations as well as commercial and government insurance payers to develop policies and programs that address health care needs specific to their communities.
11. Mandates from both the government and insurers to improve the provision of CEHC must be accompanied by funding or payment to support the infrastructure necessary to implement these programs and assess their effectiveness.
12. Public and private incentive programs must be established to encourage the implementation of national, regional, state, and community-based initiatives to improve the delivery of CEHC.

Essential Contractual Language for Medical Necessity in Children

- *Policy Statement*

POLICY STATEMENT

Essential Contractual Language for Medical Necessity in Children

abstract

FREE

The previous policy statement from the American Academy of Pediatrics, "Model Language for Medical Necessity in Children," was published in July 2005. Since that time, there have been new and emerging delivery and payment models. The relationship established between health care providers and health plans should promote arrangements that are beneficial to all who are affected by these contractual arrangements. Pediatricians play an important role in ensuring that the needs of children are addressed in these emerging systems. It is important to recognize that health care plans designed for adults may not meet the needs of children. Language in health care contracts should reflect the health care needs of children and families. Informed pediatricians can make a difference in the care of children and influence the role of primary care physicians in the new paradigms. This policy highlights many of the important elements pediatricians should assess as providers develop a role in emerging care models. *Pediatrics* 2013;132:398–401

The American Academy of Pediatrics (AAP) published the policy statement "Model Contractual Language for Medical Necessity in Children" in July 2005.[1] The chief principles articulated in that statement are still relevant, but given the structural shifts in the health care delivery system, they no longer adequately address the unique needs of children. This revised policy statement is an update of the 2005 statement.

In light of the passage and ongoing implementation of the Patient Protection and Affordable Care Act (ACA [Pub L No. 111-148]) in 2010, contractual obligations, as expressed in health plan-provider and health plan-beneficiary agreements, have a new significance with respect to the array of health care benefits made available to children and families. In particular, a much used term—"medical necessity"—is, in fact, generally ill defined. As stated in the previous policy statement, "The term 'medical necessity' is used by Medicaid and Medicare and in insurance contracts to refer to medical services that are generally recognized as appropriate for the diagnosis, prevention, or treatment of disease and injury." The term is found in insurance contractual language, and, as stated in the 2005 policy statement, "… an intervention will be covered if it is an otherwise covered category of service, not specifically excluded, and medically necessary." It

would appear that this statement provides a straightforward presentation of medical necessity. However, health insurance coverage is moderated by a host of federal regulations and statutes, state mandates, and other rules. Provider agreements are usually written to incorporate these rules and regulations. As the US Department of Health and Human Services moves to implement the provisions of the ACA, essential health care benefits are not guaranteed to be the same in every state. Consequently, benefits for children may vary from state to state or plan to plan and may contain specific exclusions. The AAP advocates for quality health care for children that promotes optimal growth and development with measures intended to prevent, diagnose, detect, ameliorate, or palliate the effects of physical, genetic, congenital, mental, or behavioral conditions, injuries, or disabilities.

Individuals with health insurance coverage, whether it be Medicaid, Medicare, or commercial insurance coverage, may be unaware of payment or benefit restrictions for the medical services they seek. In addition, services ordered by a physician might only be covered if conditions of medical necessity are met. Medical necessity means that a decision is needed about appropriateness for a specific treatment of a specific individual. The 2005 AAP statement drew on model language developed by Stanford University[2]; however, more specific considerations are needed for children because of their unique needs. Now, as the US Department of Health and Human Services is charged with implementation of the ACA, it is time to address medical necessity and the needs of children. Although Medicare has become the de facto standard of health care benefits and directly influences commercial health care benefit plans, it is important to realize that health care standards designed for adult care often will not meet the needs of children. By and large, the Medicaid program provides coverage for a significant number of children, and it, too, can be influenced by health care standards designed for adults.

A definition of medical necessity for children must recognize that the needs of children differ from those of adults. The foundation for medical necessity for children should be based on the comprehensive, fully inclusive set of services provided by the Early and Periodic Screening, Diagnosis, and Treatment regimen embodied in Medicaid as well as the preventive care recommendations in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* as stipulated in Section 2713 of the ACA.[3] The language in the Stanford statement considered the scope of health problems, evidence of effectiveness, and value of the intervention. Medical necessity should be guided by these criteria, but health plan and even Medicare language generalizes across populations, as opposed to focusing on specific individuals or groups, including children, often in a manner that is blind to their particular needs. A definition of medical necessity is needed that is more functional or operational and specific to meet the needs of children. Informed pediatricians can help advance such a definition.

Variability in "Essential Health Benefits," as intended by the ACA, is also cause for concern. There are 10 categories of Essential Health Benefits, including item 10—pediatric services including vision and oral care. The states are allowed individually to define the benefits for each of these 10 categories. Therefore, there is a great likelihood of significant variation in pediatric benefits throughout the nation. States are likely to use different methods of determining medical necessity.

Some examples may help to illustrate the unique needs of children. One such example is the nuance between rehabilitative and habilitative services. Rehabilitative and habilitative services and devices are specifically addressed as 1 of 10 necessary categories of Essential Health Benefits in the ACA. Currently, in many instances, health care coverage is limited to rehabilitative services, referring to the need to restore a lost function. Habilitation suggests a function or skill not yet acquired or attained. More specifically, the National Association of Insurance Commissioners defines habilitation as "health care services that help a person keep, *learn,* or improve skills and functioning for daily living." With today's medical knowledge, conditions poorly understood in the past may now be subject to significant improvement, even functions that have not yet been acquired. Habilitation and rehabilitation services are usually provided by the same professionals, the only difference being the indication for therapeutic intervention. The case is also illustrated when one considers speech therapy for a child with autism or physical therapy for a child with hypotonia—motor skills and developmental milestones not yet achieved. Every newborn infant is a well of unknown potential. The terms habilitative and rehabilitative should be interchangeable where children are concerned. Developmental milestones represent standards achieved by most children in a given time frame, but not all children follow the same trajectory. A primary focus needs to be on the potential for functional gain—hence, habilitative services.

Evidence of effectiveness is a cornerstone of medical necessity, yet such data for children may not be readily available. It would be beneficial if medical necessity was governed by traditional evidence grading, and if not available, a hierarchy or algorithm of standards should be applied. The AAP has published 2 policy statements to aid decision makers in classifying clinical recommendations and ensuring transparency in issuing clinical guidelines.[4,5] If patient-centered or scientific evidence for children is insufficient, then professional standards of care for children must be considered. The AAP, other pediatric medical specialty societies, and consensus expert pediatric opinion could serve as references for defining essential pediatric care in the context of medically necessary services. **Hence, the pediatric definition of medical necessity should be as follows: health care interventions that are evidence based, evidence informed, or based on consensus advisory opinion and that are recommended by recognized health care professionals, such as the AAP, to promote optimal growth and development in a child and to prevent, detect, diagnose, treat, ameliorate, or palliate the effects of physical, genetic, congenital, developmental, behavioral, or mental conditions, injuries, or disabilities.**

Value is another parameter in the consideration of medical necessity. Value is not simply a cost-benefit assumption. Value, in fact, may be a subjective consideration. The recipient may have an entirely different perception of value than the provider or payer. Value implies quality (ie, access to age-appropriate care, in an appropriate setting, by appropriate personnel) plus desired outcome at a reasonable cost. Pediatricians recognize the so-called marginal effect of some services—extensive interventions for limited or no essential benefit. However, children deserve the intent embedded in the Medicaid provision of the Early and Periodic Screening, Diagnosis, and Treatment regimen, specifically treatment. Given a pediatric definition of medical necessity as mentioned previously, the value of services might also be considered. Examples in which this is particularly true include children with autism spectrum disorders, neurodevelopmental disorders, or expressive speech delay, conditions for which needs are unique and improvement may be slow. Similarly, services that have been provided for an appropriate period of time by an appropriate provider could be discontinued if there is no measureable benefit. In short, services should be provided to children, but continuity is only ensured if there is evidence of a significant measureable benefit. It may be that the only therapeutic benefit is maintenance at a given level of function. If this facilitates more manageable daily living, then the service has value. This might best be exemplified by the continuation of occupational or physical therapy for a child with neurologic damage if only to facilitate safe transfers or to minimize the usual contractures. The goal is to achieve value for both the recipient and the provider. Resources are limited, but every child, with or without disability, deserves the opportunity to declare his or her potential for improvement in his or her daily life. Difficult decisions are part of medical necessity. Cost should not be the basis for denial of services, but the delivery of care in a setting that demonstrates lower cost could be acceptable if quality is not compromised.

Transparency in today's health care delivery system is essential to credibility. Health plans need to be clear with respect to the evaluation and determinations of medical necessity. The decision pathway, authority credentials of decision makers, and timeliness in the process should feature identifiable criteria or benchmarks in rendering decisions relevant to medical necessity. The expectations of all health plans, including Medicaid and Medicare, should be clear in anticipation of medical necessity requirements, and similarly, the decision-making process should be equally transparent. Consideration might be given to the role of a family advocate or ombudsmen in protecting children and families and intervening to aid in solving their problems related to medical necessity decisions.

As health care reform advances, contracts between providers of care and health care organizations, whether they are medical group practices, accountable care organizations, or health plans, will define expectations and obligations. Essential language should exist to address the unique needs of children in the context of medical necessity. The right of a child to optimal growth and development should be a universal expectation limited only by the restraints of physical or genetic conditions. New and emerging health care delivery models, including accountable care organizations, bundled payments covering hospital and physician services, disease-management models, and others, will influence how health care services are managed for beneficiaries. There will also be contractual arrangements with providers of primary and specialty care, and federal and/or state regulations will influence these contractual relationships. This time of transition affords pediatricians

an opportunity to affect not only overall health care benefits but also the medical necessity decisions that affect pediatric care. All of these agreements should feature essential language that recognizes the unique needs of children and ensures more equitable care for all children. The AAP and its member pediatricians are the informed advocates who can advance a better understanding of medical necessity decisions on behalf of children.

abstract

FREE

The persistent mismatch between the supply of and need for transplantable organs has led to efforts to increase the supply, including controlled donation after circulatory death (DCD). Controlled DCD involves organ recovery after the planned withdrawal of life-sustaining treatment and the declaration of death according to the cardiorespiratory criteria. Two central ethical issues in DCD are when organ recovery can begin and how to manage conflicts of interests. The "dead donor rule" should be maintained, and donors in cases of DCD should only be declared dead after the permanent cessation of circulatory function. Permanence is generally established by a 2- to 5-minute waiting period. Given ongoing controversy over whether the cessation must also be irreversible, physicians should not be required to participate in DCD. Because the preparation for organ recovery in DCD begins before the declaration of death, there are potential conflicts between the donor's and recipient's interests. These conflicts can be managed in a variety of ways, including informed consent and separating the various participants' roles. For example, informed consent should be sought for premortem interventions to improve organ viability, and organ procurement organization personnel and members of the transplant team should not be involved in the discontinuation of life-sustaining treatment or the declaration of death. It is also important to emphasize that potential donors in cases of DCD should receive integrated interdisciplinary palliative care, including sedation and analgesia. *Pediatrics* 2013;131:1021–1026

INTRODUCTION

The persistent mismatch between the supply of and need for transplantable organs and the resulting deaths of individuals on the waiting list have led to a variety of efforts to increase the supply. As of May 17, 2012, there were 878 individuals aged <18 years awaiting a kidney transplant and 513 awaiting a liver transplant. In 2011, 10 individuals aged <18 years died while waiting for a kidney transplant, and 20 children and adolescents died while waiting for a liver transplant.[1] One effort to increase the supply of transplantable organs has been renewed interest in donation after circulatory death (DCD), which is the retrieval of organs from individuals declared dead after the irreversible cessation of circulatory and respiratory functions. (This

process was initially referred to as "nonheartbeating organ donation" and then as "donation after cardiac death." The most recent change in terminology emphasizes that the determination of death is based on the cessation of circulatory, not cardiac, functions.[2]) There are several forms of DCD, and the current statement focuses on "controlled" DCD: the recovery of organs after the planned withdrawal of life-sustaining medical treatment.[3]

Although DCD was the initial form of deceased organ donation, it was eclipsed by recovery of organs from individuals declared dead according to neurologic criteria after these criteria were established and evidence showed improved graft function from such donors. There was renewed interest in DCD in the 1990s, including the publication of the so-called Pittsburgh Protocol,[4,5] given the persistent shortage of transplantable organs. Recent estimates suggest that DCD could increase the supply of transplantable organs by 20%.[6] A number of subsequent reports and consensus statements have addressed points of controversy, such as the waiting period before the declaration of death and the use of premortem interventions to improve graft function.[7–10] More recent pediatric studies reporting similar graft survival in kidneys and livers from donors declared dead according to neurologic and cardiovascular criteria have further increased interest in DCD.[11]

Increased acceptance of DCD has resulted in regulatory oversight. The Joint Commission mandates that, although hospitals need not perform DCD, their policies must address it.[12] The United Network for Organ Sharing has articulated Model Elements for Controlled DCD Recovery Protocols[13] and requires its member hospitals that perform solid organ transplants to develop protocols which address the required elements to facilitate the recovery of organs from donors in cases of DCD.[14] The Organ Donation Breakthrough Collaborative has also established the goal of having donors in DCD cases represent 10% of all organ donors.[15]

The current policy statement addresses the 2 major conceptual and ethical issues related to DCD: when can organ recovery begin, and how should conflicts of interests be managed? It provides greater detail than the American Academy of Pediatrics' policy statement "Pediatric Organ Donation and Transplantation,"[16] but it does not address general issues, such as medical examiner release of organs. Discussing these issues is particularly important given the variation among DCD policies at children's hospitals.[17] Standards must be met to maintain the integrity of and public confidence in the organ transplantation system.

DECLARATION OF DEATH

Whether and when donors in DCD cases are dead is important because cadaveric organ transplantation operates under the "dead donor rule." This rule can be characterized in 2 different ways, each with its own ethical justification. One version is that organ recovery must not cause the donor's death. This version is justified by the prohibition against the direct killing of innocent persons. The other version is that the donor must be dead before the recovery of vital organs. This version is based on preventing potential negative outcomes, such as the mistreatment of potential donors and the erosion of public confidence in transplantation.[18]

Some commentators have recommended abandoning the dead donor rule. Miller and Truog,[19] for example, argue that withdrawing life-sustaining treatment causes patients' death and that there is no ethical bright line between withdrawing life-sustaining treatment and active euthanasia. They contend that patients or their surrogates, who have previously decided to have life-sustaining medical treatment withdrawn, should be permitted to consent to the premortem recovery of vital organs. Although they do not discuss the implications of their position for pediatrics, it would, in principle, extend to parents or guardians and capacitated adolescents or their proxies. Miller and Troug's arguments are not, however, compelling. For example, they conflate patients' right to refuse treatment with the distinction between killing and letting die. They also ignore well-developed arguments that the intentional killing of innocent persons is unethical and that the ethically relevant distinction is between different forms of letting die. The dead donor rule should, therefore, be retained, not only because the reasons supporting it are compelling but also because the reasons for abandoning it are insufficient.

The discussion of death commonly distinguishes definition, criteria, and tests. The predominant definition of death is "the cessation of functioning of the organism as a whole."[20] This definition focuses on the functions possessed by the whole organism, such as consciousness and control of circulation, respiration, and temperature, rather than the functions of its constituent parts. Although the definition states the necessary and jointly sufficient conditions for correctly applying the concept of death, the criteria specify measurable conditions, and physicians use the tests to evaluate the criteria at the bedside. The 2 criteria for death are the neurologic and the cardiorespiratory.

Drawing an analogy to the declaration of death in other clinical contexts,

proponents of DCD argue that the cessation of circulatory function must be permanent but not irreversible. The cessation is permanent if it will not resume on its own through autoresuscitation or as a result of external action, such as cardiopulmonary resuscitation. Once sufficient time has elapsed to preclude the spontaneous recovery of circulatory function, it is permanent, because, as part of the decision to withdraw life-sustaining treatment, the parents or guardians previously decided to forego cardiopulmonary resuscitation. Irreversibility further requires that the function is incapable, within the limits of current technology, of being restored. Proponents of DCD contend that irreversibility is not necessary for the declaration of death.[21] Numerous professional organizations and consensus groups support this argument.[8–10]

Within this framework, how much time must elapse to preclude autoresuscitation sufficiently is a significant concern. Despite calls for additional research, data are limited on this topic. On the basis of narrative reviews, commentators have recommended waiting at least 2 minutes and not more than 5 minutes.[8–10] The authors of the most recent systematic review, noting the low quality and limited scope of reports, concluded there are no cases of autoresuscitation without cardiopulmonary resuscitation.[22] Until a large observational study that provides narrow confidence intervals around the duration of autoresuscitation is conducted, this timing remains a prudential judgment. Once death is declared, there is no need for an additional waiting period before the initiation of organ recovery efforts.

Declaring death requires tests in addition to definitions and criteria. It would be prudent to use more sensitive and/or objective tests when they are available. For example, using indwelling arterial catheters, Doppler ultrasonography, or echocardiography may be preferable to palpating pulses or auscultating heartbeats.[2]

There are, however, 2 significant criticisms of the proponents of DCD's arguments. One objection is that irreversibility is a necessary criterion for the declaration of death. Although permanence and irreversibility are causally related (ie, without intervention, permanent cessation will become irreversible), they are not contemporaneous. During the time between when circulatory function is permanently lost and when it is irreversibly lost, critics argue, individuals are dying but not yet dead.[23] This objection can also be stated in terms of the relationship between the cardiorespiratory and neurologic criteria of death. Rather than being independent criteria, the neurologic criteria are arguably fundamental. Although individuals who fulfill the cardiorespiratory criteria inevitably fulfill the neurologic criteria, if resuscitation is withheld, additional time must elapse.

A second criticism is that replacing irreversibility with permanence inappropriately makes the declaration of death contingent on the intent and action of others rather than an intrinsic condition of the organism.[23] Nevertheless, the criticism that retrieving vital organs from donors in DCD cases is the proximate cause of death is not sound. If sufficient time passes to preclude autoresuscitation, progressive hypoxia-ischemia of the central nervous system is the proximate cause of death.[24]

Although the need to increase the supply of transplantable organs is compelling and the arguments for the sufficiency of permanence for declaring death are widely accepted, the criticisms of these arguments are sufficient that physicians should not be required to retrieve organs from donors in cases of DCD.[25] Institutions have an obligation to provide patients and their families access to DCD. Whether institutions themselves should be able to refuse to perform DCD is ethically controversial because of burdens placed on patients and their families by alternatives, such as the transfer of patients to other institutions.[26] The American Academy of Pediatrics could not reach consensus on whether institutions may refuse to participate.

Recent publications have highlighted related conceptual and practical issues. In 2008, Boucek et al[27] reported successfully transplanting hearts from 3 infant donors in cases of DCD. Some criticized the waiting period of 75 seconds in 2 of the transplants as being too short. Shortening the waiting period is particularly problematic in infants because they were not part of the population in which autoresuscitation was studied, and their organs may be more resilient.[2] Others contended that the resumption of cardiac activity in the recipient negates the determination of death.[28] The current definition of death focuses on the loss of integrated functioning of the organism that is demonstrated by the absence of autoresuscitation. Residual function of individual organs and tissues is consistent with death of the organism as a whole.

Others have reported on the use of extracorporeal membrane oxygenation (ECMO) in donors to support organ perfusion between the declaration of death and organ recovery and, thereby, improve outcomes in the transplanted organs.[29,30] ECMO was originally designed to provide cardiorespiratory support to individuals with reversible cardiorespiratory failure. The use of ECMO in DCD is problematic because it artificially replaces circulatory function analogous to a

ventilator in patients with severe brainstem or spinal cord injuries. The additional concern is that reperfusion of the brain could restore consciousness. A potential modification is to prevent perfusion of the brain or organs above the diaphragm.[2] It is not clear whether these measures are sufficient to permit donors to be declared dead according to the cardiorespiratory criteria or whether donors receiving ECMO should be evaluated by using the neurologic criteria.

CONFLICTS OF INTERESTS

In addition to conceptual and practical issues regarding the declaration of death, DCD involves a variety of conflicts of interests.[31] In contrast to donors declared dead according to the neurologic criteria, preparation for organ recovery efforts in DCD begins before the declaration of death. This preparation may include premortem interventions, such as placing lines or administering heparin, and modifications of the usual process of withdrawing life-sustaining treatment. These actions create the potential for conflicts between the interests of the donor and of the recipients.

These potential conflicts are exacerbated by the need to limit warm, and to a lesser extent cold, ischemic time. Organs tolerate oxygen deprivation better at colder temperatures than at warm ones. In "brain-dead" donors, the organs are relatively normally perfused before recovery and then rapidly cooled. In donors in cases of DCD, organs may experience hypoperfusion during the time between stopping life-sustaining treatment and recovering and cooling the organs. This hypoperfusion may damage the organs and impair their function. Premortem practices are altered in DCD to diminish warm ischemia times, and the maximum duration of organ recovery efforts is frequently stipulated. (The fact that donation efforts will cease if the potential donor does not die within the specified time period should be disclosed as part of the informed consent process.)

The donor's informed consent is a potential way to manage the conflicts of interests. Capacitated adults can accept the risks involved in the donation process to benefit potential recipients. Informed consent by the donor is, however, unlikely in DCD. Most potential donors in cases of DCD have suffered serious, irreversible neurologic injuries and are incapacitated. Expressing one's interest in donation (eg, by signing a donor card) does not currently constitute informed consent for the modifications in premortem management required by DCD.[32]

Parents or guardians "consenting" for their children further complicate the issue. In contrast to surrogate decision makers for previously capacitated adults who should make decisions on the basis of substituted judgment, parents or guardians should make decisions based on their child's and family's interests. Giving permission for their child to become an organ donor may permit families to create meaning or value in a tragic circumstance. Changes in premortem treatment may create conflicts between the interests of the recipient and/or the family and the interests of the donor. Minimally, changes in premortem treatment should not be contrary to the donor's interests.

The potential for conflicts arises at multiple points in the donation process, including consent to organ donation, premortem interventions to promote organ viability, palliative care, and declaration of death.

- The decision to withdraw life-sustaining medical treatment should be separate or decoupled from the decision to attempt to donate organs.[7–10] The conceptual separation of the issues can be reinforced by separating when the decisions are discussed and who participates in the discussions. This separation should be maintained, to the extent possible, if parents or guardians raise the issue of organ donation before deciding to withdraw life-sustaining medical treatment.
- Premortem interventions to improve organ viability should not harm the donor and require informed consent.[7,9,10] Premortem interventions may include medications, such as anticoagulants or vasodilators, and procedures, such as line placement. Most of these interventions are neutral to patients' interests. There is legitimate disagreement about whether anticoagulants may, in uncommon situations, contribute to the potential donor's death and whether the pain of line placement constitutes a relevant harm.[7] Parental permission is necessary for any premortem intervention to improve organ viability.
- Potential donors in cases of DCD should receive integrated interdisciplinary palliative care,[33] including sedation and analgesia.[8,9] In DCD, palliative care occurs concurrently with preliminary organ donation efforts. Efforts should be made to limit alterations in the process of withdrawing life-sustaining treatment, such as its location. Alterations in the process of withdrawing life-sustaining treatment to reduce warm ischemia times should also be disclosed as part of the informed consent process. Medications should not be used with the direct intention of controlling the time of death.[7,8,10]
- Although organ procurement organization personnel may be involved in evaluating potential donors and scheduling, they and members of the transplant team should not be

involved in the decision to withdraw life-sustaining treatment or its actual discontinuation. Programs should consider whether physicians caring for potential recipients should also be excluded from involvement in premortem management. If there are no alternatives to members of the transplant team participating in premortem interventions, such as prepping and draping and/or line placement, they should physically leave the patient care area before the withdrawal of life-sustaining treatment.[7,10]

- As discussed previously, death should be declared by using relatively sensitive and objective tests. Organ procurement organization and transplant personnel should not be involved in the declaration of death. Programs should consider the appropriate role, if any, of those caring for potential recipients.[7–10]

Institutions should have policies regarding these issues and periodically review performance to promote adherence. Ethics committees can contribute to the development of policies and the resolution of dilemmas or conflicts in their implementation.

RECOMMENDATIONS

- The American Academy of Pediatrics considers DCD an ethically acceptable option when practiced within appropriate constraints, such as waiting a reasonable amount of time after the initial fulfillment of the cardiorespiratory criteria for death to preclude autoresuscitation before declaring death. On the basis of current evidence, the recommendation to wait between 2 and 5 minutes is reasonable.
- Additional research to better understand the phenomenon of autoresuscitation in infants and children should be conducted.
- Given legitimate ethical disagreement regarding the interpretation of the cardiorespiratory criteria for death, individual physicians should not be required to participate in DCD. Institutions should, nonetheless, provide access to DCD.
- Physicians should help institutions develop policies to manage the conflicts of interests inherent in the DCD process. Such policies should include:
  - the separation or decoupling of the decision to withdraw life-sustaining treatment from the decision to donate;
  - the prohibition of premortem interventions to improve organ viability that harm the patient;
  - the requirement of parental permission for acceptable premortem interventions;
  - the provision of integrated interdisciplinary palliative care; and
  - the prohibition of organ procurement organization staff and transplant team members from participating in the discontinuation of life-sustaining treatment or the declaration of death.

Ethical and Policy Issues in Genetic Testing and Screening of Children

- *Policy Statement*

POLICY STATEMENT

Ethical and Policy Issues in Genetic Testing and Screening of Children

abstract

FREE

The genetic testing and genetic screening of children are commonplace. Decisions about whether to offer genetic testing and screening should be driven by the best interest of the child. The growing literature on the psychosocial and clinical effects of such testing and screening can help inform best practices. This policy statement represents recommendations developed collaboratively by the American Academy of Pediatrics and the American College of Medical Genetics and Genomics with respect to many of the scenarios in which genetic testing and screening can occur. *Pediatrics* 2013;131:620–622

BACKGROUND

In 1953, Watson and Crick described the DNA double helix. Fifty years later, the full sequence of the human genome was published. Our knowledge of genetics grows rapidly, as does consumer interest in undergoing genetic testing. Statements about genetic testing of children in the United States written in the past 2 decades need to be updated to consider the ethical issues arising with new technologies and expanded uses of genetic testing and screening.[1,2] The growing literature on the psychosocial and clinical effects of such testing and screening can help inform us about best practices.

Genetic testing and screening of minors are commonplace. Every year, ~4 million infants in the United States undergo newborn screening for metabolic, hematologic, and endocrine abnormalities for which early treatment may prevent or reduce morbidity or mortality.

Outside of newborn screening, genetic testing of children is less commonly performed. Diagnostic genetic testing may be performed on a child with signs or symptoms of a potential genetic condition or for treatment decisions made on the basis of results of pharmacogenetic assays. Genetic testing may also be performed on an asymptomatic child with a positive family history for a specific genetic condition, particularly if early treatment may affect morbidity or mortality. The American Academy of Pediatrics (AAP) and the American College of Medical Genetics and Genomics (ACMG) provide the following recommendations regarding genetic testing and screening of minors. An accompanying technical report provides ethical explanations and empirical data in support of these recommendations (http://www.nature.com/gim/journal/vaop/ncurrent/full/gim2012176a.html).[3]

COMMITTEE ON BIOETHICS, COMMITTEE ON GENETICS, AND THE AMERICAN COLLEGE OF MEDICAL GENETICS AND GENOMICS SOCIAL, ETHICAL, AND LEGAL ISSUES COMMITTEE

KEY WORDS

genetic testing, genetic screening, newborn screening, predictive testing, disclosure, carrier identification

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

GENERAL RECOMMENDATIONS

1. Decisions about whether to offer genetic testing and screening should be driven by the best interest of the child.
2. Genetic testing is best offered in the context of genetic counseling. Genetic counseling can be performed by clinical geneticists, genetic counselors, or any other health care provider with appropriate training and expertise. The AAP and ACMG support the expansion of educational opportunities in human genomics and genetics for medical students, residents, and practicing pediatric primary care providers.

DIAGNOSTIC TESTING

3. In a child with symptoms of a genetic condition, the rationale for genetic testing is similar to that of other medical diagnostic evaluations. Parents or guardians should be informed about the risks and benefits of testing, and their permission should be obtained. Ideally and when appropriate, the assent of the child should be obtained.[4]
4. When performed for therapeutic purposes, pharmacogenetic testing of children is acceptable, with permission of parents or guardians and, when appropriate, the child's assent. If a pharmacogenetic test result carries implications beyond drug targeting or dose-responsiveness, the broader implications should be discussed before testing.

NEWBORN SCREENING

5. The AAP and ACMG support the mandatory offering of newborn screening for all children. After education and counseling about the substantial benefits of newborn screening, its remote risks, and the next steps in the event of a positive screening result, parents should have the option of refusing the procedure, and an informed refusal should be respected.

CARRIER TESTING

6. The AAP and ACMG do not support routine carrier testing in minors when such testing does not provide health benefits in childhood. The AAP and ACMG advise against school-based testing or screening programs, because the school environment is unlikely to be conducive to voluntary participation, thoughtful consent, privacy, confidentiality, or appropriate counseling about test results.
7. For pregnant adolescents or for adolescents considering reproduction, genetic testing and screening should be offered as clinically indicated, and the risks and benefits should be explained clearly.

PREDICTIVE GENETIC TESTING

8. Parents or guardians may authorize predictive genetic testing for asymptomatic children at risk of childhood-onset conditions. Ideally, the assent of the child should be obtained.
9. Predictive genetic testing for adult-onset conditions generally should be deferred unless an intervention initiated in childhood may reduce morbidity or mortality. An exception might be made for families for whom diagnostic uncertainty poses a significant psychosocial burden, particularly when an adolescent and his or her parents concur in their interest in predictive testing.
10. For ethical and legal reasons, health care providers should be cautious about providing predictive genetic testing to minors without the involvement of their parents or guardians, even if a minor is mature. Results of such tests may have significant medical, psychological, and social implications, not only for the minor but also for other family members.

HISTOCOMPATIBILITY TESTING

11. Tissue compatibility testing of minors of all ages is permissible to benefit immediate family members but should be conducted only after thorough exploration of the psychosocial, emotional, and physical implications of the minor serving as a potential stem cell donor. A donor advocate or similar mechanism should be in place from the outset to avert coercion and safeguard the interests of the child.[5]

ADOPTION

12. The rationale for genetic testing of children in biological families should apply for adopted children and children awaiting placement for adoption. If a child has a known genetic risk, prospective adoptive parents must be made aware of this possibility. In rare cases, it may be in a child's best interest to undergo predictive genetic testing for a known risk before adoption to ensure the child's placement with a family capable of and willing to accept the child's potential medical and developmental challenges. In the absence of such indications, genetic testing should not be performed as a condition of adoption.

DISCLOSURE

13. At the time of genetic testing, parents or guardians should be encouraged to inform their child of the test results at an appropriate age. Parents or guardians should be advised that, under most circumstances, a request by a mature adolescent for test results should be honored.
14. Results from genetic testing of a child may have implications for the parents and other family

members. Health care providers have an obligation to inform parents and the child, when appropriate, about these potential implications. Health care providers should encourage patients and families to share this information and offer to help explain the results to the extended family or refer them for genetic counseling.

15. Misattributed paternity, use of donor gametes, adoption, or other questions about family relationships may be uncovered "incidentally" whenever genetic testing is performed, particularly when testing multiple family members. This risk should be discussed, and a plan about disclosure or nondisclosure should be in place before testing.

DIRECT-TO-CONSUMER TESTING

16. The AAP and ACMG strongly discourage the use of direct-to-consumer and home kit genetic testing of children because of the lack of oversight on test content, accuracy, and interpretation.

abstract

FREE

Child abuse might be suspected when children present with cutaneous bruising, intracranial hemorrhage, or other manifestations of bleeding. In these cases, it is necessary to consider medical conditions that predispose to easy bleeding/bruising. When evaluating for the possibility of bleeding disorders and other conditions that predispose to hemorrhage, the pediatrician must consider the child's presenting history, medical history, and physical examination findings before initiating a laboratory investigation. Many medical conditions can predispose to easy bleeding. Before ordering laboratory tests for a disease, it is useful to understand the biochemical basis and clinical presentation of the disorder, condition prevalence, and test characteristics. This technical report reviews the major medical conditions that predispose to bruising/bleeding and should be considered when evaluating for abusive injury. *Pediatrics* 2013;131:e1357–e1373

INTRODUCTION

In the absence of known accidental mechanisms or medical causes, children with intracranial hemorrhage (ICH), cutaneous bruises, or other symptoms of bleeding might be suspected victims of child abuse. In such situations, physicians must often carefully evaluate for the possibility of a bleeding disorder or another medical condition as a possible cause. In addition, because of the legal proceedings associated with cases of potential abuse, physicians might feel compelled to rule out any theoretical possibility of a medical explanation for the child's findings despite clinical improbability. This can result in an expensive and, in the case of young children with limited total blood volume, potentially harmful laboratory investigation of diminished clinical value.

The list of congenital and acquired bleeding disorders that could potentially be confused with abusive injury is extensive: hemophilia, von Willebrand disease (VWD), disorders of fibrinogen, vitamin K deficiency, factor XIII and other factor deficiencies, thrombocytopenia, leukemia, aplastic anemia and other bone marrow infiltrative or failure syndromes, and platelet function abnormalities, among others. Most of these conditions can present with mucosal bleeding, such as epistaxis and cutaneous bruising, but some (especially factor deficiencies) have been noted to present with isolated ICH, or can increase susceptibility to severe ICH after minor trauma. Collagen disorders can also

predispose to easy bruising/bleeding in some circumstances. This report reviews the rationale for the consideration of bleeding disorders and collagen disorders as a cause of or as contributing to ICH, bruising, or bleeding when child abuse is suspected, and addresses several unsupported hypotheses related to these issues.

CLINICAL APPROACH TO THE EVALUATION OF CONDITIONS THAT PREDISPOSE TO BLEEDING IN THE SETTING OF POSSIBLE ABUSE

In many children with bruising/bleeding concerning for abuse, the evaluation for medical conditions causing or contributing to the findings noted on the physical examination can be completed by assessing the child's presenting symptoms, trauma history, medical history, family history, and medications. Before engaging in a laboratory evaluation, physicians should consider the following:

1. The specific clinical characteristics of the child's findings, along with a previous history of bleeding or bruising. Family history of bleeding or bruising or a history of specific coagulopathies and other conditions should be addressed.
2. The known presentations and prevalence of the various bleeding disorders, collagen disorders, or other medical conditions under consideration.
3. The medical probability that a specific medical condition might cause or contribute to the child's bleeding or bruising.
4. The statistical characteristics of the proposed laboratory testing.
5. The history of the use of blood products or other factor replacement products that might alter test results.
6. The associated costs of testing, both financial and medical, such as the blood volume needed for testing.
7. The anticipated benefit of identifying conditions that might cause bleeding or bruising.

CLINICAL CHARACTERISTICS

Nonintracranial Bleeding

The age and developmental capabilities of the child, history of trauma, and the location and pattern of bruising often provide significant evidence in determining the presence of abusive injury.[1–5] In many cases, the constellation of findings, taken in conjunction with the clinical history, can be so strongly consistent with abusive injury that a further laboratory investigation for medical conditions is not warranted. For instance, in a verbal child with a patterned slap mark who describes being hit with an open hand at the location of the slap mark, obtaining tests to rule out a bleeding disorder is unlikely to provide useful information. However, because few data exist comparing the specific clinical presentations of bleeding disorders and abuse, in some cases, a laboratory evaluation might be necessary to minimize the chances of a misdiagnosis. It also must be considered that the presence of a bleeding disorder or other medical condition does not rule out abuse as the etiology for bruising or bleeding.[6]

Other symptoms, such as hematemesis,[7] hematochezia,[8] and oronasal bleeding, can be caused by abuse or a bleeding disorder.[9–13] The relative frequencies of abuse or coagulopathies presenting with these symptoms should be considered, along with the patient's history and any other medical findings, such as fractures, neglect, and other manifestations of bleeding/bruising, before ordering laboratory tests. An increasing number of findings unrelated to bleeding disorders and consistent with abuse decrease the overall likelihood of a coagulopathy or other medical condition contributing to or causing bleeding or bruising. However, it is prudent to evaluate for bleeding disorders or other medical causes in children who have presenting symptoms that are not typical of inflicted injury.

ICH

Multiple studies have assessed the roles of history,[14] clinical and radiographic findings,[15–22] and outcomes[18,21,23,24] in making the diagnosis of abusive head trauma. In a recent study of ICH in bleeding disorders, ICH was the presenting event in 19.2%.[25] However, no studies have addressed how to differentiate whether patients who present with ICH in the absence of trauma or with a history of minimal trauma have a bleeding disorder either causing or contributing to the clinical findings. No studies have systematically compared the presentation, clinical findings, patterns of ICH, or presence of retinal hemorrhages between bleeding disorders and/or collagen disorders and abusive head trauma. Therefore, for children presenting with ICH but without other findings strongly suggestive of abuse, such as fractures,[26] significant abdominal trauma, burns, or patterned bruising, an evaluation for other medical conditions causing or contributing to the findings is necessary. Additionally, physicians must recognize that although evidence of old inflicted injury, such as healing fractures, could support the diagnosis of abuse, healing injuries may be unrelated to recent bruising or ICH. Physicians must assess their own comfort in making and supporting the diagnosis of abuse in the absence of an extensive laboratory evaluation.

REVIEW OF BLEEDING DISORDERS

This section describes the significant bleeding disorders that may require

further evaluation in cases of suspected abuse, including their common presentations, incidence of ICH, and the method of diagnosis (Table 1).

Deficiency of Factor VIII or IX

Hemophilia A and B are attributable to deficiencies of factors VIII and IX, respectively. Factor VIII deficiency occurs in approximately 1 in 5000 live male births. Factor IX deficiency is rarer, occurring in 1 in 20 000 live male births. Because of the X-linked recessive inheritance pattern of these diseases, most patients affected with hemophilia are male. However, girls who are carriers can have low enough factor VIII or IX levels to present with bleeding as a result of homozygous mutations or extreme inactivation of the normal X chromosome. Rarely, a phenotypic female can have only 1 X chromosome and be affected with the disease (ie, testicular feminization, Turner syndrome).[27,28]

Major bleeding sequelae of hemophilia include bleeding into joints and soft tissues and ICH. The most common sites of the initial bleeding episode in one series were post-circumcision and intracranial.[29] ICH in a child with hemophilia can occur as a result of birth trauma, in response to mild head trauma, or spontaneously. ICH is estimated to occur in 5% to 12% of patients with hemophilia throughout their lives.[25,30,31] A review of 57 episodes of ICH in 52 patients with congenital factor deficiencies showed intraparenchymal and/or intraventricular bleeding in 39 patients, subdural in 15, subarachnoid in 2, and cerebellar in 1. Most of these patients (38) had severe hemophilia. The median age of presentation was 8 years (range, 1 month to 22 years). The overall prevalence of ICH in patients with hemophilia in this study was 9.1%.[25] The largest series to date of ICH in hemophilia reported a rate of 2.7% over 5 years in a cohort of 3629 patients with hemophilia, or 0.0054 cases per year. Most of the cases in this series were not the result of trauma (78.4%). Most (69%) occurred in patients with severe hemophilia, and 18% occurred in those with mild hemophilia. Sites of hemorrhage were intracerebral, subdural, subarachnoid, epidural, or unspecified. Trauma was implicated in all of the epidural hemorrhages, 36% of the subarachnoid hemorrhages, 10% of subdural hemorrhages, and 3% of intracerebral hemorrhages.[31] In a recent review of 97 patients with hemophilia who underwent a total of 295 computed tomography scans for head trauma, 9 (3%) were identified as having intracranial bleeding. The mean age of these patients was 3.7 $\pm$ 4.1 years. Most of the bleeding in these patients was subdural, although in 2 patients, bleeding was intraparenchymal.[32] A recent study of hemophilia in the first 2 years of life revealed 19.0% of first bleeding episodes (n = 404) were head bleeding, of which 36.4% were ICH. Seventy-five percent of the ICH occurred in infants younger than 1 month of age, and most of these were associated with delivery. In contrast to the aforementioned studies, the occurrence of ICH was distributed across all severities of the disease.[29]

Approximately two-thirds of patients who present with a diagnosis of hemophilia have a positive family history for the disease. The one-third of patients without a family history of hemophilia might represent new germ-line mutations.[29,33] Diagnosis of hemophilia requires measuring factor VIII or IX activity level. Hemophilia is categorized as severe if the factor level is $<$1%, moderate if the factor level is between 1% and 5%, and mild if the factor level is $\geq$5%. Spontaneous bleeding is more common in severe hemophilia. The activated partial thromboplastin time (aPTT) is prolonged in moderate and severe cases, but can be normal in patients with mild disease, depending on the laboratory's emphasis on detecting mild factor deficiencies. Factor VIII is also an acute phase reactant and can be elevated into the normal range in patients with mild disease in response to trauma or inflammation.[34]

VWD

VWD is the most common heritable bleeding disorder, and typically presents with mild to moderate mucocutaneous bleeding. Low von Willebrand factor (VWF) levels may occur in up to 1% of the population, but fewer people may present with symptoms (0.01% to 0.1%). The current prevalence of VWD can be difficult to ascertain because recent changes in consensus have resulted in more specific diagnostic criteria. The new criteria for diagnosis requires VWF $<$30% (normal range, 50% to 150%), resulting in fewer people with levels below the normal range meeting diagnostic criteria. Individuals with bleeding symptoms and VWF levels between 30% and 50% create a diagnostic dilemma.[35] In addition, because the bleeding symptoms of VWD are generally mild, there are likely to be patients who have not come to medical attention. On the basis of the number of symptomatic cases seen by hematology specialists, the prevalence has been estimated to be even lower than previously suggested (23 to 110 per million, or 0.0023% to 0.01%), meaning that many individuals with low VWF levels might never manifest bleeding symptoms.[36]

The laboratory evaluation for, and common presentations of, the various types of VWD are variable (Tables 2 and 3). Type 1 VWD is the most common form (approximately 80%) and is characterized by a normally

TABLE 1 Common Testing Strategies for Bleeding Disorders

Condition	Frequency	Inheritance	Screening Tests	Sn and Sp, %	PPV and NPV, %	Confirmatory Test
Factor abnormalities/deficiencies						
VWD type 1	1 per 1000	AD	PFA-100	Sn = 79–96[a]	PPV = 93.3	VWAg[b] VWF activity

AD, autosomal dominant; AR, autosomal recessive; CBC, complete blood cell (count); NA, not available or not applicable; NPV, negative predictive value; PPV, positive predictive value; RVV, Russell viper venom (test); Sn, sensitivity; Sp, specificity; VW, von Willebrand; Ab, antibody.

[a] Values derived from data before 2008 National Institutes of Health Consensus guidelines. Sn and Sp using current diagnostic cutoffs unknown but would be expected to have higher Sp with lower Sn.

[b] May be reasonable to proceed directly to diagnostic testing depending on availability. See accompanying technical report for detailed discussion.[25]

functioning but decreased von Willebrand antigen (VWAg), resulting in low levels of both VWAg and VWF activity. Type 1 VWD has a wide range of bleeding severity and variable penetration among members of the same family. Type 2 VWD subtypes are characterized by abnormally functioning von Willebrand molecules and variable bleeding severity. Type 3 VWD presents with absence of VWF and a very low but detectable factor VIII level. The bleeding in type 3 VWD can be quite severe and can also include hemarthroses resulting from low factor VIII levels (Table 3).[35]

ICH has very rarely been reported in association with VWD. A single case series detailed 4 episodes of ICH thought to have occurred spontaneously in patients with no previous history of VWD. Patient ages ranged from 18 to 65 years of age.[37] There was an additional report of ICH in a newborn child with type 3 VWD and simultaneous sinovenous thrombosis.[38] One case report implicated type 1 VWD as a possible cause of subdural hematoma and retinal hemorrhages[39]; however, the laboratory findings in that case report did not meet the diagnostic criteria for definitive VWD,[40] and child abuse was not completely investigated, because no repeat skeletal survey was performed. Large mass-effect ICH associated with minor trauma in children with VWD outside of the typical age range for abusive head injury has been reported.[41,42] The extreme rarity of this presentation and the questions surrounding the validity of VWD causing ICH in some cases, indicate that VWD is not a typical cause of ICH.

The platelet function analyzer (PFA-100 [Siemens Healthcare Diagnostics, Tarrytown, NY]) has been proposed as a screening test for VWD, and results are often abnormal in patients who are known to have the disorder and have VWF levels <30%. It is superior to the bleeding time because of ease of testing but does not test for blood vessel integrity and is affected by medications, platelet count, and hematocrit. The bleeding time is not recommended for bleeding disorder screening because of poor test characteristics and the invasive nature of the test.[43] The utility of the PFA-100 as a screening tool for VWD has not been established with population studies. It can be a useful tool as a preliminary screen for VWD or a platelet function defect, but if the result is normal and clinical suspicion remains high, other specific testing for these disorders should be obtained. Abnormal results of the PFA-100 test should also prompt further testing as well.[35,40,44,45] It is important to realize that the PFA-100 is not a diagnostic test for bleeding disorders but rather acts as a quick screen in situations in which more specific testing is unavailable or will be delayed. If access to specific testing is available, it might be rational to skip the PFA-100. Specific testing consists of VWAg, VW activity (also referred to as ristocetin cofactor by some laboratories), factor VIII activity, and often, von Willebrand multimer analysis. Some practitioners also include ristocetin-induced platelet agglutination and/or a collagen-binding assay. Contributing to the difficulty of diagnosis, particularly for type 1 VWD, VWF levels increase in response to stress, pregnancy, and inflammation and exhibit significant variability within an individual. In addition, some patients' test results will fall below the lower limits of normal but above the current upper diagnostic cutoff (31% to 50%), creating a diagnostic dilemma.[35] Because of these issues and the lack of a single diagnostic test, the diagnosis of VWD might require repeated testing and is best accomplished by a pediatric hematologist.

TABLE 2 VWD Variants

Test	Type 1	Type 2A	Type 2B	PT-VWD	Type 2N	Type 2M	Type 3
VWF:Ag	Low	Low	Low	Low	Low	Low	Absent
VWF:Act	Low	VWF:Act/VWF:Ag <0.5	Low	Low	Low	VWF:Act/VWF:Ag <0.5	Absent
FVIII	Low	NI	NI	NI	Low	NI	Absent
RIPA	NI	Low	NI	NI	NI	Low	Absent
RIPA-LD	Absent	Absent	Increased	Increased	Absent	Absent	Absent
Frequency	70%–80%	10%–12%	3%–5%	0%–1%	1%–2%	1%–2%	1%–3%
Multimers	NI	Small	Small	Small	NI	NI	Absent

FVIII, factor VIII activity; NI, normal; PT-VWD, platelet-type pseudo VWD; RIPA, ristocetin-induced platelet aggregation; RIPA-LD, low-dose ristocetin-induced platelet aggregation; VWF:Act, VWF activity; VWF:Ag, VWF antigen. TABLE 3 Common Bleeding Symptoms of Healthy Individuals and Patients With VWD

Symptoms	Healthy Individuals (n = 500; n = 341; n = 88; n = 60), %	All Types of VWD (n = 264; n = 1885),%	Type 1 VWD (n = 42; n = 671), %	Type 2 VWD (n = 497), %	Type 3 VWD (n = 66; n = 385), %
Epistaxis	4.6–22.7	38.1–62.5	53–61	63	66–77
Menorrhagia	23.0–68.4	47–60	32	32	56–69
Bleeding after dental extraction	4.8–41.9	28.6–51.5	17–31	39	53–70
Ecchymoses	11.8–50.0	49.2–50.4	50	NR	NR
Bleeding from minor cuts and abrasions	0.2–33.3	36	36	40	50
Gingival bleeding	7.4–47.1	26.1–34.8	29–31	35	56
Postoperative bleeding	1.4–28.2	19.5–28	20–47	23	41
Hemarthrosis	0–14.9	6.3–8.3	2–3	4	37–45
Gastrointestinal tract bleeding	0.6–27.7	14	5	8	20

NR, not reported. Reprinted with permission from Nichols WL, Hultin MB, James AH, et al. von Willebrand disease (VWD): evidence-based diagnosis and management guidelines, the National Heart, Lung, and Blood Institute (NHLBI) Expert Panel Reports (USA). *Haemophilia.* 2008;14(2):186.

Acquired von Willebrand syndrome is a rare phenomenon in pediatrics that can be associated with a number of clinical disorders, such as vascular anomalies, Wilms tumor and other cancers, cardiovascular lesions, hypothyroidism, lymphoproliferative or myeloproliferative disorders, storage disorders, autoimmune illnesses, monoclonal gammopathies, and certain medications. It has been estimated to occur at a prevalence of 0.04% to 0.13% in the general population, although the rate in pediatrics may be lower.[46] It is usually caused by autoimmune clearance or inhibition of VWF, increased shear stress causing consumption of VWF, or adsorption of VWF to cell surfaces. Laboratory tests used to diagnose acquired VWD are the same as those used to diagnose the congenital disorder. The addition of the von Willebrand propeptide can help to distinguish between the 2 entities.[46]

Factor VII Deficiency

Factor VII deficiency is the only plasma coagulation factor deficiency in which the prothrombin time (PT) alone is prolonged. The incidence is estimated as 1 in 300 000 to 1 in 500 000. To date, more than 150 cases have been reported. A quantitative factor VII determination by standard factor assay methods provides a definitive diagnosis. Homozygous patients usually have less than 10 U/dL of factor VII. Heterozygous patients have factor VII levels between 40 and 60 U/dL and might represent single or double heterozygous abnormalities. It is very important to use age and gestational-related normal ranges, because factor VII is naturally low at birth.[47]

ICH has been reported in 4.0% to 6.5% of patients with factor VII deficiency and usually occurs in those with severe disease (<1% factor activity), both spontaneously and as a result of trauma.[48,49] Central nervous system (CNS) bleeding was reported in 4.4% of factor VII–deficient patients as a presenting symptom in 1 registry and was found to occur in subjects younger than 6 months.[49] Bleeding symptoms can be extremely variable, and individuals can have minimal bleeding despite very low levels of factor VII. Using the most recent severity grading system, all patients with CNS bleeding have severe disease by definition.[50] Intracranial bleeding in these patients has been recorded as intraparenchymal, intraventricular, subdural, and tentorial, often accompanied with overlying cephalohematoma and usually occurring soon after birth.[48,51,52]

It is also important to rule out acquired factor VII deficiency as a result of vitamin K deficiency, liver disease, or consumptive coagulopathy. Although in these conditions, one would expect

more extensive coagulopathy, prolongation of the PT is often the only finding in the early stages of these disorders because of the short half-life of factor VII.

Factor XI Deficiency

Factor XI deficiency (also termed hemophilia C) has an estimated frequency in the general population of 1 in 100 000.[53,54] Factor XI deficiency occurs more frequently in the Ashkenazi Jewish population; approximately 0.2% of Ashkenazi Jewish people are homozygous and 11.0% are heterozygous for this disorder.[55]

Bleeding in factor XI deficiency tends to be mild and associated with trauma or surgery. Bleeding symptoms often cannot be predicted by the factor level. Serious spontaneous hemorrhage is uncommon, even in individuals with very low factor levels.[56] There was 1 report of subarachnoid hemorrhage in a 53-year-old man with previously undiagnosed factor XI deficiency. This patient was also found to have cerebral aneurysms.[57]

Laboratory screening tests reveal a prolonged aPTT and normal PT, though the aPTT can be normal in heterozygous patients with mild deficiency. Other screening test results are normal. The specific assay for factor XI is the definitive test for this deficiency. In homozygous individuals, factor XI activity ranges from <1 U/dL up to 10 U/dL. Severe deficiency is defined as <15 U/dL.[58] It is important to compare results with age-matched norms, because healthy ranges in infants are lower than those in adults.[59]

Factor XIII Deficiency

Factor XIII acts to covalently cross-link and stabilize fibrin. Because the PT and aPTT measure the production of fibrin from fibrinogen and the action of factor XIII is subsequent to the formation of fibrin, these tests are normal in factor XIII deficiency and therefore cannot be used to screen for this disorder. The clot solubility test, which is the most commonly used test to screen for factor XIII deficiency, is abnormal only in very severe deficiencies of factor XIII, typically with factor XIII activities <3% of normal. This is the level most experts believe is necessary to cause spontaneous bleeding. A quantitative test for factor XIII exists.[60,61]

Deficiency of factor XIII is rare, occurring in only approximately 1 in 2 to 5 million people. However, intracranial bleeding is a common manifestation of this disorder, occurring in up to one-third of those with the deficiency.[60,62] Bleeding has been reported in subdural, intraparenchymal, and epidural locations, although because most registries and case reports have not specified the location of ICH, it is likely that it has occurred in more disparate sites. ICH has been reported to occur occasionally in patients with factor levels >3%, and therefore, the diagnosis can be missed if only the clot solubility test is used.[63–65] Other manifestations of factor XIII deficiency are umbilical cord bleeding, muscle hematomas, and postoperative bleeding.[62]

Other Factor Deficiencies (Factors II, V, Combined V and VIII, and X)

Prothrombin (Factor II) Deficiency

Homozygous prothrombin deficiency occurs at an estimated prevalence of 1 in 1 to 2 million. The most common bleeding presentation in homozygous and heterozygous patients is bleeding involving the skin and mucous membranes. In the North American Rare Bleeding Disorders Registry (NARBDR), 11% of the subjects with factor II deficiency suffered a CNS complication (which included both ICH and ischemic stroke). In subjects with factor II levels <0.01 U/mL, the rate of ICH was 20%.[66] Little description of these hemorrhages exists, although case reports have described subdural and epidural hematomas.[67–69] Homozygous patients can also present with surgical or trauma-induced bleeding.[70] Hemarthroses occurred in 42%, and gastrointestinal bleeding in 12% of homozygous subjects in one registry.[71] Acquired prothrombin deficiency can occur with vitamin K deficiency, liver disease, warfarin therapy, or overdose or in the setting of connective tissue disorders with accompanying lupus anticoagulant.[70]

The degree to which the PT and aPTT are prolonged varies from patient to patient, from a few seconds in some patients to more than 60 seconds in others, and occasionally, these screening results can be in the normal range.[47,71] The diagnosis is established with a factor assay for functional prothrombin (FII), along with immunologic tests for antigen levels if necessary.

Factor V Deficiency

Factor V deficiency is estimated to occur in 1 in 1 million people. Both homozygous and heterozygous patients with factor V deficiency typically have bleeding symptoms. Bleeding in homozygous patients tends to be spontaneous and occurs in the skin and mucous membranes, joints and muscles, genitourinary tract, gastrointestinal tract, and CNS. In the NARBDR, 8% of homozygous patients presented with intracranial bleeding.[66] Intrauterine subdural hematomas have been reported, as have spontaneous intraparenchymal hemorrhages.[72,73] Fifty-percent of heterozygous patients also had bleeding. Skin and mucous membrane bleeding were the most common manifestations, and none experienced ICH.[66]

Factor V can also be low in some platelet disorders, because it is also

present in platelet α granules. In addition, acquired factor V deficiency can occur in patients with rheumatologic disorders or malignancies, patients using antimicrobial agents, or patients using topical bovine thrombin because of antibodies to factor V.[74]

In factor V deficiency, the PT and aPTT are both prolonged. Abnormal bleeding time or positive PFA-100 result is reported in approximately one-third of patients, perhaps related to a deficiency of factor V in platelet α granules.[53] Other screening test results are normal. Definitive diagnosis requires a factor V assay.

Combined Factor V and Factor VIII Deficiency

Combined deficiency of factor V and factor VIII is rare, occurring in 1 in 1 million people, with higher frequency in populations in which consanguinity is more common. In this syndrome, factor V and factor VIII levels (both antigen and activity) range from 5% to 30% of normal.[47,75] Bleeding is usually mild to moderate. Patients typically have easy bruising, epistaxis, and gum bleeding, as well as bleeding after trauma or surgery. Menorrhagia and postpartum bleeding in affected women have also been reported. Hemarthrosis can also occur. Intracranial bleeding is rare but has been reported in 1 patient of 46 reported in the 2 largest registries of this disorder (27 and 19 subjects, respectively).[76,77]

Combined deficiency of factor V and factor VIII is passed down in an autosomal-recessive fashion and is attributable to a mutation of a protein of the endoplasmic reticulum–Golgi intermediate compartment (ERGIC 53) encoded by the *LMAN1* gene. This protein has been shown to be important in facilitating protein transport from the endoplasmic reticulum to the Golgi apparatus. The decrease in factors V and VIII is, thus, attributable to defective intracellular transport and secretion unique to these 2 coagulation factors.[47] The PT and aPTT are prolonged in this disorder, with the prolongation of aPTT out of proportion to that of the PT.

Factor X Deficiency

The prevalence of factor X deficiency is 1 in 1 million in the general population and more common in populations with higher rates of consanguinity.[47] It is passed down in an autosomal-recessive pattern. As many as 1 in 500 people might be carriers of the disorder.[78] More severe deficiency would be expected to present earlier in life. Heterozygous cases might be identified incidentally by laboratory tests performed preoperatively or for another purpose.[79]

In the NARBDR, most bleeding symptoms in factor X deficiency were mucocutaneous, including easy bruising, followed by musculoskeletal bleeding. Intracranial bleeding occurred in 15% of the homozygous cohort, of which 54% had a factor X level <0.01 U/ mL. This cohort had the highest rate of ICH in the study, compared with other rare bleeding disorders. No heterozygous subjects experienced ICH.[66] Severely affected patients also present in the neonatal period with bleeding at circumcision, umbilical stump bleeding, or gastrointestinal hemorrhage.[78] The Greifswald factor X deficiency registry, which enrolls patients from Europe and Latin America, showed ICH in 21% of its cohort. ICH was reported only in patients who were homozygous and compound heterozygous.[80]

Severe liver disease can result in deficiency of all liver-produced factors, including factor X. Acquired factor X deficiency can also occur with amyloidosis, cancer, myeloma, infection, and use of sodium valproate. Acquired inhibitors to factor X have also been reported in association with upper respiratory infections and burns and usually present with active bleeding from multiple body sites.[78,80] Because of the frequency of the associated diseases, acquired factor X deficiency is actually fairly common. Although the overall rate is unknown, this disorder has been reported in up to 5% of patients with amyloidosis.[78] Therefore, diagnosis of inherited factor X deficiency in the face of concomitant medical diagnoses should be made carefully and ideally with the assistance of a pediatric hematologist.

Both the PT and aPTT are usually prolonged and correct with a 1:1 mix with normal plasma; however, with 2 types of mutations, the PT is prolonged and the aPTT is normal, whereas the opposite is true in another variant.[81] The Russell viper venom test is usually prolonged, although it can be normal in some variants.[53] A factor X assay is the definitive test, although it is important to compare results with normal levels for age and exclude vitamin K deficiency before confirming the diagnosis.

Vitamin K Deficiency

Vitamin K is required to complete the posttranslational alteration of factors II, VII, IX, and X and proteins C and S. In the absence of vitamin K, precursor proteins are synthesized by hepatic cells, but because γ-carboxyglutamic acid residues are absent, the calcium-binding sites are nonfunctional. Deficiency of vitamin K results in induced functional deficiencies of all of these proteins. If the level of functional proteins falls below 30 U/dL, bleeding symptoms can result, and the PT and/or the aPTT will be prolonged.[82]

Vitamin K deficiency bleeding (VKDB) is most often seen in newborn infants in the first days of life (in infants who do

not receive vitamin K at birth). Because their livers are still immature, synthesis of the vitamin K–dependent factors in newborn infants is 30% to 50% of adult levels. Almost all neonates are vitamin K deficient as a result of poor placental transmission of maternal vitamin K and the lack of colonization of the colon by vitamin K–producing bacteria in the neonate, although not all infants will go on to have VKDB without prophylaxis.

VKDB is divided into 3 subtypes: early, classic, and late. Early VKDB occurs primarily in infants of mothers who have been on a vitamin K–blocking medication, such as anticonvulsants, and usually occurs within hours to the first week of life. Classic-onset VKDB occurs between the first week and first month of life and is largely prevented by prophylactic vitamin K administration at birth. Late VKDB occurs from the first month to 3 months after birth.[83] This deficiency is more prevalent in breastfed babies, because human milk contains less vitamin K than does cow milk. It can be precipitated by acquired or inherited gastrointestinal tract disease. Infants with liver disease might also be susceptible.

Manifestations of VKDB are bleeding in the skin or from mucosal surfaces, bleeding from circumcision, generalized ecchymoses, large intramuscular hemorrhages, and ICH. Although VKDB is rare in countries that provide prophylaxis, more than 50% of infants with late VKDB will present with ICH.[82] VKDB is prevented in the United States by encouraging administration of vitamin K to all newborn infants. Although most states have laws that require administration, some do not. Administration of oral vitamin K prophylaxis reduces the incidence of late VKDB from 4.4 to 10.5/100 000 live births to 1.5 to 6.4/100 000 live births.[83] Intramuscular vitamin K prophylaxis prevents almost all cases of late VKDB; however, these can still occur, particularly if there is an unrecognized underlying cause of vitamin K deficiency. Secondary VKDB can occur in the setting of hepatobiliary disease, antimicrobial therapy, coumarol poisoning/rat poison ingestion, biliary atresia, and chronic diarrhea. ICH in this setting is rare but does occur.[84]

Diagnosis of VKDB is the same regardless of underlying cause. Laboratory tests show prolonged PT and possibly aPTT for age. Specific factor assays for factors II, VII, IX, and X are markedly decreased. In patients who have already received vitamin K as treatment or transfusion of plasma, measurement of proteins induced by vitamin K absence can confirm the diagnosis.[82,84]

Inherited combined deficiencies of vitamin K–dependent proteins occur when there is a mutation in the γ-glutamyl carboxylase gene or the vitamin K epoxide reductase complex. Fewer than 30 cases have been reported. Bleeding symptoms range from mild to severe, and ICH has been reported. Some patients also have dysmorphic features or skeletal defects.[85]

Defects of Fibrinogen

Abnormalities of fibrinogen can result in complete lack of the protein (afibrinogenemia), decreased levels (hypofibrinogenemia), or an abnormally functioning molecule (dysfibrinogenemia). Clinical presentations range from mild to severe bleeding, and some patients have an increased risk of thrombosis as well, depending on the causative mutation.[86,87] Fibrinogen deficiencies can also be acquired in other medical disorders, such as liver disease or consumptive coagulopathy.[87]

Severe disorders of fibrinogen result in prolongation of PT and aPTT, but milder disorders might be missed by these screening tests. Thrombin time tests conversion of fibrinogen to fibrin and is more sensitive to both deficiencies and abnormalities of fibrinogen than are PT and aPTT. Reptilase time is similar to thrombin time, except that it is not affected by heparin and might help distinguish hypofibrinogenemia from dysfibrinogenemia because of its slightly different mechanism of action. One can also measure the amount of fibrinogen antigen through a variety of methods.[87]

Most patients with dysfibrinogenemia are asymptomatic. Bleeding, when it is present, is typically mild and triggered by surgery or trauma, and thrombosis can occur. The presence of a bleeding or thrombotic phenotype is dependent on the underlying mutation.[88] One case report of ICH and cephalhematomas in a child with suspected dysfibrinogenemia has been published. The case in that report was unique in that the patient had a long history of bleeding and almost undetectable fibrinogen levels. In addition, the patient appeared to inherit his disease in a double heterozygous-recessive manner from consanguineous parents, in contrast to most cases, which are autosomal dominant in nature.[89]

Overall, bleeding symptoms in afibrinogenemia are variable and can range from mild to life threatening. ICH has been reported in patients with afibrinogenemia (5% to 10% of patients).[90,91] Up to 85% of patients present in the neonatal period with umbilical cord bleeding.[92]

Defects of Fibrinolysis

Fibrinolysis refers to the breakdown of the fibrin clot and is directed by plasmin. Plasmin is generated from plasminogen by the actions of plasminogen activators. The inhibitors of this action are α-2 antiplasmin (AP, also known as α-2 plasmin inhibitor

and plasmin inhibitor), thrombin-activatable fibrinolysis inhibitor, and plasminogen activator inhibitor type 1 (PAI-1). Deficiencies in AP and PAI-1 have been described, although both are rare.[93,94]

Patients with PAI-1 deficiency have been described as having mild to moderate bleeding symptoms, such as epistaxis, menorrhagia, and delayed bleeding after surgery or trauma. Spontaneous bleeding is rare. Diagnosis of PAI-1 deficiency can be problematic in that the laboratory assay used for diagnosis is inaccurate at low levels. Normal ranges often are reported beginning at 0, creating a large crossover between those patients with an abnormality in PAI-1 and healthy individuals. Only 2 of the reported deficiencies of PAI-1 have been correlated with an underlying genetic defect.[94] In 1 large kindred in whom a null mutation was identified, ICH and bleeding into joints were reported after mild trauma.[95] ICH has been reported in 2 adults in whom the only underlying coagulation abnormality identified was a low PAI-1 level. One adult also had osteogenesis imperfecta (OI).[96,97]

There have been approximately 40 cases of AP deficiency reported in the literature. AP deficiency is inherited in an autosomal-recessive pattern, although heterozygous patients can also present with bleeding. Acquired deficiency has also been reported in patients with liver disease, disseminated intravascular coagulation, and acute promyelocytic leukemia. Homozygous patients tend to have severe bleeding similar to that seen in factor XIII deficiency, although ICH has not been reported. Heterozygous patients can have bleeding in response to trauma, surgery, or dental procedures or can be asymptomatic.[93,98] Intramedullary hematomas of long bones, which can occur without a history of trauma, are an unusual feature of homozygous AP deficiency.[99,100] Similar lesions have been seen in patients with afibrinogenemia. A shortened euglobulin lysis time can be used as a screening test for AP deficiency. Definitive diagnosis requires measurement of AP antigen and activity.[101]

Congenital Platelet Abnormalities

Platelets interact with VWF to adhere to sites of vessel wall injury. Subsequent activation and aggregation of platelets, which includes the release of granular contents, leads to formation of a platelet plug. Congenital platelet disorders can result in fewer platelets, abnormal function of platelets, or a combination of the two. There is a wide range in the presenting symptoms of these disorders, from mild mucocutaneous bleeding to severe life-threatening hemorrhage.[102]

The most severe and best-characterized platelet function disorders are also the rarest. These are the autosomal recessive disorders Bernard-Soulier syndrome (BSS) and Glanzmann thrombasthenia (GT). BSS results from absence or abnormal function of the GP Ib-IX-V receptor, which is responsible for platelet adhesion to VWF. Patients with BSS also commonly have mild thrombocytopenia with enlarged platelet size. In GT, the $\alpha IIb\beta 3$ platelet integrin is abnormal or missing, leading to impaired platelet aggregation, but the platelet count is normal. In both of these disorders, significant mucocutaneous bleeding and ICH have been reported, although ICH is rare, occurring in only 0.3% to 2.0% of patients with GT and even less in those with BSS.[103,104] The PFA-100 is a fairly reliable screening mechanism for these diagnoses (Table 1).[102,103]

Less well characterized but more common, the disorders of platelet signaling and secretion result from a variety of defects. Platelet activation leads to a conformational change in the platelet and normally results in secretion of platelet granule contents, which recruits other platelets to the site of injury. Without this response, platelets are unable to recruit other platelets. This group of disorders includes Quebec platelet disorder, the MYH9-related disorders, Scott syndrome, Hermansky-Pudlak syndrome, Chediak-Higashi syndrome, and Wiskott-Aldrich syndrome. Most bleeding with these disorders is mild and manifests as excessive bruising or menorrhagia. The PFA-100 does not reliably screen for these disorders.[105] More specific platelet aggregation and secretion testing is required, and occasionally, electron microscopic examination or genetic mutation testing is necessary to confirm the diagnosis.[102] All forms of genetic inheritance have been reported. Most patients with these disorders present with mucocutaneous bleeding manifestations or bleeding after surgery or trauma. Bleeding symptoms are variable and dependent on the specific defect. Joint bleeding can occur in some disorders. ICH has been reported after childbirth in neonates and trauma in older individuals. Some platelet function disorders are part of syndromes with associated physical findings. Individual review of these entities is outside of the scope of this report.[106,107] Of note, a variety of medications can lead to platelet dysfunction (eg, nonsteroidal antiinflammatory drugs, sodium valproate); therefore, a careful medication history should be obtained before diagnosing a congenital platelet abnormality.[108] Acquired thrombocytopenia, whether from medication, immune thrombocytopenia (ITP), maternal ITP, or neonatal alloimmune thrombocytopenia, should be readily diagnosed on the basis of a complete

blood cell count. The rate of ICH in patients with idiopathic ITP is <1%.[109]

Vascular Disorders

Certain vascular disorders can present with bruising or bleeding. Two disorders that might be confused for abuse are outlined. Discussion of all vascular disorders is outside of the scope of this report but can be found elsewhere.[110]

Ehlers-Danlos

Ehlers-Danlos syndrome (EDS) consists of a group of genetically and clinically heterogeneous connective tissue diseases that might be mistaken for child abuse.[111,112] The exact prevalence of EDS is unknown but is estimated to be 1 in 5000.[113] There are 6 genetic subtypes, which differ in the underlying biochemical defect, inheritance pattern, and clinical symptoms[114]; however, prominent bruising and bleeding are seen in all subtypes.[115] Mutations in collagen type I, type III, type V, or the genes involved in processing type I collagen result in most EDS subtypes. The tendency to bleed and/or bruise in EDS is caused by an abnormal capillary structure with deficiency of normal perivascular collagen. Cutaneous blood vessels are poorly supported and can rupture when subject to shearing forces. Tests for bleeding disorders are generally normal, except for the Hess test, which can be abnormal, indicating capillary fragility.[115] Clinically, the disorder manifests itself with easy bruising, bleeding gums, prolonged bleeding after surgical procedures, and menorrhagia. When evaluating children with possible abusive findings, pediatricians should assess for the typical signs of EDS. Skin hyperextensibility describes skin that extends easily and snaps back after release and is best tested at the volar surface of the forearm.[115] Widened, thin scarring often occurs at knees, shins, elbows, and the forehead.[115] Joint hypermobility is also often seen.

The vascular type of EDS, also known as EDS type IV, particularly might be confused with child abuse.[111] The precise prevalence is not known but has been estimated to be 1 in 250 000.[116,117] Both autosomal-recessive and -dominant inheritance patterns, as well as sporadic mutations, have been described.[118] The clinical diagnosis is made on the basis of 4 criteria: easy bruising; skin with visible veins; characteristic facial features; and rupture of arteries, uterus, or intestines.[114] The diagnosis is confirmed by the demonstration that cultured fibroblasts synthesize abnormal type III procollagen molecules or by the identification of a mutation in the gene for type III procollagen (*COL3A1*).[119] Excessive bruising is the most common presentation, but other severe complications, such as spontaneous rupture of the bowel and hemorrhagic pneumothorax, can occur. Vascular ruptures, including renal or splenic arteries, aneurysmal rupture, or stroke can also occur. ICH, including subdural hemorrhage, has only very rarely been described, and findings would likely not be confused with those commonly seen in inflicted head injury.[118,120] Severe complications are rare in childhood.[116] Joint hypermobility is often limited to the small joints of the hands. Skin hypermobility is typically not present, but the skin is often translucent, showing a visible venous pattern.[121,122] The characteristic facial appearance includes prominent eyes, pinched nose, small lips, hollow cheeks, and lobeless ears.[117,121]

If clinical suspicion exists, the diagnosis of most subtypes of EDS can be evaluated with biochemical and molecular analysis. Cultured skin fibroblasts can be used for gel electrophoresis of collagen types I, III, and V. For the vascular subtype (EDS type IV), biochemical analysis of type III procollagen identifies more than 95% of patients, whereas molecular screening of the *COL3A1* gene identifies up to 99% of mutations.[117,119]

OI

OI is a heterogeneous group of diseases characterized by bone fragility, dentinogenesis imperfecta, and adult hearing loss.[123] OI has been associated with easy bruising and ICH after minimal or no trauma.[124,125] Bleeding diathesis in OI is thought to occur as a result of platelet dysfunction and capillary fragility.[126,127]

Inheritance is generally autosomal-dominant, but autosomal-recessive inheritance and new mutations are known to occur. Most cases are the result of mutations in *COL1A1* and *COL1A2*. At least 8 types of OI are known to exist, and the prevalence is approximated at 1 in 15 000 to 1 in 20 000.[128,129]

Testing for OI by using DNA sequencing or collagen analysis is available. Sensitivities and specificities vary depending on the type of OI, but approximately 90% of individuals with OI types I, II, III, and IV (but none with OI types V, VI, VII, or VIII) have an identifiable mutation in either *COL1A1* or *COL1A2*.[125] Rare case reports have attributed multiple varieties of ICH, including subdural hematomas in children, to OI.[130–134] Additionally, 3 cases of relatively minor retinal hemorrhages coupled with subdural hematomas have been reported after trivial trauma in patients with OI type 1.[124] Despite these case reports, OI is a rare condition, and the occurrence of subdural hematomas and/or retinal hemorrhages attributable to OI is exceedingly rare.

Despite the reported associations of OI with easy bruising, no large-scale studies have characterized the

frequency and nature of bruising in children with OI or compared these patterns to nonabused children without OI or abused children. In children with bruises only, in the absence of other clinical indicators of OI, such as short stature, blue sclera, wormian or demineralized bones, or family history, it is generally not necessary to rule out OI via collagen or DNA testing.

Unsupported Hypotheses

Many alternative hypotheses have been proposed to explain bruising or bleeding concerning for abuse that are not supported by scientific evidence. It is outside of the scope of this report to discuss all hypotheses of this nature. Two of the more common are intracranial findings concerning for abuse caused by the effects of vaccines or by intracranial thrombosis.

Vaccines Mimicking Abusive Head Trauma

Some have proposed that vaccines cause findings that might be confused with abusive head trauma.[135–137] The hypothesized mechanism is a combination of ascorbate (vitamin C) depletion and foreign protein in vaccines causing a high histamine level, which then leads to capillary fragility and venous bleeding. No scientific evidence exists to support the hypothesis that immunizations cause findings that might be confused with inflicted trauma.

Intracranial Venous Thrombosis Mimicking Abusive Head Trauma

The incidence of intracranial venous thrombosis in children is estimated to be 0.67 cases per 100 000 children per year.[138] Of these, approximately 28% involve hemorrhagic venous infarction; thus, the incidence of hemorrhagic venous infarction is 0.19 cases per 100 000 children per year.[138] Common congenital associations include factor V Leiden, prothrombin gene mutation, protein C or S deficiency, and antithrombin deficiency. Other causes include infections (eg, otitis media, mastoiditis, sinusitis), dehydration, and trauma. Affected infants typically present with seizures and diffuse neurologic signs.[138] No studies have systematically compared characteristics of ICH resulting from intracranial thrombosis with characteristics of ICH resulting from trauma. A single study evaluating nontraumatic intracranial venous thrombosis detected no subdural hematoma in the study population (n = 36).[139] Additionally, bleeding from intracranial thrombosis has a typical appearance on magnetic resonance imaging, including localized bleeding near the thrombus, typically in an intraparenchymal distribution. This appearance is in contrast to the typical presenting features of deceleration head trauma, including thin-film subdural hemorrhages involving the interhemispheric region and the cerebral convexities.[22] If there is concern for intracranial thrombosis, magnetic resonance venography is the test of choice. Given the significant difference in appearance of ICH as a result of intracranial venous thrombosis in comparison with ICH from deceleration trauma, confusion between the 2 conditions should not exist.

INTERPRETATION OF TESTS

It should be noted that aPTT can be falsely prolonged in certain conditions, such as in the presence of a lupus anticoagulant, or can be prolonged and not indicate a true bleeding disorder, such as in factor XII deficiency or other contact factor deficiencies. In addition, patients who suffer a traumatic brain injury often have a transient coagulopathy that does not reflect an underlying congenital disorder.[140,141] It should also be noted that coagulation tests are very sensitive to specimen handling and should be performed in laboratories experienced with these assays. Inappropriate handling commonly leads to false-positive results.

Patients who have sustained significant trauma also might receive transfusions of blood products. Fresh-frozen plasma (FFP) is prepared by separating the liquid portion of blood from the cellular portion after the collection of whole blood or by collecting the liquid portion of blood by using apheresis technique. By definition, each milliliter of FFP contains 1 unit of all normal coagulation factors and inhibitors of coagulation, but in general, 10 to 20 mL/kg will raise factor levels only by 15% to 25%.[142]

Cryoprecipitate is prepared by thawing FFP and refreezing the precipitate. It contains high concentrations of fibrinogen, factor VIII, VWF, and factor XIII. Each coagulation factor has a different half-life (Table 4). Therefore, the administration of FFP or cryoprecipitate will affect the investigation for a coagulation factor deficiency differently depending on the factor being measured.

FREQUENCY OF THE CONDITION AND MEDICAL PROBABILITY

Specific data regarding the prevalence of bleeding disorders within the population of children with ICH or subdural hemorrhage are not available; however, there are data on the frequency of ICH as a result of specific bleeding disorders. If the prevalence of a condition and the frequency of a particular presentation of that condition are known, a physician can construct the probability of that specific condition (bleeding disorder) resulting in the specific presentation (ICH):

$$P(B) = \text{Prev}(A) \times \text{Prev}(B|A),$$

where B is ICH attributable to condition A, P is probability, and Prev is prevalence. For example, factor XIII deficiency is extremely rare, occurring at an

TABLE 4 Half-Lives of Coagulation Factors

Factor	Half-Life Postinfusion, h
Fibrinogen	96–150
II	60
V	24
VII	4–6
VIII	11–12
IX	22
X	35
XI	60
XIII	144–300
VWF	8–12

upper limit estimated population prevalence of 1 in 2 million; however, it can present with isolated intracranial bleeding in up to one-third of cases.[59] The estimated probability that factor XIII deficiency will cause an ICH in a person in the population at large is:

(Prevalence of factor XIII deficiency)
× (Prevalence of ICH in factor XIII deficiency)
$(1/2 \text{ million}) \times (1/3) = 1/6 \text{ million}$

Table 5 contains probabilities for congenital bleeding disorders to cause ICHs in the population at large. No calculation was made in situations in which no reliable estimates of prevalence of the condition or frequency of ICH exist. The most liberal prevalence and frequency numbers were used, so as to provide the upper limits of probability.

CONCLUSIONS

In cases of suspected abuse involving bruising and/or bleeding, physicians must consider the possibility of coagulopathies causing or contributing to the findings. In many cases, the possible coagulopathies can be effectively evaluated by a thorough history and physical examination, and possibly by the specific nature of the child's findings; however, in some cases, a laboratory evaluation for coagulopathies might be necessary. The diagnosis of a bleeding disorder does not automatically rule out the presence of nonaccidental trauma. Because of the chronic nature of their disease, children with bleeding disorders may be at higher risk of abuse.[143]

Limited evidence exists comparing bruising and bleeding in children with coagulopathies with child victims of abuse. Conducting such studies would be difficult, given the overall rarity of coagulopathies; however, large databases exist for rare hematologic conditions, and modification of these databases to include factors, such as location of bruising or location/character of ICH, which would assist in discriminating between bleeding disorders and abuse, would be beneficial. In the absence of such data, physicians must use existing data, including epidemiologic and clinical factors, in their decision-making process.

TABLE 5 Probabilities for Congenital Coagulopathies to Cause ICH[a]

Condition	Prevalence of Condition, Upper Limits	Prevalence of ICH, Upper Limits	Probability[b]
VWD	1/1000	Extremely rare	Low
Factor II deficiency	1/1 million	11%	1/10 million
Factor V deficiency	1/1 million	8% of homozygotes	1/10 million homozygotes
Combined factors V and VIII deficiency	1/1 million	2%	1/50 million
Factor VII deficiency	1/300 000	4%–6.5%	1/5 million
Factor VIII deficiency	1/5000 males	5%–12%	1/50 000 males
Factor IX deficiency	1/20 000 males	5%–12%	1/200 000 males
Factor X deficiency	1/1 million	21%	1/5 million
Factor XI deficiency	1/100 000	Extremely rare	Low
Factor XIII deficiency	1/2 million	33%	1/6 million
AP deficiency	40 cases reported	Not reported	Low
PAI-1 deficiency	Extremely rare	Common	Low
Afibrinogenemia	1/500 000	10%	1/5 million
Dysfibrinogenemia	1/1 million	Single case report	Low

[a] The probability of having a specific bleeding disorder increases in the setting of a family history of that specific named bleeding disorder or if the patient is from an ethnicity in which a specific bleeding disorder is more common (eg, Ashkenazi Jewish people and factor XI deficiency).

[b] "Probability" indicates the probability that an individual in the general population would have the following specific coagulopathy causing an ICH.

Evaluation for Bleeding Disorders in Suspected Child Abuse

• *Clinical Report*

CLINICAL REPORT

Evaluation for Bleeding Disorders in Suspected Child Abuse

abstract

FREE

Bruising or bleeding in a child can raise the concern for child abuse. Assessing whether the findings are the result of trauma and/or whether the child has a bleeding disorder is critical. Many bleeding disorders are rare, and not every child with bruising/bleeding concerning for abuse requires an evaluation for bleeding disorders. In some instances, however, bleeding disorders can present in a manner similar to child abuse. The history and clinical evaluation can be used to determine the necessity of an evaluation for a possible bleeding disorder, and prevalence and known clinical presentations of individual bleeding disorders can be used to guide the extent of the laboratory testing. This clinical report provides guidance to pediatricians and other clinicians regarding the evaluation for bleeding disorders when child abuse is suspected. *Pediatrics* 2013;131:e1314–e1322

INTRODUCTION

Children often present for medical care with bleeding or bruising that can raise a concern for child abuse. Most commonly, this occurs with cutaneous bruises and intracranial hemorrhage (ICH), but other presentations, such as hematemesis,[1] hematochezia,[2] and oronasal bleeding can be caused by child abuse and/or bleeding disorders.[3–7] When bleeding or bruising is suspicious for child abuse, careful consideration of medical and other causes is warranted. The inappropriate diagnosis of child abuse could occur,[8–10] potentially resulting in the removal of a child from a home and/or the potential prosecution of an innocent person. Conversely, attributing an abusive injury to medical causes or accidental injury puts a child at risk for future abuse and possible death.[11] Laboratory evaluations should be conducted with the understanding that the presence of a bleeding disorder does not rule out abuse as the etiology for bruising or bleeding.[9] Similarly, the presence of a history of trauma (accidental or nonaccidental) does not exclude the presence of a bleeding disorder or other medical condition. This clinical report provides guidance to pediatricians and other clinicians regarding the evaluation for bleeding disorders when child abuse is suspected (Fig 1).

ASSESSING THE NEED FOR A LABORATORY EVALUATION FOR BLEEDING DISORDERS

The age and developmental capabilities of the child, history of trauma, the location and pattern of bruising, and, in the case of ICH, findings on neuroimaging should be considered when assessing children with bruising/bleeding for possible abuse.[12–18] Additionally, a medical history of symptoms suggestive of a bleeding disorder, such as significant bleeding after a circumcision or other surgery, epistaxis, bleeding from the umbilical stump, or excessive bleeding after dental procedures, increases the possibility of a bleeding disorder. Family history of a specific bleeding disorder or ethnicity of a population with higher rates of a certain bleeding disorder (eg, Amish) might necessitate testing for that condition. The child's medications should be documented, because certain drugs can affect the results of some tests that might be used to detect bleeding disorders, such as the platelet function analyzer (PFA-100; Siemens Healthcare Diagnostics, Tarrytown, NY) and platelet aggregation testing. Caregivers might state that their child "bruises easily." These statements are difficult to assess during an evaluation for possible abuse, as they can be a sign of a bleeding disorder, a reflection of the child's (fair) skin tone, or a fabrication to mask abuse. Children who are verbal and capable of providing a history should be interviewed away from potential offending caregivers, if possible. A thorough physical examination should include an evaluation of areas of bruising that have higher specificity for abuse,[14] such as the buttocks, ears, and genitals.

Any bleeding disorder can cause cutaneous bruising, and sometimes this bruising can be mild, can appear in locations that are considered suspicious for abuse,[19] and can appear at any age. Given the extreme rarity of some bleeding disorders, it is not reasonable to perform extensive laboratory testing for bleeding disorders in every child. In some cases, the constellation of findings, taken in conjunction with the clinical history and physical examination, can be so strongly consistent with an abusive injury that further laboratory investigation for medical conditions is not warranted. For instance, a child with a patterned slap mark who describes being hit with an open hand does not require a laboratory evaluation for a bleeding disorder.

In addition to bleeding disorders, the possibility of other medical causes of easy bruising or bleeding, such as Ehlers-Danlos syndrome, scurvy, cancer and other infiltrative disorders, glutaric aciduria, and arteriovenous malformations, should be assessed, as should a history of use of any medications or alternative therapies that may increase bleeding/bruising. Comprehensive descriptions of medical conditions that could be confused with child abuse and alternative therapies that may predispose to

bleeding/bruising are beyond the scope of this report and can be found elsewhere.[20,21] Results of the history, review of systems, physical examination, and, in the case of ICH, neuroimaging are generally adequate to exclude these conditions. When there are concerns that a medical condition might be the cause of bruising or bleeding, the evaluation for the conditions in question should occur simultaneously with the evaluation for abuse.

Bruising

In the absence of independently witnessed accidental trauma or a known medical cause, any bruising in a nonmobile child is highly concerning for abuse and necessitates an evaluation for child abuse.[12–15] Additionally, bruising in a young infant could also be the first presentation of a bleeding disorder.[19] As such, a simultaneous evaluation for bleeding disorders is recommended in these cases. In mobile children, the locations and patterns of the bruising can be used to assess for the possibility of abuse (Table 1).

TABLE 1 Suspicion of Child Abuse in Ambulatory Children on the Basis of Characteristics of Bruises[14,15,17]

Less Suspicious for Child Abuse	More Suspicious for Child Abuse
Forehead	Location
Under chin	Face
Elbows	Ears
Lower arms	Neck
Hips	Upper arms
Shins	Trunk
Ankles	Hands
	Genitalia
	Buttocks
	Anterior, medial thighs
	Pattern
	Slap or hand marks
	Object marks
	Bite marks
	Bruises in clusters
	Multiple bruises of uniform shape
	Large cumulative size of bruising

In cases of bruising, the assessment of the need for an evaluation for bleeding disorders should focus on the following:

- the specific history offered to explain the bruising;
- the nature and location of bruising; and
- mobility and developmental status of the child.

The following factors generally exclude the need for an evaluation for a bleeding disorder:

- the caregivers' description of trauma sufficiently explains the bruising;
- the child or an independent witness is able to provide a history of abuse or nonabusive trauma that explains the bruising; or
- abusive object or hand-patterned bruising is present.

The injury history offered by caregivers might be purposefully misleading if the caregivers have caused the bruising by abusive means.

In nonmobile infants, bleeding disorders can present with bruising or petechiae in sites of normal handling or pressure. Examples of this include the following:

- petechiae at clothing line pressure sites;
- bruising at sites of object pressure, such as in the pattern and location of infant seat fasteners; and
- excessive diffuse bleeding if the child has a severe bleeding disorder.

Absence of these examples does not rule out a bleeding disorder; however, their presence might increase the probability of a bleeding disorder.

ICH

Excepting obvious known trauma, ICH in a nonmobile child is highly concerning for child abuse. Children can suffer ICH, such as a small subdural or an epidural hematoma underlying a site of impact, from a short fall; however, short falls rarely result in significant brain injury.[16] Birth trauma and some medical conditions can also result in ICH in infants. Consultation with a child abuse pediatrician should be considered in complex or concerning cases.

No studies have systematically compared the presentation, clinical findings, patterns of ICH, or presence of retinal hemorrhages found in children with bleeding disorders with those found in children in whom abusive head trauma is diagnosed. However, bleeding disorders can cause ICH in any part of the cranial contents, and up to 12% of children and young adults with bleeding disorders have had ICH at some time.[22,23] Children with ICH concerning for abuse require an evaluation for bleeding disorders. Exceptions to required evaluation can include the following:

- Independently witnessed or verifiable trauma (abusive or nonabusive),
- Other findings consistent with abuse, such as fractures, burns, or internal abdominal trauma.

Other Bleeding Symptoms

Children with conditions such as hematemesis, hematochezia, or oronasal bleeding as presenting symptoms should be evaluated on a case-by-case basis for possible abuse, particularly child abuse in a medical setting. Medical conditions and/or child abuse can cause these findings.

BLEEDING DISORDERS AND EXTENT OF EVALUATION

Bleeding disorders that can produce patterns of bruising or bleeding that mimic abuse include coagulation factor deficiencies/abnormalities, fibrinolytic

defects, defects of fibrinogen, and platelet disorders. Table 2 contains a listing of the most common bleeding disorders in children and characteristics of potential testing strategies for each disorder. Most factor deficiencies can be detected by the prothrombin time (PT) and activated partial thromboplastin time (aPTT); however, von Willebrand disease (VWD) and factor XIII deficiency are not reliably detected by these screening tests. Additionally, mild deficiencies in factor VIII or factor IX (mild hemophilia) might not cause abnormalities in the aPTT but might still result in significant bleeding, including ICH, particularly after mild trauma. Fibrinolytic defects can cause significant bleeding/bruising but are extremely rare and require specific testing. Defects of fibrinogen are also rare and can be detected by the fibrinogen concentration and thrombin time.

The prevalence of mild platelet disorders is unknown, and testing for mild platelet disorders is challenging. The most common clinical presentations include bruising and mucocutaneous bleeding. The prevalence of ICH in mild platelet disorders is unknown but is likely to be low. Platelet aggregation testing, best performed by a pediatric hematologist, requires a relatively large volume of blood, and interpretation of the test result requires a specialist.[25] A PFA-100 can screen for many platelet function disorders, including more severe types, such as Bernard Soulier syndrome and Glanzmann thrombasthenia, as well as many types of VWD. However, the PFA-100 is not an effective screen for some types of VWD and milder platelet abnormalities. Individual patient characteristics, such as hematocrit, platelet count, pregnancy, age, multisystem trauma, sepsis, and medications, can affect the results of the PFA-100. Accurate diagnosis often requires additional testing, such as specific von Willebrand testing or platelet aggregation; therefore, many centers have decreased or ceased use of the PFA-100.[25,26] Assessment of the results of a PFA-100 and the need for further testing are best accomplished in consultation with a pediatric hematologist.

Vitamin K Deficiency

Vitamin K deficiency in infants can result in bleeding in the skin or from mucosal surfaces from circumcision, generalized ecchymoses, large intramuscular hemorrhages, or ICH. Because of the widespread provision of vitamin K at birth, vitamin K deficiency bleeding (VKDB) is rare; however, not all states require vitamin K to be administered at birth, and some medical conditions predispose to VKDB.[24] In VKDB, there is a prolonged PT and possibly aPTT for age. In patients who have already received vitamin K, fresh-frozen plasma, or specific factor replacement as treatment, measurement of proteins induced by vitamin K absence can confirm the diagnosis.[27,28]

Coagulation Tests in Cases of Bruising

The initial screening panel in a patient who presents with bruising evaluates for conditions with a known prevalence more common than 1 per 500 000 people, including idiopathic thrombocytopenic purpura, all factor deficiencies (except factor XIII deficiency), and VWD (Fig 1). It does not evaluate for extremely rare conditions, including factor XIII deficiency, defects of fibrinogen, and fibrinolytic defects. This strategy also does not screen for extremely rare platelet disorders, such as Glanzmann thrombasthenia, and more common but relatively more difficult to detect platelet disorders, such as platelet storage pool disorders. If test results are abnormal or expanded/detailed testing is necessary or preferred, consultation with a pediatric hematologist is recommended.

In many circumstances, children with bruising that is suspicious for abuse may be removed from a potentially dangerous setting where the abuse likely occurred. A thorough physical examination performed in the weeks after removal that reveals minimal bruising and/or bruising only in locations of common accidental bruises is supportive of abuse as the cause of the original suspicious bruising. Each case must be evaluated individually, however, considering the totality of findings, and with the understanding that the need for safety must be balanced with the emotional trauma of removing a child from his or her home. Bleeding disorders are generally permanent conditions that do not result in abatement after a change in caregivers. One exception to this is immune thrombocytopenia (ITP), which is a transient, often self-resolving bleeding disorder. Screening for ITP (platelet count) is necessary at the time of presentation with bruises.

Determining the Need for a Test: The Medical Probability

Specific data regarding the prevalence of bleeding disorders in the population of children with ICH or subdural hematoma is not available. However, there are data regarding the probability of specific bleeding disorders to cause ICH. If the prevalence of a condition and the frequency of a particular presentation of that condition are known, a physician can construct the probability of that specific condition (bleeding disorder) resulting in the specific presentation (ICH). The presence of "classic" bleeding symptoms, such as bleeding after circumcision,

TABLE 2 Common Testing Strategies for Bleeding Disorders

Condition	Frequency	Inheritance	Screening Tests	Sn and Sp, %	PPV and NPV,%	Confirmatory Test
Factor abnormalities/deficiencies						
VWD type 1	1/1000	AD	PFA-100	Sn = 79–96[a]	PPV = 93.3	VWAg[b] VWF activity
				Sp = 88–96[a]	NPV = 98.2	VW multimer analysis Factor VIII activity
VWD type 2A	Uncommon	AD or AR	PFA-100	Sn = 94–100[a]	PPV = 93.3	VWAg[b] VWF activity

Factor XIII deficiency	1/2–5 million	AR	Clot solubility	Sn = variable	NA	Factor XIII activity
Fibrinolytic defects						
α-2 antiplasmin deficiency	~40 reported cases	AR	Euglobin lysis test	Sn = variable	NA	α-2 antiplasmin activity
PAI-1 deficiency	Very rare	AR		Sn = variable	NA	PAI -1 antigen and activity
Defects of fibrinogen						
Afibrinogenemia	1/500 000	AR	PT, aPTT	Sn = high	NA	Fibrinogen level
Hypofibrinogenemia	Less than afibrinogenemia		PT, aPTT	Sn = variable	NA	Thrombin time, fibrinogen activity
Dysfibrinogenemia	1/million		Thrombin time, fibrinogen level	Sn = variable	NA	Thrombin time, fibrinogen antigen and activity level comparison, reptilase time
Platelet disorders						
ITP	Age-related	NA	CBC	Sn = high	NA	Antiplatelet Ab (rarely needed)
Glanzmann thrombasthenia	Very rare	AR	PFA-100	Sn = 97–100	NA	Platelet aggregation testing Flow cytometry

TABLE 2 Continued

Condition	Frequency	Inheritance	Screening Tests	Sn and Sp, %	PPV and NPV,%	Confirmatory Test
Bernard Soulier syndrome	Rare	AR	PFA-100	Sn = 100	NA	Platelet aggregation testing Flow cytometry
Platelet release/storage disorders	Unknown, more common than other platelet function disorders	variable	PFA-100	Sn = 27–50	NA	Platelet aggregation and secretion Electron microscopy Molecular and cytogenetic testing

AD, autosomal dominant; AR, autosomal recessive; CBC, complete blood cell (count); NA, not available or not applicable; NPV, negative predictive value; PAI-1, plasminogen activator inhibitor-1; PPV, positive predictive value; RVV, Russell viper venom (test); Sn, sensitivity; Sp, specificity; VW, von Willebrand; VWAg, von Willebrand antigen; VWF, von Willebrand factor Ab, antibody.

[a] Values derived from data before 2008 National Institutes of Health Consensus guidelines. Sn and Sp using current diagnostic cutoffs unknown but would be expected to have higher Sp with lower Sn.

[b] May be reasonable to proceed directly to diagnostic testing depending on availability. See accompanying technical report for detailed discussion.[24]

umbilical stump bleeding, joint hemorrhage, and excessive soft tissue bleeding, increase the probability for a bleeding disorder; however, these findings are neither sensitive nor specific for bleeding disorders.

Coagulation Tests in the Setting of ICH

For bleeding disorders that cause ICH, the prevalence of the bleeding disorder and the prevalence of ICH in patients with each specific bleeding disorder can be used to construct the probability of the specific bleeding disorder to cause ICH (Table 3). Some probabilities are so low as to preclude calculation. Testing for these conditions is likely not useful. Mild hemophilia, which might be missed if only an aPTT test is ordered, can be detected by measuring specific levels of factor VIII and factor IX. Mild hemophilia can result in ICH, particularly after mild trauma, and because of the relatively high prevalence of the condition, the probability of mild factor VIII deficiency causing or contributing to ICH is 1 in 280 000 males. In populations with a high prevalence of factor XI deficiency, such as the Ashkenazi Jewish population, it might be reasonable to measure factor XI level.

Clinical and historical information can be used to determine the need for testing in children with isolated ICH concerning for abuse (Fig 1). The initial testing panel for ICH evaluates for conditions for which the probability for the condition resulting in ICH is greater than 1 per 5 million. The panel includes testing for most factor deficiencies and afibrinogenemia. This screening panel does not test for factor XIII deficiency, VWD, fibrinolytic defects, hypofibrinogenemia, and dysfibrinogenemia. These conditions either have not been associated with ICH or they are so rarely the cause of ICH that testing for the conditions is not reasonable. Additionally, the initial screening panel evaluates for disseminated intravascular coagulation (DIC). Because DIC can cause any type of bruising/bleeding, including ICH, the finding of DIC in the context of suspected child abuse could significantly change the clinical approach to a patient. In children with DIC and bleeding symptoms as the only finding concerning for abuse, consideration must be given to the multitude of primary causes of DIC, including trauma, sepsis, and primary bleeding disorders, among many others.

Many children with ICH suspicious for abuse, if they survive, are placed in safe settings after hospital discharge. In these cases, testing for bleeding disorders can be deferred to a later date, with the exception of ITP. If blood products have been given to the patient, as can happen in severe ICH, the definitive evaluation for bleeding disorders should be postponed until the transfused blood components are no longer in the patient's system (Table 4). Assistance from a pediatric hematologist should be considered in addressing the possibility of factor deficiencies after a transfusion has occurred.

Many aspects of bleeding disorders are under investigation, and thus, changes in the understanding of the prevalence and severity of certain bleeding symptoms related to these disorders should be expected. For example, although hemophilia A and B are X-linked diseases and, therefore, typically thought to affect only male individuals, 25% to 50% of female carriers of hemophilia report excess bleeding; therefore, measurement of factor VIII and IX levels in female patients should be considered.[29] In addition, the population prevalence and/or clinical effects of mild platelet function disorders continue to be studied. In a patient with mucocutaneous symptoms, particularly if petechiae are

TABLE 3 Probabilities for Congenital Coagulopathies Causing ICH[a]

Condition	Prevalence of Condition, Upper Limits	Prevalence of ICH, Upper Limits	Probability[b]
VWD	1/1000	Extremely rare	Low
Factor II deficiency	1/1 million	11%	1/10 million
Factor V deficiency	1/1 million	8% of homozygotes	1/10 million homozygotes
Combined factors V and VIII deficiencies	1/1 million	2%	1/50 million
Factor VII deficiency	1/300 000	4%–6.5%	1/5 million
Factor VIII deficiency	1/5000 males	5%–12%	1/50 000 males
Factor IX deficiency	1/20 000 males	5%–12%	1/200 000 males
Factor X deficiency	1/1 million	21%	1/5 million
Factor XI deficiency	1/100 000	Extremely rare	Low
Factor XIII deficiency	1/2 million	33%	1/6 million
α-2 antiplasmin deficiency	40 cases reported	Not reported	Low
Plasminogen activator inhibitor-1 deficiency	Extremely rare	Common	Low
Afibrinogenemia	1/500 000	10%	1/5 million
Dysfibrinogenemia	1/1 million	Single case report	Low

[a] The probability of having a specific bleeding disorder increases in the setting of a family history of that specific named bleeding disorder or if the patient is from an ethnicity in which a specific bleeding disorder is more common (eg, Ashkenazi Jewish people and factor XI deficiency).
[b] "Probability" indicates the probability that an individual in the general population would have the following specific coagulopathy causing an ICH.

present, platelet aggregation testing should be considered.[25] Finally, because von Willebrand factor is an acute phase reactant, its levels can vary in response to clinical status, resulting in falsely elevated results. Many times, testing must be repeated up to 3 times to ensure reliable results.[30] If significant concern for VWD exists, consultation with a pediatric hematologist is suggested.

When Testing Indicates a Possible Bleeding Disorder in the Context of an Abuse Evaluation

Positive laboratory test results require further evaluation for the possibility of false-positive results and/or the necessity for further testing. Prolongation of the PT and aPTT because of parenchymal damage has been noted in abusive head trauma and should not automatically be interpreted as evidence of a primary bleeding disorder.[31] Additionally, consideration must be given to the likelihood of a preexisting bleeding disorder as the primary cause of a child's bleeding/bruising. For example, given the relatively high prevalence of VWD, it is inevitable that some children with VWD will be abused and present with bleeding/bruising symptoms. Determining the causative factor in these situations is challenging. Bruising is a common finding in VWD. If a child has test results consistent with VWD and bruising concerning for abuse, a short-term change in home setting may be considered, understanding the cautions needed when using this approach. Only a few case reports have attributed ICH to VWD. Most reported ICH in children with VWD would not be confused with typical abusive ICH.[32–34] Given the rarity of ICH in VWD, particularly spontaneous ICH, testing consistent with VWD does not mean that ICH is definitively attributable to VWD, and abuse must still be considered.

TABLE 4 Half-Lives of Coagulation Factors

Interpretation of Tests

It should be noted that the aPTT can be falsely prolonged in certain circumstances, such as in the presence of a lupus anticoagulant, or can be prolonged and might not indicate a true bleeding disorder, such as in factor XII deficiency or other contact factor deficiencies. In addition, patients who experience a traumatic brain injury often have a transient coagulopathy that does not reflect an underlying congenital disorder.[31,35] Coagulation tests are very sensitive to specimen handling and should be performed in laboratories experienced with these assays. Inappropriate handling commonly leads to false-positive results.

CONCLUSIONS

Children who present with bleeding and bruising symptoms that are concerning for abuse require careful evaluation for the potential of bleeding disorders as a cause. No single panel of tests rules out every possible bleeding disorder. Given the rarity of most bleeding disorders and the possible presence of specific clinical factors that decrease the likelihood of a bleeding disorder causing a child's findings, in many situations, extensive laboratory evaluation is not

necessary. If a laboratory evaluation is conducted, tests should be chosen on the basis of the prevalence of the condition, patient and family history, ease of testing, blood volume required for testing, and, in the case of ICH, probability of a bleeding disorder causing ICH. Further consultation with a pediatric hematologist is recommended if specific, expanded testing is necessary, if preliminary testing suggests the presence of a bleeding disorder, if testing to rule out a specific bleeding disorder is needed, or if testing for very rare conditions is preferred.

GUIDANCE FOR PEDIATRICIANS

In children who have bruising or bleeding that is suspicious for abuse,

1. Complete medical, trauma, and family histories and a thorough physical examination are critical tools in evaluating for the possibility of abuse or medical conditions that predispose to bleeding/bruising.
2. In each case, careful consideration of the possibility of a medical condition causing the bleeding/bruising is essential. Specific elements of the history and characteristics of the bleeding/bruising can be used to determine the need for a laboratory evaluation for bleeding disorders.
3. If the evaluation indicates a need for laboratory testing for bleeding disorders, initial testing is focused on the prevalence of the condition and potential of each specific condition to cause the specific findings in a given child (Fig 1).
4. Laboratory testing suggestive or indicating the presence of a bleeding disorder does not eliminate abuse from consideration. In children with bruising and laboratory testing suggestive of a bleeding disorder, a follow-up evaluation after a change in home setting can provide valuable information regarding the likelihood of a bleeding disorder causing the concerning findings.
5. Children with ICH often receive blood product transfusions. It is suggested that screening for bleeding disorders in these patients be delayed until elimination of the transfused blood clotting elements.
6. The discovery of new information regarding condition prevalence, laboratory testing, and clinical presentations of bleeding disorders is to be expected. Close collaboration with a pediatric hematologist is necessary to ensure the most current evaluation and testing methods.

The Evaluation of Children in the Primary Care Setting When Sexual Abuse Is Suspected

• *Clinical Report*

CLINICAL REPORT

The Evaluation of Children in the Primary Care Setting When Sexual Abuse Is Suspected

abstract

FREE

This clinical report updates a 2005 report from the American Academy of Pediatrics on the evaluation of sexual abuse in children. The medical assessment of suspected child sexual abuse should include obtaining a history, performing a physical examination, and obtaining appropriate laboratory tests. The role of the physician includes determining the need to report suspected sexual abuse; assessing the physical, emotional, and behavioral consequences of sexual abuse; providing information to parents about how to support their child; and coordinating with other professionals to provide comprehensive treatment and follow-up of children exposed to child sexual abuse. *Pediatrics* 2013;132:e558–e567

INTRODUCTION

Sexual abuse of children and adolescents is a common problem that is potentially damaging to their long-term physical and psychological health. The Fourth National Incidence Study on Child Abuse and Neglect[1] estimated that in 2006, 1.8 children per 1000 (or a total of 135 300 children) were victims of sexual abuse. Other national studies have found that 5% to 25% of adults reported being sexually abused as children, depending on the population studied and the methods used to define sexual abuse.[2–7] Pediatricians are likely to care for sexually abused children in their practices, even though many victims wait years before telling anyone about their abuse.[8,9] More than half of sexually abused children do not disclose their abuse until they are adults.[10]

A history of childhood sexual abuse can have lifelong deleterious effects on a child's physical and mental health. Sexual abuse increases the risk of developing posttraumatic stress disorder, anxiety disorder, depression,[11,12] low self-esteem,[13] and social phobias.[14] Children exposed to sexual abuse are more likely to need hospitalization for mental illness.[15] Adult survivors of child sexual abuse are more likely to become victims of intimate partner violence and sexual assault.[16,17] They are at higher risk of developing obesity,[18] sexual problems,[19] irritable bowel syndrome,[20] fibromyalgia,[21] and sexually transmitted infections (STIs), including infection with the human immunodeficiency virus (HIV).[22,23] They use more medical services as adults than those without a history of child sexual abuse[21,24] and are more likely to develop addictions to tobacco, drugs, and alcohol.[25–27]

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

In summary, child sexual abuse occurs commonly and can have lifelong effects on victims' physical and mental health. When the issue of possible sexual abuse is raised in the clinical setting, it is important for pediatricians to know how to respond to and evaluate the child, when to refer the child for evaluation by other professionals, when to report the case to the appropriate investigative agency, and how to counsel parents to decrease the long-term deleterious effects of the abuse. This clinical report updates an American Academy of Pediatrics (AAP) report from 2005 titled "The Evaluation of Sexual Abuse in Children."[28]

RESPONDING TO A PARENT'S CONCERN ABOUT POSSIBLE SEXUAL ABUSE

When a parent brings up the possibility of sexual abuse of his or her child, the pediatrician should immediately exclude the child from the discussion. Children (particularly young children) might be influenced by hearing their parents' concerns about abuse. Sometimes parents are overconcerned about normal childhood sexual behavior.[29] In those cases, reassuring and educating the parents will probably assuage their fears. Parents' overconcern could be related to their own adverse experiences in childhood, and in such cases, a more in-depth assessment to assist the parent is needed. Occasionally, parents might have concerns about possible sexual abuse because of relationship issues that arise between caregivers. Many of these concerns are raised in good faith but ultimately unfounded. Notwithstanding these caveats, every concern about possible sexual abuse should be approached objectively, thoughtfully, and with an open mind.

The pediatrician faces many challenges in evaluating possible sexual abuse to determine which cases warrant an immediate intervention in the office and which cases warrant reporting to investigative agencies or referral for evaluation by other professionals. In all these cases, the pediatrician should carefully document the parent's concerns, take a detailed history of the nature of the child's disclosure from the parents' perspective, ask what questions the parent used in eliciting the disclosure, and document a complete medical history, social history, and review of systems for urogenital and behavioral problems. It is important to note in the record the source of the information documented in the medical record. For example, be sure to say, "Mother tells me that the child said . . .," rather than writing, "The child said. . . ."

Often, a child will present to the pediatrician after direct disclosure to another person regarding sexual abuse. Less commonly, a child presents to the pediatrician with an abnormal genital or anal examination, pregnancy, an STI, or sexual abuse witnessed by a third party or by discovery of sexually graphic images or videos in the possession of a potential perpetrator. The general pediatrician's response depends on what resources are available in the community. Many communities and regions have specialized clinics or child advocacy centers where children can be referred when concerns of sexual abuse arise. In areas without these resources, the general pediatrician is often the most knowledgeable professional in the community regarding the evaluation and interviewing of children. If pediatricians find that their regions do not offer specialized abuse-related services (eg, child advocacy centers or hospital-based child protection programs), it is important for them to educate themselves about childhood genital and anal examinations and about how to interview children to get enough information to make appropriate decisions about reporting to child protective service agencies, referring to counseling facilities, or referring to pediatric clinics specializing in abuse evaluations. The AAP offers a variety of educational materials on child abuse to physicians, including a comprehensive CD-ROM,[30] textbooks on child abuse,[31,32] and educational offerings at the National Conference and Exhibition.

Whenever the issue of possible child sexual abuse arises in the office setting, 5 important issues should be addressed.

1. **The child's safety.** Is the child safe to go home? Is the child at imminent risk of additional harm if sent back to an environment where a possible perpetrator has access to the child? Is the child likely to be harmed or punished for disclosing abuse? Is there concern that the child might be coerced or intimidated to recant the disclosure? If any of these questions are answered "yes" or "maybe," this is a child protection emergency, and the appropriate authorities (child protective services or law enforcement) should be contacted immediately.
2. **Reporting to child protection authorities.** If the child is not at imminent risk, the pediatrician should decide whether child protective services should be contacted about the allegation. It is important to remember that in every state, and in all provinces and territories in Canada, it is mandated that professionals report *suspected* child abuse and neglect to the appropriate government agency (child protective services or police agencies, including tribal agencies). Studies have shown that some pediatricians are hesitant to involve outside agencies,

even if they strongly suspect abuse has occurred.[33] Pediatricians worry about the intrusion of agencies into family life, the risk of the child being separated from the parents, or the possibility that the family will leave the practice if reported to a child protection agency. Some pediatricians have experienced negative interactions with child protection agencies, which could make them distrustful of an agency's response and its effect on the family.[34] Some physicians might overestimate their ability to manage the situation within their practice. Physicians should not let these concerns act as barriers to protecting a child. In the United States, physicians are protected against liability for reporting a reasonable suspicion of child abuse and neglect if the report is made in good faith. This is also the case in many other jurisdictions, but because laws can vary, it is important for physicians to be familiar with the laws that pertain to their practice. Still, the safety of the child should take precedence over the physician's fear of lawsuits.

One problem lies in the definition of *suspected.* If a parent is going through a contentious divorce and the child is having symptoms of anxiety and depression, should abuse be suspected? If a child is sexually acting out with peers, should abuse be suspected? Each pediatrician will need to consider the facts of the individual case when making the decision to report suspected child abuse while bearing in mind the statutory requirements for reporting suspected abuse in his or her state. The threshold for reporting is low. The pediatrician should report when there is a reasonable suspicion that the child was abused. The child protective services agency then has the responsibility to conduct a thorough investigation to determine whether abuse has occurred.

3. **The child's mental health.** In every case, the patient should be assessed for possible mental health problems, and if any are identified, appropriate emergency mental health care should be sought. The initial disclosure of abuse can be extremely stressful for a young person. It is important to consider the possibility that symptoms of depression and posttraumatic stress disorder might already have developed. The family might be angry at the child because the disclosure has introduced stress into the family or because the threatened loss of a family member could result in financial insecurity. A disclosure of sexual abuse is perhaps one of the most explosive events that can occur in a family.
4. **The need for a physical examination.** If sexual abuse is suspected, a thorough examination should be performed to rule out injury, particularly if a child is reporting genital or anal pain or bleeding. If the abuse occurred in the distant past and the asymptomatic child is going to be referred to a specialty center for medical evaluation, examination might be deferred. If the child reports dysuria, a urinalysis is indicated. Rarely, acute sexual assault can cause severe genital or anal injury that can lead to excessive blood loss (a medical emergency).
5. **The need for forensic evidence collection.** Children who have had recent sexual contact involving the exchange of bodily fluids should be immediately referred to a specialized clinic or emergency department capable of collecting evidence using a forensic evidence kit.[35] Many states recommend that forensic evidence be collected if less than 72 hours have passed since the assault. Some states require evidence kits to be performed as late as 96 hours after assault. Some evidence supports limiting collection of forensic evidence in prepubertal children to those who present within 24 hours after assault.[36,37] As more laboratories use DNA testing to analyze forensic specimens, however, the time for collection of useful forensic evidence might be extended beyond the current 72-hour standard.[38,39] Pediatricians should familiarize themselves with the relevant policies of the jurisdiction in which they practice. The referral center also should be capable of evaluating the child for the appropriateness of antiretroviral HIV prophylaxis,[40] postexposure prophylaxis for STIs,[41] and pregnancy prophylaxis. HIV and pregnancy prophylaxis should be given as soon after the sexual contact as possible and are not recommended more than 72 hours after contact.

INTERVIEWING CHILDREN ABOUT POSSIBLE SEXUAL ABUSE

Depending on the community services available, the pediatrician should be prepared to conduct a basic interview with a verbal child about an abuse experience. Often, this is necessary to make the appropriate decision about referral to another facility or to report to child protective services. Several fundamental guidelines inform this process.

1. If the child spontaneously discloses abuse, it is important that the person hearing the disclosure respond by telling the child it is okay to talk about it with adults. If the child begins to make a disclosure and the physician says, "I'm

not the person you should tell this to," the child might be hesitant to disclose at another time.

2. The child should be separated from the parent for the interview if at all possible. Parents can subtly or not-so-subtly influence the child's statements. Separation from the parent is particularly important if the parent is a suspected perpetrator or is supportive of the suspected perpetrator, to prevent the child from feeling intimidated or threatened. The parent will later be present for the examination if that is the child's preference.
3. If the pediatrician has not already established a relationship with the patient, some time should be spent talking about nonthreatening issues, such as school, friends, or pets. It is difficult for a child to be asked painful or embarrassing questions without first feeling safe and supported by the adult asking the questions.
4. Pediatricians should tell children that it is their job as doctors to keep children healthy and that it is okay for children to talk about difficult or uncomfortable subjects with their doctors.
5. The pediatrician should not ask leading or suggestive questions. It is important to begin with open-ended, general questions about the child's likes and dislikes or about the people in the child's family. Then ask about things the child is worried or confused about, or about things that have happened to the child that have been unpleasant or stressful. A question should never suggest an answer. Examples of open-ended questions include the following:

"Is anything bothering you?"

"Tell me why you're here today."

"Do you think he would want you to tell me what happened?"

Examples of incorrect questions are as follows:

"Who touched your privates?"

"I know that Uncle Joe hurt you; tell me about it."

6. Developmentally appropriate language should be used with the child. The terms and concepts understood by a 12-year-old are very different from those understood by a 4-year-old. Be aware of the terms the child uses for the genitalia and anus. The parents should be asked in advance which terms the family uses for private parts and bathroom activities.
7. Any descriptions of abuse given by the child should be recorded word for word (using quotation marks) in the medical record, using the child's own language, and should be attributed to the child. When practical, the response should be recorded together with the question. For example, "When asked why she was not wearing underwear, the patient answered that . . ." or "Without my asking, the child stated that. . . ." Careful notes should be taken during the interview. Video or audio recording of the interview is not needed unless this is part of the pediatrician's regular practice.
8. The child should not be urged or coerced to talk about abuse. The child should be allowed to talk about it if he or she wants to, but there should never be an expectation that the child must disclose to the professional. The child should not be rewarded after a disclosure. (For example, "Tell me what happened with Uncle Joe, and then you can go back to your mom" is not an appropriate statement.) Forcing a child who has been abused to give a disclosure can be experienced by the child as revictimization and loss of control and can make an already painful experience worse.
9. The pediatrician should remember that this is a *medical* interview and that he or she is obtaining information needed to make the appropriate diagnostic and treatment decisions. If the child makes an initial disclosure to the pediatrician, it is likely that the child will be interviewed again by another adult professional. Parents and children can be told this before the interview begins. Professionals with advanced training in forensic interviewing conduct a very different type of interview than the medical interview conducted in the clinical setting. Although it is important to avoid multiple interviews of the child, in many situations the interview will be a 2-stage process in which the initial evaluator obtains minimal facts to evaluate the need to report to the authorities, and a forensic evaluator conducts a more detailed interview.
10. The pediatrician should be supportive and empathic. Treat the patient with the same respect and caring given to all your patients. If the child tells you about abuse, show appropriate concern; do not act shocked, outraged, or dismissive.
11. Appropriate language should be used to interview children. Translators should be used if necessary, and the child's use of words to describe body parts should be understood.
12. If the pediatrician records his or her impression of the child's emotions during the examination or interview, these subjective impressions should be identified as such (eg, "It was my impression

that the child seemed agitated."). Similarly, if an observation is made that may bear on the truthfulness of the history, it should be clearly identified as separate from fact (eg, "I noted that the child and her mother used identical words when answering this same question. I therefore considered the possibility that the answers may have been rehearsed.").

THE PHYSICAL EXAMINATION WHEN SEXUAL ABUSE IS SUSPECTED

Studies have shown that pediatricians often have not been properly trained to examine the genitals and anuses of children when abuse is suspected.[42] Some of the most basic knowledge, such as the appropriate identification of anatomic structures, has not always been part of pediatric residencies or physicians' continuing education.[43,44] Appropriate techniques for evaluating children's anogenital regions are an important part of pediatric education.

When the question of sexual abuse arises in the medical setting, the pediatrician might want to consider whether the child should be triaged to another facility for evaluation, such as a child advocacy center or a specialized abuse assessment clinic at a children's hospital (after considering the safety questions discussed previously). If the pediatrician does not think that the situation constitutes an emergency, he or she should consider referring the child for evaluation if he or she is not confident that he or she has the necessary examination skills. Unnecessary multiple anogenital examinations should be avoided because they can be upsetting to a sexually abused child. On the other hand, routine examination of the genitals and anus (appropriately chaperoned)[45] during well child examinations can help patients and parents understand that anogenital health is as important as the health of other parts of the body and will familiarize pediatricians with normal anatomic structures.

The anogenital examination should be preceded by a thorough general physical examination. Children who have experienced one type of abuse also are at risk for other types of abuse or neglect. In addition, the general physical examination establishes the physician's role and is likely to be an event the child has previously experienced at a physician's office.

The nature and process of the examination should be explained to the child in age-appropriate language before the examination takes place. An appropriate chaperone must be present. Most children will want a same-gender parent in the room during the examination. If a parent is not available, a second medical professional should be in the room to reassure the child, to assist the examining physician, and to act as a chaperone. A parent or caring professional at the head of the examination table can provide support for the child as well as reasonable assurance and distraction during the examination. Use of appropriate gowns and drapes can protect the child's modesty and make the child feel less vulnerable.

The examination of the genitalia and anus does not require the use of instruments in most cases. For girls, separation of the labia and gentle labial traction while the child is supine with the knees bent and hips abducted (frog-leg position) will adequately expose the genital structures. Speculum examinations are contraindicated in prepubertal children in the office setting. If intravaginal trauma is suspected, vaginoscopy should be performed under anesthesia.

In an adolescent, an examination for sexual abuse should follow the recommendations of the AAP regarding intravaginal examination using a speculum.[46] In many cases, a speculum examination is not needed in the absence of signs or symptoms of genital disease but is usually indicated after acute vaginal sexual assault to document injuries and to collect forensic specimens.[47] Girls should receive their first cervical cytologic examination (Papanicolaou test) at 21 years of age unless there are special circumstances, such as immune suppression or infection with HIV.[46,48]

For boys, the examination of the genitals consists of inspection of the penis and scrotum, documenting any noted trauma or scarring and any other abnormalities.

Examination of the anus is performed in most cases by external inspection with gentle traction of the buttocks to expose the anal sphincter while the child is supine with the knees pulled up to the chest (cannon-ball position). Anoscopy or a digital rectal examination is not routinely indicated.

Documenting the findings of the anogenital examination is important. In specialty centers, the examination is usually documented with photographs or videos. In the pediatric office, a detailed description of the structures will suffice. If photographs are taken, however, they should be treated as a confidential part of the medical record, and care should be taken to label them for proper identification.

An expert committee that has written practice standards for medical examinations in child advocacy centers recommends that all examinations be reviewed by an expert clinician.[49] This usually entails a secondary review of photographs or videos to verify the physical findings. If the examination findings are deemed to be abnormal

or consistent with trauma, pediatricians also should have a secondary review of physical findings, either by having a clinician experienced in forensic anogenital examinations review the photographs or by referring the child to a center specializing in child abuse. Studies have shown there to be better agreement on interpretation of examination findings when clinicians have had extensive experience and education in the evaluation of child sexual abuse.[50]

All pediatricians should gain experience in the anogenital examination of children and adolescents. Many conditions can mimic trauma. It is important to recognize these findings and to distinguish them from lesions caused by child abuse.[51] The Supplemental Appendix reviews genital and anal conditions that can be confused with sexual abuse.

Most sexually abused children have normal anogenital examinations.[52,53] Many types of molestation (eg, oral genital contact or fondling) leave no permanent scars or marks. Even children who have been sexually penetrated often have normal examinations.[53,54] Anogenital tissues heal quickly and completely after many types of anal or genital trauma.[55,56] A normal examination of the genitals and anus neither confirms nor rules out sexual abuse. This fact should be mentioned in the assessment portion of the record. After the examination, it is important to reassure the child that he or she is healthy.

TESTING FOR STIs

STIs occur infrequently in prepubertal sexually abused children. A recent multisite prospective study of 536 children evaluated for suspected sexual abuse revealed that 8.2% of the female children younger than 14 years had an STI.[57] *Chlamydia trachomatis* infections were found in 3.1% of the girls, and *Neisseria gonorrhoeae* infections were found in 3.3%. Only 1 girl tested positive for syphilis (0.3%), and none tested positive for HIV. Five of 12 girls with genital lesions tested positive for herpes simplex virus. Five of 85 symptomatic girls (5.9%) had *Trichomonas vaginalis* identified on a wet mount. Girls with vaginal discharge were more likely to have an STI.

Because STIs are not common in prepubertal children evaluated for abuse, culturing all sites for all organisms is not recommended if the child is asymptomatic. Each case should be evaluated individually for STI risk. Factors that should lead the physician to consider screening for STI include the following[41]:

1. Child has experienced penetration of the genitalia or anus.
2. Child has been abused by a stranger.
3. Child has been abused by a perpetrator known to be infected with an STI or at high risk of STIs (intravenous drug abusers, men who have sex with men, or people with multiple sexual partners).
4. Child has a sibling or other relative in the household with an STI.
5. Child lives in an area with a high rate of STI in the community.
6. Child has signs or symptoms of STIs.
7. Child has already been diagnosed with 1 STI.

Sexually abused adolescents are at higher risk of STIs and should be screened for all STIs, as would any sexually active adolescent presenting for routine care.

Genital and anal infections with *N gonorrhoeae* are rarely acquired perinatally, and outside the newborn period they are considered likely to be caused by sexual abuse.[58] *C trachomatis* infections in children older than 3 years also are likely to be sexually transmitted.[59] *T vaginalis* infection also should raise a concern of possible abuse.[60] Herpes simplex virus and genital warts (human papillomavirus) can be sexually transmitted in children, but these infections are not diagnostic of abuse by themselves.[61] HIV infections in children who have not been exposed to the virus perinatally, through blood products, or by needle sticks are also highly likely to be caused by abuse.[62] In any case of an STI in a child, a careful investigation into risk factors and contacts should be conducted, a thorough medical and social history should be obtained, and the child should be evaluated for possible sexual abuse.

The recommendations for laboratory methods best used to detect infection with *C trachomatis* and *N gonorrhoeae* in abused children are evolving. Current standards require these organisms to be confirmed by culture in cases of suspected sexual abuse that involve the legal system.[41] However, a recent multicenter study found that commercially available nucleic acid amplification tests (NAATs) are highly sensitive and specific for these organisms and that these tests provide "a better alternative than culture as a forensic standard."[63] The study also found that NAATs performed on urine specimens worked as well as vaginal swabs to detect infection in both prepubertal and postpubertal girls, obviating more invasive tests. All positive NAAT results in this study were confirmed by genotypic and sequence analysis tests, leading to a high positive predictive value for *C trachomatis* and *N gonorrhoeae*.

In medicolegal cases, culture-based tests have been preferred because of their high specificity (nearing 100%). This would make the possibility of a false-positive result highly unlikely. Unfortunately, culture-based tests for *C trachomatis* and *N gonorrhoeae* are

very insensitive. In addition, many laboratories no longer offer culture-based tests, making it impossible to screen victims for infection using culture methods. If laboratories do maintain limited culture facilities, they would be more likely to provide false results, given limited experience with cultures. Because NAATs provide highly sensitive detection of organisms and their specificity approaches that of culture, the AAP recommends the use of NAATs when evaluating children and adolescents for genital infections with *C trachomatis* and *N gonorrhoeae*.

All positive test results should be considered presumptive evidence of infection and, if used, should be interpreted with caution. Positive results should be confirmed using additional tests in populations with a low prevalence of the infection or when a false-positive test could have an adverse outcome. When establishing a protocol to evaluate positive NAAT results for *N gonorrhoeae* or *C trachomatis,* experts in laboratory medicine and pediatric infectious diseases should be consulted to determine appropriate secondary tests. All positive specimens in suspected abuse cases should be retained by the laboratory for additional testing.

Recently, various rapid antigen tests, DNA hybridization tests, and NAATs have been developed for *Candida* species, *Gardnerella vaginalis,* and *T vaginalis*.[64] These tests have not been extensively studied in children and should not be used at this time. Bacterial vaginosis (the vaginosis associated with *G vaginalis*) and genital candidiasis are not specific indicators of sexual abuse.

By recommending the use of NAATs for *N gonorrhoeae* and *C trachomatis* in cases of suspected sexual abuse of children, the AAP recognizes that pediatricians' first priority should be protecting the health of children. The pediatrician should be considered primarily a provider of health care for children and should prioritize ensuring the health and well-being of their patients rather than focusing on the legal outcome of criminal cases. In practice, rarely have cases of suspected sexual abuse been adjudicated on the basis of a positive test result for an STI alone in the absence of a history, physical finding, or other confirmatory evidence of abuse. Although properly collected, tested, and confirmed laboratory specimens can aid in the prosecution of sex offenders, the pediatrician's main responsibility lies in protecting the child's health.

The Food and Drug Administration has not approved NAATs for the diagnosis of *C trachomatis* or *N gonorrhoeae* infections of the throat or anus. The Food and Drug Administration does allow laboratories to use NAATs for testing nongenital specimens if the individual laboratory undergoes internal validation of the method used in a method verification study. In verification studies, positive and negative specimens are compared with reference standards or with results from a second laboratory.[65] No studies have been published evaluating the use of nongenital-site NAATs in prepubertal children. However, studies in adults have had promising results when using some NAATs to test for rectal or pharyngeal *N gonorrhoeae* and *Chlamydia* infections in high-risk populations.[66–68] At this point, the use of NAATs in children for rectal or pharyngeal specimens is not warranted until more research is available. If used, they should be interpreted with caution.

If diagnosed with an STI, the child should be treated promptly. When there is a possibility that the child has been exposed to HIV, proper follow-up or prophylaxis is needed. When appropriate, consideration should be given to treating the patient with emergency contraception.

WORKING WITH FAMILIES TO MITIGATE THE ADVERSE EFFECTS OF SEXUAL ABUSE

When children disclose sexual abuse, people close to them are usually deeply affected. Parents often have feelings of guilt for not protecting their children[68,69] and might experience intense anger at the abusers. A child's disclosure can exacerbate a parent's own feelings about his or her adverse childhood experiences. Previous family conflict (eg, marital conflict, substance abuse issues) can be aggravated. Some parents want to sweep the disclosure under the rug to avoid dealing with the painful reality. Family members can feel protective of the accused abuser, especially if that person is another family member. Families should be given the following guidance about how to respond to children who disclose abuse.

1. Parents should understand that medical professionals are required to report suspected abuse to the proper authorities for investigation. It is not an option for the pediatrician to keep the disclosure secret.
2. It is important for families to cooperate with agencies investigating the alleged abuse.
3. Studies have shown that the long-term outcomes of children who have experienced sexual abuse are better if they are believed and supported after a disclosure.[11,70] The parents' initial response to the disclosure is important. If the parents show extreme distress and become nonfunctional, the child will feel less secure and less protected. If the parents are openly emotional and weeping, the child might feel that he or she has to recant or minimize the abuse to decrease the parents' distress.

Parents should respond in a calm and protective manner, assuring the child that the abuse was not his or her fault and that they will do all they can to protect the child and keep him or her safe.

4. Parents should not independently try to question the child or accuse the child of lying. If the child wants to talk about the abuse experience, the parent should listen and be supportive, but it is not helpful to repeatedly question the child or force the child to describe the abuse in detail. This type of questioning can be damaging to the legal adjudication of the case.
5. Pediatricians can provide guidance to families by recognizing the importance of mental health assessment after childhood trauma and by familiarizing themselves with mental health treatments that have been shown to be effective in ameliorating the effects of abuse.[71] Children should be treated by therapists with proper training and experience in dealing with child trauma. Options are available to facilitate the delivery of psychological services to abused children through child advocacy centers, community mental health centers, and victims' compensation programs.

GUIDANCE FOR PEDIATRICIANS

1. Pediatricians should understand the mandatory child abuse reporting laws in their states and should know how to make a report to the responsible agency in their jurisdiction that investigates cases of alleged child sexual abuse.
2. Pediatricians should recognize that sexual abuse of children occurs commonly, and they should be prepared to respond appropriately in their clinical practices.
3. Pediatricians should be aware of normal, developmentally appropriate variations in children's sexual behaviors.[29]
4. Pediatricians should be aware of community resources available to assist in the evaluation of alleged child abuse.
5. Pediatricians should be educated about normal and abnormal genital and anal anatomy in children.
6. Pediatricians should seek a second expert opinion in cases of child sexual abuse when the child's anal or genital examination is thought to be abnormal.
7. Pediatricians should know when and where to refer cases of acute alleged sexual abuse or assault that require forensic testing, prophylaxis for STIs and HIV, and emergency contraception.
8. Pediatricians should know the importance of using nonleading, open-ended questions if they are asking questions about possible abuse.
9. Pediatricians should understand how to support children and families when child sexual abuse is suspected.
10. Pediatricians should be aware of the effects of sexual abuse on children's mental health and be able to refer abused children to mental health professionals who have expertise in treating child trauma.
11. Advice on protection of children from sexual abuse should be part of the anticipatory guidance given to parents in the medical home. The AAP Web site provides guidance for pediatricians (http://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Medical-Home-for-Children-and-Adolescents-Exposed-to-Violence/Pages/Sexual-Abuse.aspx) and for parents (http://www.aap.org/en-us/about-the-aap/aap-press-room/news-features-and-safety-tips/Pages/Parent-Tips-for-Preventing-and-Identifying-Child-Sexual-Abuse.aspx) about preventing child sexual abuse. In addition, the AAP developed an educational toolkit for "Preventing Sexual Violence" (https://www2.aap.org/pubserv/PSVpreview/pages/main.html).

CLINICAL REPORT

Gastroesophageal Reflux: Management Guidance for the Pediatrician

Jenifer R. Lightdale, MD, MPH, David A. Gremse, MD, and SECTION ON GASTROENTEROLOGY, HEPATOLOGY, AND NUTRITION

abstract

FREE

Recent comprehensive guidelines developed by the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition define the common entities of gastroesophageal reflux (GER) as the physiologic passage of gastric contents into the esophagus and gastroesophageal reflux disease (GERD) as reflux associated with troublesome symptoms or complications. The ability to distinguish between GER and GERD is increasingly important to implement best practices in the management of acid reflux in patients across all pediatric age groups, as children with GERD may benefit from further evaluation and treatment, whereas conservative recommendations are the only indicated therapy in those with uncomplicated physiologic reflux. This clinical report endorses the rigorously developed, well-referenced North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition guidelines and likewise emphasizes important concepts for the general pediatrician. A key issue is distinguishing between clinical manifestations of GER and GERD in term infants, children, and adolescents to identify patients who can be managed with conservative treatment by the pediatrician and to refer patients who require consultation with the gastroenterologist. Accordingly, the evidence basis presented by the guidelines for diagnostic approaches as well as treatments is discussed. Lifestyle changes are emphasized as first-line therapy in both GER and GERD, whereas medications are explicitly indicated only for patients with GERD. Surgical therapies are reserved for children with intractable symptoms or who are at risk for life-threatening complications of GERD. Recent black box warnings from the US Food and Drug Administration are discussed, and caution is underlined when using promoters of gastric emptying and motility. Finally, attention is paid to increasing evidence of inappropriate prescriptions for proton pump inhibitors in the pediatric population. *Pediatrics* 2013;131:e1684–e1695

PPI—proton pump inhibitor

INTRODUCTION

Gastroesophageal reflux (GER) occurs in more than two-thirds of otherwise healthy infants and is the topic of discussion with pediatricians at one-quarter of all routine 6-month infant visits.[1,2] In addition to seeking guidance from their pediatricians, parents often request evaluation by pediatric medical subspecialists.[3] It is, therefore, not surprising that strongly evidence-based guidelines incorporating

state-of-the-art approaches to the evaluation and management of pediatric GER have been welcomed by both general pediatricians and pediatric medical subspecialists and surgical specialists. GER, defined as the passage of gastric contents into the esophagus, is distinguished from gastroesophageal reflux disease (GERD), which includes troublesome symptoms or complications associated with GER.[4] Differentiating between GER and GERD lies at the crux of the guidelines jointly developed by the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition and the European Society for Pediatric Gastroenterology, Hepatology, and Nutrition.[4] These definitions have further been recognized as representing a global consensus.[5] Therefore, it is important that all practitioners who treat children with reflux-related disorders are able to identify and distinguish those children with GERD, who may benefit from further evaluation and treatment, from those with simple GER, in whom conservative recommendations are more appropriate.

GER is considered a normal physiologic process that occurs several times a day in healthy infants, children, and adults. GER is generally associated with transient relaxations of the lower esophageal sphincter independent of swallowing, which permits gastric contents to enter the esophagus. Episodes of GER in healthy adults tend to occur after meals, last less than 3 minutes, and cause few or no symptoms.[6] Less is known about the normal physiology of GER in infants and children, but regurgitation or spitting up, as the most visible symptom, is reported to occur daily in 50% of all infants.[7,8]

In both infants and children, reflux can also be associated with vomiting, defined as a forceful expulsion of gastric contents via a coordinated autonomic and voluntary motor response. Regurgitation and vomiting can be further differentiated from rumination, in which recently ingested food is effortlessly regurgitated into the mouth, masticated, and reswallowed. Rumination syndrome has been identified as a relatively rare clinical entity that involves the voluntary contraction of abdominal muscles.[9] In contrast, both regurgitation and vomiting can be considered common and often nonpathologic manifestations of GER.

Symptoms or conditions associated with GERD are classified by the practice guidelines as being either esophageal or extraesophageal.[4] Both classifications can be used to define the disease, which can be further characterized by findings of mucosal injury on upper endoscopy. Esophageal conditions include vomiting, poor weight gain, dysphagia, abdominal or substernal/retrosternal pain, and esophagitis. Extraesophageal conditions have been subclassified according to both established and proposed associations; established extraesophageal manifestations of GERD can include respiratory symptoms, including cough and laryngitis, as well as wheezing in infancy.[10,11] Although older studies from the 1990s suggested that GERD may aggravate asthma, recent publications have suggested that the impact of GERD on asthma control is considerably less than previously thought.[10,12–18] Other extraesophageal manifestations include dental erosions, and proposed associations include pharyngitis, sinusitis, and recurrent otitis media. Patients can be described clinically by their symptoms or by the endoscopic description of their esophageal mucosa. GERD-associated esophageal injuries and complications found on endoscopy include reflux esophagitis, less commonly peptic stricture, and rarely Barrett esophagus and adenocarcinoma.

Although the reported prevalence of GERD in patients of all ages worldwide is increasing,[5] GERD is nevertheless far less common than GER. Population-based studies suggest reflux disorders are not as common in Eastern Asia, where the prevalence is 8.5%,[19] compared with Western Europe and North America, where the current prevalence of GERD is estimated to be 10% to 20%.[20] New epidemiologic and genetic evidence suggests some heritability of GERD and its complications, including erosive esophagitis, Barrett esophagus, and esophageal adenocarcinoma.[21–23] A few pediatric populations at high risk of GERD have also been identified, including children with neurologic impairment, certain genetic disorders, and esophageal atresia[24,25] (Table 1). The prevalence of severe, chronic GERD is much higher in pediatric patients with these "GERD-promoting" conditions. These patients may be more prone to experiencing complications of severe GERD than patients who are otherwise healthy.[26]

Population trends hypothesized to contribute to a general increase in the prevalence of GERD include global epidemics of both obesity and asthma. In some instances, GERD can be implicated as either the underlying etiology (ie, recurrent pneumonia in

Preterm infants

the premature infant exacerbated by GERD) or a direct repercussion (ie, obesity leading to GERD) of such conditions. In the great majority of cases, however, GERD and comorbidities are known to occur simultaneously in patients without a clear causal relationship.

CLINICAL FEATURES OF GERD

Troublesome symptoms or complications of pediatric GERD are associated with a number of typical clinical presentations in infants and children, depending on patient age[5] (Table 2). Reflux may occur commonly in preterm newborn infants but is generally nonacidic and improves with maturation. A full discussion of reflux in neonates and preterm infants is beyond the scope of this report.

Guidelines have distinguished between manifestations of GERD in full-term infants (younger than 1 year) from those in children older than 1 year and adolescents. Common symptoms of GERD in infants include regurgitation or vomiting associated with irritability, anorexia or feeding refusal, poor weight gain, dysphagia, presumably painful swallowing, and arching of the back during feedings. Relying on a symptom-based diagnosis of GERD can be difficult in the first year of life, especially because symptoms of GERD in infants do not always resolve with acid-suppression therapy.[5,27] GERD in infants can also be associated with extraesophageal symptoms of coughing, choking, wheezing, or upper respiratory symptoms.[7] The incidence of GERD is reportedly lower in breastfed infants than in formula-fed infants.[27] In line with the natural history of regurgitation, GERD in infants is considered to have a peak incidence of approximately 50% at 4 months of age and then to decline to affect only 5% to 10% of infants at 12 months of age.[7,8]

TABLE 2 Common Presenting Symptoms of GERD in Pediatric Patients

Infant	Older Child/Adolescent
Feeding refusal	Abdominal pain/ heartburn
Recurrent vomiting	Recurrent vomiting
Poor weight gain	Dysphagia
Irritability	Asthma
Sleep disturbance	Recurrent pneumonia
Respiratory symptoms	Upper airway symptoms (chronic cough, hoarse voice)

Common symptoms of GERD in children 1 to 5 years of age include regurgitation, vomiting, abdominal pain, anorexia, and feeding refusal.[28] Generally, GERD causes troublesome symptoms without necessarily interfering with growth; however, children with clinically significant GERD or endoscopically diagnosed esophagitis may also develop an aversion to food, presumably because of a stimulus-response association of eating with pain. This aversion, combined with feeding difficulties associated with repeated episodes of regurgitation, as well as potential and substantial nutrient losses resulting from emesis, may lead to poor weight gain or even malnutrition.

Older children and adolescents are most likely to resemble adults in their clinical presentation with GERD and to complain of heartburn, epigastric pain, chest pain, nocturnal pain, dysphagia, and sour burps. When eliciting a history in school-aged children with suspected GERD, it may be important to directly ask patients themselves about their symptoms rather than relying strongly on parent report. In 1 study, adolescents were significantly more likely than their parents to report themselves to be experiencing symptoms of sour burps or nausea.[1] Extraesophageal symptoms in older children and adolescents can include nocturnal cough, wheezing, recurrent pneumonia, sore throat, hoarseness, chronic sinusitis, laryngitis, or dental erosions. In a pediatric patient with GERD and dental erosions, the progression of tooth structure loss may be indicative that existing therapy for GERD is not effective. Conversely, stability of dental erosions is 1 measure of adequacy of GERD management.

DIAGNOSTIC STUDIES

For most pediatric patients, a history and physical examination in the absence of warning signs are sufficient to reliably diagnose uncomplicated GER and initiate treatment strategies. Generally speaking, diagnostic testing is not necessary. The reliability of symptoms to make the clinical diagnosis of GERD is particularly high in adolescents, who often present with heartburn typical of adults.[29–31] Nevertheless, dedicating at least part of a clinical visit to obtaining a clinical history and performing a physical examination are also essential to exclude more worrisome diagnoses that can present with reflux or vomiting (Table 3).

To date, no single symptom or cluster of symptoms can reliably be used to diagnose esophagitis or other complications of GERD in children or to predict which patients are most likely

to respond to therapy.[21] Nonetheless, a number of GERD symptom questionnaires have been validated and may be useful in the detection and surveillance of GERD in affected children of all ages. Kleinman et al developed a questionnaire for infants that was validated for documentation and monitoring of parent-reported GERD symptoms.[30] Another questionnaire by Størdal et al[32] for pediatric patients 7 to 16 years of age compared favorably with results of pH monitoring. As yet another example, the GERD Symptom Questionnaire developed by Deal et al[33] appears valid for differentiating children with GERD from healthy controls but has not been compared with objective standards, such as pH monitoring or endoscopic findings.

The strategy of using diagnostic testing to diagnose GERD may also be fraught with complexity, because there is no single test that can rule it in or out. Instead, diagnostic tests must be used in a thoughtful and serial manner to document the presence of reflux of gastric contents in the esophagus, to detect complications, to establish a causal relationship between reflux and symptoms, to evaluate the efficacy of therapies, and to exclude other conditions. The diagnostic methods most commonly used to evaluate pediatric patients with GERD symptoms are upper gastrointestinal (GI) tract contrast radiography, esophageal pH and/or impedance monitoring, and upper endoscopy with esophageal biopsy. Upper GI tract series are useful to delineate anatomy and to occasionally document a motility disorder, whereas esophageal pH monitoring and intraluminal esophageal impedance represent tools to quantify GER. Upper endoscopy with esophageal biopsy represents the primary method to investigate the esophageal mucosa to both exclude other conditions that can cause GERD-like symptoms and evaluate for esophageal injury attributable to GERD.[4]

Upper GI Tract Series

Upper GI tract contrast radiography generally involves obtaining a series of fluoroscopic images of swallowed barium until the ligament of Treitz is visualized. According to the new guidelines, the routine performance of upper GI tract radiographic imaging to diagnose GER or GERD is not justified,[4] because upper GI tract series are too brief in duration to adequately rule out the occurrence of pathologic reflux, and the high frequency of nonpathologic reflux during the examination can encourage false-positive diagnoses. Additionally, observation of the reflux of a barium column into the esophagus during GI tract contrast studies may not correlate with the severity of GERD or the degree of esophageal mucosal inflammation in patients with reflux esophagitis. It is recognized that upper GI tract series are useful in the evaluation of vomiting to screen for possible anatomic abnormalities of the upper GI tract.[4] For example, in infants with bilious vomiting, an upper GI tract series may be useful for evaluating for possible malrotation or duodenal web. Persistent, forceful vomiting in the first few months of life should be evaluated with pyloric ultrasonography to evaluate for possible pyloric stenosis. An upper GI tract series should be reserved if the results of the pyloric ultrasound are equivocal.

Esophageal pH Monitoring

Continuous intraluminal esophageal pH monitoring can be used to quantify the frequency and duration of esophageal acid exposure during a study period. The conventional definition of acid exposure in the esophagus is a pH <4.0, the pH most associated with a complaint of heartburn in adults. Esophageal pH metrics generally include an absolute number of reflux episodes detected during monitoring, the duration of reflux episodes detected, and the reflux index, which is calculated as the percentage of a study period during which esophageal pH is <4.0. Although esophageal pH monitoring may be useful for associating a temporal relationship between a symptom and acid reflux and to evaluate the efficacy of pharmacologic therapy on acid suppression, mounting evidence suggests poor reproducibility of pH testing, as well as a clear continuum between pH findings in physiologic GER and pathologic GERD. In turn, esophageal pH monitoring is losing value as a primary modality for diagnosing or managing pediatric GERD.[34]

Multichannel Intraluminal Impedance Monitoring

Multiple intraluminal impedance (MII) is an emerging technology for detecting the movement of both acidic and nonacidic fluids, solids, and air in the esophagus, thereby providing a more detailed picture of esophageal events than pH monitoring.[34] MII can be used to measure volume, speed, and physical length of both anterograde and retrograde esophageal boluses. Combined pH/MII testing is evolving into the test of choice to detect temporal relationships between specific symptoms and the reflux of both acid and nonacid gastric contents. In particular, MII has been used in recent years to investigate how GER and GERD correlate with apnea, cough, and behavioral symptoms.[35] According to the new guidelines, MII and pH electrodes can and should be combined on a single catheter.[4]

Gastroesophageal Scintigraphy

Gastroesophageal scintigraphy scans for reflux of ^{99m}Tc-labeled solids or liquids into the esophagus or lungs after administration of the test

material into the stomach. This nuclear scan evaluates postprandial reflux and can also quantitate gastric emptying; however, the lack of standardized techniques and age-specific normal values limits the usefulness of this test. Therefore, gastroesophageal scintigraphy is not recommended in the routine evaluation of pediatric patients with GER.[4]

Endoscopy and Esophageal Biopsy

It is certainly preferable to pursue conservative measures for treating GERD in children before considering the use of more invasive testing. In particular, any diagnostic benefits of pursuing upper endoscopy in pediatric patients suspected of having GERD must also be weighed against minimal, but not entirely negligible, procedural and sedation risks.[36] Nevertheless, the performance of upper endoscopy allows direct visualization of the esophageal mucosa to determine the presence and severity of injury from the reflux of gastric contents into the esophagus.[26] Esophageal biopsies allow evaluation of the microscopic anatomy.[24] Upper endoscopy with esophageal biopsy may be useful to evaluate inflammation in the esophageal mucosa attributable to GERD and to exclude other associated conditions with symptoms that can mimic GERD, such as eosinophilic esophagitis. Recent data confirm that approximately 25% of infants younger than 1 year will have histologic evidence of esophageal inflammation.[37] This test is indicated in patients with GERD who fail to respond to pharmacologic therapy or as part of the initial management if symptoms of poor weight gain, unexplained anemia or fecal occult blood, recurrent pneumonia, or hematemesis exist.

Upper endoscopy may also be helpful in the assessment of other causes of abdominal pain and vomiting in pediatric patients, such as esophageal or antral webs, Crohn esophagitis, peptic ulcer, *Helicobacter pylori* infection, and infectious esophagitis. Erosive esophagitis is reported less often in infants and children with GERD than in adults with GERD; however, a normal endoscopic appearance of the esophageal mucosa in pediatric patients does not exclude histologic evidence of reflux esophagitis.[5,8] Esophageal biopsy is beneficial in evaluating for conditions that may mimic symptoms of GERD, such as eosinophilic esophagitis, infectious esophagitis (*Candida* esophagitis or herpetic esophagitis), Crohn disease, or Barrett esophagus.[24] Because endoscopic findings correlate poorly with histologic testing in infants and children, performing esophageal biopsies during endoscopy is recommended for the evaluation of GERD in children.[4]

MANAGEMENT

The new guidelines describe several treatment options for treating children with GER and GERD. In particular, lifestyle changes are emphasized, because they can effectively minimize symptoms of both in infants and children. For patients who require medication, options include buffering agents, acid secretion suppressants, and promoters of gastric emptying and motility. Finally, surgical approaches are reserved for children who have intractable symptoms unresponsive to medical therapy or who are at risk for life-threatening complications of GERD.

LIFESTYLE CHANGES

Lifestyle Modifications for Infants

Lifestyle changes to treat GERD in infants may involve a combination of feeding changes and positioning therapy. Modifying maternal diet if infants are breastfed, changing formulas, and reducing the feeding volume while increasing the frequency of feedings may be effective strategies to address GERD in many patients. In particular, the guidelines emphasize that milk protein allergy can cause a clinical presentation that mimics GERD in infants. Therefore, a 2- to 4-week trial of a maternal exclusion diet that restricts at least milk and egg is recommended in breastfeeding infants with GERD symptoms, whereas an extensively hydrolyzed protein or amino acid–based formula may be appropriate in formula-fed infants.[4,30] It is important to note that this recommendation applies to the subset of infants with complications of GER, and not "happy spitters."

In 1 study of formula-fed infants, GERD symptoms resolved in 24% of infants after a 2-week trial of changing to a protein hydrolysate formula thickened with 1 tablespoon rice cereal per ounce, avoiding overfeeding, avoiding seated and supine positions, and avoiding environmental tobacco smoke.[3] Feeding changes can also be recommended in breastfed infants, because it is well known that small amounts of cow milk protein ingested by the mother may be expressed in human milk. Indeed, several studies have found that breastfed infants may benefit from a maternal diet that restricts cow milk and eggs.[38,39]

The feeding management strategy that involves the use of thickened feedings, either by adding up to 1 tablespoon of dry rice cereal per 1 oz of formula[30] or changing to commercially thickened (added rice) formulas for full-term infants who are not cow milk protein intolerant, is recognized as a reasonable management strategy for otherwise healthy infants with both GER and GERD.[4] On the other hand, all pediatric clinicians should be aware of a possible association between thickened feedings and necrotizing enterocolitis in preterm infants.[40] The Food and Drug Administration issued a warning regarding a

common commercially available thickening agent in 2011, suggesting that "parents, caregivers and health care providers not…feed 'SimplyThick' to infants born before 37 weeks gestation who are currently receiving hospital care or have been discharged from the hospital in the past 30 days."

Thickened feedings appear to decrease observed regurgitation rather than the actual number of reflux episodes. Little is known about the effect of thickening formula on the natural history of infantile reflux or the potential allergenicity of commercial thickening agents. Excessive energy intake may occur with long-term use of feedings thickened with rice cereal or corn. To this point, it is important to realize that thickening a 20-kcal/oz infant formula with 1 tablespoon of rice cereal per ounce increases the energy density to 34 kcal/oz. Commercially available antiregurgitant formulae contain processed rice, corn, or potato starch; guar gum; or locust bean gum and may present an option that does not involve excess energy intake by infants when consumed in normal volumes. To date, there has been little investigation into any relationship between use of added rice cereal or antiregurgitant formulae and childhood obesity.

Lifestyle changes that may also benefit infants with GERD include keeping them in the completely upright position or even placing them prone. Indeed, a number of recent studies that used impedance and pH monitoring have confirmed older studies that used pH monitoring to demonstrate significantly less GER in infants in the flat prone position compared with the flat supine position.[41,42] However, the guidelines are unequivocal that the risk of sudden infant death syndrome in sleeping infants outweighs the benefits of prone positioning in the management of GERD and, therefore, that prone positioning should be considered acceptable only if the infant is observed and awake.[4] Prone positioning is suggested to be beneficial in children older than 1 year with either GER or GERD, because the risk of sudden infant death syndrome is greatly decreased in older age groups.

Perceived and actual benefits of seated or semisupine positioning are also explored in the new guidelines. Semisupine positioning, particularly in an infant carrier or car seat, may exacerbate GER and should be avoided when possible, especially after feeding.[43] More recent data obtained with esophageal impedance–pH monitoring have confirmed that postprandial reflux occurs similarly when infants are in car seats as when they are supine but also suggests that being in a car seat for 2 hours after a feeding reduces reflux-related respiratory events.[44]

Lifestyle Modifications for Children and Adolescents

Lifestyle changes that may benefit GERD in older children and adolescents are more akin to recommendations made for adult patients, including the importance of weight loss in overweight patients, cessation of smoking, and avoiding alcohol use. Recommendations for conservatively managing GERD in older children and adolescents, likewise, may involve dietary modification and positioning changes, although the effectiveness of the latter as a treatment of GERD in older children has not been as well studied as in infants. In terms of dietary changes, older children and adolescents are advised to avoid caffeine, chocolate, alcohol, and spicy foods as potential symptom triggers. The guidelines also point out that 3 independent studies have demonstrated decreased reflux episodes with postprandial chewing of sugarless gum.[45–47]

PHARMACOTHERAPEUTIC AGENTS FOR PEDIATRIC GERD

Several medications may be used to treat GERD in infants and children. The 2 major classes of pharmacologic agents for treatment of GERD are acid suppressants and prokinetic agents (Table 4). Growing evidence that demonstrates the former to be more effective than the latter has led to an increased use of acid suppressants to manage suspected GERD in pediatric patients[4,39]; however, there is also significant concern for the overprescription of acid suppressants, particularly proton pump inhibitors (PPIs), and it is important to understand the new guidelines for medication indications.

Acid Suppressants

The main classes of acid suppressants are antacids, histamine-$_2$ receptor antagonists (H2RAs), and PPIs. The principles of using these medications in the treatment of pediatric GERD are similar to those in adults, other than the need to prescribe weight-adjusted doses and the need to consider the form of the drug prescribed (ie, for ease of ingestion in infants and children). Dosage ranges for drugs commonly prescribed for pediatric patients with GERD are listed in Table 4.

Antacids

Antacids are a class of medications that can be used to directly buffer gastric acid in the esophagus or stomach to reduce heartburn and ideally allow mucosal healing of esophagitis. There is limited historical evidence that on-demand use of antacids can lead to symptom relief in infants and children.[48] Instead, although antacids are generally seen as a relatively benign approach to treating pediatric

TABLE 4 Pediatric Doses of Medications Prescribed for GERD

Medications	Doses	Formulations	Ages Indicated by the Food and Drug Administration
Cimetidine	30–40 mg/kg/d, divided in 4 doses	Syrup	≥16 y
Ranitidine	5–10 mg/kg/d, divided in 2 to 3 doses	Peppermint-flavored syrup; Effervescent tablet	1 mo–16 y
Famotidine	1 mg/kg/d, divided in 2 doses	Cherry-banana-mint–flavored oral suspension	1–16 y
Nizatidine	10 mg/kg/d, divided in 2 doses	Bubble gum–flavored solution	≥12 y
Omeprazole	0.7–3.3 mg/kg/d	Sprinkle contents of capsule onto soft foods	2–16 y
Lansoprazole	0.7–3 mg/kg/d	Sprinkle contents of capsule onto soft foods or select juices Administer capsule contents in juice through nasogastric tube Strawberry-flavored disintegrating tablet Orally disintegrating tablet via oral syringe or nasogastric tube (≥8 French)	1–17 y
Esomeprazole	0.7–3.3 mg/kg/d	Sprinkle contents of capsule onto soft foods Administer capsule contents in juice through nasogastric tube	1–17 y
Rabeprazole	20 mg daily	Oral tablet	12–17 y
Dexlansoprazole	30–60 mg daily	Oral tablet	No pediatric indication
Pantoprazole	40 mg daily (adult dose)	Oral tablet	No pediatric indication

GERD, it is important to recognize that they are not entirely without risk. Indeed, several studies link aluminum-containing preparations with aluminum toxicity and its complications in children.[49–51] Similarly, milk-alkali syndrome, a triad of hypercalcemia, alkalosis, and renal failure, has been described in children receiving calcium-containing preparations and adds to a note of caution. According to the new guidelines, chronic antacid therapy is generally not recommended in pediatrics for the treatment of GERD.[4] In addition, the safety and efficacy of surface protective agents, such as alginates or sucralfate, an aluminum-containing preparation, have not been adequately studied in the pediatric population. As such, no surface agent is currently recommended as independent treatment of severe symptoms of GERD or erosive esophagitis in children.[4]

H2RAs

H2RAs represent a major class of medications that has completely revolutionized the treatment of GERD in children. H2RAs decrease the secretion of acid by inhibiting the histamine-$_2$ receptor on the gastric parietal cell. Expert opinion suggests little clinical difference between the various formulations of H2RAs. Randomized placebo-controlled pediatric clinical trials have shown that cimetidine and nizatidine are superior to placebo for the treatment of erosive esophagitis in children.[52,53] Pharmacokinetic studies in school-aged children suggest that gastric pH begins to increase within 30 minutes of administration of an H2RA and reaches peak plasma concentrations 2.5 hours after dosing. The acid-inhibiting effects of H2RAs last for approximately 6 hours, so H2RAs are quite effective if administered 2 or 3 times a day.

However, H2RAs inherently have some limitations. In particular, a fairly rapid tachyphylaxis can develop within 6 weeks of initiation of treatment, limiting its potential for long-term use. In addition, H2RAs have been shown to be less effective than PPIs in symptom relief and healing rates of erosive esophagitis. Although most of these downsides have been demonstrated most clearly in adults, they are also believed to affect children. It is also important to recognize that cimetidine has specifically been linked to an increased risk of liver disease and gynecomastia, and that these associations may be generalizable to other H2RAs.

PPIs

Most recently, PPIs have emerged as the most potent class of acid suppressants by repeatedly demonstrating superior efficacy compared with H2RAs. PPIs decrease acid secretion by inhibition of H^+, K^+-ATPase in the gastric parietal cell canaliculus. PPIs are uniquely able to inhibit meal-induced acid secretion and have a capacity to maintain gastric pH >4 for a longer period of time than H2RAs. These properties contribute to higher and faster healing rates for erosive esophagitis with PPI therapy compared with H2RA therapy. Finally, unlike H2RAs, the acid suppression ability of PPIs has not been observed to diminish with chronic use.

The timing of dosing most PPIs is important for maximum efficacy. Both pediatricians and pediatric medical subspecialists must be diligent at educating their patients to administer PPIs, ideally, approximately 30 minutes before meals.[7] All clinicians should also recognize that the metabolism of PPIs is known to differ in children compared with adults, with a trend toward a shorter half-life, necessitating a higher per-kilogram dose to achieve a peak serum concentration

and area under the curve similar to those in adults.[45] A fairly wide range of effective doses is evident in children. For example, an open-label study of omeprazole in children revealed an effective dosage range of 0.7 to 3.3 mg/kg daily, on the basis of improvement in clinical symptoms and the results of esophageal pH monitoring.[47] Lansoprazole, 0.7 to 3.0 mg/kg daily, improved GERD symptoms and healed all cases of erosive esophagitis in the treatment of 1- to 12-year-old children with GERD.[48] Other trials of PPI therapy support the efficacy of treatment of severe esophagitis and esophagitis refractory to H2RAs in children.[4,45]

As in adults, PPIs are considered safe and generally well tolerated with relatively few adverse effects. In terms of their long-term use, published studies have reported PPI use for up to 11 years in small numbers of children.[16] The Food and Drug Administration has approved a number of PPIs for use in pediatric patients in recent years, including omeprazole, lansoprazole, and esomeprazole for people 1 year and older and rabeprazole for people 12 years and older. Nonetheless, the new guidelines strike a note of caution when discussing the dramatic increase in past years in the number of PPI prescriptions written for pediatric patients, particularly infants, who may be at increased risk of lower respiratory tract infections.[54–56]

Overuse or misuse of PPIs in infants with reflux is a matter for great concern. Placebo-controlled trials in infants have not demonstrated superiority of PPIs over placebo for reduction in irritability.[57] Headaches, diarrhea, constipation, and nausea have been described as occurring in up to 14% of older children and adults prescribed PPIs.[25,58] Although considered a benign histologic change, enterochromaffin cell hyperplasia has

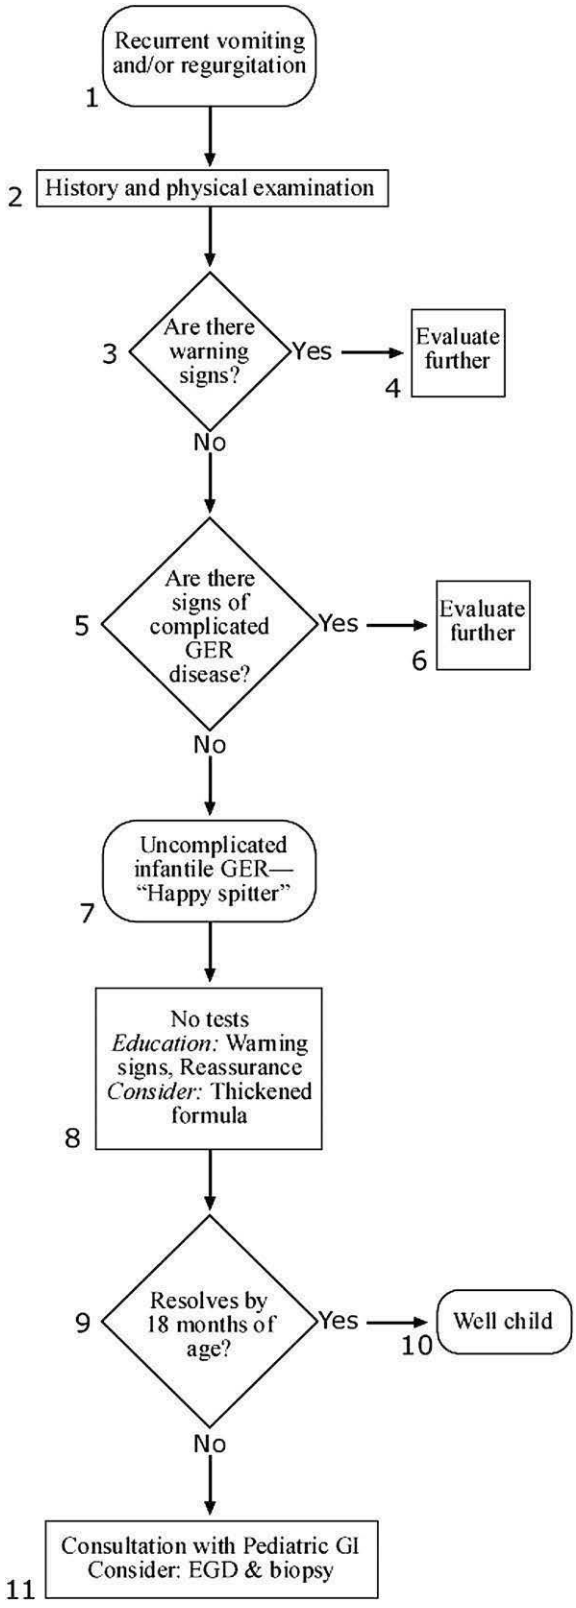

FIGURE 1
Approach to the infant with recurrent regurgitation and vomiting.

recently been demonstrated in up to 50% of children receiving PPIs for more than 2.5 years.[25] Finally, a growing body of evidence suggests that acid suppression, in general, with either H2RAs or PPIs, may be a risk factor for pediatric community-acquired pneumonia, gastroenteritis, candidemia, and necrotizing enterocolitis in preterm infants.[59,60]

Prokinetic Agents

Desired pharmacologic effects of prokinetic agents include improving contractility of the body of the esophagus, increasing lower esophageal sphincter pressure, and increasing the rate of gastric emptying. To date, efforts to design a prokinetic agent with benefits that outweigh adverse effects has proven difficult. Even metoclopramide, the most common prokinetic agent still available, recently received a black box warning regarding its adverse effects. Indeed, adverse effects have been reported in 11% to 34% of patients treated with metoclopramide, including drowsiness, restlessness, and extrapyramidal reactions. Although a meta-analysis of 7 randomized controlled trials of metoclopramide in patients younger than 2 years with GERD confirmed a decrease in GERD symptoms, it was clearly at the cost of such significant adverse effects.[61] Other drugs in this category include bethanechol, cisapride (no longer available commercially in the United States), baclofen, and erythromycin. Each works as a prokinetic by using a different mechanism. Nevertheless, after careful review, guidelines unequivocally state that there is insufficient evidence to support the routine use of any prokinetic agent for the treatment of GERD in infants or older children.[4]

Surgery for Pediatric GERD

Several surgical procedures can be used to decrease GER disorders in children. Fundoplication, whereby the gastric fundus is wrapped around the distal esophagus, is most common and can be performed to prevent reflux by increasing baseline pressure of the lower esophageal sphincter, decreasing the number of transient lower esophageal sphincter relaxations, and increasing the length of the esophagus that is intra-abdominal to accentuate the angle of His and reduce a hiatal hernia, if indicated.[17,56,57] Total esophagogastric dissociation is another operative procedure that is rarely used after failed fundoplication. Both procedures are associated with significant morbidity and do not reduce the risk of direct aspiration of oral contents. Careful patient selection is one of the keys to successful outcome.[17] Children who have failed pharmacologic treatment may be candidates for surgical therapy, as are children at severe risk of aspiration of their gastric contents. In most patients, if acid suppression with PPIs is ineffective, the accuracy of the diagnosis of GERD should be reassessed, because fundoplication may not produce optimum clinical results. Clinical conditions, such as cyclic vomiting, rumination, gastroparesis, and eosinophilic esophagitis, should

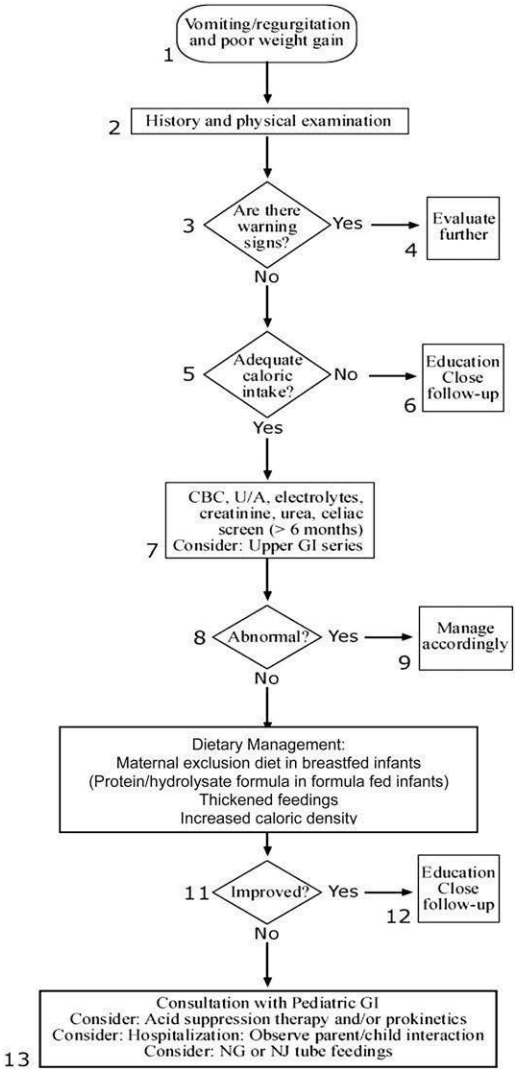

FIGURE 2
Approach to the infant with recurrent regurgitation and weight loss.

be carefully ruled out before surgery, because they are likely to still cause symptoms after surgery. If antireflux surgery is pursued, the new guidelines also stress the importance of providing families with adequate counseling and education before the procedure so that they have a "realistic understanding of the potential complications…including symptom recurrence."[4]

SUMMARY

The updated guidelines published in 2009 are particularly rich with descriptions of typical presentations of GERD across all pediatric age groups.[4] With an emphasis on evidence-based, best practice, they present a number of algorithms that can be of great use to both general pediatricians and pediatric medical subspecialists. The guidelines discuss the evaluation and management of recurrent regurgitation and vomiting in both infants and older children and the importance of distinguishing GERD from numerous other disorders. The figures shown demonstrate the recommended approaches for commonly encountered presentations of GERD in pediatric patients and are summarized here.

In the infant with uncomplicated recurrent regurgitation, it may be important to recognize physiologic GER that is effortless, painless, and not affecting growth (Fig 1). In this situation, pediatricians should focus on minimal testing and conservative management. Overuse of medications in the so-called "happy spitter" should be avoided by all pediatric physicians. Instead, pediatricians are well served to diagnose GER and provide significant parental education, anticipatory guidance, and reassurance. In turn, they will provide high-value, high-quality care without risk to their patients or unnecessary direct and indirect costs.

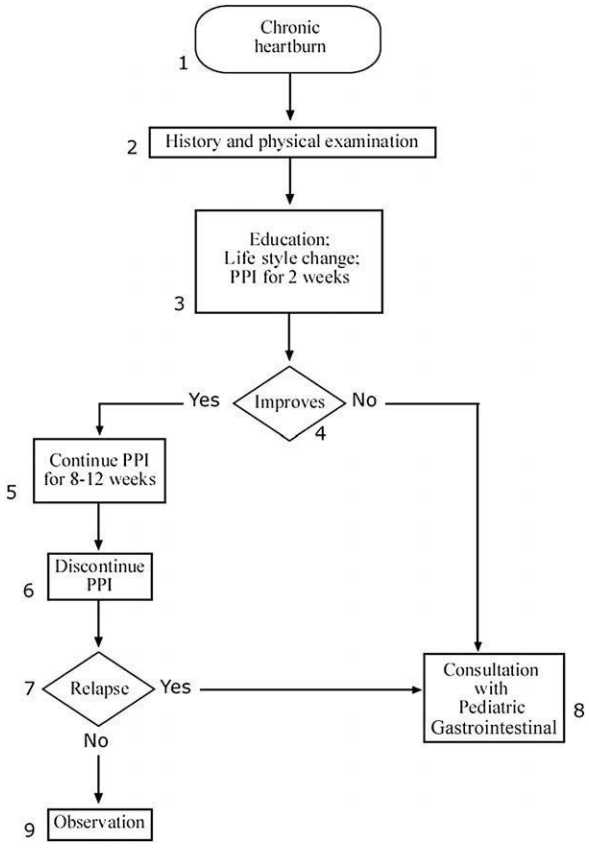

FIGURE 3
Approach to the older child or adolescent with heartburn.

Pediatricians must also be able to recognize infants with recurrent regurgitation and troublesome symptoms of GERD (Fig 2). The new guidelines emphasize weight loss as a crucial warning sign that should alter clinical management. Older children with heartburn may benefit from empirical treatment with PPIs (Fig 3). In general, there is a paucity of studies in pediatrics that demonstrate the effectiveness of this approach. Instead, it is essential to carefully follow all patients empirically treated for GERD to ensure that they are improving, because there are many clinical conditions that may mimic its symptoms. It cannot be overemphasized that pediatric best practice involves both identifying children at risk for complications of GERD and reassuring parents of patients with physiologic GER who are not at risk for complications to avoid unnecessary diagnostic procedures or pharmacologic therapy.[62–64]

FREE NIH

Herpes simplex virus (HSV) infection of the neonate is uncommon, but genital herpes infections in adults are very common. Thus, although treating an infant with neonatal herpes is a relatively rare occurrence, managing infants potentially exposed to HSV at the time of delivery occurs more frequently. The risk of transmitting HSV to an infant during delivery is determined in part by the mother's previous immunity to HSV. Women with primary genital HSV infections who are shedding HSV at delivery are 10 to 30 times more likely to transmit the virus to their newborn infants than are women with recurrent HSV infection who are shedding virus at delivery. With the availability of commercial serological tests that reliably can distinguish type-specific HSV antibodies, it is now possible to determine the type of maternal infection and, thus, further refine management of infants delivered to women who have active genital HSV lesions. The management algorithm presented herein uses both serological and virological studies to determine the risk of HSV transmission to the neonate who is delivered to a mother with active herpetic genital lesions and tailors management accordingly. The algorithm does not address the approach to asymptomatic neonates delivered to women with a history of genital herpes but no active lesions at delivery. *Pediatrics* 2013;131:e635–e646

INTRODUCTION

Herpes simplex virus (HSV) infection of the neonate is an uncommon occurrence, with an estimated 1500 cases diagnosed annually in the United States from a birth cohort of more than 4 000 000. In contrast, genital herpes infections in adults are very common. Between 1 in 4 and 1 in 5 adults in the United States has genital herpes caused by HSV type 2 (HSV-2).[1,2] In addition, HSV type 1 (HSV-1) now accounts for at least 20% and, in some locales, more than 50% of cases of genital herpes in the United States.[3,4] Therefore, managing infants potentially exposed to HSV at the time of delivery is not uncommon, and prevention of the devastating outcomes of neonatal HSV disease is paramount.

Current recommendations for the management of infants after intrapartum exposure are based on expert opinion, because a randomized controlled trial to determine whether an exposed neonate should be treated would be unethical. However, the existing recommendations do

not take into account recent information correlating risk of transmission with type of maternal infection (primary versus recurrent) at the time of delivery.[5] The algorithm contained within this American Academy of Pediatrics (AAP) clinical report for the diagnostic and therapeutic approach to the neonate with known potential exposure to HSV during the perinatal period incorporates the most current scientific understanding of the biology, epidemiology, and pathology of HSV infection and disease.

TERMINOLOGY OF HSV INFECTION AND DISEASE

When an individual with no HSV-1 or HSV-2 antibody acquires either virus in the genital tract, a first-episode primary infection results. If a person with preexisting HSV-1 antibody acquires HSV-2 genital infection (or vice versa), a first-episode nonprimary infection ensues. Viral reactivation from latency and subsequent antegrade translocation of virus back to skin and mucosal surfaces produces a recurrent infection.

Genital HSV infection can be either clinically apparent (eg, genital lesions) or inapparent (asymptomatic, or subclinical). Transmission to the neonate at the time of birth can occur with either presentation.

The distinction between neonatal HSV infection and neonatal HSV disease warrants discussion. Infection occurs when viral replication has been established, but the virus is not causing illness. Disease occurs when viral replication produces clinical signs of illness (eg, skin lesions, encephalitis, hepatitis). Once an infant is infected with HSV, progression to neonatal HSV disease is virtually certain. In an effort to prevent this progression from neonatal infection to neonatal disease, experts have recommended for many years that parenteral acyclovir be administered preemptively to HSV-infected neonates.[6]

RISK OF MATERNAL INFECTION DURING PREGNANCY

Recurrent infections are the most common form of genital HSV during pregnancy.[7] Approximately 10% of HSV-2–seronegative pregnant women have an HSV-2–seropositive sexual partner and, thus, are at risk for contracting a primary HSV-2 infection during the pregnancy[8] and transmitting the virus to their infants during delivery. Approximately one-fifth to one-third of women of childbearing age are seronegative for both HSV-1 and HSV-2,[9,10] and, among discordant couples, the chance that a woman will acquire either virus during pregnancy is estimated to be 3.7%.[11] For women who are already seropositive for HSV-1, the estimated chance of HSV-2 acquisition during the pregnancy is 1.7%.[11] Approximately two-thirds of women who acquire genital herpes during pregnancy remain asymptomatic and have no symptoms to suggest a genital HSV infection.[11] This is consistent with the finding that 60% to 80% of women who deliver an HSV-infected infant have a clinically unapparent genital HSV infection at the time of delivery and have neither a past history of genital herpes nor a sexual partner reporting a history of genital HSV.[12–14]

RISK OF NEONATAL HSV INFECTION

HSV infection of the newborn infant is acquired during 1 of 3 distinct times: intrauterine (in utero), intrapartum (perinatal), and postpartum (postnatal). The time of transmission of HSV-1 or HSV-2 for the overwhelming majority of infected infants (~85%) is in the intrapartum period. An additional 10% of infected neonates acquire HSV-1 postnatally from either a maternal or nonmaternal source, and the final 5% are infected with HSV-2 or HSV-1 in utero. Five factors known to influence transmission of HSV from mother to neonate are:

1. Type of maternal infection (primary versus recurrent)[5,15–18];
2. Maternal HSV antibody status[5,14,19,20];
3. Duration of rupture of membranes[18];
4. Integrity of mucocutaneous barriers (eg, use of fetal scalp electrodes)[5,21,22]; and
5. Mode of delivery (cesarean versus vaginal delivery).[5]

Infants born to mothers who have a first episode of genital HSV infection near term and are shedding virus at delivery are at much greater risk of developing neonatal herpes than are infants whose mothers have recurrent genital herpes (Fig 1).[5,15–18]

The largest assessment of the influence of type of maternal infection on likelihood of neonatal transmission is a landmark study involving almost 60 000 women in labor who did not have clinical evidence of genital HSV disease, approximately 40 000 of whom had cultures performed within 48 hours of delivery (Fig 1).[5] Of these, 121 women were identified who were asymptomatically shedding HSV and who had sera available for analysis. In this large trial, 57% of infants delivered to women with first-episode primary HSV infection developed neonatal HSV disease, compared with 25% of infants delivered to women with first-episode nonprimary infection and 2% of infants delivered to women with recurrent HSV disease (Fig 1).[5]

CLINICAL MANIFESTATIONS OF NEONATAL HSV DISEASE

HSV infections acquired either intrapartum or postpartum can be classified as: (1) disease involving multiple visceral organs, including lung, liver, adrenal glands, skin, eye, and/or brain (disseminated disease); (2) central nervous system (CNS) disease, with or without skin lesions (CNS disease); and (3) disease limited to the skin, eyes, and/or mouth (skin, eye, mouth [SEM]

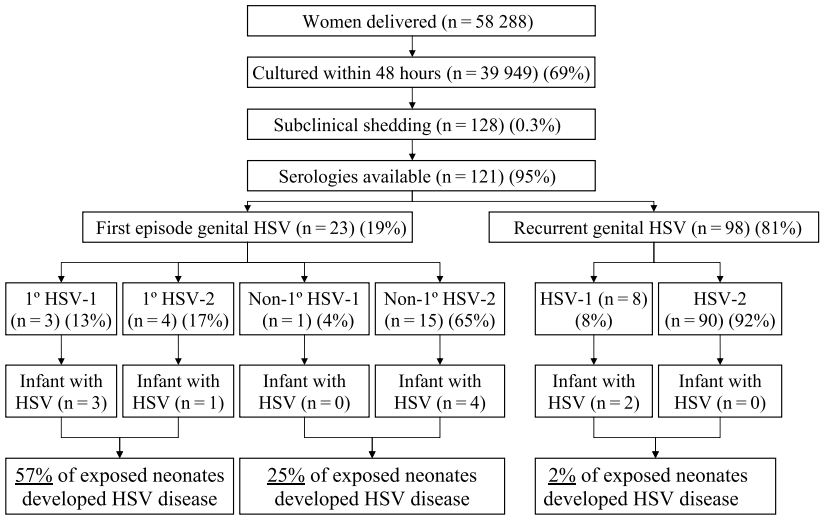

FIGURE 1
Type of maternal infection and risk of HSV transmission to the neonate.[5]

disease). This classification system is predictive of both morbidity and mortality.[23–27] Neonates with disseminated and SEM HSV disease typically present for medical attention at 10 to 12 days of age, whereas infants with CNS disease typically present at 17 to 19 days of age.[24] Overall, approximately half of all infants with neonatal HSV disease will have CNS involvement (CNS disease or disseminated disease with CNS involvement), and approximately 70% will have characteristic vesicular skin lesions (SEM disease, 83%; CNS disease, 63%; disseminated disease, 58%).[24]

DIAGNOSIS OF GENITAL HSV DISEASE

HSV can be detected from genital lesions by polymerase chain reaction (PCR) assay, viral culture, or antigen detection. Of these, PCR assay or viral culture are the testing modalities recommended by the Centers for Disease Control and Prevention for the diagnosis of genital HSV lesions.[28] The sensitivity of viral culture from genital lesions is low, especially for recurrent infection, and declines rapidly as lesions begin to heal. PCR assays for HSV DNA are more sensitive and are increasingly used for the diagnosis of genital HSV.[28,29] A potential limitation of the PCR assay at the current time relates to its availability in all clinical settings; some smaller or more remote medical facilities have limited or no access to laboratories offering this technology. At many tertiary care centers, PCR assay results may be available within a day, whereas it takes 2 to 5 days for HSV to grow in viral culture. Typing of an HSV culture isolate or PCR assay product to determine if it is HSV-1 or HSV-2 can be accomplished by one of several techniques. The reliability of viral culture depends on the stage of the episode, with higher quantities of virus being present during the prodromal and vesicular stages than during crusting.[30] Antigen detection methods are available commercially but may not distinguish HSV-1 from HSV-2 and are not recommended by the Centers for Disease Control and Prevention for the diagnosis of genital herpes.

Before the year 2000, commercially available serological assays were unable to distinguish between HSV-1 and HSV-2 antibodies, severely limiting their utility. Over the past decade, a number of type-specific serological assays that reliably distinguish between immunoglobulin G (IgG) directed against HSV-1 and HSV-2 have been approved by the US Food and Drug Administration (Table 1). Many of these products are sold in kits that are used by clinical laboratories throughout the United States. Several additional tests that claim to distinguish between HSV-1 and HSV-2 antibody are available commercially, but high cross-reactivity rates attributable to their use of crude antigen preparations limit their utility,[31] and their use is not recommended.

DIAGNOSIS OF NEONATAL HSV DISEASE

Isolation of HSV by culture remains the definitive diagnostic method of establishing neonatal HSV disease. If skin lesions are present, a scraping of the vesicles should be transferred in appropriate viral transport media on ice to a diagnostic virology laboratory.[6] Other sites from which specimens should be obtained for culture of HSV include the conjunctivae, mouth, nasopharynx, and rectum ("surface cultures").[6] Specimens for viral culture from mucosal body sites may be combined before inoculating in cell culture to decrease costs, because the important information gathered from such cultures is the presence or absence of replicating virus rather than its precise body site. The sensitivity of PCR assay on surface specimens has not been studied; if used, surface PCR assay should be performed in addition to (and not instead of) the gold-standard surface culture. Rapid diagnostic techniques also are available, such as direct fluorescent antibody staining of vesicle scrapings or enzyme immunoassay detection of HSV antigens. These techniques are as specific but slightly less sensitive than culture.

The diagnosis of neonatal HSV CNS disease has been greatly enhanced by PCR testing of cerebrospinal fluid (CSF) specimens,[32–38] and PCR assay is now the method of choice for documenting CNS involvement in an infant

TABLE 1 Quick Reference Guide for Blood Tests to Accurately Detect Type-Specific HSV Antibodies

suspected of having HSV disease. However, PCR assay of CSF should only be performed in conjunction with HSV surface cultures, given that up to 40% of infants with disseminated disease will not have CNS involvement, and, by definition, no infants with SEM disease will have CNS involvement. The sensitivity of CSF PCR testing in neonatal HSV disease ranges from 75% to 100%.[33,36,38] PCR analysis of CSF also should play a role in determining the duration of antiviral therapy, because available data suggest that having HSV DNA detected in CSF at or after completion of intravenous therapy is associated with poor outcomes.[36,37] All infants with a positive CSF PCR assay result for HSV DNA at the beginning of antiviral therapy should have a repeat lumbar puncture near the end of treatment to determine that HSV DNA has been cleared from the CNS.[24] Infants whose PCR assay result remains positive should continue to receive intravenous antiviral therapy until the CSF PCR assay result is negative.[24,36]

Application of PCR testing to blood specimens from infants with suspected HSV disease appears promising,[37–42] and, in the 2012 *Red Book*,[6] PCR assay of blood has been added to the laboratory evaluation for neonatal HSV disease. Data are insufficient at the current time to allow the use of serial PCR assays of blood to establish response to antiviral therapy or to guide decisions about the duration of therapy.

Serological testing is not helpful in the diagnosis of neonatal HSV infection, because transplacentally acquired maternal HSV IgG is present in most infants, given the substantial proportions of the adult American population who are HSV-1 and/or HSV-2 seropositive.

PREVENTION OF NEONATAL HSV DISEASE

Cesarean delivery in a woman with active genital lesions can reduce the infant's risk of acquiring HSV.[5,18] In

1999, the American College of Obstetricians and Gynecologists updated its management guidelines for genital herpes in pregnancy.[43] To reduce the risk of neonatal HSV disease, cesarean delivery should be performed if genital HSV lesions or prodromal symptoms are present at the time of delivery. Neonatal HSV infection has occurred despite cesarean delivery performed before the rupture of membranes.[12,44]

In women with a previous diagnosis of genital herpes, cesarean delivery to prevent neonatal HSV infection is not indicated if there are no genital lesions at the time of labor. In an effort to reduce cesarean deliveries performed for the indication of genital herpes, the use of oral acyclovir or valacyclovir near the end of pregnancy to suppress genital HSV recurrences has become increasingly common in obstetric practice. Several studies with small sample sizes suggest that suppressive acyclovir therapy during the last weeks of pregnancy decreases the occurrence of clinically apparent genital HSV disease at the time of delivery,[45–48] with an associated decrease in cesarean delivery rates for the indication of genital HSV.[45,46,49,50] However, because viral shedding still occurs (albeit with reduced frequency),[47,51] the potential for neonatal infection is not avoided completely, and cases of neonatal HSV disease in newborn infants of women who were receiving antiviral suppression recently have been reported.[52,53]

ALGORITHM FOR MANAGEMENT OF ASYMPTOMATIC NEONATES BORN VAGINALLY OR BY CESAREAN DELIVERY TO WOMEN WITH ACTIVE GENITAL HSV LESIONS (FIGS 2 AND 3)

The risk of transmitting HSV to the newborn infant during delivery is influenced directly by the mother's previous immunity to HSV; women who have primary genital HSV infections who are shedding HSV at delivery are 10 to 30 times more likely to transmit the virus to their newborn infants than women with a recurrent infection.[5] The increased risk is attributable both to lower concentrations of transplacental HSV-specific antibodies (which also are less reactive to expressed polypeptides) in women with primary infection[19] and to the higher quantities of HSV that are shed for a longer period of time in the maternal genital tract in comparison with women who have recurrent genital HSV infection.[54] However, a substantial percentage of women with first clinical episodes of symptomatic genital herpes actually are experiencing reactivation of a previously unrecognized genital herpetic infection.[55] Thus, to tailor management of exposed neonates according to their degree of risk, one must distinguish primary versus recurrent maternal HSV infection in a manner that relies on more than just the history, or lack thereof, of genital herpes in the woman or her partner (s). Ideally, detection of HSV DNA from genital swabs obtained from women in labor would identify both symptomatic and asymptomatic HSV shedding, allowing for focused management of only those infants who are exposed; however, the technology to accomplish this on a broad scale is not readily available commercially at this time.

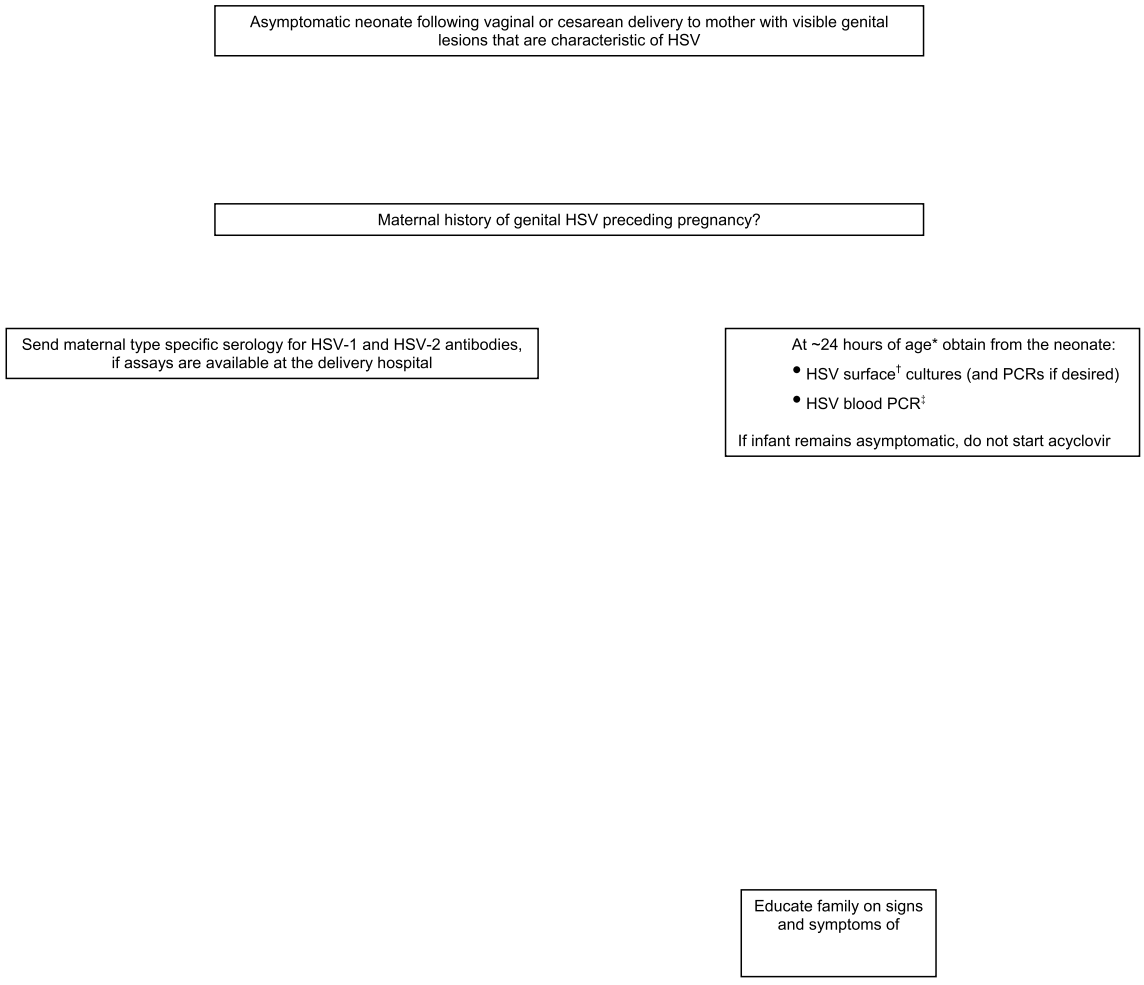
With the approval of commercially available serological tests that can reliably distinguish type-specific HSV antibodies (Table 1), the means to further refine management of asymptomatic neonates delivered to women with active genital HSV lesions is now possible. The algorithm detailed in Figs 2 and 3 applies only to asymptomatic neonates after vaginal or cesarean (because cesarean delivery reduces but does not eliminate the risk of neonatal HSV disease) delivery to women with active genital HSV lesions. It is intended to outline 1 approach to the management of these infants and may not be feasible in settings with limited access to PCR assays for HSV DNA or to the newer type-specific serological tests. If, at any point during the evaluation outlined in the algorithm, an infant develops symptoms that could possibly indicate neonatal HSV disease (fever, hypothermia, lethargy, irritability, vesicular rash, seizures, etc), a full diagnostic evaluation should be undertaken, and intravenous acyclovir therapy should be initiated. In applying this algorithm, obstetric providers and pediatricians likely will need to work closely with their diagnostic laboratories to ensure that serological and virological testing is available and turnaround times are acceptable. In situations in which this is not possible, the approach detailed in the algorithm will have limited, and perhaps no, applicability.

TESTING OF WOMEN IN LABOR

Women in labor with visible genital lesions that are characteristic of HSV should have the lesions swabbed for HSV PCR and culture (AI). Any positive test result then requires further analysis to determine if the virus is HSV-1 or HSV-2. Correlation of viral type with serological status allows for determination of maternal infection classification (Table 2).

Management of Asymptomatic Neonates After Vaginal or Cesarean Delivery to Women With Lesions at Delivery and History of Genital HSV Preceding Pregnancy

For women with a history of genital herpes preceding the pregnancy, the likelihood that the current outbreak represents reactivation of latent HSV is high, and, therefore, the likelihood of transmission to the infant is low (2%). Skin and mucosal specimens (conjunctivae, mouth, nasopharynx, and rectum, and scalp electrode site, if present) should be obtained from the



neonate for culture (and PCR assay, if desired) at approximately 24 hours after delivery (BII), and blood should be sent for HSV DNA PCR assay. Acyclovir need not be started as long as the infant remains asymptomatic (BIII). The importance of waiting until approximately 24 hours after delivery to obtain virological studies is based on the fact that a positive virological test result at that point represents actively replicating virus on the infant's mucosa, whereas a positive test result shortly after birth could reflect only transient maternal contamination that may not lead to replication with resulting neonatal HSV disease.[56] It is permissible to discharge an asymptomatic infant after

women who smoked in pregnancy. *Early Hum Dev*. 1996;45(3):245–255

Principles of Judicious Antibiotic Prescribing for Upper Respiratory Tract Infections in Pediatrics

- *Clinical Report*

CLINICAL REPORT

Principles of Judicious Antibiotic Prescribing for Upper Respiratory Tract Infections in Pediatrics

abstract

FREE

Most upper respiratory tract infections are caused by viruses and require no antibiotics. This clinical report focuses on antibiotic prescribing strategies for bacterial upper respiratory tract infections, including acute otitis media, acute bacterial sinusitis, and streptococcal pharyngitis. The principles for judicious antibiotic prescribing that are outlined focus on applying stringent diagnostic criteria, weighing the benefits and harms of antibiotic therapy, and understanding situations when antibiotics may not be indicated. The principles can be used to amplify messages from recent clinical guidelines for local guideline development and for patient communication; they are broadly applicable to antibiotic prescribing in general. *Pediatrics* 2013;132:1146–1154

INTRODUCTION

More than 1 in 5 pediatric ambulatory visits to a physician result in an antibiotic prescription, which accounts for nearly 50 million antibiotic prescriptions annually in the United States.[1] It is widely documented that inappropriate antibiotic prescribing, especially for upper respiratory tract infections (URIs) of viral origin, is common in ambulatory care.[1–3] As many as 10 million antibiotic prescriptions per year are directed toward respiratory conditions for which they are unlikely to provide benefit.[1] Recent evidence shows that broad-spectrum antibiotic prescribing has increased and frequently occurs when either no therapy is necessary or when narrower-spectrum alternatives are appropriate.[1,2] Such overuse of antibiotics causes avoidable drug-related adverse events,[4–6] contributes to antibiotic resistance,[7,8] and adds unnecessary medical costs. This is compounded by the fact that few new antibiotics to treat antibiotic-resistant infections are under development.[9] The growing health and economic threats of antibiotic resistance make promoting judicious antibiotic prescribing, which encompasses both reducing overuse and ensuring that appropriate agents are prescribed, an urgent public health and patient safety priority (http://www.cdc.gov/drugresistance/threat-report-2013).

Clinical decision-making about whether to prescribe antibiotics for a patient with URI symptoms is a daily occurrence for ambulatory-care physicians and other health care professionals who provide care for children. Although antibiotic prescribing is a routine part of clinical

care, judicious antibiotic prescribing is challenging because it is difficult to distinguish between viral and bacterial URIs. A major objective of this clinical report is to provide a framework for clinical decision-making regarding antibiotic use for pediatric URIs. A point of emphasis is the importance of using stringent and validated clinical criteria when diagnosing acute otitis media (AOM), acute bacterial sinusitis, and pharyngitis caused by group A *Streptococcus* (GAS), as established through clinical guidelines. Additionally, this document emphasizes situations in which the use of antibiotics is not indicated, in particular for viral respiratory infections. Considering the frequency of URIs and the large proportion of antibiotic prescribing attributable to URI visits, these conditions represent a high-impact target for guidelines and other interventions designed to optimize antibiotic prescribing. The careful application of these criteria has the potential to mitigate overuse of antibiotics for pediatric URIs.

The first "Principles of Judicious Use of Antimicrobial Agents for Pediatric Upper Respiratory Tract Infections" were published in 1998 in response to concerns over the emergence and spread of antibiotic-resistant organisms.[10] The Centers for Disease Control and Prevention, in collaboration with the American Academy of Pediatrics (AAP), sought to update these principles in a current context. Antibiotic resistance remains a major public health concern, and appropriate antibiotic use is an important health care quality goal. Although the introduction of a 7-valent pneumococcal polysaccharide-protein conjugate vaccine (PCV7) in 2000 led to large declines in the incidence of invasive pneumococcal infections,[11] an increase in the prevalence of nonvaccine serotypes, most notably serotype 19A, a commonly antibiotic-resistant serotype,[12,13] prompted the 2010 introduction of a 13-valent pneumococcal polysaccharide-protein conjugate vaccine (PCV13). Provider concerns about antibiotic resistance may be 1 factor leading to increasing use of broad-spectrum antibiotics. In recent years, several high-quality randomized controlled trials, meta-analyses, and new and updated clinical guidelines have been published that better define the effectiveness of antibiotic use for selected URIs, including AOM and acute bacterial sinusitis.[14–23] At the same time, new evidence highlighting the extent to which antibiotics lead to adverse events requiring medical attention[4–6] or potentially life-threatening events[24,25] has emerged.

This clinical report focuses on antibiotic prescribing for key pediatric URIs that, in certain instances, may benefit from antibiotic therapy: AOM, acute bacterial sinusitis, and pharyngitis. The specific recommendations are applicable to healthy children who do not have underlying medical conditions (eg, immunosuppression) placing them at increased risk of developing serious complications. The purpose of this report is to provide practitioners specific context using the most current recommendations and guidelines while applying 3 principles of judicious antibiotic use: (1) determination of the likelihood of a bacterial infection, (2) weighing the benefits and harms of antibiotics, and (3) implementing judicious prescribing strategies (Table 1).

PRINCIPLE 1: DETERMINE THE LIKELIHOOD OF A BACTERIAL INFECTION

Many aspects of the clinical history, symptoms, and signs of bacterial URIs overlap with or mirror those of viral infections or noninfectious conditions. To make a judicious decision about antibiotic use, it is essential first to determine the likelihood of a bacterial infection. When a practitioner has made the diagnosis of viral infection and has reasonably excluded the presence of concurrent bacterial infection, antibiotics should not be used because the potential for harm outweighs the potential benefit. In the specific cases of AOM, acute bacterial sinusitis, and pharyngitis, there are well-established stringent criteria that aid in distinguishing bacterial from nonbacterial causes.

AOM

The AAP and American Academy of Family Physicians released updated clinical practice guidelines for the diagnosis and treatment of AOM in 2013.[22] AOM may be defined as "the rapid onset of signs and symptoms of inflammation in the middle ear." The signs include bulging with or without erythema of the tympanic membrane (TM), and the symptoms may include otalgia, irritability, otorrhea, and fever. The diagnosis of AOM always requires a careful otoscopic examination to confirm the presence of inflammatory changes in the TM. The AAP guideline recommends that physicians diagnose AOM definitively under either of 2 conditions: (1) evidence of middle-ear effusion, as demonstrated by moderate to severe bulging of the TM, or (2) new onset of otorrhea that is not attributable to otitis externa. AOM may also be diagnosed when a child presents with only mild bulging of the TM but with additional symptoms of recent onset of ear pain or with intense erythema of the TM. Although clear visualization of the TM at times is difficult and because AOM is typically a self-limiting disease, a high degree of diagnostic certainty is essential to minimize antibiotic overuse. After AOM is diagnosed, judicious antibiotic use can be enhanced by further categorizing patients on the basis of illness severity (severe otalgia, otalgia lasting

TABLE 1 Application of Judicious Antibiotic Principles for Pediatric URIs

Principles	AOM	Acute Bacterial Sinusitis	Acute Pharyngitis
Principle 1: Determine the likelihood of a bacterial infection	Requires middle ear effusion and signs of inflammation:	URI symptoms that are either worsening, severe, or persistent	Diagnosis of GAS pharyngitis requires confirmation by rapid testing or culture
	• moderate or severe bulging of TM; or	• Worsening symptoms: worsening or new onset fever, daytime cough, or nasal discharge after improvement of viral URI	• Only test if 2 of the following are present: fever, tonsillar exudate/ swelling, swollen/tender anterior cervical nodes, absence of cough
	• otorrhea not due to otitis externa; or	• Severe symptoms: fever ≥39°C, purulent nasal discharge	• Do not treat empirically
	• mild bulging of TM with ear pain or erythema of TM	• Persistent symptoms without improvement: nasal discharge or daytime cough >10 d	
		No role for routine imaging	
Principle 2: Weigh benefits versus harms of antibiotics	Benefits: for strictly defined AOM, NNT of as few as 4 patients to achieve improvements in symptoms	Benefits: for strictly defined bacterial sinusitis, antibiotics improve symptoms at 3 and 14 d	Benefits: for confirmed GAS, antibiotics shorten symptom duration, prevent rheumatic fever and may limit secondary transmission.
	• no significant benefits in preventing complications such as mastoiditis	• no evidence that antibiotic therapy prevents complications such as brain abscess	• Limited evidence that therapy prevents complications such as PTA
First-line therapy	Amoxicillin with or without clavulanate	Amoxicillin with or without clavulanate	Amoxicillin or penicillin
	Harms: for all conditions, no benefits to therapy when bacterial infection is not likely. Increased risk of adverse events including diarrhea, dermatitis, *C difficile* colitis, antibiotic resistance		
Principle 3: Implement judicious prescribing strategies	• Consider watchful waiting for older patients (>2 y), those with unilateral disease and without severe symptoms	• Consider watchful waiting for patients with persistent symptoms only	• Once daily dosing of amoxicillin
	• Shorter-duration therapy (7 d)		
	Not recommended: azithromycin and oral third-generation cephalosporins are generally not recommended for these conditions attributable to *S pneumoniae* resistance.		

>48 hours, or temperature ≥39°C), laterality of infection (bilateral versus unilateral), and age (≤23 months vs ≥24 months). Patients with more severe symptoms, bilateral involvement, and younger age are more likely to benefit from antibiotics. Watchful waiting is reasonable for patients who are older and have nonsevere, unilateral disease.

Acute Bacterial Sinusitis

The AAP[23] and the Infectious Diseases Society of America[21] recently developed evidence-based clinical guidelines for the diagnosis and treatment of acute bacterial sinusitis. These guidelines support use of strict diagnostic criteria to distinguish bacterial from viral URIs. In particular, acute bacterial sinusitis is diagnosed on the basis of symptoms that are (1) persistent and not improving, (2) worsening, or (3) severe. Persistent symptoms are most common and include nasal discharge (of any quality) or daytime cough not improving by 10 days. Worsening symptoms include a worsening or new onset of fever, daytime cough, or nasal discharge after improvement of a typical viral URI. Severe symptoms include persistent fever (temperature ≥39°C) and purulent nasal discharge for at least 3 days. These clinical criteria are the basis for the diagnosis of acute bacterial sinusitis. Because many children with viral URI will have radiographic abnormalities, imaging should not be performed routinely.

Acute Pharyngitis

Pharyngitis, or sore throat, may be accompanied by other nonspecific symptoms including cough, congestion, and fever. The most important diagnostic consideration is whether β-hemolytic GAS is the cause. Unlike AOM and acute bacterial sinusitis, the diagnosis of GAS infection can be confirmed with laboratory testing (either a rapid-antigen detection test or culture).[26,27] Scoring systems (Modified Centor or McIsaac Scores[28]) can assist in identifying candidates for testing. Patients with 2 or more of the following features should undergo testing: (1) absence of cough, (2) presence of tonsillar exudates or swelling, (3) history of fever, (4) presence of swollen and tender anterior cervical lymph nodes, and (5) age younger than 15 years. Children with URI signs and symptoms, including cough, nasal congestion, conjunctivitis, hoarseness, diarrhea, or oropharyngeal lesions (ulcers, vesicles) more likely have viral illnesses and not GAS infection and should not be tested for GAS. Testing should generally not be performed in children younger than 3 years in whom GAS rarely causes pharyngitis and in whom rheumatic fever is uncommon. GAS should not be diagnosed in the

absence of testing, even among patients with all of the aforementioned clinical criteria, with rare exceptions (eg, symptomatic and household contact with confirmed GAS pharyngitis). The importance of limiting testing to children with appropriate clinical criteria is further supported by the fact that colonization rates can reach 15% to 20% even among asymptomatic children.

Common Cold, Nonspecific URI, Acute Cough Illness, and Acute Bronchitis

Symptoms of the common cold, nonspecific URI, and bronchitis may overlap with or mirror those of bacterial URIs and can include cough, congestion, and sore throat. Collectively, these viral conditions account for millions of office visits per year. Acute bronchitis, in particular, is a cough illness that is diagnosed during more than 2 million pediatric office visits annually, and antibiotics are prescribed more than 70% of the time.[1] Application of diagnostic clinical criteria for AOM, sinusitis, and pharyngitis should aid clinicians in excluding these conditions. Management of the common cold, nonspecific URI, acute cough illness, and acute bronchitis should focus on symptomatic relief. Antibiotics should not be prescribed for these conditions.

PRINCIPLE 2: WEIGH BENEFITS VERSUS HARMS OF ANTIBIOTICS

If a bacterial infection is determined to be likely, the next step is to compare the evidence about the benefits of antibiotic therapy for each condition to the potential for harms. Relevant outcomes to consider for benefits include the cure rate, symptom reduction, prevention of complications, and secondary cases. Outcomes for harms include antibiotic-related adverse events (eg, abdominal pain, diarrhea, rash), *Clostridium difficile* colitis, development of resistance, and cost.

AOM

Benefits

Several high-quality randomized controlled trials and meta-analyses have been published since the publication of the first principles of judicious use of antibiotics.[18–20,29–33] Collectively, these have emphasized the following: (1) at least half of patients with AOM will recover without antibiotic therapy; (2) recovery is more likely and is hastened for children who receive antibiotic therapy compared with placebo; and (3) recovery without antibiotic therapy is less likely for younger children, those with bilateral versus unilateral disease, and those with more severe signs and symptoms. These observations underlie the rationale for treatment recommendations for AOM.

Multiple meta-analyses indicate that children receiving antibiotic therapy are more likely to achieve clinical success in terms of symptom resolution compared with placebo with a number needed to treat (NNT) of 7 or 8 patients.[18,33] Two recent randomized controlled trials among younger children that used even more stringent diagnostic criteria demonstrated that children who received antibiotics had more favorable symptom scores than those who received placebo, achieved faster symptom recovery, and had significantly lower rates of clinical failure as measured by otoscopic examination and persistence of symptoms, with an NNT closer to 4.[19,20] Nonetheless, it is important to note that in numerous studies of antibiotic efficacy for AOM, the majority of patients have symptoms that ultimately resolve spontaneously regardless of therapy and without complications. The potential for preventing complications, such as mastoiditis, may contribute, in part, to the clinical decision to use antibiotics for AOM. However, across the aforementioned controlled studies and meta-analyses, antibiotics have not demonstrated significant benefit in preventing these rare but serious complications. Observational data from the United Kingdom including more than 1 million AOM episodes indicates that when mastoiditis occurs, it typically is present at time of initial clinical presentation to care.[34] The estimated NNT to prevent 1 episode of mastoiditis is nearly 5000.[34]

The AAP recommends antibiotic therapy for children diagnosed with AOM on the basis of presence of established clinical criteria. Observation can be considered for selected children, particularly children older than 2 years with nonsevere symptoms and unilateral disease.

Acute Bacterial Sinusitis

Benefits

The evidence base evaluating the effectiveness of antibiotics for treatment of acute bacterial sinusitis in children is limited and mixed. Three randomized controlled trials have assessed the effectiveness of antibiotics versus placebo for clinically diagnosed acute bacterial sinusitis in children, 2 of which have been published since the 1998 principles of judicious use of antibiotics.[14,17,35] Two trials concluded that antibiotics significantly improved the likelihood of symptom resolution after both 3 and 14 days,[14,35] but 1 study revealed no benefit of antibiotics over placebo.[17] Key differences in the study design between these studies likely contributed to the differences in outcomes; the trials showing benefit included patients with more severe symptoms and applied more strict diagnostic criteria. This emphasizes the importance of careful attention to clinical diagnosis because antibiotics confer no clinical benefit for patients

without diagnostic criteria suggesting acute bacterial sinusitis.

The benefit of antibiotic therapy in preventing suppurative complications, such as orbital cellulitis or intracranial abscess, is unproven. Individual efficacy trials lack the statistical power to demonstrate effectiveness against these rare complications, and a meta-analysis of randomized controlled trials in children and adults found no significant association between antibiotic use and the rate of complications.[36]

The AAP recommends antibiotic therapy for children with clinical features of acute bacterial sinusitis, especially those with symptoms that are worsening or severe. Observation with close follow-up or antibiotic therapy can be considered for those with persistent symptoms (>10 days).

GAS Pharyngitis

Benefits

Antibiotic treatment of acute pharyngitis has been studied with respect to the effects on symptom resolution, transmission, and prevention of complications, including rheumatic fever. Five randomized controlled studies and 1 meta-analysis have examined the effect of immediate antibiotics on resolution of symptoms, 1 of which was completed since publication of the first principles of judicious use of antibiotics.[37–41] These studies provide strong evidence that antibiotic therapy for children with pharyngitis and confirmation of GAS shortens the duration of symptoms, including sore throat and headache, by approximately 1 day. These benefits are apparent within as few as 3 days. However, the benefits of antibiotic therapy on shortening duration of fever are uncertain. Although data are somewhat limited, antibiotic therapy for index cases of GAS may reduce horizontal transmission and thereby prevent secondary cases.[40,42] These benefits are especially relevant in large households, child care settings, schools, and military settings.

Historically, the primary motivation for prescribing antibiotics for GAS pharyngitis was prevention of rheumatic fever. Randomized controlled trials in children before 1975 showed a fourfold benefit in preventing the onset of rheumatic fever, which occurred in approximately 3% of untreated patients.[43] Although localized outbreaks have occurred in recent decades, the incidence of rheumatic fever in most developed countries has declined dramatically.[44] Some of this decline might be attributable to better recognition and antibiotic treatment,[45] but more likely this relates to a decline in the prevalence of rheumatogenic strains of GAS.[46]

Antibiotics may also have a role in preventing suppurative complications associated with GAS pharyngitis, such as peritonsillar abscess (PTA), AOM, and acute sinusitis. One meta-analysis suggested that antibiotic treatment prevents PTA; however, the majority of cases were derived from a single study conducted in 1951.[43] Data from a large observational cohort conducted in the United Kingdom suggest that antibiotic treatment may prevent development of PTA, but with an NNT >4000.[47]

The AAP recommends antibiotic therapy for children with pharyngitis confirmed to be caused by GAS.

Common Cold, Nonspecific URI, Acute Cough Illness, and Acute Bronchitis

Because the predominant etiologies for these conditions are viruses, antibiotic therapy is not indicated. Because of uncertainty about the relevance of the diagnosis of acute bronchitis for children, data are limited. Nonetheless, a large meta-analysis concluded that there was no benefit to antibiotic therapy (including for delayed prescriptions) for patients with nonspecific cough and cold.[48]

Harms of Antibiotic Therapy

It is crucial to account for the potential for antibiotics to cause harm when used for treatment of URIs. The significance of potential harms should be directly balanced against the potential for benefit on a case-by-case basis. The importance of harms associated with antibiotic use is directly related to (1) an assessment of the magnitude of potential benefit (eg, greater benefit achieved for young children with bilateral AOM than unilateral) and (2) the extent to which uncertainty remains in the diagnosis. The preponderance of evidence for benefits of antibiotic therapy in treatment of bacterial URIs relates to attenuation of symptoms. When it is unclear whether the URI represents an acute bacterial infection, in general, the harms of antibiotic use have the potential to outweigh benefits. The importance of applying stringent clinical criteria to establish the diagnosis of a bacterial infection aids in differentiating children with nonspecific URI and common cold. Prescribing antibiotics for nonspecific URI and colds generally does not provide benefit and only exposes these children to potential harm.

Antibiotics are responsible for the largest number of unplanned medical visits for medication-related adverse events among children, which exceeds 150 000 per year and incurs substantial potential morbidity and cost.[4] Antibiotic-associated adverse events can range from mild (diarrhea and rash), to more severe (Stevens-Johnson syndrome), to life-threatening (anaphylaxis or sudden cardiac death) reactions. Most clinical trials conducted to assess the treatment of AOM, sinusitis, and pharyngitis have used amoxicillin or amoxicillin-clavulanate,

and these remain the first-line recommended agents for antibiotic therapy for these conditions. Studies comparing antibiotic treatment to placebo for AOM suggest a modestly increased rate of adverse events among treated patients, particularly diarrhea and rash. Two meta-analyses estimated rate differences of approximately 5% for adverse events.[18,32] Not included in these are the results from 2 recent trials using amoxicillin-clavulanate (older studies frequently used amoxicillin), which demonstrated even higher rates of diarrhea and dermatitis among patients receiving antibiotic therapy.[19,20] Among studies of sinusitis, in the most recent trial that demonstrated a benefit of antibiotic therapy, adverse events (defined as rash, diarrhea, vomiting, and abdominal pain) occurred in 44% of patients treated with high-dose amoxicillin-clavulanate compared with 14% in the placebo group.[14]

The adverse events described previously occur relatively frequently, although are relatively mild in most cases. Antibiotics can produce serious allergic reactions such as Stevens-Johnson syndrome.[25] There is rapidly growing evidence that antibiotic exposures early in life may disrupt the microbial balance of the intestines and other parts of the body in such a way as to contribute to long-term adverse health effects, such as inflammatory bowel disease, obesity, eczema, and asthma.[49–51] A recent study highlighted risk of sudden death in adults treated with azithromycin, likely related to drug-associated prolongation of the QT interval.[24] Azithromycin is not a first-line antibiotic for any pediatric URI and is the antibiotic most likely to be used inappropriately (inadequate coverage for the most common pathogens causing AOM and sinusitis).[1] The incidence of *C difficile* colitis in hospitalized children has increased substantially during the past decade.[52] Although children with comorbid conditions are at greatest risk, community-onset infections occur,[53] with recent antibiotic exposure as an important risk factor.

The relationship between antibiotic exposure and development of antibiotic resistance at the level of the individual patient and at the level of the community is well established.[7,8] Because of limited therapeutic options, antibiotic-resistant infections are difficult to treat and, in some cases, are associated with poor clinical outcomes.[54] Application of stringent diagnostic criteria and use of therapy only when the diagnosis and potential benefits are well established is essential to minimizing the impact of antibiotic overuse on resistance in individuals and within communities.

PRINCIPLE 3: IMPLEMENT JUDICIOUS PRESCRIBING STRATEGIES

When evidence suggests that antibiotics may provide benefit, several aspects of judicious prescribing should be considered. These include selecting an appropriate antibiotic agent that treats the most likely pathogens (including accounting for local resistance patterns), selecting the appropriate dose, and treating for the shortest duration required. Additionally, physicians may consider the role of observation and use of delayed prescribing strategies.

The treatment of AOM and acute bacterial sinusitis illustrates several key aspects of judicious antibiotic use. Amoxicillin has traditionally been the recommended first-line agent for these conditions because *Streptococcus pneumoniae* is the most important cause. However, in some communities, the prevalence of amoxicillin-resistant β-lactamase-producing *Haemophilus influenzae* among bacterial URIs has increased significantly.[55] This underlies (in part) the recommendation to consider amoxicillin-clavulanate in certain instances (eg, severe symptoms, recent [<6 weeks] antibiotic exposure, known high local prevalence of amoxicillin-resistant *H influenzae*). It is important to note, however, that the benefits of antibiotic therapy appear to be greatest for patients with *S pneumonia*e infection, compared with other bacterial causes of URI, including *H influenzae* and *Moraxella* species, which may have higher rates of spontaneous resolution.[16] In recognition of the possibility of a higher rate of adverse events caused by amoxicillin-clavulanate compared with amoxicillin, some physicians may choose to use amoxicillin as the first-line agent in most instances.

An understanding of local epidemiology and resistance patterns is especially important for understanding appropriate antibiotic selection. The rates of pneumococcal resistance to macrolides[56] and oral third-generation cephalosporins[57,58] make these agents poor choices for treating most children with suspected bacterial URIs. Emergence of macrolide resistance to GAS is also an important problem, although susceptibility testing is not routinely performed.

The role of observation (also termed "wait and see" or "delayed prescribing") instead of immediate antibiotic therapy is an important consideration for children with AOM and acute bacterial sinusitis. Studies among patients with AOM have shown that this approach reduces antibiotic use, is well accepted by families, and, when supported by close follow-up, does not result in worse clinical outcomes.[22] Observation therapy may be considered as an alternative strategy to immediate therapy for AOM and sinusitis for older patients without severe symptoms.[22,23] The use of this approach is an opportunity to engage in shared decision-making with patients and families to include a discussion

about the potential benefits and risks associated with immediate antibiotic therapy.

Another important consideration for judicious antibiotic use is overall magnitude of exposure. Relatively short courses of therapy may achieve the same clinical benefits as longer courses while minimizing the risks of adverse events and development of resistance and lead to better compliance. Important examples are the use of once-daily amoxicillin for GAS pharyngitis[26] (vs 2 or 3 times daily dosing but the same daily dose of 50 mg/kg) and short-course therapy (eg, 7 days vs 10 days) for older children with AOM.[22]

CONCLUSIONS

This clinical report discusses principles of judicious antibiotic use for pediatric URIs. There is a strong emphasis on appropriate diagnosis, which is the foundation for making judicious decisions about prescribing antibiotics. Although focused on specific URIs, the main message has broader application for antibiotic use in general. These principles can be used to promote educational efforts for physicians, amplify the messages from recent clinical guidelines, assist with communication about appropriate antibiotic use to patients and families, and support local guideline development for judicious antibiotic use.

To promote optimal health and well-being of all children, the American Academy of Pediatrics (AAP) supports access for all children to (1) civil marriage rights for their parents and (2) willing and capable foster and adoptive parents, regardless of the parents' sexual orientation. The AAP has always been an advocate for, and has developed policies to support, the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. In so doing, the AAP has supported families in all their diversity, because the family has always been the basic social unit in which children develop the supporting and nurturing relationships with adults that they need to thrive. Children may be born to, adopted by, or cared for temporarily by married couples, nonmarried couples, single parents, grandparents, or legal guardians, and any of these may be heterosexual, gay or lesbian, or of another orientation. Children need secure and enduring relationships with committed and nurturing adults to enhance their life experiences for optimal social-emotional and cognitive development. Scientific evidence affirms that children have similar developmental and emotional needs and receive similar parenting whether they are raised by parents of the same or different genders. If a child has 2 living and capable parents who choose to create a permanent bond by way of civil marriage, it is in the best interests of their child(ren) that legal and social institutions allow and support them to do so, irrespective of their sexual orientation. If 2 parents are not available to the child, adoption or foster parenting remain acceptable options to provide a loving home for a child and should be available without regard to the sexual orientation of the parent(s). *Pediatrics* 2013;131:827–830

INTRODUCTION

All children need support and nurturing from stable, healthy, and well-functioning adults to become resilient and effective adults. On the basis of a review of extensive scientific literature, the American Academy of Pediatrics (AAP) affirms that "children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents."[1]

Families' structural forms are varied. In 2010, married adults were raising 65.3% of all children in this country.[2] The other 34.7% of children (25.9 million of 74.63 million children) were living in a variety of situations. Many were being raised by parents who were single or cohabiting, either by choice or by circumstance. Growing numbers of grandparents are stepping in as parents to 2.5 million children when necessary.[2] When none of a child's biological relatives is available or able to provide necessary nurturing and support, other arrangements exist to nurture children. Foster parenting and adoption are substitute arrangements that can provide financial, emotional, social, and legal support for children. In 2007, >400 000 children were in foster care, and 130 000 children were adopted by unrelated adults.[3,4]

Increasing numbers of same-gender couples are raising children today, and the numbers are likely to increase in the future. The US 2010 Census reported that 646 464 households included 2 adults of the same gender.[5,6] These same-gender couples are raising ~115 000 children aged ≤18 years and are living in essentially all counties of the United States.[5,6] When these children are combined with single gay and lesbian parents who are raising children, almost 2 million children are being raised by gay and lesbian parents in the United States.[7]

Civil marriage is the legal and social institution in modern society that serves as the basic building block for family structure and child-rearing. Marriage is generally considered the optimal relationship between 2 adults who share responsibility for children. Marriage brings 2 extended families together to provide long-term security and social and emotional support to all members of the newly formed family. Marriage offers many legal rights and responsibilities, including the joint responsibility to care for children and to make decisions (including medical decisions) for them. A report from the AAP Task Force on the Family noted that married couples have more financial and social resources to nurture and raise children.[8] Additionally, "married men and women are physically and emotionally healthier and are less likely to engage in health risk behaviors . . . than are unmarried adults."[8] A number of studies have documented "a positive relationship between the quality of marital life and family functioning."[9] The Task Force report emphasized: "As we move forward, the Academy and pediatricians stand ready to serve all children in all families, regardless of the family structure in which they live."[8]

There are few social or legal restrictions limiting the ability of 2 unrelated adults to marry in the United States. These include (1) age: states have different age limits before which parental permission is required for marriage; (2) numerosity: there is a long-standing prohibition on bigamy/polygamy; (3) the existence of blood relationships; and (4) cognitive capacity to consent. The only other exception applies to adults seeking same-gender relationships (in most states).

There is extensive research documenting that there is no causal relationship between parents' sexual orientation and children's emotional, psychosocial, and behavioral development.[1,10–19] Many studies attest to the normal development of children of same-gender couples when the child is wanted, the parents have a commitment to shared parenting, and the parents have strong social and economic supports. Indeed, current research has concluded that "In all, it is now well-established that the adjustment of children and adolescents is best accounted for by variations in the quality of the relationships with their parents, the quality of the relationship between the parents or significant adults in the children's and adolescents' lives, and the availability of economic and socio-economic resources."[19]

Therefore, the AAP has endorsed, for more than a decade, a policy supporting the benefits of both parents in a same-gender couple having legal rights and responsibilities for their child(ren), for example, through second-parent or coparent adoption.[20] A special article in *Pediatrics* in 2006 reviewed the legal issues associated with civil marriage, civil union, and domestic partnership and noted a number of disparities for children growing up in various legal arrangements.[10] The American Medical Association has recently noted the disparities that exist for parents of the same gender who lack marriage equality as well as for their children.[21] Many other professional organizations have adopted policies urging legislative changes and legal mechanisms, including adoption, foster parenting, and civil marriage, for gay and lesbian adults who wish to be parents.* Civil unions and domestic partnerships do not confer the same legal rights, protections, and benefits to children that civil marriage provides.[10]

Public policy related to marriage and family is largely a state function. Consequently, the laws across the country that regulate marriage, adoption, and foster parenting by gay men and lesbians are an inconsistent patchwork. Even civil marriage in a state that

*National organizations that support marriage equality: American Civil Liberties Union (June 1998), National Association of Social Workers (June 2004), American Psychological Association (July 2004), American Psychiatric Association (May 2005), American Psychoanalytic Association (January 2008), American Bar Association (August 2010), American College of Nursing (July 2012), and American Academy of Family Physicians (October 2012). National organizations that support gay and lesbian parenting and the nurturing of children: American Academy of Child and Adolescent Psychiatry, American College of Obstetrics and Gynecology, American Medical Association, Child Welfare League of America, National Adoption Center, National Education Association, North American Council on Adoptable Children, and Voice for Adoption.

permits it does not ensure access to federal benefits. The federal Defense of Marriage Act (1996; Pub. L. No. 104-199) denies members of married same-gender households access and benefits equivalent to those available to households headed by married parents of different genders, such as (1) Social Security and related programs, (2) housing and food stamps, (3) federal civilian and military service benefits, (4) employment benefits, (5) immigration and nationality status, (6) remedies and protections for crimes and family violence, and (7) certain loans and financial guarantees.[10,21] For this reason, the AAP has joined with other national organizations in support of the position that the Defense of Marriage Act is unconstitutional.[†]

A core mission of the AAP is to support the best interests of all children, regardless of their home or family structure, on the basis of the common principles of justice. If a child has 2 living and capable parents who choose to create a permanent bond by way of civil marriage, it is in the best interests of their child(ren) that legal and social institutions allow and support them to do so. If 2 parents are not available to the child, adoption or foster parenting remain acceptable options to provide a loving home for a child and should be available without regard to the sexual orientation of the parent(s).

RECOMMENDATIONS

The AAP works to ensure that public policies help all parents, regardless of sexual orientation and other characteristics, to build and maintain strong, stable, and healthy families that are able to meet the needs of their children. In particular, the AAP supports:

1. Marriage equality for all capable and consenting couples, including those who are of the same gender, as a means of guaranteeing all federal and state rights and benefits, and long-term security for their children.
2. Adoption by single parents, coparents adopting together, or a second parent when 1 parent is already a legal parent by birth or adoption, without regard to the sexual orientation of the adoptive parent(s).
3. Foster care placement for eligible children to qualified adults without regard to their sexual orientation.

ACKNOWLEDGMENT

The authors and the committee thank James G. Pawelski, MS, for his valuable contributions to the development of this policy statement.

TECHNICAL REPORT

Promoting the Well-Being of Children Whose Parents Are Gay or Lesbian

abstract

FREE

Extensive data available from more than 30 years of research reveal that children raised by gay and lesbian parents have demonstrated resilience with regard to social, psychological, and sexual health despite economic and legal disparities and social stigma. Many studies have demonstrated that children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents. Lack of opportunity for same-gender couples to marry adds to families' stress, which affects the health and welfare of all household members. Because marriage strengthens families and, in so doing, benefits children's development, children should not be deprived of the opportunity for their parents to be married. Paths to parenthood that include assisted reproductive techniques, adoption, and foster parenting should focus on competency of the parents rather than their sexual orientation. *Pediatrics* 2013;131: e1374–e1383

INTRODUCTION

The mission of the American Academy of Pediatrics (AAP) is to promote optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. Historically, the AAP has worked, through its educational, research, advocacy, and policy efforts, to highlight the powerful connection between children's well-being and the functioning of their most enduring source of support and influence—their parents. It is vital that pediatricians understand the unique and complex characteristics of their patients' families and support them to ensure optimal development of children.

All children have the same needs for, and the right to, nurturing, security, and social stability. Children whose parents are gay and lesbian have historically been subjected to laws, social policies, and disapproving attitudes that create social distance and ostracism and challenge the stability of their families as well as their optimal social and psychological development. This technical report provides the scientific rationale, based on the current available evidence, to support the recommendations outlined in the policy statement "Promoting the Well-Being of Children Whose Parents are Gay or Lesbian"[1]: support for marriage equality, including repeal of the federal Defense of

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

Marriage Act and similar public policies that limit access to federal benefits associated with civil marriage for gay and lesbian couples, and the right of gay and lesbian adults to adopt and provide foster care for eligible children.

Children depend on their parents for guidance, nurturing, protection, support, and love. Their resiliency derives from their sense of permanence, security, and unconditional attachment. As a consequence of this central value to their children, modern societies have developed the legal and social contract of marriage to ensure the permanent commitment of parents to each other and to their children, and thus to provide an optimal environment for children to thrive. The value of children to society is reflected also in the many public policies and programs that are designed to ensure adequate resources and support to parents who are raising a child alone, by choice or circumstance, and to families that because of physical or mental illness, abuse, neglect, and/or financial difficulty, cannot function successfully in their capacity as parents. Families created by gay and lesbian adults are no exception to these broad social policies.

Because of the value of marriage to the society, there are few legal restrictions on who can marry. The only legal limitations to marriage equality for consenting adults in the United States are for adults who are certified as mentally/emotionally incompetent, for whom marriage would lead to a polygamous relationship, who are of minor age, who are related by blood, or who are the same gender (in a majority of the states). Even a history of child abuse, domestic violence, or other criminal activity does not disqualify adults from civil marriage. Despite conflicts based on individuals' political and religious beliefs, it is important to recognize that laws restricting competent adults of the same gender from codifying their commitment to each other and their children via civil marriage may result not only in pain and hardship for their children but also in legal, economic, psychological, social, and health disparities that can no longer be justified.

DIVERSE FAMILIES

The 2003 report of the AAP Task Force on the Family stated that: "No particular family constellation makes poor or good outcomes for children inevitable."[2] The report continued: "A stable, well-functioning family that consists of 2 parents and children is potentially the most secure, supportive, and nurturing environment in which children may be raised. That children can be successfully brought to adulthood without this basic functioning unit is a tribute to those involved who have developed the skill and resiliency to overcome a difficult and fundamental challenge."[2]

Families are diverse, complex, and changing. Most US public policy is built on the presumption that the majority of families are composed of a married mother and father raising their biological children. In contrast, the 2010 US Census revealed that the proportion of children living with 2 married biological parents had declined to 65.3%, down from 69.2% in 2001.[3] See Table 1 for further elucidation of family types based on the 2010 Census.

Determining the number of children being raised by lesbian and gay parents is challenging, because most surveys do not ask about parents' sexual orientation. Starting with the 2000 Census, gay and lesbian couples have had the option to identify themselves as spouses.[4] The 2010 Census identified 131 729 self-reported married same-gender households and 514 735 same-gender unmarried partner households located in essentially all counties of the United States.[4–6]

Thirty-one percent of same-gender couples who identified as spouses and 14% of those who identified as unmarried partners indicated that they were raising children, more than 111 000 in all.[5] In addition to these parents, many single gay men and lesbians are also raising children. Combined, current estimates suggest that almost 2 million children younger than 18 years are being raised by at least 1 gay or lesbian parent in the United States.[6,7]

Families with a gay or lesbian parent (or parents) are, themselves, a diverse group.[8,9] For example, 55% to 59% of same-gender couples with children identify as white compared with 70% to 73% of married heterosexual couples with children.[7] Same-gender couples, like heterosexual couples, may become parents by having children in previous heterosexual relationships or through fostering, adoption, donor insemination, and/or surrogacy.[10]

LEGAL DISPARITIES CREATED BY STATE LAWS

Regulations and laws about the rights and responsibilities of parenthood are primarily state specific, resulting in

TABLE 1 Children in the United States 2010: Family Status

Family Status	Number of Children (Millions)[a]	Children in the United States, %
Children in 2-parent households	51.456	73.0
Children with married parents living together	48.516	65.3
Children with unmarried parents	2.940	3.9
Children with single/separated parents	20.263	27.1
Children being raised by 1 or more grandparents	2.595	3.5

[a] Total number of children in the United States: 74.630 million.

great variability among the states. Many legal and social disparities exist for same-gender couples and their children.[11]

- A critical disparity for children of unmarried parents is the absence of the protections reflected in divorce law. Thus, in the event of the dissolution of the couple's relationship, these families lack the protections that exist for children whose parents are married, such as:
  1. Access to the courts for a legally structured arrangement for dissolution of the relationship;
  2. A court-approved legal arrangement for visitation rights and/or custody of children; and
  3. Entitlement for children to financial support from and ongoing relationships with both parents.
- The majority of states prohibit, by statute or state constitutional amendment, recognition of same-gender marriage.[12] A few states extend other forms of relationship recognition, such as civil union or domestic partnership.
- A few states, either by statute, regulation, or legal interpretation, restrict or prohibit foster parenting by same-gender couples and/or lesbians and gay men.
- Laws regarding joint adoption by same gender couples, wherein both individuals become the legal parents of a biologically unrelated child, vary from state to state.[13] Joint adoption by lesbian and gay couples is expressly prohibited in a few states, granted by law in fewer than half, and not addressed by statutes in most states.
- Only in states that recognize civil marriage or other forms of domestic relationships can a lesbian or gay spouse or partner be recognized as a legal parent or step-parent to the child(ren) she or he is helping raise. In the majority of states, this is not a legal option.
- In the United States (but not in much of Europe), sperm and egg donors may choose to remain anonymous and take on no legal responsibility for any children born. In a few states, a donor may be considered a legally recognized parent and have related responsibilities. A few states have laws ensuring that both parents are legally recognized as "presumed parents" of the child.
- Most states lack a formal mechanism to ensure basic rights and responsibilities to nonbiological, nonadoptive coparents. Such laws are important to children when adult couple relationships are in dissolution and appropriate custody is under consideration.
- Legal arrangements with a surrogate carrier are available in only a few states to gay men who wish to have a biologically related child.
- In the event of death of a spouse, partner, or parent, state laws do not provide for Social Security or veteran's survivor benefits for the surviving spouse/partner and children.

LEGAL DISPARITIES CREATED BY FEDERAL LAWS AND REGULATIONS

Restrictions against civil marriage for same-gender couples, such as the federal Defense of Marriage Act (Pub L No. 104-199 [1996]) and replications of it in state statutes and constitutions, deny these couples and their children numerous other protections and benefits deemed valuable by society and government to which heterosexual married couples and their children have access. Under the Defense of Marriage Act, these benefits are not available to couples of the same gender even if they are legally married in a state that recognizes same-gender marriage. The US Government Accountability Office has identified a total of 1138 federal statutory provisions in which marital status was a factor in determining or receiving rights, benefits, and protections. These have been outlined elsewhere in detail[14]; a few examples are presented here:

- Legal recognition of a couple's commitment to and responsibility for one another and legal recognition of a child's relationship to both parents and joint parenting rights;
- Tax-exempt employer-sponsored health and other insurance benefits for spouse/partner and nonbiological/not jointly adopted children;
- Ability to consent to medical care or authorize emergency medical treatment of nonbiological/not jointly adopted children;
- The ability to travel with a child if it will require proof of being a legal parent;
- The ability to file joint income tax returns and take advantage of family-related deductions, including the ability to use the child tax credit, child and dependent care tax credit, dependency exemption, earned income tax credit, and gift and estate tax exemption; and
- A surviving parent's right to the custody of and care for, and children's right to maintain a relationship with, a nonbiological or not legally recognized parent in the event of the death of the other parent.

HEALTH DISPARITIES

- Because children cannot legally consent to medical treatment, the lack of uniform legal recognition of

lesbian and gay parents results in parents being prohibited from accompanying their child(ren) and making medical decisions for them in routine and even emergency situations. Parents may even be barred from visiting their child in the hospital if their parental status is ambiguous.

- Another challenge for same-gender couples and their families is obtaining health insurance. As a result of the federal Defense of Marriage Act, employers are not required to, although some choose to, offer health benefits to same-gender spouses or partners or children of lesbian and gay employees, even if those workers are legally married in their state. As a result, same-gender couples are 2 to 3 times less likely to have health insurance than are heterosexual couples.[7,15] This disparity affects children directly, because the vast majority of children (more than 84%) have the same health insurance status as their parents (public or private insurance or uninsured[16]). Evidence that health insurance coverage is directly associated with health status is undeniable.[17]
- Even when employers do make health insurance benefits available to same-gender spouses, partners, and related children, these families are faced with an economic disadvantage compared with their heterosexual counterparts. Such benefits are considered by the Internal Revenue Code to be taxable or "imputed" income to the employee unless the spouse or partner or child qualifies as a legal dependent. In addition, employers must also pay taxes on this imputed income for their share of the employee's payroll tax.
- Lesbian- and gay-headed families are at greater peril than heterosexual-headed families when a parent loses a job or takes a cut in pay. The Consolidated Omnibus Budget Reconciliation Act of 1995 (COBRA [Pub L No. 99-272]) provides workers and their families who lose their health benefits the capacity to continue group health benefits provided by their employer group health plan for limited periods of time. However, the COBRA, as federal legislation, does not require employers, even those who provide benefits for same-gender spouses/partners and their dependents, to offer lesbian and gay employees the opportunity to enroll their spouses, partners, or children.
- Additional challenges exist in the provision of health care. Physicians, hospitals, and other health care professionals and environments may not offer a welcoming environment for same-gender parents and their children. The reaction a family may encounter ranges from acceptance to disdain: sometimes pediatricians and others encountered in health care settings or institutions may express stigmatizing attitudes or refuse to recognize an unmarried parent, especially when that parent is part of a gay or lesbian couple. Among respondents in a survey of gay and lesbian parents in New York, 42% reported that dislike of lesbian and gay people was a barrier to accessing health care and reported a lack of appropriately trained, competent professionals to deliver health care to lesbian and gay people.[18] According to the October 2011 report, *All Children Matter: How Legal and Social Inequalities Hurt LGBT Children*, "a family may shy away from scheduling a child's doctor's visit in an effort to shield him or her from hostile questions or misunderstandings. For parents who must rely on medical professionals with unknown attitudes toward lesbian and gay patients, concerns linger about treatment of them and their children, which can make care more difficult to obtain."[7] Some parents report worries about being blamed for their child's physical or emotional disorders because of their sexual orientation or family constellation.[19]

CHILDREN'S DEVELOPMENTAL TRAJECTORY AND PSYCHOLOGICAL OUTCOMES

Many factors confer risk to children's healthy development and adult outcomes, such as poverty, parental depression, parental substance abuse, divorce, and domestic violence, but the sexual orientation of their parents is not among them. Many studies have assessed the developmental and psychosocial outcomes of children whose parents are gay or lesbian and note that a family's social and economic resources and the strength of the relationships among members of the family are far more important variables than parental gender or sexual orientation in affecting children's development and well-being.[20] A large body of scientific literature demonstrates that children and adolescents who grow up with gay and/or lesbian parents fare as well in emotional, cognitive, social, and sexual functioning as do children whose parents are heterosexual.[21–37] Although the methodologic challenges are daunting in addressing phenomena as complex and multifactorial as children's long-term developmental and psychosocial outcomes, the literature accumulated over more than 30 years, taken together, provides robust, reliable, and valid assurance about the well-being

of children raised by parents of the same gender.[28,29]

The first review of available data regarding the well-being of children living with lesbian or gay parents concluded that "While research on these topics is relatively new….there is no evidence that the development of children with lesbian and gay parents is compromised in any significant respect relative to that among children of heterosexual parents in otherwise comparable circumstances."[30]

Another early review summarized 23 articles published before 2000 that, together, described 615 offspring of lesbian mothers and gay fathers and 387 controls by using a variety of psychological tests and interviews. The conclusion drawn from these studies was that children raised by gay and lesbian parents did not systematically differ from other children in emotional/behavioral functioning, sexual orientation, experiences of stigmatization, gender role behavior, or cognitive functioning.[31]

A more recent comprehensive review of the experiences of gay and lesbian parents and their children reaffirmed that most children raised by lesbian and gay parents are developmentally and socially well-adjusted and that the societal presence of stigma, heterosexism, family circumstance, structure, and process are more important influences on children's developmental trajectory than is the gender or sexual orientation of their parents.[32]

Much of this early research about children with gay and lesbian parents was, by necessity, based on relatively small convenience samples. Nevertheless, more than 100 scientific publications over 30 years, taken together, have demonstrated that children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents.[20,33,34]

Increasing recognition and acceptance of lesbian and gay parents has allowed for larger, community-based and national studies in the United States and Europe. Three studies are of particular note. Using data obtained in a large US population-based survey, the National Longitudinal Study of Adolescent Health, the 44 adolescents who reported being raised by 2 women in a "marriage-like" family arrangement were compared with a random sample of 44 adolescents raised by heterosexual parents.[35,36] There were no differences noted in measures of self-esteem, depression, anxiety, school connectedness, and school success. The authors concluded that "adolescents were functioning well and their adjustment was not associated with family type." In both groups of adolescents, those who described a "closer relationship with their parents" reported less delinquent behavior and substance abuse; that is, the quality of parent-adolescent relationships better predicted adolescent outcomes than did family type.

Another community-wide study was based on data from a cohort of 14 000 mothers of children born within a particular county in England during 1 year.[37] The study examined the quality of parent-child relationships and socioemotional and gender development in a community sample of 5- to 7-year-old children with lesbian mothers. Thirty-nine lesbian mother families were compared with 74 two-parent heterosexual families and 60 families headed by single heterosexual mothers. No differences were found in maternal warmth, emotional involvement, enjoyment of motherhood, frequency of conflicts, supervision of the child, abnormal behaviors reported by parents or teachers in the child, children's self-esteem, or psychiatric disorders. Both mothers and teachers reported more behavioral problems among children in single-parent families than among children who had 2 parents in the home, irrespective of their sexual orientation.

A recent publication was based on a large national sample of US adults who were asked whether their parents had ever had a relationship with a person of the same gender while they were growing up and whether they had ever lived with that parent while the parent was involved in such a relationship.[38] Parents who were said to have had a same-gender relationship were categorized as lesbian or gay parents, although their sexual orientation was not directly determined. In comparison with those who did not report that a parent had had a same-gender relationship, a number of adverse outcomes were identified, including being on public assistance, being unemployed, and having poorer educational attainment. Extensive critique of this study[39–44] has pointed out that:

- It is well known that family instability, and in particular divorce, is a risk factor for children,[45,46] and almost all of the respondents whose parent had had a same-gender relationship had also experienced the divorce of their parents.
- These data reflect an era when stigmatization and discrimination toward same-gender couples and their children were strong and were likely to have contributed to less-than-optimal child-rearing environments.[40]
- Respondents were certainly not children "raised by" lesbian or gay parents, because only half were living with these parents,

and the sexual orientation of the parents was not determined.[41,42]

- The great variability in the form and characteristics of both same-gender and heterosexual relationships, combined with the small number of those relationships, even in a large data set like this one, makes it impossible to sort out true evidence of causality.[43]

A longstanding longitudinal study of children born to lesbian parents in the United States provides further insight into the well-being of children raised from birth by lesbian parents. The National Longitudinal Lesbian Family Study began in 1986, enrolling 154 lesbian mothers who became pregnant through donor insemination (70 birth mothers, 70 comothers, and 14 single mothers). These mothers have been enrolled in the study for more than 17 years, maintaining a retention rate of 92%. Recent publications describe the outcome of 78 adolescent offspring at age 17 (39 girls and 39 boys) on the basis of mothers' and adolescents' reports and comparing them with national standardization samples. The mothers' reports about their 17-year-old sons and daughters indicated that they had high levels of social, school/academic, and total competence and fewer social problems, rule breaking, and aggressive and externalizing behavior compared with their age-matched counterparts in the Achenbach Child Behavior Checklist's standardization sample. There were no differences between offspring who were conceived by known or anonymous donors or between offspring whose parents were still together and those whose mothers had separated.[47] An accompanying editorial noted, "Can these data reassure those who fear that homosexual relationships with or without children will herald the end of the family as we know it? Our experience tells us of the resilience of children who are loved and know that love. … And when we see these moms or dads with their kids in our practice, we call them families."[48]

The self-reported quality of life of the adolescents in this sample was similar to that reported by a comparable sample of adolescents with heterosexual parents.[49] Lesbian parents reported that they planned to expose their children to male role models as an important child-rearing strategy. Half of both the girls and the boys had identified a male role model in their lives. There were no significant associations between gender role traits, adolescent psychological adjustment, gender of the adolescent, and the presence or absence of male role models.[50]

More data are available to document the well-being of children whose parents are lesbian than of those whose parents are gay men, because the numbers of gay men parenting have, until recently, been small. Recent studies affirm that families created by gay men resemble closely those created by lesbians.[51] For example, a recent study assessed child development and parenting among 27 lesbian, 29 gay, and 50 heterosexual couples who had adopted a child.[52] Lesbian and gay parents were similar in a variety of parenting characteristics to their heterosexual counterparts. Children in all family types were functioning similarly and had few behavior problems. Average scores for internalizing, externalizing, and total behavior problems reported by parents and teachers were similar to population averages for the child development instruments. In particular, there were no differences among the family types in children's adjustment, parenting stress, parent discipline techniques, and couple adjustment. As in previous studies, teachers' ratings of behavior noted that behavior problems were more likely in children with single parents than with 2 parents, irrespective of their sexual orientation. Instead, "parents who reported less parenting stress, use of more effective disciplinary techniques and who had greater happiness in their couple relationships had children who were described as well off."[51]

Some authors have investigated children's academic performance as an indicator of their well-being. Two articles compared the academic achievement of children whose parents were gay or lesbian with children whose parents were heterosexual. Although the studies were performed with different methodologies and in different population groups, both revealed similar academic achievement in the 2 groups. Using an analysis of US Census data to perform the first large-sample, nationally representative analysis of educational outcomes, the author concluded that "children of same-sex couples are as likely to make normal progress through school as the children of most other family structures."[53] Another study demonstrated that lower academic achievement was related more to the number of family transitions experienced by children than to the sexual orientation of their parents.[54]

A few publications have suggested less positive outcomes for children raised by same-gender parents. For example, a small study from Australia[55] has sometimes been cited in support of the proposition that children raised by lesbians and gay men are less well-adjusted than those raised by heterosexual couples. The study was based on a comparison of teachers' reports about 58 children in each of 3 groups of parents: married, heterosexual cohabiting, and gay or lesbian cohabiting. A primary goal of the

study was to understand possible disadvantages to children's school and social performance on the basis of the marriage versus cohabitation of their parents. It is critical to note that:

- At the time of the research, marriage was available only to heterosexual parents, and therefore, all gay or lesbian couples were, by definition, cohabiting.
- There is strong evidence provided in the article that the children with gay or lesbian parents were severely stigmatized in their schools and communities.
- Most of the children with gay or lesbian parents had experienced the divorce of their heterosexual birth parents, in many cases shortly before the time of study, thus potentially adding to the children's stress.[45,46]

The study's findings included considerable variation in the ratings given by teachers with regard to the children's school behavior and performance. For example, children with gay or lesbian parents were rated as performing less well in language and math but better in social studies and as having a better attitude toward learning, compared with the children being raised by cohabiting or married heterosexual parents. The deleterious effects of divorce and of stigmatization on children's development are described by the author as likely contributors to the areas of poorer performance of the children with gay or lesbian parents. Overall, the author's conclusions emphasized the benefits of marriage: "married couples seem to offer the best environment for a child's social and educational development."[55] In another article, the same author reported a comparison of cohabiting adults of the same and of different genders and concluded that, in substantial ways, the relationships of cohabiting adults are similar, whether the partners are of the same or different genders.[56]

A 2012 commentary has described various shortcomings of the aforementioned research in support of adoption rights and marriage equality for same-gender couples.[57] In general, this critique pointed out that most studies have included small and selective samples; have rarely reported longitudinal data and, therefore, have reported only short-term outcomes; and often have not included a comparison group. While agreeing with the imperfections of past research in this area, others have pointed out the intrinsic complexities of this research agenda[40] and commented that, despite these imperfections, it is likely that the extensive research efforts that have been carried out would have documented serious and significant damages if they existed. In addition, it is important to note that all past research about children growing up with gay or lesbian parents has taken place in the context of pervasive social stigma and includes a majority of children whose parents were either single or divorced, each of which can be expected to contribute to poor outcomes for children.[39]

Although studies of uncommon and varied phenomena are difficult to perform and yield incomplete and imperfect results, there is an emerging consensus, based on an extensive review of the scientific literature, that children growing up in households headed by gay men or lesbians are not disadvantaged in any significant respect relative to children of heterosexual parents. Indeed, the fact that most data suggest that children grow up successfully in families created by gay and lesbian parents despite the almost-universal family disruption and social stigma they have experienced attests to the resilience of these families. Greater acceptance and support of these families will provide an environment even more conducive to successful social and emotional development.

Over the past decade, 11 countries have recognized marriage equality and, thus, allow marriage between 2 partners of the same gender: Argentina, Belgium, Canada, Denmark, Iceland, Netherlands, Norway, Portugal, Spain, South Africa, and Sweden. There has been no evidence that children in these countries have experienced difficulties as a result of these social changes.

WHEN MARRIAGE IS NOT AN OPTION

The AAP recognizes that some children are members of families headed by a single parent or by 2 parents who do not choose to be legally married and that it is possible for these parents to overcome the challenges involved in raising children in these circumstances. The AAP also acknowledges that some children have been removed from severely challenged families and are in temporary custody of a state agency or a related adult. There is no evidence that restricting these children's access to loving and nurturing adoptive or foster care homes on the basis of gender or sexual orientation of the parents is in their best interests.[52,58]

MARRIAGE MATTERS

The AAP Task Force on the Family reported that "married men and women are physically and emotionally healthier and are less likely to engage in health risk behaviors, such as alcohol or drug abuse, than are unmarried adults."[2] Both men and women live longer when married, presumably in part because they have healthier lifestyles, eat better, and

monitor each other's health.[2] They tend to have relationships with more people and social institutions, which increases their level of social support. It has been well established that permanently married parents can create the best environment for children's development.[2,59]

Marriage supports permanence and security (the basic ingredients for the healthy development of children). Marriage is also the official societal mechanism for conferring rights, benefits, and protections that support couples as spouses and parents and their children financially and legally. In a survey of married same-gender couples in Massachusetts, the first state to allow civil marriage for same-gender couples, 24% of the respondents noted that their children had previously been explicitly teased or taunted about having a gay or lesbian parent, but 93% of respondents stated that marriage has made their children happier and better off.[60] Eighty-four percent of parents stated that their being married made them feel more comfortable working with their child (ren)'s teachers at school.

CONCLUSIONS

On the basis of this comprehensive review of the literature regarding the development and adjustment of children whose parents are the same gender, as well as the existing evidence for the legal, social, and health benefits of marriage to children, the AAP concludes that it is in the best interests of children that they be able to partake in the security of permanent nurturing and care that comes with the civil marriage of their parents, without regard to their parents' gender or sexual orientation.

Marriage equality can help reduce social stigma faced by lesbian and gay parents and their children, thereby enhancing social stability, acceptance, and support. Children who are raised by married parents benefit from the social and legal status that civil marriage conveys to their parents.

When marriage of their parents is not a viable option, children should not be deprived of the opportunity for temporary foster care or adoption by single parents or couples, irrespective of their sexual orientation. Public policy and community support are vital to the success of children in these circumstances.

Pediatricians working to eliminate disparities and establish support, stability, and security of all families through marriage equality and legal parental recognition honor the AAP mission to promote the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults.

ACKNOWLEDGMENT

The authors and the committee thank James G. Pawelski, MS, for his valuable contributions to the development of this technical report.

Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity

- *Policy Statement*

POLICY STATEMENT

Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity

abstract

FREE

Child health and housing security are closely intertwined, and children without homes are more likely to suffer from chronic disease, hunger, and malnutrition than are children with homes. Homeless children and youth often have significant psychosocial development issues, and their education is frequently interrupted. Given the overall effects that homelessness can have on a child's health and potential, it is important for pediatricians to recognize the factors that lead to homelessness, understand the ways that homelessness and its causes can lead to poor health outcomes, and when possible, help children and families mitigate some of the effects of homelessness. Through practice change, partnership with community resources, awareness, and advocacy, pediatricians can help optimize the health and well-being of children affected by homelessness. *Pediatrics* 2013;131:1206–1210

INTRODUCTION

An estimated 1.6 million children, or nearly 1 in 45 American children, experienced homelessness in 2010.[1] Although a national economic downturn and an increase in housing foreclosures contribute to family homelessness, additional adversity and risk factors often contribute to this complex problem. Children affected by homelessness may experience a variety of challenges to their health because of difficulty accessing health care, inadequate nutrition, education interruptions, trauma, and family dynamics. By recognizing these challenges, pediatricians can help improve the care of these children in practices and communities.

DEFINING AND MEASURING HOMELESSNESS

The US Department of Education defines a homeless individual as "(A) an individual who lacks a fixed, regular, and adequate nighttime residence . . . and (B) includes (i) children and youths who are sharing the housing of other persons due to loss of housing, economic hardship, or a similar reason; are living in motels, hotels, trailer parks, or camping grounds due to the lack of alternative accommodations; are living in emergency or transitional shelters; are abandoned in hospitals; or are awaiting foster care placement; (ii) children and youths who have a primary nighttime residence that is a public or private place not designed for or ordinarily used as

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

a regular sleeping accommodation for human beings …; (iii) children and youths who are living in cars, parks, public spaces, abandoned buildings, substandard housing, bus or train stations, or similar settings; and (iv) migratory children who qualify as homeless for the purposes of this subtitle because the children are living in circumstances described in clauses (i) through (iii)."[2]

Measuring the homeless population is difficult, and there are no definitive counts of homeless persons in the United States. The US Census Bureau does not currently attempt to estimate the total homeless population; however, the US Department of Housing and Urban Development collects data on shelter usage and makes point-in-time estimates of homelessness. The 2011 Annual Homeless Assessment Report to Congress estimates that approximately 1.5 million homeless people used an emergency shelter or transitional housing during 2010–2011, and on a single night in January 2011, 636 017 people were homeless. From 2007 to 2011, the number of children in shelters increased by 1.9% and families with children comprised 35.8% of the total sheltered population in 2011. In addition, from 2007 to 2011, the number of families that moved from stable housing arrangements to the shelter system increased by 38.5%.[3] These estimates did not include homeless persons who were unsheltered or living temporarily with other families. The incidence of homelessness in the United States in a given year is thought to be much higher.

RISK FACTORS

Although all populations experience homelessness, some populations are disproportionately affected. Major risk factors for homelessness among parents include unemployment, substance abuse, mental illness, previous military service, and a previous history of domestic violence or physical or sexual abuse.[4] An analysis of homelessness in a national cohort of US adolescents revealed that poor family relationship quality, school adjustment problems, and victimization during adolescence were each independent predictors of homelessness in adulthood.[5] Among homeless youth, a sexual orientation other than heterosexual and a history of foster care placement and school expulsion are all potential predictors of homelessness as well.[6,7] Racial and ethnic minorities are significantly overrepresented in the sheltered homeless population. In 2011, 71.9% of sheltered families were racial minorities.[3] Recognition of these risk factors is an important part of understanding and supporting homeless children and families.

Homeless children and families often experience a number of negative exposures and life events that create a cumulative risk for poor health outcomes. For example, children who live in poverty, are exposed to violence, or experience food insecurity also have poor health care service attainment, increased emergency department utilization, and overall poor health outcomes, independent of housing status.[8,9] However, these risks can be additionally compounded by homelessness. A series of studies on adverse childhood experiences has shown that multiple toxic stressors that begin in childhood can have long-term adverse effects on a child's neurobiological make-up, cognitive ability, mental health, and ability to manage stressors as an adult.[10,11] It is therefore important to understand and address these stressors both separately and in totality.

HEALTH EFFECTS OF HOMELESSNESS

Homelessness and housing insecurity negatively impact child health and development in many ways. Homeless children have shown higher rates of acute and chronic health problems than low-income children with homes. Cross-sectional surveys conducted in the 1990s reveal increased rates of multiple infectious, respiratory, gastrointestinal, and dermatologic diseases and otitis media, diarrhea, bronchitis, scabies, lice, and dental caries.[12,13] Both the prevalence and severity of asthma are markedly increased among homeless children, and homeless children suffer from higher rates of accidents and injuries than low-income children with homes.[12,14] In an evaluation completed in a school-based health center, homeless children were 2.5 times more likely to have health problems and 3 times more likely to have severe health problems than children with homes.[15] Children without a stable home are more likely to skip meals, worry about the availability of food, and consume foods with low nutritional quality and high fat content.[16,17] As a result, they suffer from high rates of malnutrition, stunting, and obesity.[8,18] Homeless children are at an increased risk of abuse, exposure to violence, and psychological trauma. Emotional distress, developmental delays, and decreased academic achievement are all more common in this population.[19–21] Speech and language deficits lead to significantly decreased literacy rates in school-aged children.[19,21] Homeless children may experience frequent moves that interrupt their education and impact school performance. In a study in elementary school students, homeless children scored lower on math and reading achievement tests than low-income students living in homes.[21] A study in homeless adolescents who received crisis services at a homeless shelter revealed just 34% of those students attained a high school diploma or general equivalency diploma (GED) by 18 years of age.[22]

Unaccompanied homeless and runaway youth differ from homeless children in families. They are more often separated from their families and more frequently exposed to violence and exploitation. Unaccompanied homeless youth are more likely to engage in high-risk sexual behaviors, have teenage pregnancies, engage in drug use, experience mood and anxiety disorders, and face violence than youth with homes.[23,24]

ACCESS TO HOUSING

Homeless families face many barriers to accessing appropriate housing. In the 2012 Hunger and Homelessness Survey conducted by the US Conference of Mayors, 64% of the surveyed cities reported that shelters turn away families with children experiencing homelessness because of lack of available beds.[25] Access to shelters is challenging in urban settings and rural communities. Although homeless families are more likely to be sheltered than individuals, age and gender restrictions in many shelters often lead to family separations. Homeless mothers are also more likely than housed mothers to have their children separated from them by the child welfare system.[26]

ACCESS TO HEALTH CARE

Children and families in unstable housing often receive fragmented health care and rely on the emergency department as a primary source of care.[27] Some of the barriers that prevent homeless children and families from accessing optimal care include the following:

- difficulty obtaining affordable, accessible, and coordinated health care services;
- frequent and unpredictable changes in living circumstances that prevent timely presentation for care, follow-up, and communications with health care providers;
- inadequate access to storage places for medication and medical supplies; and
- potential exposure to violence or fear of violence that limits freedom.

Despite these barriers, pediatricians can support homeless children. By partnering with community resources and making changes in practice, pediatricians have the opportunity to help families establish a stable source of quality health care, improve family dynamics, and obtain housing and needed services. Addressing these barriers has been shown to have a positive effect on the health outcomes of those who have experienced homelessness.[21,22,28,29]

RECOMMENDATIONS

The following recommendations address how pediatricians can help improve the health of homeless children through practice strategies.

1. Pediatricians should help homeless children increase access to health care services by promoting and, when possible, facilitating Medicaid enrollment to eligible children and families.
2. Pediatricians should familiarize themselves with best practices for care of homeless populations and the management of chronic diseases in homeless populations.
3. Pediatricians should optimize acute care visits to best resolve patient concerns and provide comprehensive care when possible. For example, pediatricians can update immunizations if a patient is significantly behind rather than having him or her schedule a separate appointment.
4. Pediatricians should seek to identify the issues of homelessness and housing insecurity in their patient populations. Pediatricians can use methods such as routine screening on intake and making note of frequent address changes or a history of scattered care provision.
5. Pediatricians should seek to identify underlying causes of homelessness in specific families and help facilitate connection to appropriate resources. This may include asking sensitive questions about unemployment, intimate partner violence, substance abuse, and sexual and gender identity issues. Supporting families to address these difficult issues in addition to their housing needs is critical to improving child health and development.
6. Pediatricians should partner with families to develop care plans that acknowledge barriers posed by homelessness. This can involve a variety of innovations, such as making a communications plan that takes into consideration patient access to telephone and mail services, assisting with transportation through vouchers, offering more flexible office visit scheduling, and prescribing the most affordable treatments available. Pediatricians can also learn about the availability of mobile health services in communities to facilitate care that is convenient for homeless children and families.
7. Pediatricians should become familiar with government and community-based services that assist families with unmet social and economic needs. These include such programs as Temporary Assistance for Needy Families (TANF), Special Nutrition Assistance for Nutrition (SNAP), and the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC). Medical-legal partnerships and local departments of health

and human services are also helpful resources.

8. Pediatricians should support and assist in the development of shelter-based care, including partnering with mental health, dental, and other health programs when possible.
9. Pediatricians can learn about the causes and prevalence of homelessness in their communities. The State Report Card on Child Homelessness (www.homelesschildrenameric.org) issued by the National Coalition on Family Homelessness (www.familyhomelessness.org) is one of many good resources.

Pediatricians and the American Academy of Pediatrics can advocate for the needs of homeless children and families in the following ways:

1. Support local, state, and federal policies that lead to increased availability of low-income, transitional, and permanent housing.
2. Support policies and programs, such as the "Homelessness Prevention and Rapid Re-Housing Program," that aim to quickly place families in stable, permanent housing rather than a continuum of emergency and temporary housing. Permanent housing has been demonstrated to be more cost-effective and more stabilizing for families, who can be exposed to significant trauma while experiencing homelessness.
3. Support violence protection policies such as the Family Violence Prevention and Services Act and Child Abuse Prevention and Treatment Act, which provide substantial funding for shelter in addition to social services and legal aid for victims of family violence.
4. Support creative approaches to providing stable health insurance to homeless and unemployed populations, and promote strategies that enable homeless families to enroll and maintain health coverage without requiring a permanent address.
5. Support policies to eliminate any barriers for children without addresses to enroll in school.
6. Support local, state, and federal policies that provide child care vouchers for homeless families.
7. Support reformation of the foster care system to allow longer time in foster care, increased resources for maintaining families when children are aging out of foster care, and greater resources toward training/supporting foster children as they transition into independent adulthood.

Homelessness is a complex issue that presents a number of challenges for children and families. Pediatricians can support all children who are impacted, by implementing practice-level strategies and engaging in advocacy to promote their health and well-being.

Providing Care for Immigrant, Migrant, and Border Children

- *Policy Statement*

POLICY STATEMENT

Providing Care for Immigrant, Migrant, and Border Children

abstract

FREE

This policy statement, which recognizes the large changes in immigrant status since publication of the 2005 statement "Providing Care for Immigrant, Homeless, and Migrant Children," focuses on strategies to support the health of immigrant children, infants, adolescents, and young adults. Homeless children will be addressed in a forthcoming separate statement ("Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity"). While recognizing the diversity across and within immigrant, migrant, and border populations, this statement provides a basic framework for serving and advocating for all immigrant children, with a particular focus on low-income and vulnerable populations. Recommendations include actions needed within and outside the health care system, including expansion of access to high-quality medical homes with culturally and linguistically effective care as well as education and literacy programs. The statement recognizes the unique and special role that pediatricians can play in the lives of immigrant children and families. Recommendations for policies that support immigrant child health are included. *Pediatrics* 2013;131:e2028–e2034

COUNCIL ON COMMUNITY PEDIATRICS

KEY WORDS

immigrant, migrant, border, underserved communities

CHIP—Children's Health Insurance Program

INTRODUCTION

Many children in immigrant communities face multiple barriers to accessing comprehensive, affordable, and culturally and linguistically effective health care services. Some of these barriers include poverty, fear and stigma, high mobility, limited English proficiency, little information or misunderstandings about how the US health care system works, and lack of insurance and/or access to care. Many children of immigrant families belong to racial and ethnic minority groups that face health status disparities resulting from complex determinants that are exacerbated by children's living circumstances. Inadequate availability of basic necessities, such as housing, and lack of information regarding previous medical care are among the persistent challenges faced by these vulnerable families. For some, the fear of violence or harassment because of their immigrant status compounds their already fragile living conditions. For many within this population, care can be episodic, fragmented, and oriented to care of acute conditions.[1] Although many children in these circumstances face similar challenges, there are some differences of experiences among migrant and border immigrant subgroups (see Fig 1).

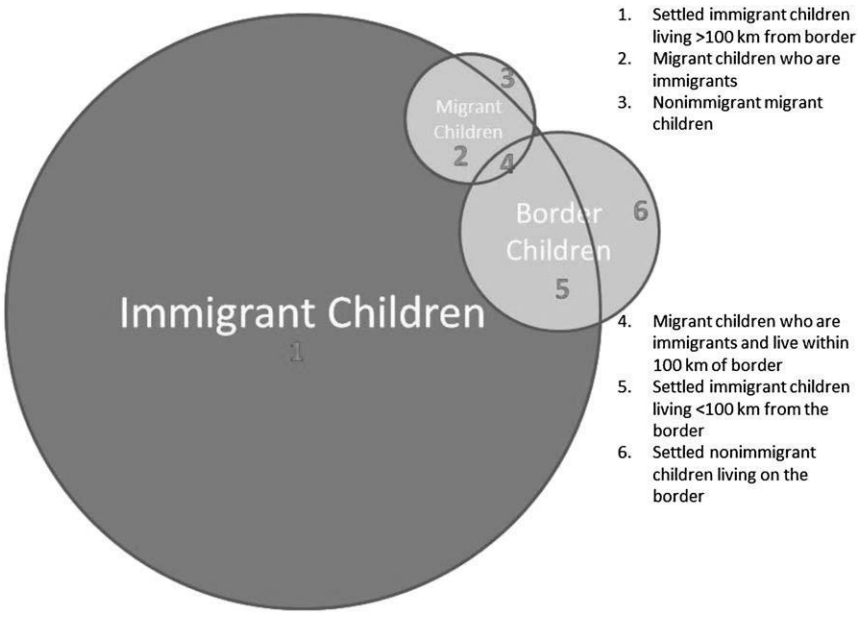

FIGURE 1
Representation of the populations of immigrant, border, and migrant children: separate and overlapping groups.

DEFINITIONS

"Immigrant children" are defined as children who are foreign-born or children born in the United States who live with at least 1 parent who is foreign-born.[2]

Many immigrant children are in migrant families that move across the country seeking seasonal or temporary employment in a variety of industries. "Migrant children" may work in the industries in which their family members are employed and move frequently because of changes in their parents' employment. Migrant families are often located in areas that have many agricultural workers and/or where rapid growth is occurring.

"Border children" are those who live within 100 km of the US-Mexico border.[3] Immigrant children have a significant presence in the border states of Arizona, California, New Mexico, and Texas. Many border children are of Mexican origin, and a significant number are US citizens whose ancestors have been US citizens for generations. For the purposes of this discussion, only children living north of the Mexican border are described, although many children south of the border share similar characteristics. Children living along the Canadian border are not discussed in this statement, because there is far less immigration across that border and discrete immigrant communities there have been rare.

DEMOGRAPHICS

Immigrant children represent the fastest growing segment of the US population. One in every 4 children in the United States, approximately 18.4 million children, live in an immigrant family. Eighty-nine percent of these children are born in the United States and are US citizens.[4] Immigrant children accounted for most of the US child population growth over the past decade. Although 64% of all children of immigrants live in 6 states (California, Texas, New York, Florida, Illinois, and New Jersey), immigrant children are dispersed throughout the country. Since 1990, the largest growth in percentage of immigrant children has occurred in North Carolina, Nevada, Georgia, and Arkansas.[5] Families immigrate for a variety of reasons that may include seeking opportunity, fleeing war/chaos, or escaping persecution.

Pediatricians may be surprised by the high degree of diversity of the immigrant population and by the variety of immigrant communities within their midst, such as Haitians in Florida and eastern Virginia or Somali families in Seattle and Minneapolis. Hmong families are present in the Central Valley of California.[6] In response to the growth of these immigrant communities, some health care and social/community service providers have begun providing culturally appropriate care and services.

Approximately 43% of immigrant children have parents of Mexican origin, and 20% are of Central American descent. An estimated 22% of immigrant children have parents of Asian or Middle Eastern origin. Fifteen percent of children have parents with origins in Africa, Central and Eastern Europe, Western Europe, Canada, and Australia.[7] Given this rapid demographic growth, most pediatricians will provide care for immigrant children in their practices.

COMMON CHALLENGES FOR IMMIGRANT, MIGRANT, AND BORDER CHILDREN

All 3 groups of children face a variety of challenges to their health and well-being, including poverty, lack of health insurance, low educational attainment, substandard housing, and language barriers.

Poverty is a strong determinant of child well-being and is very common among immigrant children. Poverty is closely linked to negative physical, developmental, and mental health–related outcomes.[8] A family's socioeconomic status has a direct effect on its ability to access high-quality health

care services and to achieve good health, social, and emotional outcomes. In 2010, 30% of children in immigrant families lived below the federal poverty level, compared with 19% of children with US-born parents.[4] This is despite the fact that immigrant children are more likely to live in 2-parent families and have parents who work and work more hours compared with parents of US-born children.[9] Immigrant children tend to live in larger families, with 19% having 4 or more siblings, compared with 14% of US-born families.[10] Housing is often substandard and/or overcrowded for these families.

Lack of health care coverage is more common among children in each of these groups than for nonimmigrant children. Children of immigrants are nearly twice as likely to be uninsured (15%) as are children of nonimmigrant families (8%).[4] Many of the immigrant children who are uninsured are eligible for Medicaid or the Children's Health Insurance Program (CHIP) but are not enrolled. Many immigrant parents fear that accessing services for their eligible children will lead them to be considered a "public charge" (a person dependent on the government for the expenses of living[11]) and worry about how that may negatively affect their immigration status and prospects. They may also fear that agencies offering assistance will share information with immigration enforcement agencies. Other families may not be aware of their children's eligibility for coverage. These same reasons may affect parents' ability and willingness to access other programs and benefits that their children may be eligible for, such as the Special Supplemental Nutrition Program for Women, Infants, and Children; Supplemental Nutrition Assistance Program; the Temporary Assistance for Needy Families program; and Supplemental Security Income. Current federal law allows states to apply waiting periods for up to 5 years for legal permanent residents to become eligible for Medicaid coverage. Medicaid also excludes undocumented children from all but emergency health care. Although states may choose to cover children sooner, waiting periods can exacerbate the lack of health insurance coverage for immigrant children. The Affordable Care Act of 2010 (Pub L No. 111-148) also restricts the access to health insurance exchanges of children and adults who are undocumented immigrants.[12]

Language and communication barriers may impede medical care for many children in each of these 3 groups. Although many immigrant children speak English, their parents may not, creating a barrier that can prevent families from accessing health services and/or causing inadequate communication with health care providers. Without access to qualified medical interpreters in health care settings, language barriers can place English-speaking children in the difficult position of interpreting between health care providers and their family members. Use of children and other family members as untrained interpreters should be avoided. These challenges can result in major barriers to accessing health care and decreased satisfaction with services received. Providing care to families with limited English proficiency without appropriate medical interpretation services can ultimately lead to a higher incidence of medical errors when delivering care.[13]

Educational levels and health literacy are often lower among parents of immigrant, border, and migrant families than among native-born US families. Thirty-one percent of immigrant children have a mother without a high school education; the proportion of fathers without a high school education is similar.[4] It is important to note that the level of maternal education is an important determinant of child health. Lower education levels are associated with lower health literacy. Low health literacy creates a barrier for patients in understanding medical information and is associated with poor health outcomes.

Health Status and Health Disparities

Although immigrant children may be vulnerable to many risk factors for poorer health outcomes, some groups of immigrant children enjoy a healthier infancy than expected. For example, Latino families have a relatively low incidence of low birth weight, preterm birth, and infant mortality compared with children of US-born parents.[4] This phenomenon has been called the "healthy immigrant phenomenon."[9] Immigrant mothers are more likely to breastfeed their infants than mothers born in the United States.[14] Immigrant children also seem to benefit from some additional protective factors, such as growing up in 2-parent or extended families,[9] as well as close identification with the cultural and spiritual practices of their family and community. In addition, as they grow up, immigrant children may also display relatively better adjustment and behavior in school compared with nonimmigrant peers. This phenomenon has been shown to fade with increased length of stay in the United States and is, therefore, an infrequent protective factor for health outcomes.

On the other hand, the health of immigrant children as a group is, in some respects, worse than US-born children. For example, they are less likely to be perceived by their parents to be in excellent/good health and are less likely to have a usual source of medical care and to obtain specialty care when needed.[15] They also have less access to dental care, despite the fact that

they have a higher prevalence of dental caries.[16] The Affordable Care Act excluded undocumented immigrants from health care coverage made available through the Act, leaving that group of adults and children as the largest group who still will not have health insurance after the changes of 2014.[12]

Immigrant children who are foreign-born may not have been screened at birth for congenital syphilis, hemoglobinopathies, hearing deficits, and inborn errors of metabolism. In comparison with US-born children, they also have lower immunization rates, especially for vaccines that are not routinely administered in their countries of origin. Some children may lack immunization records. Foreign-born immigrant children have a higher incidence or prevalence of some infectious diseases, such as tuberculosis, hepatitis A, amebiasis, and parasitosis.[17] Immigrant children with asthma are less likely to be prescribed the recommended preventive medications.[18] Immigrant families may be uniquely vulnerable to mental health problems and experience high levels of stress, depression, grief, and traumatic events compared with nonimmigrant families.[19] Additionally, many experience the stress of family separation, in which some of the siblings or, in some cases, 1 or both of the parents do not reside in this country with them.

Development, Early Education, and School Success

Many immigrant, migrant, and border children also experience educational disparities compared with US-born children. As noted, immigrant children may enjoy a healthy start as infants but may experience developmental stagnation as toddlers compared with nonimmigrant children.[20]

In general, children who grow up in bilingual homes should attain major language developmental milestones at the normally expected times. At the same time, children raised in homes with impoverished language have a greater chance of being delayed in language acquisition, whether their families are monolingual or bilingual. When language delays are suspected in children growing up in limited English proficiency households, they present complex evaluation and intervention issues. When in doubt about a suspected language delay in a bilingual child, timely referral to a knowledgeable, bilingual speech and language pathologist is ideal.

Many immigrant children have less access to quality early education programs and are less likely to be enrolled in preschool programs, such as Head Start.[4] Once enrolled in school, cultural and linguistic barriers between parents and schools can lead to decreased family interaction and involvement. As they advance in their schooling, children in immigrant families are less likely to graduate from high school than are their nonimmigrant peers.[4]

Fear and Discrimination

Immigrant children and families may face discrimination and be fearful of attitudes and behaviors of the people they interact with outside their communities, including health care providers, which can reduce access to health care and lead to negative child health outcomes. Families may face anti-immigrant sentiment. Fear and discrimination can exacerbate a feeling of isolation and contribute to mental health problems, such as child and family depression, leaving these populations vulnerable.

Family Separation

Immigrant children may have 1 or more undocumented family members. An undocumented immigrant lacks the proper records and identification to live in the United States.[21] Immigration enforcement and related policies can lead to the sudden removal of an undocumented parent or other key family member without notice or preparation. Children whose parents are taken into custody and/or deported have been shown to experience mental and emotional health problems, including sleeping and eating disturbances, anxiety, depression, poor school performance, and other types of distress. Forced separations because of immigration enforcement can also result in the loss of family income and have been shown to result in family housing and food instability.[22] This can negatively affect a child's safety, health, and development.

FACTORS SPECIFIC TO MIGRANT CHILDREN

A large number of migrant children are also immigrants. For that reason, virtually all of the points made earlier about immigrant children may also apply to those who are migrants. Because of their migration patterns, migrant children are even more likely to lack medical coverage and a medical home than other immigrant children. They are also more likely to be socially, culturally, and linguistically isolated because of their mobile lifestyle.

Many migrant children face a panoply of health problems related to their living and working conditions, including workplace injuries, substandard housing, and unreliable transportation.[23] These factors can contribute to higher rates of respiratory tract and ear infections, bacterial and viral gastroenteritis, tuberculosis, nutritional deficiencies, intestinal parasites, skin infections, dental problems, lead and pesticide exposure, and undiagnosed congenital anomalies.[24] Additionally, at times, migrant adolescents travel

on their own from 1 job site to another, putting them at increased risk of many health-related problems.

FACTORS SPECIFIC TO BORDER CHILDREN

Immigrant children living at the US-Mexico border share almost all of the characteristics of other immigrant children but may experience additional challenges. Children who have crossed the border to enter the United States may have experienced trauma in the form of threat of death, abuse, and exploitation that leave serious psychological scars. Once in the United States, these children may experience an enhanced fear of a family member's deportation, imprisonment, or abuse because of documentation status. Children and families who have recently crossed the border can also experience difficulty adapting to the new cultural environment of the United States and experience stress from the absence of an extended family (including a parent or head of household) that is located in another country. Border children may be even more stigmatized or mistreated by the nonimmigrant populations living nearby, as their families are falsely presumed to take advantage of scarce resources and not pay taxes.

Many border communities are poor and lacking in resources, including medical care. In general, border communities lack sufficient numbers of primary care pediatricians, and those present may lack appropriate cultural and linguistic capacity to serve minority border children. In addition, primary care providers bear an especially high proportion of Medicaid, CHIP, and self-pay patients, with few privately insured patients to whom costs may be shifted. As a consequence of these deficiencies and because of high costs of medical care in the United States, families living close to the border may use medical care and pharmaceutical resources south of the border.

RECOMMENDATIONS

Immigrant children represent a considerable part of the economic and social future of the nation. It is in the national interest that we work to ensure that all children within the United States, including immigrant, border, and migrant children, grow up physically and developmentally healthy. The future prosperity and well-being of the United States depends on the health and vitality of all of its children, without exception. The following recommendations address how pediatricians can help support immigrant child health in practice.

1. Pediatricians and the American Academy of Pediatrics should advocate for health insurance coverage for every child and every individual living in the United States, as lack of coverage for any family member affects the health of the entire family.[25] This advocacy should focus on expanding access to quality health care within a medical home. Barriers to enrollment must be addressed, including the removal of any waiting periods for documented immigrant children to enroll into coverage. Efforts must also address barriers to enrollment for children who are potentially eligible for Medicaid and CHIP but not enrolled. Simplified enrollment for both programs and federal or state funding for those who are not currently eligible for Medicaid or CHIP is also essential.
2. The provision of comprehensive, coordinated, culturally and linguistically effective care, and continuous health services provided in a quality medical home should be integral to all efforts on behalf of immigrant children.[26] This is especially critical for children with chronic health care needs and emotional or behavioral health problems. Private and public insurance payers should pay for qualified medical interpretation services.
3. Pediatricians caring for immigrant children should evaluate immunization adequacy and should conduct careful developmental surveillance and screening at regular intervals as recommended by the American Academy of Pediatrics.[27] Appropriate referral for early intervention services or psychoeducational evaluation should be initiated as soon as a concern is identified.
4. Pediatricians should recognize the barriers to health that are faced by immigrant children and take these barriers into account while providing care. They should inquire about beliefs and practices related to health, illness, and disability, as well as traditional healing practices and medication use while obtaining a patient's medical history. Knowledge, attitude, and skill development in culturally and linguistically effective practices and cross-cultural communication should be part of every pediatrician's professional agenda.
5. Pediatricians should be knowledgeable about the unique emotional, behavioral, mental, and physical health advantages and problems that may be faced by immigrant children, including those related to family separation. Appropriate screening to identify family, environmental, and social circumstances, as well as biological factors, should be incorporated into routine pediatric assessments, such as in Bright Futures history forms.

6. Pediatricians should have access to information regarding federal, state, and community programs that can serve as resources to at-risk children and families. Culturally relevant programs that address social and economic challenges, such as food and housing security, English literacy, and legal services, are particularly important. Medical-legal partnerships should be supported to help immigrant families with these issues.
7. Pediatricians should play a key role in helping immigrant parents assess and review the educational progress of the child and encouraging parents to become involved in and interact with teachers and the school community. If a child exhibits difficulty or academic underachievement, pediatricians are in a unique position to advocate for the child and encourage and help parents to obtain appropriate evaluation and intervention from the school system.
8. Pediatricians should routinely use available screening and diagnostic protocols for evaluating foreign-born children for infectious diseases and other medical conditions when providing care for newly arrived immigrant children.[28] Additional screenings, including lead, vision, and hearing screenings, should be considered whether required for school entry or not.
9. Pediatricians should advocate for an array of culturally effective early intervention services, including the establishment of evidence-based early literacy promotion programs, such as Reach Out and Read, in immigrant, border, and migrant communities. Because reading is such an important skill, these programs are important tools for improving the school readiness of all children, just as fostering health literacy in parents is important to the well-being of their children.
10. Pediatricians should use their positions of respect in communities to promote the value of diversity and inclusion and to advocate for children and families of all backgrounds.

Given the challenging circumstances many immigrant children face because of their family's immigration status, the following recommendations address how immigration policies can support child health and well-being.

11. The health, well-being, and safety of children should be prioritized in all immigration proceedings. Whenever possible, the separation of a child from his or her family and home environment should be prevented, and family reunions should be expedited.
12. In no circumstances should a child have to represent himself or herself in an immigration proceeding.
13. Health care facilities should be safe settings for immigrant children and families to access health care. Medical records and health care facilities should not be used in any immigration enforcement action.

Recognition and Management of Iatrogenically Induced Opioid Dependence and Withdrawal in Children

• *Clinical Report*

CLINICAL REPORT

Recognition and Management of Iatrogenically Induced Opioid Dependence and Withdrawal in Children

abstract

FREE

Opioids are often prescribed to children for pain relief related to procedures, acute injuries, and chronic conditions. Round-the-clock dosing of opioids can produce opioid dependence within 5 days. According to a 2001 Consensus Paper from the American Academy of Pain Medicine, American Pain Society, and American Society of Addiction Medicine, dependence is defined as "a state of adaptation that is manifested by a drug class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist." Although the experience of many children undergoing iatrogenically induced withdrawal may be mild or goes unreported, there is currently no guidance for recognition or management of withdrawal for this population. Guidance on this subject is available only for adults and primarily for adults with substance use disorders. The guideline will summarize existing literature and provide readers with information currently not available in any single source specific for this vulnerable pediatric population. *Pediatrics* 2014;133:152–155

KEY WORDS

opioids, dependence, withdrawal, sedation, analgesia

INTRODUCTION

Opioids are commonly prescribed to children of all ages.[1] Primarily, they are used in short duration for pain related to either a procedure or an acute injury. Utilization of opioids in these circumstances is widely accepted and generally considered low risk. Even in this circumstance, it is important to realize that children prescribed opioids for as little as 7 days can develop opioid dependence and exhibit drug-specific withdrawal symptoms on abrupt discontinuation of medications. Children in ICU settings are especially prone to these issues, because they are often exposed to opioids for longer periods of time when they have ongoing pain or require long-term sedation/analgesia as part of their care.

To understand the consequences of opioid use, it is important that one understands some basic definitions related to opioid use and adaptation to this use. The most commonly accepted definitions for these behaviors are based on a 2001 Consensus Paper from the American Academy of Pain Medicine, American Pain Society, and American Society of Addiction Medicine.[2] The definitions are as follows:

www.pediatrics.org/cgi/doi/10.1542/peds.2013-3398

doi:10.1542/peds.2013-3398

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

- Addiction is a primary, chronic, neurobiological disease with genetic, psychosocial, and environmental factors influencing its development and manifestations. It is characterized by behaviors that include one or more of the following: impaired control over drug use, compulsive use, continued use despite harm, and craving.
- Physical dependence is a state of adaptation that is manifested by a drug class–specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist.
- Tolerance is a state of adaptation in which exposure to a drug induces changes that result in a diminution of one or more of the drug's effects over time.

The consensus paper also noted, "most specialists in pain medicine and addiction agree that patients treated with prolonged opioid therapy do develop physical dependence and sometimes tolerance, but do not usually develop addictive disorders."

Although the experience of many children undergoing iatrogenically induced withdrawal may be mild or go unreported, there is currently no guidance for recognition or management of withdrawal for this population. (Guidance for newborn infants is available from the American Academy of Pediatrics.[3]) Guidance available on this subject is mostly from adults and primarily from literature on adults with substance use disorders. This clinical report summarizes existing literature on this subject and provides readers with information currently not available in any single source specific for this vulnerable pediatric population. The scope of this document is limited to children who received opioid medications outside the neonatal and infant period.

EPIDEMIOLOGY OF OPIOID USE IN THE PEDIATRIC POPULATION

In 2009, approximately 7.2 million outpatient opioid prescriptions were dispensed for children in the United States.[1] The frequency of opioid prescriptions to children has doubled in the past decade.[4] The vast majority of these prescriptions were written for children between the ages of 10 and 17 years, with many of these prescriptions for postprocedural and postoperative use.

BEHAVIORAL AND PHYSIOLOGIC CHARACTERISTICS OF OPIOID DEPENDENCE AND WITHDRAWAL

In most clinical situations, opioid dependence does not manifest any symptoms until opioid administration is abruptly decreased or discontinued (sometimes in favor of nonopioid analgesics), resulting in symptoms of withdrawal. Withdrawal also occurs when an alteration in gastrointestinal absorption leads to decreased absorption of oral opioid and a subsequent decrease in opioid blood concentration. Finally, transition from intravenous to oral administration is not always a predictable conversion, and withdrawal symptoms can occur when oral dosing results in a significantly lower blood concentration of opioid than the previous intravenous dosing. The signs and symptoms associated with withdrawal in the pediatric population can vary somewhat by age but are relatively consistent overall.[5,6]

Behavioral changes are often the primary manifestation of withdrawal and include anxiety, agitation, insomnia, and tremors. In addition to behavioral symptoms, physiologic changes commonly seen in withdrawal include increased muscle tone, nausea, vomiting, diarrhea, decreased appetite, tachypnea, tachycardia, fever, sweating, and hypertension. Care must be taken to rule out other causes of these symptoms, such as infection and sepsis.

Many of these symptoms are assessed in tools used to monitor children undergoing potential opioid withdrawal.[5] Specific scales for children include the Modified Narcotic Abstinence Scale, the Sedation Withdrawal Score, the Sophia Observation Withdrawal Symptoms Scale, and the Opioid Benzodiazepine Withdrawal Scale. Of these pediatric-specific scales, only the Sophia Observation Withdrawal Symptoms Scale has been validated.[7] The only validated scales to measure withdrawal in adults are the Clinical Opiate Withdrawal Scale (an 11-item clinician-administered scale assessing opioid withdrawal) and the Clinical Institute Narcotic Assessment scale, but these are not specific for children.[8] Consistently using and becoming familiar with any of these scales (adult or pediatric) will allow a clinician a means of detecting early signs of withdrawal so a treatment strategy can be implemented. Clinicians should also interpret results from the use of these scales within the clinical context of each individual patient, because there may be reasons other than opioid withdrawal that could explain certain behaviors being scored.

MANAGEMENT STRATEGIES FOR APPROPRIATE WEANING OF OPIOIDS AND TREATMENT OF WITHDRAWAL SYMPTOMS

Prevention is the preferred approach to management of opioid withdrawal symptoms and is achieved by decreasing the dose of opioid over time rather than abruptly discontinuing the medication, commonly referred to as "weaning." When discontinuing an opioid, the first step is to decide whether a patient is at risk for opioid withdrawal. Opioid withdrawal symptoms have been reported in as little as 5 days,[6] but there seems to be

considerable interpatient variability. Most patients who have received an opioid for less than 7 days do not suffer from withdrawal and can have their medication discontinued quickly. Patients who have been exposed to an opioid for longer than 14 days will usually need to follow a weaning protocol to prevent withdrawal symptoms. Those patients with opioid exposure lasting between 7 and 14 days may need to be weaned off their opioid but usually can be weaned more quickly than those with exposure longer than 14 days. It is critical to assess a patient's pain status at the time of anticipated weaning. A patient should not have ongoing painful stimuli or a condition that requires continuation or escalation of opioid dose to adequately manage pain before weaning.

After it is determined that a patient should be weaned from an opioid, a weaning protocol is developed taking into account the length of opioid exposure and total daily opioid dose. Unfortunately, there is no clear outcome-based evidence to support an ideal weaning protocol, but it does seem logical that individual patient response to weaning is more important than following a rigid schedule. It is beyond the scope of this article to prescribe specific guidelines; the generally accepted approach involves transition to a longer-acting opioid formulation, such as methadone, extended-release morphine, or extended-release oxycodone (this is an off-label use for these drugs). Once the patient is stabilized on the long-acting opioid, weaning is usually accomplished by steps of a 10% to 20% decrease in the original dose every 24 to 48 hours.[6] During opioid weaning, parents and care providers should carefully monitor for signs of withdrawal. If withdrawal symptoms are observed, the planned dose of opioid, from the weaning schedule, should be administered, and administration of additional rescue opioid should be considered if withdrawal symptoms are severe. A shorter-acting opioid should be available for signs of withdrawal, painful procedures, or for breakthrough pain. Adjunctive medications, such as clonidine, gabapentin, and dexmedetomidine, have been used[6] to decrease withdrawal symptoms and to help in the opioid-weaning process. These drugs are not labeled for this indication, and there is little information, other than the articles referenced in this clinical report, to provide guidance on their use.

Another common clinical scenario in patients with opioid dependence is concomitant long-term benzodiazepine exposure. Again, there are no clear guidelines for the concurrent weaning of benzodiazepines and opioids. It would seem prudent to have patients wean from 1 medication at a time rather than attempt to wean from both at the same time. This way, any signs of withdrawal can be more clearly attributed to 1 medication.

There is little in the literature describing the use of behavioral strategies for management of iatrogenic opioid withdrawal symptoms in children and adolescents. However, there are reports of the successful use of these interventions for the management of benzodiazepine withdrawal in adult patients with insomnia.[9,10] Behavioral intervention has also been used as part of treatment programs in adolescents who are dependent on either prescription opioids or heroin.[11] Given the success of multidisciplinary pain management interventions that include some form of behavioral therapy, it would seem logical that behavioral intervention would be a useful part of any weaning program to help with sleep hygiene, anxiety/mood symptoms, and pain-related symptoms that may occur during the weaning period.

Overall, the management of opioid dependence and tolerance can be managed safely and comfortably for most patients. The most common difficulties in the process are using a weaning schedule that is too rapid or not understanding that the patient's weaning protocol may not provide adequate analgesia if there are ongoing (or new) painful stimuli.

CONCLUSIONS

There is a high prevalence in the use of prescription opioids in the pediatric population (see the earlier section "Epidemiology of Opioid Use in the Pediatric Population") for durations exceeding 1 week. It is essential to realize that abrupt discontinuation of opioids can lead to drug-specific withdrawal symptoms. For patients receiving prolonged opioid therapy, it is best to develop strategies in conjunction with the patient's care team and family to minimize withdrawal symptoms while following a set opioid-weaning strategy. Understanding opioid withdrawal is key to its prevention. Research in this field is just beginning and should be looked at as a priority, because the frequency of prescribed opioid use in children has doubled in the past decade.[4]

The purpose of this statement is to update recommendations for routine use of seasonal influenza vaccine and antiviral medications for the prevention and treatment of influenza in children. Highlights for the upcoming 2013–2014 season include (1) this year's trivalent influenza vaccine contains an A/California/7/2009 (H1N1) pdm09-like virus (same as 2012–2013); an A/Texas/50/2012 (H3N2) virus (antigenically like the 2012–2013 strain); and a B/Massachusetts/2/2012-like virus (a B/Yamagata lineage like 2012–2013 but a different virus); (2) new quadrivalent influenza vaccines with an additional B virus (B/Brisbane/60/2008-like virus [B/Victoria lineage]) have been licensed by the US Food and Drug Administration; (3) annual universal influenza immunization is indicated with either a trivalent or quadrivalent vaccine (no preference); and (4) the dosing algorithm for administration of influenza vaccine to children 6 months through 8 years of age is unchanged from 2012–2013. As always, pediatricians, nurses, and all health care personnel should promote influenza vaccine use and infection control measures. In addition, pediatricians should promptly identify influenza infections to enable rapid antiviral treatment, when indicated, to reduce morbidity and mortality. *Pediatrics* 2013;132:e1089–e1104

INTRODUCTION

The American Academy of Pediatrics (AAP) recommends annual seasonal influenza immunization for all people, including *all* children and adolescents, 6 months of age and older during the 2013–2014 influenza season. In addition, special effort should be made to vaccinate people in the following groups:

- All children, including infants born preterm, who are 6 months of age and older with conditions that increase the risk of complications from influenza (eg, children with chronic medical conditions, such as asthma, diabetes mellitus, hemodynamically significant cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders)
- Children of American Indian/Alaskan Native heritage
- All household contacts and out-of-home care providers of
  - children with high-risk conditions; and
  - children younger than 5 years, especially infants younger than 6 months

- All health care personnel (HCP)
- All women who are pregnant, are considering pregnancy, have recently delivered, or are breastfeeding during the influenza season

KEY POINTS RELEVANT FOR THE 2013–2014 INFLUENZA SEASON

1. **Annual seasonal influenza vaccine is recommended for *all* people, including all children and adolescents, 6 months of age and older during the 2013–2014 influenza season.** It is important that household contacts and out-of-home care providers of children younger than 5 years, especially infants younger than 6 months and children of any age at high risk of complications of influenza (eg, children with chronic medical conditions, such as asthma, diabetes mellitus, hemodynamically significant cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders) receive annual influenza vaccine. In the United States, more than two-thirds of children younger than 6 years and almost all children 6 years and older spend significant time in child care and school settings outside the home. Exposure to groups of children increases the risk of contracting infectious diseases. Children younger than 2 years are at an increased risk of hospitalization and complications attributable to influenza. School-age children bear a large influenza disease burden and have a significantly higher chance of seeking influenza-related medical care compared with healthy adults. Therefore, reducing influenza virus transmission among children who attend child care or school has been shown to decrease the burden of childhood influenza and transmission of influenza virus to household contacts and community members of all ages.
2. The 2012–2013 influenza season was moderately severe, with a higher percentage of outpatient visits for influenza-like illness, higher rates of hospitalization, and more deaths attributed to pneumonia and influenza compared with the 2011–2012 influenza season. As of August 10, 2013, 158 laboratory-confirmed influenza-associated pediatric deaths were reported to the Centers for Disease Control and Prevention (CDC) during the 2012–2013 influenza season. Influenza A (H3N2) viruses predominated overall, but influenza B viruses and, to a lesser extent, A (H1N1) pdm09 (pH1N1) viruses also were reported in the United States. Eighty-two of the 158 deaths were associated with influenza B viruses, 32 deaths were associated with influenza A (H3) viruses, and 4 deaths were associated with pH1N1 viruses. Thirty-seven deaths were associated with an influenza A virus for which the subtype was not determined, 1 death was associated with an undetermined type of influenza virus, and 2 deaths were associated with both influenza A and B viruses. The majority of pediatric deaths were among children who had not been immunized against influenza. Among children hospitalized with influenza and for whom medical chart data were available, approximately 44% did not have any recorded underlying condition, whereas 23% had underlying asthma or reactive airway disease (Fig 1). Although children with certain conditions are at higher risk of complications, substantial proportions of seasonal influenza morbidity and mortality occur among healthy children.
3. Both trivalent and quadrivalent influenza vaccines are licensed and available in the United States for the 2013–2014 season. Neither vaccine formulation is preferred over the other. The trivalent vaccine contains an A/California/7/2009 (H1N1) pdm09-like virus (same as 2012–2013), an A/Texas/50/2012 (H3N2) virus (antigenically like the 2012–2013 strain), and a B/Massachusetts/2/2012-like virus (a B/Yamagata lineage like 2012-2013 but a different virus). The new quadrivalent influenza vaccines include an additional B virus (B/Brisbane/60/2008-like virus [B/Victoria lineage]). In addition, 2 trivalent influenza vaccines manufactured using new technologies that do not use eggs will also be available during the 2013–2014 season: cell culture-based inactivated influenza vaccine (ccIIV3) and recombinant influenza vaccine (RIV3).
4. The number of seasonal influenza vaccine doses to be administered in the 2013–2014 influenza season depends on the child's age at the time of the first administered dose and his or her vaccine history (Fig 2):
   - Influenza vaccines are not licensed for administration to infants younger than 6 months of age.
   - Children 9 years and older need only 1 dose.
   - Children 6 months through 8 years of age receiving the seasonal influenza vaccine for the first time should receive a second dose this season at least 4 weeks after the first dose.
   - Children 6 months through 8 years of age who received seasonal influenza vaccine before the 2013–2014 influenza season
     - need only 1 dose of vaccine, if they previously received 2 or more doses of seasonal vaccine since July 1, 2010.
     - need 2 doses of vaccine, if they have not previously received 2 or more doses of seasonal vaccine since July 1, 2010.

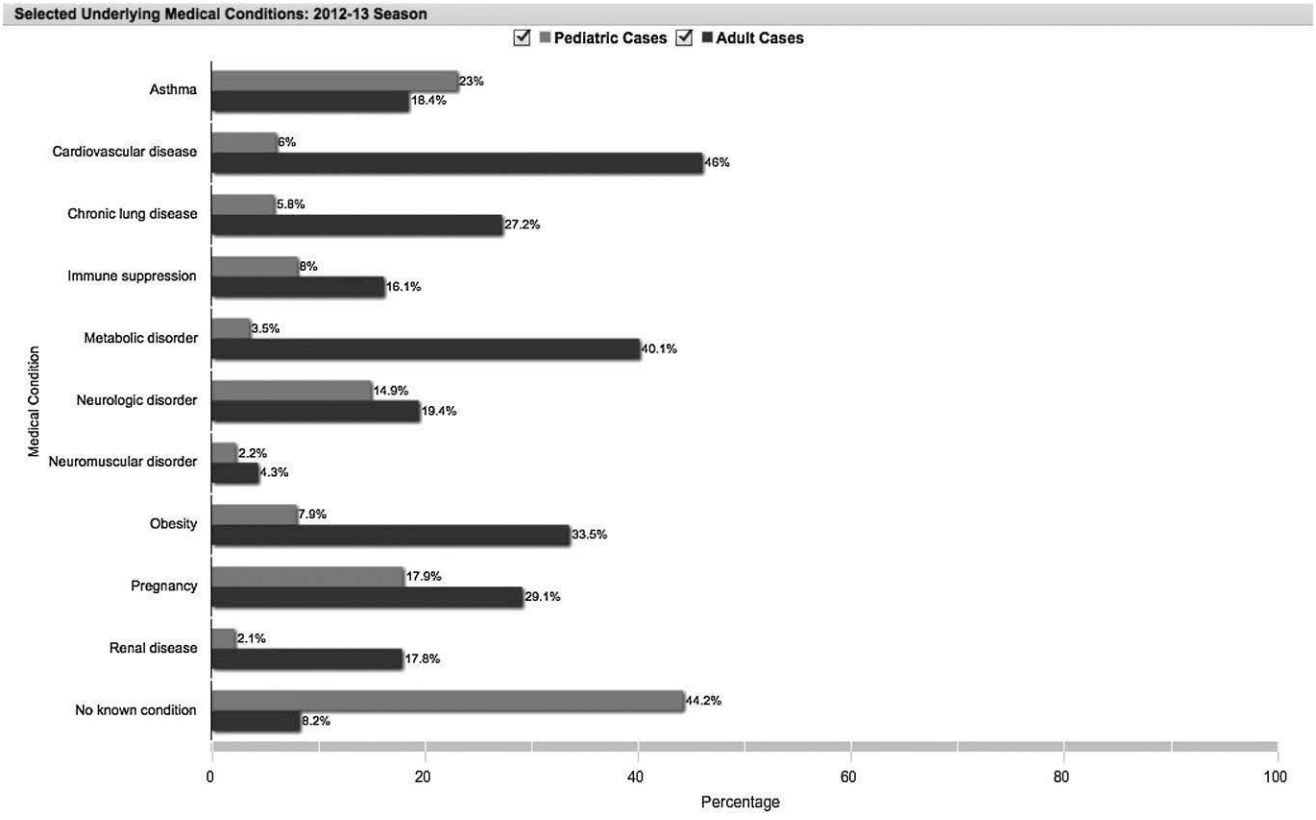

FIGURE 1

Selected underlying medical conditions in patients hospitalized with influenza, FluSurv-NET 2012–2013. Source: Centers for Disease Control and Prevention. FluView 2012–2013 Preliminary Data as of August 10, 2013. Available at: http://gis.cdc.gov/grasp/fluview/FluHospChars.html. FluSurv-NET data are preliminary and displayed as they become available. Therefore, figures are based on varying denominators because some variables represent information that may require more time to be collected. Data are refreshed and updated weekly. Asthma includes a medical diagnosis of asthma or reactive airway disease. Cardiovascular disease includes include conditions such as coronary heart disease, cardiac valve disorders, congestive heart failure, pulmonary hypertension, and aortic stenosis. It does not include hypertension disease only. Chronic lung disease includes conditions such as bronchitis obliterans, chronic aspiration pneumonia, and interstitial lung disease. Immune suppression includes conditions such as immunoglobulin deficiency, leukemia, lymphoma, HIV/AIDS, and individuals taking immunosuppression medications. Metabolic disorder includes conditions such as diabetes mellitus, thyroid dysfunction, adrenal insufficiency, and liver disease. Neurologic disorder includes conditions such as seizure disorders, cerebral palsy, and cognitive dysfunction. Neuromuscular disorder includes conditions such as multiple sclerosis and muscular dystrophy. Obesity was assigned if indicated in patients' medical chart or if BMI was >30. Pregnancy percentage was calculated using number of female cases aged between 15 and 44 years as the denominator. Renal disease includes conditions such as acute or chronic renal failure, nephrotic syndrome, glomerulonephritis, and impaired creatinine clearance. No known condition indicates that the case did not have any known underlying medical condition indicated in the medical chart at the time of hospitalization.

- need only 1 dose of influenza vaccine if there is clear documentation of having received at least 2 seasonal influenza vaccines from any previous season and at least 1 dose of a pH1N1-containing vaccine, which could have been in 1 of the seasonal vaccines (2010–2011, 2011–2012, or 2012–2013) or as the monovalent pH1N1 vaccine from 2009–2010.

Vaccination should not be delayed to obtain a specific product for either dose. Any available, age-appropriate trivalent or quadrivalent vaccine can be used. A child who receives only 1 of the 2 doses as a quadrivalent formulation is likely to be less primed against the additional B virus.

5. Pediatric offices should consider serving as alternate venues for providing influenza immunization to parents and other adults who care for children, if this approach is acceptable to both the pediatrician and the adult to be immunized.[1] There are important medical liability issues and medical record documentation requirements that need to be addressed before a pediatrician begins immunizing adults (see details at www.aapredbook.org/implementation). Pediatricians are reminded to document the recommendation for adult immunization in the vulnerable child's medical record. In addition, adults should still be encouraged to have a medical home and communicate their immunization status to their primary care provider. Immunization of close contacts of children at high risk of influenza-related complications is

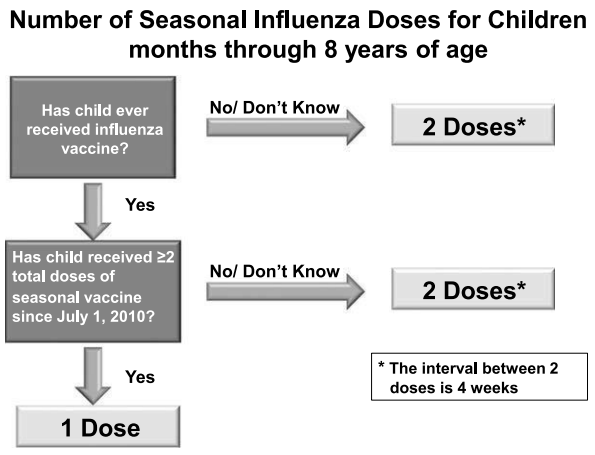

FIGURE 2
Number of 2013–2014 seasonal influenza vaccine doses for children 6 months through 8 years of age.

intended to reduce their risk of contagion (ie, "cocooning"). The concept of cocooning is particularly important to help protect infants younger than 6 months, because they are too young to be immunized with influenza vaccine. Infants younger than 6 months of age can also be protected through vaccination of their mothers during pregnancy with transplacental transfer of antibodies. The risk of influenza-associated hospitalization in healthy children aged younger than 24 months has been shown to be greater than the risk of hospitalization in previously recognized high-risk groups, such as the elderly, during influenza season. Children 24 through 59 months of age have shown increased rates of outpatient visits and antimicrobial use associated with influenza-like illnesses.

6. As soon as the seasonal influenza vaccine is available locally, HCP should be immunized, parents and caregivers should be notified about vaccine availability, and immunization of all children 6 months and older, especially children at high risk of complications from influenza, should begin. HCP endorsement plays a major role in vaccine uptake. A strong correlation exists between HCP endorsement of influenza vaccine and patient acceptance.[2] Prompt initiation of influenza immunization and continuance of immunization throughout the influenza season, whether or not influenza is circulating (or has circulated) in the community, are critical components of an effective immunization strategy. Giving the vaccine promptly and early during the influenza season is not felt to pose a significant risk that immunity might wane before the end of the season. The seasonal vaccine is not perfect, but it still is the best strategy available for preventing illness from influenza. It is moderately effective in reducing the risk for outpatient medical visits caused by circulating influenza viruses by approximately one-half to two-thirds in most people. Even a moderately effective influenza vaccine has been shown to reduce illness, antibiotic use, doctor visits, time lost from work, hospitalizations, and deaths.
7. Providers should continue to offer vaccine until the vaccine expiration date because influenza is unpredictable. Protective immune responses persist throughout the influenza season, which can have >1 disease peak and often extends into March or later. Although most influenza activity in the United States tends to occur in January through March, influenza activity can occur in early fall (ie, October and November) or late spring (eg, influenza circulated through the third week in May during the 2012–2013 season). This approach also provides ample opportunity to administer a second dose of vaccine because children aged <9 years may require 2 doses to confer optimal protection. In addition, with international travel so common, there is potential exposure to influenza at virtually all times of the year.
8. HCP, influenza campaign organizers, and public health agencies should collaborate to develop improved strategies for planning, communication, and administration of vaccines.
   - Plan to make seasonal influenza vaccine easily accessible for all children. Examples include creating walk-in influenza clinics; extending hours beyond routine times during peak vaccination periods; administering influenza vaccine during both well and sick visits; considering how to immunize parents, adult caregivers, and siblings at the same time in the same office setting as children[1]; and working with other institutions (eg, schools, child-care centers, and religious organizations) or alternative care sites, such as emergency departments, to expand venues for administering vaccine. If a child or adult receives influenza vaccine outside of his or her medical home, such as at a pharmacy or other retail-based clinic, appropriate documentation of immunization

must be provided to the medical home.

- Concerted efforts among the aforementioned groups, plus vaccine manufacturers, distributors, and payers, also are necessary to prioritize distribution appropriately to the primary care office setting and patient-centered medical home before other venues, especially when vaccine supplies are delayed or limited.
- Vaccine safety, effectiveness, and indications must be properly communicated to the public. HCP should act as role models by receiving influenza immunization annually as well as recommending annual immunizations to both colleagues and patients. Influenza immunization programs for HCP benefit the health of employees, their patients, and members of the community.[2] Beginning in 2012, as an immunization core measure, the Centers for Medicare and Medicaid Services, the US federal agency that administers Medicare, Medicaid, and the State Children's Health Insurance Program, began requiring hospitals and certain other inpatient facilities to screen for a history of influenza vaccination and to administer influence vaccine to all unimmunized hospitalized patients 6 months and older between October and March unless contraindicated or the patient or family refuses.

9. Antiviral medications also are important in the control of influenza but are not a substitute for influenza immunization. The neuraminidase inhibitors oral oseltamivir (Tamiflu; Roche Laboratories, Nutley, NJ) and inhaled zanamivir (Relenza; GlaxoSmithKline, Research Triangle Park, NC) are the only antiviral medications routinely recommended for chemoprophylaxis or treatment of influenza during the 2013–2014 season. Intravenous preparations of oseltamivir, zanamivir, and peramivir are not currently approved by the US Food and Drug Administration (FDA) and are not routinely available. However, with consultation with infectious diseases specialists, experimental intravenous antiviral medications could be considered for some critically ill children, especially those who are immunocompromised. Recent viral surveillance and resistance data indicate that the majority of currently circulating influenza viruses likely to cause 2013–2014 seasonal influenza in North America continue to be sensitive to oseltamivir and zanamivir. In contrast, amantadine and rimantadine should not be used because circulating influenza A viruses have sustained high levels of resistance to these drugs, and they are not effective against influenza B viruses. Resistance characteristics may change rapidly; pediatricians should verify susceptibility data at the start of the influenza season and monitor it during the season. Up-to-date information can be found on the AAP Web site (www.aap.org or www.aapredbook.org/flu), through state-specific AAP chapter Web sites, or on the CDC Web site (www.cdc.gov/flu/index.htm).

SEASONAL INFLUENZA VACCINES

During previous influenza seasons, only trivalent influenza vaccines that included antigen from 1 influenza B virus were available. However, since 1985, 2 antigenically distinct lineages (ie, Victoria or Yamagata) of influenza B viruses have circulated globally. In most years, vaccination against a B virus of 1 lineage confers little cross-protection against a B virus strain from the other lineage. Thus, trivalent vaccines offer limited immunity against circulating influenza B strains of the lineage not present in the vaccine. Furthermore, in recent years, it has proven difficult to consistently predict which B lineage will predominate during a given influenza season. Therefore, a quadrivalent influenza vaccine with influenza B strains of both lineages may offer improved protection. Postmarketing safety and vaccine effectiveness data are not yet available, prohibiting a full risk-benefit analysis of newer versus previously available products.

For the 2013–2014 season, the inactivated influenza vaccines (IIVs) will be available for intramuscular (IM) injection in both trivalent (IIV3) and quadrivalent (IIV4) formulations. Note that the abbreviation IIV has replaced TIV (trivalent inactivated influenza vaccine) because inactivated influenza vaccines now contain either 3 or 4 virus strains. The intranasally administered live-attenuated influenza vaccine (LAIV) will be available only in a quadrivalent formulation (LAIV4). IIV4 and LAIV4 will contain the identical influenza strains anticipated to circulate during the 2013–2014 influenza season.

IIVs contain no live virus. IIV3 formulations are now available for IM and intradermal (ID) use. The IM formulation of IIV3 is licensed and recommended for children 6 months of age and older and adults, including people with and without chronic medical conditions. The most common adverse events after IIV administration are local injection site pain and tenderness. Fever may occur within 24 hours after immunization in approximately 10% to 35% of children younger than 2 years but rarely in older children and adults. Mild systemic symptoms, such as nausea, lethargy, headache, muscle

aches, and chills, may occur after administration of IIV3.

An ID formulation of IIV3 is licensed for use in people 18 through 64 years of age. ID vaccine administration involves a microinjection with a shorter needle than needles used for IM administration. The most common adverse events are redness, induration, swelling, pain, and itching, which occur at the site of administration; although all adverse events occur at a slightly higher rate with the IM formulation of IIV3, the rate of pain was similar between ID and IM. Headache, myalgia, and malaise may occur and tend to occur at the same rate as that with the IM formulation of IIV3. There is no preference for IM or ID immunization with IIV3 in people 18 years or older. Therefore, pediatricians may choose to use either the IM or ID product in their late adolescent and young adult patients as well as for any adults they may be vaccinating (ie, as part of a cocooning strategy).

IIV4 is available in IM but not ID formulations. One formulation is licensed for use in children as young as 6 months of age. In children, the most common injection site adverse reactions were pain, redness, and swelling. The most common systemic adverse events were drowsiness, irritability, loss of appetite, fatigue, muscle aches, headache, arthralgia, and gastrointestinal tract symptoms. These events were reported with comparable frequency among participants receiving the licensed comparator trivalent vaccines. IIV4 is an acceptable alternative to other approved vaccines indicated for persons 6 months or older when otherwise appropriate and may offer greater protection than IIV3. The relative quantity of doses of IIV4 that will be available is not certain and likely to be limited.

During the 2010–2011 and 2011–2012 influenza seasons, increased reports of febrile seizures in the United States were noted by the Vaccine Adverse Event Reporting System and were associated with IIV3 manufactured by Sanofi Pasteur (Fluzone), mainly in children in the 12- through 23-month age group (the peak age for febrile seizures). The most common vaccine administered concomitantly with IIV3 when a febrile seizure was reported was the 13-valent pneumococcal conjugate vaccine (PCV13). This disproportionate reporting of febrile seizures did not persist through the most recent 2012–2013 influenza season. On the basis of these data, simultaneous administration of IIV and PCV13 for the 2013–2014 influenza season continues to be recommended when both vaccines are indicated.

LAIV4 is a quadrivalent live-attenuated influenza vaccine that is administered intranasally and replaces the previous trivalent formulation of LAIV (LAIV3). It is licensed by the FDA for previously healthy people aged 2 through 49 years. It is not recommended for people with a history of asthma, diabetes mellitus, or other high-risk medical conditions associated with an increased risk of complications from influenza (see Contraindications and Precautions). LAIV4 has a similar safety profile to that of LAIV3. The most commonly reported reactions in children were runny nose/nasal congestion, headache, decreased activity/lethargy, and sore throat. LAIV should not be administered to people with notable nasal congestion that would impede vaccine delivery.

Two trivalent influenza vaccines manufactured using new technologies that do not use eggs will also be available for people 18 years or older during the 2013–2014 season: ccIIV3 and recombinant influenza vaccine (RIV3). These manufacturing methods are beneficial because they would be expected to permit a more rapid scale up of vaccine production when needed, such as during a pandemic.

ccIIV3 is a trivalent cell culture–based inactivated influenza vaccine indicated for people 18 years or older, administered as an IM injection. ccIIV3 has comparable immunogenicity to US-licensed comparator vaccines. Although ccIIV3 is manufactured from virus propagated in Madin Darby Canine Kidney cells rather than embryonated eggs, before production, seed virus is created using the World Health Organization reference virus strains that have been passaged in eggs. However, egg protein is not detectable in the final vaccine, and egg allergy is not mentioned in the package insert. Contraindications are similar to those for other IIVs. The most common solicited adverse reactions included injection site pain, erythema at the injection site, headache, fatigue, myalgia, and malaise.

RIV3 is a recombinant hemagglutinin vaccine. It is indicated for people 18 through 49 years of age and is administered via IM injection. The most frequently reported adverse events were pain, headache, myalgia, and fatigue.

Tables 1 and 2 summarize information on the types of 2013–2014 seasonal influenza vaccines licensed for immunization of children and adults. With the addition of 5 newly licensed vaccines, it is likely that more than 1 type or brand of vaccine may be appropriate for vaccine recipients. However, no preferential recommendation is made for use of any influenza vaccine product over another. Vaccination should not be delayed to obtain a specific product.

A large body of scientific evidence demonstrates that thimerosal-containing vaccines are not associated with increased risk of autism spectrum disorders in children. As such, the AAP extends its strongest support to the recent World Health Organization recommendations to retain the use of thimerosal in the global vaccine supply.

Some people may still raise concerns about the minute amounts of thimerosal in IIV vaccines, and in some states, there is a legislated restriction on the use of thimerosal-containing vaccines. The benefits of protecting children against the known risks of influenza are clear. Therefore, children should receive any available formulation of IIV rather than delaying immunization while waiting for vaccines with reduced-thimerosal content or thimerosal-free vaccine. Although some formulations of IIV contain only a trace amount of thimerosal, certain types can be obtained thimerosal free. LAIV does not contain thimerosal. Vaccine manufacturers are delivering increasing amounts of thimerosal-free influenza vaccine each year.

INFLUENZA VACCINES AND EGG ALLERGY

Almost all IIV and LAIV are produced in eggs and contain measurable amounts of egg protein, expressed as the concentration of ovalbumin per dose. However, recent data have shown that IIV administered in a single, age-appropriate dose is well tolerated by virtually all recipients who have egg allergy. More conservative approaches, such as skin testing or a 2-step graded challenge, are no longer recommended. No data exist on the safety of administering LAIV to egg-allergic recipients.

As a precaution, pediatricians should continue to determine whether the presumed egg allergy is based on a mild (ie, hives alone) or severe (ie, anaphylaxis involving cardiovascular changes, respiratory and/or gastrointestinal tract symptoms, or reactions that required the use of epinephrine) reaction. Pediatricians should consult with an allergist for children with a history of severe reaction. Most vaccine administration to individuals with egg allergy can happen without the need for referral. Data indicate that approximately 1% of children have immunoglobulin E-mediated sensitivity to egg, and of those, a rare minority has a severe allergy.

Standard immunization practice should include the ability to respond to acute hypersensitivity reactions. Therefore, influenza vaccine should be given to people with egg allergy with the following preconditions (Fig 3):

TABLE 1 Recommended Seasonal Influenza Vaccines for Different Age Groups: United States, 2013–2014 Influenza Season

Vaccine	Trade Name	Manufacturer	Presentation	Thimerosal Mercury Content[a]	Age Group
Inactivated					
IIV3	Fluzone	Sanofi Pasteur	0.25-mL prefilled syringe	0	6–35 mo
			0.5-mL prefilled syringe	0	≥36 mo
			0.5-mL vial	0	≥36 mo
			5.0-mL multidose vial	25	≥6 mo
IIV3	Fluzone Intradermal	Sanofi Pasteur	0.1-mL prefilled microinjection	0	18–64 y
IIV3	Fluzone HD	Sanofi Pasteur	0.5-mL prefilled syringe	0	≥65 y
IIV3	Fluvirin	Novartis	0.5-mL prefilled syringe	≤1.0	≥4 y
			5.0-mL multidose vial	25	≥4 y
IIV3	Agriflu	Novartis	0.5-mL prefilled syringe	0	≥18 y
IIV3	Fluarix	GlaxoSmithKline	0.5-mL prefilled syringe	0	≥36 mo
IIV3	FluLaval	ID Biomedical Corporation of Quebec (distributed by GlaxoSmithKline)	5.0-mL multidose vial	25	≥3 y
IIV3	Afluria	CSL Biotherapies (distributed by Merck)	0.5-mL prefilled syringe	0	≥9 y[b]
			5-mL multidose vial	24.5	≥9 y[b]
ccIIV3	Flucelvax	Novartis Vaccines	0.5-mL prefilled syringe	0	≥18 y
IIV4	Fluzone Quadrivalent	Sanofi Pasteur	0.25-mL prefilled syringe	0	6-35 mo
			0.5-mL prefilled syringe	0	≥36 mo
			0.5-mL vial	0	≥36 mo
IIV4	Fluarix Quadrivalent	GlaxoSmithKline	0.5-mL prefilled syringe	0	≥36 mo
IIV4	FluLaval Quadrivalent	ID Biomedical Corporation of Quebec (distributed by GlaxoSmithKline)	5.0-mL multidose vial	25	≥3 y
Recombinant					
RIV3	FluBlok	Protein Sciences	0.5-mL vial	0	18–49 y
Live-attenuated					
LAIV4	FluMist Quadrivalent	MedImmune	0.2-mL sprayer	0	2–49 y

[a] Microgram of Hg/0.5-mL dose.

[b] Age indication per package insert is ≥5 y; however, the Advisory Committee on Immunization Practices recommends Afluria not be used in children 6 months through 8 years of age because of increased reports of febrile reactions noted in this age group. If no other age-appropriate, licensed, inactivated seasonal influenza vaccine is available for a child 5 through 8 years of age who has a medical condition that increases the child's risk of influenza complications, Afluria can be used; however, pediatricians should discuss with the parents or caregivers the benefits and risks of influenza vaccination with Afluria before administering this vaccine.

TABLE 2 LAIV4 Compared With IIV3 and IIV4

Vaccine Characteristic	LAIV4	IIV3	IIV4
Route of administration	Intranasal spray	IM or ID injection[a]	IM injection[a]
Type of vaccine	Live virus	Killed virus	Killed virus
Product	Attenuated, cold-adapted	Inactivated subvirion or surface antigen	Inactivated subvirion or surface antigen
No. of included virus strains	4 (2 influenza A, 2 influenza B)	3 (2 influenza A, 1 influenza B)	4 (2 influenza A, 2 influenza B)
Vaccine virus strains updated	Annually	Annually	Annually
Frequency of administration[b]	Annually	Annually	Annually
Approved age groups	All healthy people aged 2–49 y	All people aged ≥6 mo (ID 18–64 y)	All people aged ≥6 mo
Interval between 2 doses in children	4 wk	4 wk	4 wk
Can be given to people with medical risk factors for influenza-related complications?	No	Yes	Yes
Can be given to children with asthma or children aged 2–4 y with wheezing in the previous year?	No[c]	Yes	Yes
Can be simultaneously administered with other vaccines?	Yes[d]	Yes[d]	Yes[d]
If not simultaneously administered, can be administered within 4 wk of another live vaccine?	No, prudent to space 4 wk apart	Yes	Yes
Can be administered within 4 wk of an inactivated vaccine?	Yes	Yes	Yes

Data sources: American Academy of Pediatrics, Committee on Infectious Diseases. Recommendations for prevention and control of influenza in children, 2012–2013. *Pediatrics.* 2012;130 (4):780–792; Centers for Disease Control and Prevention. Prevention and control of influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices (ACIP)—United States, 2012–13 influenza season. *MMWR Morb Mortal Wkly Rep.* 2012;61(32):613–618; and Centers for Disease Control and Prevention. [a] The preferred site of IIV intramuscular injection for infants and young children is the anterolateral aspect of the thigh.

[b] See Fig 2 for decision algorithm to determine number of doses of seasonal influenza vaccine recommended for children during the 2013–2014 influenza season.

[c] LAIV4 is not recommended for children with a history of asthma. In the 2- through 4-year age group, there are children who have a history of wheezing with respiratory illnesses in whom reactive airways disease is diagnosed and in whom asthma may later be diagnosed. Therefore, because of the potential for increased wheezing after immunization, children 2 through 4 years of age with recurrent wheezing or a wheezing episode in the previous 12 months should not receive LAIV4. When offering LAIV4 to children in this age group, a pediatrician should screen those who might be at higher risk of asthma by asking the parents/guardians of 2-, 3-, and 4-year-olds (24- through 59-month-olds) the question: "In the previous 12 months, has a health care professional ever told you that your child had wheezing?" If the parents answer yes to this question, LAIV4 is not recommended for these children.

[d] LAIV4 coadministration has been evaluated systematically only among children 12 to 15 months of age with measles-mumps-rubella and varicella vaccines. IIV coadministration has been evaluated systematically only among adults with pneumococcal polysaccharide and zoster vaccines.

- Appropriate resuscitative equipment must be readily available.[3]
- The vaccine recipient should be observed in the office for 30 minutes after immunization, the standard observation time for receiving immunotherapy.

Providers may consider use of ccIIV3 or RIV3 vaccines produced via non-egg-based technologies for adults with egg allergy in settings in which these vaccines are available and otherwise age appropriate. Because there is no known safe threshold for ovalbumin content in vaccines, ccIIV3, which does contain trace amounts of ovalbumin, should be administered according to the guidance for other IIVs (Fig 3). In contrast, RIV3, which contains no ovalbumin, may be administered to people with egg allergy of any severity who are 18 through 49 years of age and do not have other contraindications. However, vaccination of individuals with mild egg allergy should not be delayed if RIV3 or ccIIV3 are not available. Instead, any licensed, age-appropriate IIV should be used.

VACCINE STORAGE AND ADMINISTRATION

The AAP Storage and Handling Tip Sheet provides resources for practices to develop comprehensive vaccine management protocols to keep their vaccine supply safe during a power failure or other disaster (www2.aap.org/immunization/pediatricians/pdf/DisasterPlanning.pdf). Any of the influenza vaccines can be administered at the same visit with all other recommended routine vaccines.

IM Vaccine

The IM formulation of IIV is shipped and stored at 2°C to 8°C (35°F–46°F). It is administered intramuscularly into the anterolateral thigh of infants and young children and into the deltoid muscle of older children and adults. The volume of vaccine is age dependent; infants and toddlers 6 months through 35 months of age should receive a dose of 0.25 mL, and all people 3 years (36 months) and older should receive 0.5 mL/dose.

ID Vaccine

The ID formulation of IIV is also shipped and stored at 2°C to 8°C (35°F–46°F). It is administered intradermally only to people 18 through 64 years of age, preferably over the deltoid muscle, and only using the device included in the vaccine package. Vaccine is supplied in a single-dose, prefilled microinjection system (0.1 mL) for adults. The package insert should be reviewed for full administration details of this product.

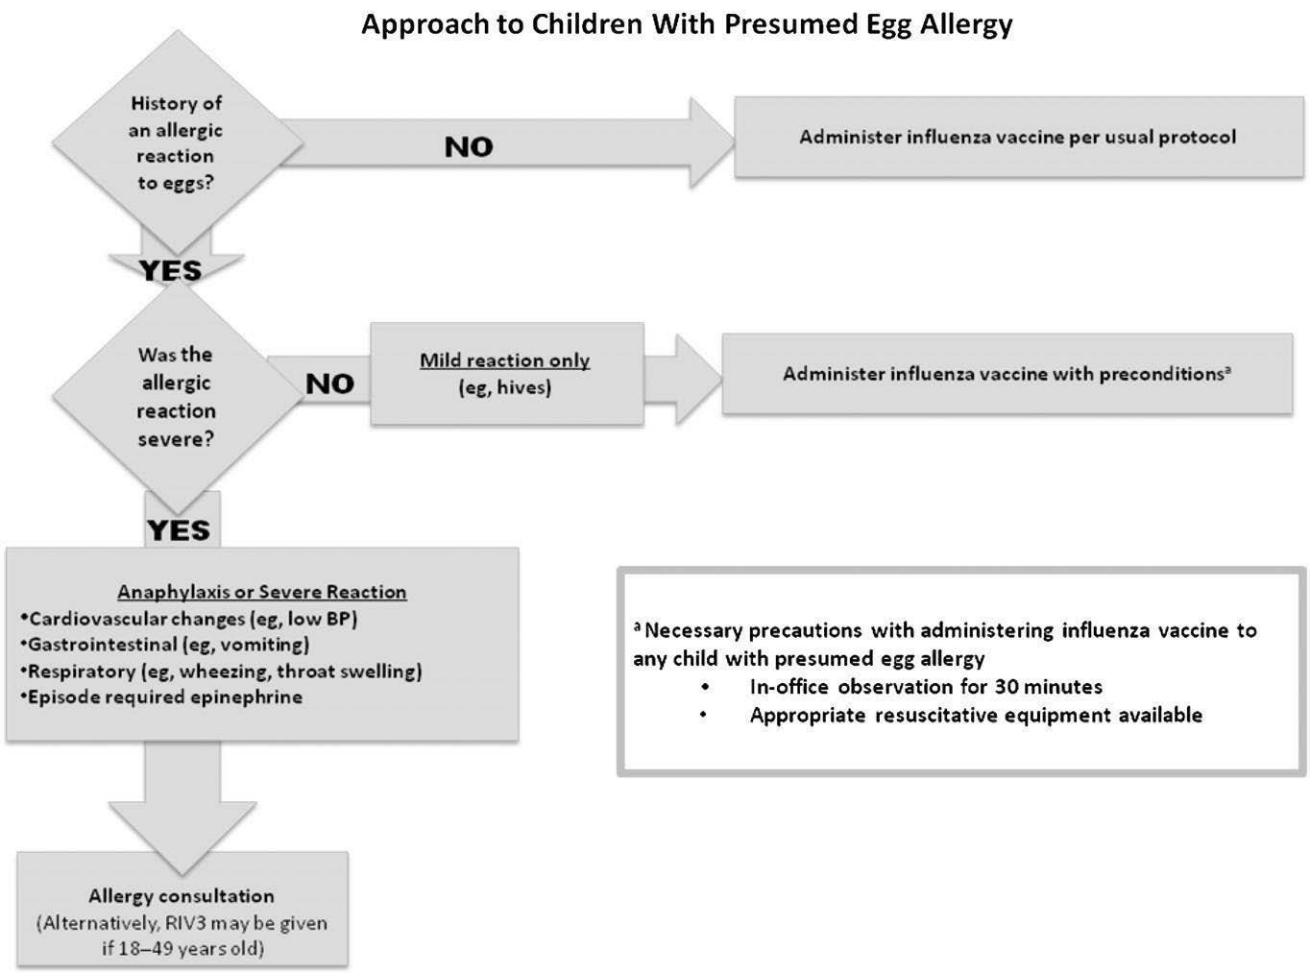

FIGURE 3
Precautions for administering IIV to presumed egg-allergic individuals. BP, blood pressure.

Live-Attenuated (Intranasal) Vaccine

The cold-adapted, temperature sensitive LAIV formulation currently licensed in the United States must be shipped and stored at 2°C to 8°C (35°F–46°F) and administered intranasally in a prefilled, single-use sprayer containing 0.2 mL of vaccine. A removable dose-divider clip is attached to the sprayer to administer 0.1 mL separately into each nostril. After administration of any live-virus vaccine, at least 4 weeks should pass before another live-virus vaccine is administered.

CURRENT RECOMMENDATIONS

Seasonal influenza immunization is recommended for all children 6 months and older. Healthy children 2 years and older can receive either IIV or LAIV. Particular focus should be on the administration of IIV for all children and adolescents with underlying medical conditions associated with an increased risk of complications from influenza, including the following:

- Asthma or other chronic pulmonary diseases, including cystic fibrosis.
- Hemodynamically significant cardiac disease.
- Immunosuppressive disorders or therapy.
- HIV infection.
- Sickle cell anemia and other hemoglobinopathies.
- Diseases that require long-term aspirin therapy, including juvenile idiopathic arthritis or Kawasaki disease.
- Chronic renal dysfunction.
- Chronic metabolic disease, including diabetes mellitus
- Any condition that can compromise respiratory function or handling of secretions or can increase the risk of aspiration, such as neurodevelopmental disorders, spinal cord injuries, seizure disorders, or neuromuscular abnormalities.

Although universal immunization for all people 6 months and older is recommended for the 2013–2014 influenza season, particular immunization

efforts with either IIV or LAIV should be made for the following groups to prevent transmission of influenza to those at risk, unless contraindicated:

- Household contacts and out-of-home care providers of children younger than 5 years of age and at-risk children of all ages (healthy contacts 2 through 49 years of age can receive either IIV or LAIV).
- Any woman who is pregnant, is considering pregnancy, has recently delivered, or is breastfeeding during the influenza season (IIV only). Studies have shown that infants born to immunized women have better influenza-related health outcomes. However, according to Internet panel surveys conducted by the CDC, only 47% of pregnant women reported receiving an influenza vaccine during the 2011–2012 season, even though both pregnant women and their infants are at higher risk of complications. In addition, data from some studies suggest that influenza vaccination in pregnancy may decrease the risk of preterm birth as well as giving birth to infants who are small for gestational age. Pregnant women can safely receive the influenza vaccine during any trimester.
- Children and adolescents of American Indian/Alaskan Native heritage.
- HCP or health care volunteers. Despite the recent AAP recommendation for mandatory influenza immunization for all HCP,[2] many HCP remain unvaccinated. As of November 2012, the CDC estimated that only 62.9% of HCP received the seasonal influenza vaccine. The AAP recommends mandatory vaccination of HCP, because they frequently come into contact with patients at high risk of influenza illness in their clinical settings.
- Close contacts of immunosuppressed people.

CONTRAINDICATIONS AND PRECAUTIONS

Minor illnesses, with or without fever, are not contraindications to the use of influenza vaccines, particularly among children with mild upper respiratory infection symptoms or allergic rhinitis.

Children Who Should Not Be Vaccinated With IIV

- Infants younger than 6 months.
- Children who have a moderate-to-severe febrile illness on the basis of clinical judgment of the clinician.

Children Who Should Not Be Vaccinated With LAIV

- Children younger than 2 years.
- Children who have a moderate-to-severe febrile illness.
- Children with an amount of nasal congestion that would notably impede vaccine delivery.
- Children with chronic underlying medical conditions, including metabolic disease, diabetes mellitus, asthma, other chronic disorders of the pulmonary or cardiovascular systems, renal dysfunction, or hemoglobinopathies.
- Children 2 through 4 years of age with a history of recurrent wheezing or a medically attended wheezing episode in the previous 12 months because of the potential for increased wheezing after immunization. In this age range, many children have a history of wheezing with respiratory tract illnesses and are eventually diagnosed with asthma. Therefore, when offering LAIV to children 24 through 59 months of age, the pediatrician should screen them by asking the parent/guardian the question, "In the previous 12 months, has a health care professional ever told you that your child had wheezing?" If a parent answers yes to this question, LAIV is not recommended for the child. IIV would be recommended for the child to whom LAIV is not given.
- Children who have received other live-virus vaccines within the past 4 weeks; however, other live-virus vaccines can be given on the same day as LAIV.
- Children who have known or suspected immunodeficiency disease or who are receiving immunosuppressive or immunomodulatory therapies.
- Children who are receiving aspirin or other salicylates.
- Any woman who is pregnant or considering pregnancy.
- Children with any condition that can compromise respiratory function or handling of secretions or can increase the risk for aspiration, such as neurodevelopmental disorders, spinal cord injuries, seizure disorders, or neuromuscular abnormalities.
- Children taking an influenza antiviral medication should not receive LAIV until 48 hours after stopping the influenza antiviral therapy. If a child recently received LAIV but has an influenza illness for which antiviral agents are appropriate, the antiviral agents should be given. Reimmunization may be indicated because of the potential effects of antiviral medications on LAIV replication and immunogenicity.

IIV is the vaccine of choice for anyone in close contact with a subset of severely immunocompromised people (ie, individuals in a protected environment). IIV is preferred over LAIV for contacts of severely immunocompromised people (ie, in a protected environment) because of the theoretical risk of infection in an immunocompromised contact of a LAIV-immunized person. Available data indicate a low risk of transmission of the virus in both children and adults vaccinated

with LAIV. HCP immunized with LAIV may continue to work in most units of a hospital, including the NICU and general oncology wards, using standard infection-control techniques. As a precautionary measure, people recently vaccinated with LAIV should restrict contact with severely immunocompromised patients (eg, hematopoietic stem cell transplant recipients during periods that require a protected environment) for 7 days after immunization, although there have been no reports of LAIV transmission from a vaccinated person to an immunocompromised person. In the theoretical scenario in which symptomatic LAIV infection develops in an immunocompromised host, oseltamivir or zanamivir could be prescribed because LAIV strains are susceptible to these antiviral medications.

SURVEILLANCE

Information about influenza surveillance is available through the CDC Voice Information System (influenza update, 888-232-3228) or at www.cdc.gov/flu/index.htm. Although current influenza season data on circulating strains do not necessarily predict which and in what proportion strains will circulate in the subsequent season, it is instructive to be aware of 2012–2013 influenza surveillance data and use them as a guide to empirical therapy until current seasonal data are available from the CDC. Information is posted weekly on the CDC Web site (www.cdc.gov/flu/weekly/fluactivity.htm).

VACCINE IMPLEMENTATION

These updated recommendations for prevention and control of influenza in children will have considerable operational and fiscal effects on pediatric practice. Therefore, the AAP has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at www.aapredbook.org/implementation.

In addition, the AAP's Partnership for Policy Implementation has developed a series of definitions using accepted health information technology standards to assist in the implementation of this guideline in computer systems and quality measurement efforts. This document is available at www2.aap.org/informatics/PPI.html.

USE OF ANTIVIRAL MEDICATIONS

Oseltamivir remains the antiviral drug of choice for the management of influenza infections. Zanamivir is an acceptable alternative but is more difficult to administer. Antiviral resistance can emerge quickly from one season to the next. If local or national influenza surveillance data indicate a predominance of a particular influenza strain with known antiviral susceptibility profile, then empirical treatment can be directed toward that strain. For example, among 2123 influenza A (H3N2) viruses tested, 1 (0.05%) was found to be resistant to oseltamivir alone and 1 (0.05%) to both oseltamivir and zanamivir. Among the 542 pH1N1 viruses tested for resistance to oseltamivir, 2 (0.4%) were resistant, and all of the 258 viruses tested for resistance to zanamivir were sensitive. In contrast, high levels of resistance to amantadine and rimantadine exist, so these drugs should not be used in the upcoming season unless resistance patterns change significantly.

- Current treatment guidelines for antiviral medications (Table 3) are applicable to both infants and children with suspected influenza when known virus strains are circulating in the community or when infants or children are confirmed to have seasonal influenza.
- Oseltamivir is available in capsule and oral-suspension formulations. The commercially manufactured liquid formulation has a concentration of 6 mg/mL. If the commercially manufactured oral suspension is not available, the capsule may be opened and the contents mixed with simple syrup or Oral-Sweet SF (sugar-free) by retail pharmacies to a final concentration of 6 mg/mL (Table 3, footnote a).
- Continuous monitoring of the epidemiology, change in severity, and resistance patterns of influenza strains may lead to new guidance.

Treatment should be offered for the following:

- Any child hospitalized with presumed influenza or with severe, complicated, or progressive illness attributable to influenza, regardless of influenza immunization status.
- Influenza infection of any severity in children at high risk of complications of influenza infection (Table 4).

Treatment should be considered for the following:

- Any otherwise healthy child with influenza infection for whom a decrease in duration of clinical symptoms is felt to be warranted by his or her pediatrician; the greatest impact on outcome will occur if treatment can be initiated within 48 hours of illness onset.

Reviews of available studies by the CDC, the World Health Organization, and independent investigators have consistently found that timely oseltamivir treatment can reduce the risks of complications, including those resulting in hospitalization and death. Although a 2012 Cochrane review suggested that oseltamivir may not be effective in preventing complications or hospitalizations from influenza, its authors correctly pointed out that the data reviewed were not always complete, were analyzed in a variety of treated populations, and used a number of clinical trial designs. Regardless, treatment with oseltamivir for children with presumed serious, complicated, or progressive disease, irrespective of

influenza immunization status and/or even if illness began > 48 hours before admission, continues to be recommended. Earlier treatment provides optimal clinical responses. However, treatment after 48 hours of symptoms in adults and children with moderate-to-severe disease or with progressive disease has been shown to provide some benefit and should be strongly considered.

Dosages for antiviral agents for both treatment and chemoprophylaxis in children can be found in Table 3 and on the CDC Web site (http://www.cdc.gov/flu/professionals/antivirals/index.htm). Children younger than 2 years are at an increased risk of hospitalization and complications attributable to influenza. The FDA recently licensed oseltamivir down to 2 weeks of age. Given its known safety profile, oseltamivir can be used to treat influenza in both term and preterm infants from birth.

Clinical judgment (on the basis of underlying conditions, disease severity, time since symptom onset, and local influenza activity) is an important factor in treatment decisions for pediatric patients who present with influenza-like illness. Antiviral treatment should be started as soon as possible after illness onset and should not be delayed while waiting for a definitive influenza test result. Currently available rapid antigen tests have low sensitivity, particularly for the pH1N1 virus strain, and should not be used to exclude influenza infection. Although negative results from rapid antigen tests should not be used to make treatment or infection-control decisions, positive results are helpful because they may reduce additional testing to identify the cause of the child's influenza-like illness. Nucleic-acid-based molecular diagnostic techniques (eg, polymerase chain reaction–based) are more widely available and have greater sensitivity than antigen tests for influenza infection.

People with suspected influenza who present with an uncomplicated febrile illness typically do not require treatment with antiviral medications unless they are at higher risk of influenza complications (eg, children with chronic medical conditions such as asthma, diabetes mellitus, hemodynamically significant

TABLE 3 Recommended Dosage and Schedule of Influenza Antiviral Medications for Treatment and Chemoprophylaxis for the 2013–2014 Influenza Season: United States

Medication	Treatment (5 d)	Chemoprophylaxis (10 d)
Oseltamivir[a]		
Adults	75 mg twice daily	75 mg once daily
Children ≥12 mo		
≤15 kg (≤33 lb)	30 mg twice daily	30 mg once daily
>15–23 kg (33–51 lb)	45 mg twice daily	45 mg once daily
>23–40 kg (>51–88 lb)	60 mg twice daily	60 mg once daily
>40 kg (>88 lb)	75 mg twice daily	75 mg once daily
Infants 9 through 11 mo[b]	3.5 mg/kg/dose twice daily	3.5 mg/kg/dose once per day
Term Infants 0 through 8 mo[b]	3 mg/kg/dose twice daily[c]	3 mg/kg/dose once daily for infants 3 through 8 mo; not recommended for infants younger than 3 mo, unless situation judged critical, because of limited safety and efficacy data in this age group
Zanamivir[d]		
Adults	10 mg (two 5-mg inhalations) twice daily	10 mg (two 5-mg inhalations) once daily
Children (≥7 y for treatment, ≥5 y for chemoprophylaxis)	10 mg (two 5-mg inhalations) twice daily	10 mg (two 5-mg inhalations) once daily

Sources: Centers for Disease Control and Prevention. Antiviral agents for the treatment and chemoprophylaxis of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). *MMWR Recomm Rep.* 2011;60(RR-1):1–24; Kimberlin DW, Acosta EP, Prichard MN, et al. National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group. Oseltamivir pharmacokinetics, dosing, and resistance among children aged <2 y with influenza. *J Infect Dis.* 2013;207(5):709–720.

[a] Oseltamivir is administered orally without regard to meals, although administration with meals may improve gastrointestinal tolerability. Oseltamivir is available as Tamiflu in 30-mg, 45-mg, and 75-mg capsules and as a powder for oral suspension that is reconstituted to provide a final concentration of 6 mg/mL. For the 6-mg/mL suspension, a 30-mg dose is given with 5 mL of oral suspension, a 45-mg dose is given with 7.5 mL oral suspension; a 60-mg dose is given with 10 mL oral suspension, and a 75-mg dose is given with 12.5 mL oral suspension. If the commercially manufactured oral suspension is not available, a suspension can be compounded by retail pharmacies (final concentration also 6 mg/mL), based on instructions on the package label. In patients with renal insufficiency, the dose should be adjusted on the basis of creatinine clearance. For treatment of patients with creatinine clearance 10 to 30 mL/min: 75 mg once daily for 5 days. For chemoprophylaxis of patients with creatinine clearance 10 to 30 mL/min: 30 mg, once daily, for 10 days after exposure or 75 mg, once every other day, for 10 days after exposure (5 doses). See http://www.cdc.gov/flu/professionals/antivirals/antiviral-drug-resistance.htm.

[b] Approved by the FDA down to 2 weeks of age. Given its known safety profile, oseltamivir can be used to treat influenza in both term and preterm infants from birth.

[c] Oseltamivir dosing for preterm infants. The weight-based dosing recommendation for preterm infants is lower than for term infants. Preterm infants may have lower clearance of oseltamivir because of immature renal function, and doses recommended for full-term infants may lead to high drug concentrations in this age group. Limited data from the National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group provide the basis for dosing preterm infants using their postmenstrual age (gestational age + chronological age): 1.0 mg/kg/dose, orally, twice daily, for those <38 weeks' postmenstrual age; 1.5 mg/kg/dose, orally, twice daily, for those 38 through 40 weeks' postmenstrual age; 3.0 mg/kg/dose, orally, twice daily, for those >40 weeks' postmenstrual age.

[d] Zanamivir is administered by inhalation using a proprietary "Diskhaler" device distributed together with the medication. Zanamivir is a dry powder, not an aerosol, and should not be administered using nebulizers, ventilators, or other devices typically used for administering medications in aerosolized solutions. Zanamivir is not recommended for people with chronic respiratory diseases, such as asthma or chronic obstructive pulmonary disease, which increase the risk of bronchospasm.

TABLE 4 People at Higher Risk of Influenza Complications Recommended for Antiviral Treatment of Suspected or Confirmed Influenza

Children <2 y
Adults ≥65 y
People with chronic pulmonary (including asthma), cardiovascular (except hypertension alone), renal, hepatic, hematologic (including sickle cell disease), or metabolic disorders (including diabetes mellitus) or neurologic and neurodevelopment conditions (including disorders of the brain, spinal cord, peripheral nerve, and muscle such as cerebral palsy, epilepsy [seizure disorders], stroke, intellectual disability [mental retardation], moderate to severe developmental delay, muscular dystrophy, or spinal cord injury)
People with immunosuppression, including that caused by medications or by HIV infection
Women who are pregnant or postpartum (within 2 wk after delivery)
People <19 y who are receiving long-term aspirin therapy
American Indian/Alaska Native people
People who are morbidly obese (ie, BMI ≥40)
Residents of nursing homes and other chronic-care facilities

Source: Centers for Disease Control and Prevention. Antiviral agents for the treatment and chemoprophylaxis of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP). *MMWR Recomm Rep.* 2011;60(RR-1):1–24

cardiac disease, immunosuppression, or neurologic and neurodevelopmental disorders), especially in situations with limited antiviral medication availability. Should there be a shortage of antiviral medications, local public health authorities will provide additional guidance about testing and treatment.

Randomized placebo-controlled studies showed that oseltamivir and zanamivir were efficacious when administered as chemoprophylaxis to household contacts after a family member had laboratory confirmed influenza. During the 2009 pandemic, the emergence of oseltamivir resistance was observed among people receiving postexposure prophylaxis. Decisions on whether to administer antiviral agents for chemoprophylaxis should take into account the exposed person's risk of influenza complications, vaccination status, the type and duration of contact, recommendations from local or public health authorities, and clinical judgment. Optimally, postexposure chemoprophylaxis should only be used when antiviral agents can be started within 48 hours of exposure. Early treatment of high-risk patients without waiting for laboratory confirmation is an alternative strategy.

Although immunization is the preferred approach to prevention of infection, chemoprophylaxis during an influenza outbreak, as defined by the CDC, is recommended:

- For children at high risk of complications from influenza for whom influenza vaccine is contraindicated.
- For children at high risk during the 2 weeks after influenza immunization.
- For family members or HCP who are unimmunized and are likely to have ongoing, close exposure to
  - unimmunized children at high risk; or
  - unimmunized infants and toddlers who are younger than 24 months.
- For control of influenza outbreaks for unimmunized staff and children in a closed institutional setting with children at high risk (eg, extended-care facilities).
- As a supplement to immunization among children at high risk, including children who are immunocompromised and may not respond to vaccine.
- As postexposure prophylaxis for family members and close contacts of an infected person if those people are at high risk of complications from influenza.
- For children at high risk and their family members and close contacts, as well as HCP, when circulating strains of influenza virus in the community are not matched with seasonal influenza vaccine strains, on the basis of current data from the CDC and local health departments.

These recommendations apply to routine circumstances, but it should be noted that guidance may change on the basis of updated recommendations from the CDC in concert with antiviral availability, local resources, clinical judgment, recommendations from local or public health authorities, risk of influenza complications, type and duration of exposure contact, and change in epidemiology or severity of influenza. Chemoprophylaxis is not recommended for infants younger than 3 months, unless the situation is judged critical, because of limited safety and efficacy data in this age group.

Chemoprophylaxis should not be considered a substitute for immunization.

Influenza vaccine should always be offered when not contraindicated, even when influenza virus is circulating in the community. Antiviral medications currently licensed are important adjuncts to influenza immunization for control and prevention of influenza disease, but there are toxicities associated with antiviral agents, and indiscriminate use might limit availability. Pediatricians should inform recipients of antiviral chemoprophylaxis that risk of influenza is lowered but remains while taking the medication, and susceptibility to influenza returns when medication is discontinued. For recommendations about treatment and chemoprophylaxis against influenza, see Table 3. Updates will be available at www.aapredbook.org/flu and http://www.cdc.gov/flu/professionals/antivirals/index.htm.

FUTURE NEEDS

Currently, within the approved indications and recommendations, no preferential recommendation is made for any type or brand of influenza vaccine over another. This is partly because the supply of newer vaccines may be limited during the 2013–2014 season. Moreover, postmarketing safety and vaccine effectiveness data are not yet available, prohibiting a full risk-benefit analysis of newer versus previously available products. However, such analyses will be performed as the data become available and, in the future, specific vaccines may be preferentially recommended for particular groups.

A large body of evidence indicates that even children with severe (anaphylactic) allergic reactions to the ingestion of eggs tolerate IIV in a single, age-appropriate dose. Examination of Vaccine Adverse Event Reporting System data after new Advisory Committee on Immunization Practices guidelines recommending influenza vaccine for egg-allergic recipients indicated no disproportionate reporting of allergy or anaphylaxis. Studies are also underway examining the safety of LAIV in egg-allergic recipients. If, as expected, additional safety monitoring continues to show no increased risk for anaphylactic reactions in egg-allergic recipients of influenza vaccine, special precautions regarding allergy referral and waiting periods after administration to egg-allergic recipients beyond those recommended for any vaccine may no longer be recommended.

Efforts should be made to create adequate outreach and infrastructure to ensure an optimal distribution of vaccine so that more people are immunized. Pediatricians should also become more involved in pandemic preparedness or disaster planning efforts. A bidirectional partner dialogue between pediatricians and public health decision makers ensures that children's issues are addressed during the initial state, regional, and local plan development stages. Further information concerning disaster preparedness can be found at www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/children-and-disasters/Pages/Pediatric-Preparedness-Resource-Kit.aspx.

Health care for children should be provided in the child's medical home. However, medical homes may have limited capacity to accommodate all patients (and their families) seeking influenza immunization. Because of the increased demand for immunization during each influenza season, the AAP and the CDC recommend vaccine administration at any visit to the medical home during influenza season when it is not contraindicated, at specially arranged "vaccine-only" sessions, and through cooperation with community sites, schools, and child care centers to provide influenza vaccine. If alternate venues are used, including pharmacies and other retail-based clinics, a system of patient record transfer is beneficial to ensuring maintenance of accurate immunization records. Immunization information systems should be used whenever available. The use of 2-dimensional barcodes may help facilitate more efficient and accurate documentation of vaccine administration. Multiple barriers appear to have an impact on influenza vaccination coverage for children in foster care, refugee and immigrant children, and homeless children. Access to care issues, lack of immunization records, and questions regarding who can provide consent may be addressed by linking children with a medical home, using all health care encounters as vaccination opportunities, and more consistently using immunization registry data.

Cost-effectiveness and logistic feasibility of vaccinating everyone continue to be concerns. With universal immunization, particular attention is being paid to vaccine supply, distribution, implementation, and financing. Potential benefits of more widespread childhood immunization among recipients, their contacts, and the community include fewer influenza cases, fewer outpatient visits and hospitalizations for influenza infection, and a decrease in the use of antimicrobial agents, absenteeism from school, and lost parent work time. To optimally administer antiviral therapy in hospitalized patients with influenza who cannot tolerate oral or inhaled antiviral agents, FDA-approved intravenous neuraminidase inhibitors for children also are needed.

Continued evaluation of the safety, immunogenicity, and effectiveness of influenza vaccine, especially for children younger than 2 years, is important. The potential role of previous influenza vaccination on overall vaccine effectiveness by virus strain and subject age in preventing outpatient medical visits, hospitalizations, and deaths continues to be explored. There is also a need for more systematic health services research on influenza vaccine uptake and refusal as well as identification of methods to enhance uptake. In addition, development of a safe, immunogenic vaccine for infants younger than 6 months is essential. Until such a vaccine is available for infants younger than 6 months, vaccination of their mothers while pregnant is the best way to protect them. Breastfeeding is also recommended to protect against influenza viruses by activating innate antiviral mechanisms, specifically type 1 interferons, in the host. Mandatory annual influenza immunization of all HCP has been implemented successfully at an increasing number of pediatric institutions. Future efforts should include broader implementation of mandatory immunization programs. Optimal prevention of influenza in the health care setting depends on the vaccination of at least 90% of HCP.

Additional studies are needed to investigate the extent of offering to immunize parents and adult child care providers in the pediatric office setting; the level of family contact satisfaction with this practice; how practices handle the logistic, liability, legal, and financial barriers that limit or complicate this service; and, most important, how this practice will affect disease rates in children and adults. In addition, adjuvants have been shown to enhance immune responses to influenza vaccines, but certain adjuvants have been associated with the development of narcolepsy in some studies. Additional studies on the effectiveness and safety of influenza vaccines containing adjuvants are needed. Finally, as mentioned earlier, efforts to improve the vaccine-development process to allow for a shorter interval between identification of vaccine strains and vaccine production continue.

ACKNOWLEDGMENTS

This AAP policy statement was prepared in parallel with CDC recommendations and reports. Much of this statement is based on literature reviews, analyses of unpublished data, and deliberations of CDC staff in collaborations with the Advisory Committee on Immunization Practices (ACIP) Influenza Working Group, with liaison from the AAP.

The 2014 recommended childhood and adolescent immunization schedules have been approved by the American Academy of Pediatrics, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention, the American Academy of Family Physicians, and the American College of Obstetricians and Gynecologists. The 2014 format is similar to last year and includes a single schedule for persons 0 through 18 years of age (Fig 1). The yellow bars indicate the recommended age range for all children and contain a notation indicating the recommended dose number by age. The green bars indicate the recommended catch-up age. The purple bars designate the range for immunization for certain groups at high risk. The combined green and purple bar indicates the recommended age when hepatitis A vaccine catch-up is recommended. The white boxes show the ages when a vaccine is not recommended routinely. The catch-up schedule offers recommendations for children and adolescents who start late or are >1 month behind (Fig 2).

Footnotes contain recommendations for routine vaccination, for catch-up vaccination, and for vaccination of children and adolescents with high-risk conditions or in special circumstances. Numerous changes have been made to improve the clarity and readability of the footnotes. A parent-friendly vaccine schedule for children and adolescents is available at http://www.cdc.gov/vaccines/schedules/index.html. An adult immunization schedule also is published in February of each year and is available at www.cdc.gov/vaccines. These schedules are revised annually to reflect current recommendations for the use of vaccines licensed by the US Food and Drug Administration and include the following specific changes from last year:

- Both generic names and trade names are referenced in the title of each vaccine footnote; thereafter, only the trade name is used, as in the rotavirus footnote.
- The Tdap footnote includes information on vaccination of persons 7 years and older with a single lifetime dose of Tdap, except for pregnant adolescents, who should be vaccinated with each pregnancy. For pregnant adolescents, administration is preferred during week 27 through week 36 of gestation, regardless of time since previous Td or Tdap.
- The *Haemophilus influenzae* type b footnote clarifies vaccination of children 12 through 59 months of age who are at increased risk because of incomplete vaccination, asplenia, HIV infection, receipt of hematopoietic stem cell transplant, or receipt of chemotherapy or radiation treatment.

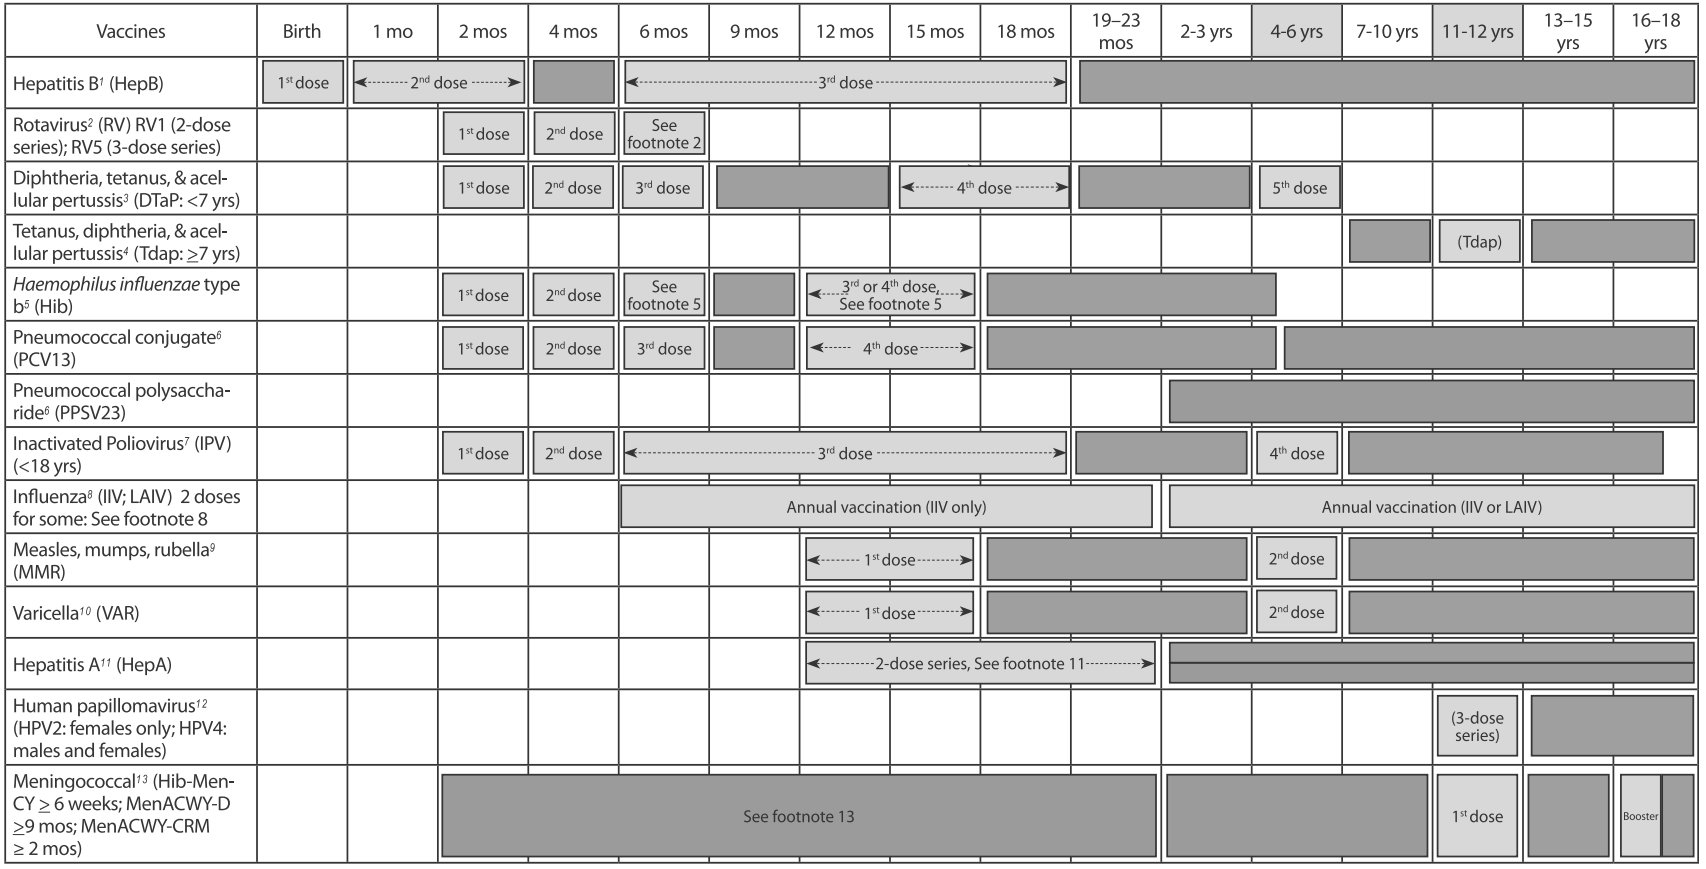
- The pneumococcal vaccine footnote itemizes recommendations for PCV13 and PPSV23 use in children and adolescents at increased risk on the basis of age and degree of risk.
- The influenza vaccine footnote describes vaccine dosing for children 6 months through 8 years of age and for those 9 years of age and older for the 2013–2014 season.
- The hepatitis A vaccine footnote includes the list of persons at increased risk of hepatitis A disease.
- The HPV footnote clarifies the intervals between vaccine doses.
- The meningococcal footnote includes guidance for use of Menveo (Novartis, Cambridge, MA) starting at 2 months of age for certain persons at increased risk. Clarification is added regarding immunization of children with sickle cell disease or persistent complement component deficiency, travelers to areas where meningococcal disease is hyperendemic/epidemic, and children at risk during a community outbreak. Catch-up recommendations for persons at high risk are addressed.

Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form can be obtained at www.vaers.hhs.gov or by calling 800-822-7967. Additional information can be found in the *Red Book* and at *Red Book* Online (http://aapredbook.aappublications.org/). Statements from the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that contain details of recommendations for individual vaccines, including recommendations for children with high-risk conditions, are available at www.cdc.gov/vaccines/pubs/ACIP-list.htm. Information on new vaccine releases, vaccine supplies, and interim recommendations resulting from vaccine shortages and statements on specific vaccines can be found at www.aapredbook.org/news/vaccstatus.shtml and www.cdc.gov/vaccines/pubs/ACIP-list.htm.

FIGURE 1

Recommended immunization schedule for persons aged 0 through 18 years—2014. (For those who fall behind or start late, see the catch-up schedule [Fig 2].)

These recommendations must be read with the footnotes that follow. For those who fall behind or start late, provide catch-up vaccination at the earliest opportunity as indicated by the green bars in Figure 1. To determine minimum intervals between doses, see the catch-up schedule (Figure 2). School entry and adolescent vaccine age groups are in bold.



This schedule includes recommendations in effect as of January 1, 2014. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Vaccination providers should consult the relevant Advisory Committee on Immunization Practices (ACIP) statement for detailed recommendations, available online at http://www.cdc.gov/vaccines/hcp/acip-recs/index.html. Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (http://www.vaers.hhs.gov) or by telephone (800-822-7967).Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for vaccination, is available from CDC online (http://www.cdc.gov/vaccines) or by telephone (800-CDC-INFO [800-232-4636]).

This schedule is approved by the Advisory Committee on Immunization Practices (http//www.cdc.gov/vaccines/acip), the American Academy of Pediatrics (http://www.aap.org), the American Academy of Family Physicians (http://www.aafp.org), and the American College of Obstetricians and Gynecologists (http://www.acog.org).

NOTE: The above recommendations must be read along with the footnotes of this schedule.

FIGURE 2

Catch-up immunization schedule for persons aged 4 months through 18 years who start late or who are >1 month behind—United States, 2014.

The figure below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age. Always use this table in conjunction with Figure 1 and the footnotes that follow.

Persons aged 4 months through 6 years					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to dose 2	Dose 2 to dose 3	Dose 3 to dose 4	Dose 4 to dose 5
Hepatitis B[1]	Birth	4 weeks	8 weeks and at least 16 weeks after first dose; minimum age for the final dose is 24 weeks		
Rotavirus[2]	6 weeks	4 weeks	4 weeks		
Diphtheria, tetanus, & acellular pertussis [3]	6 weeks	4 weeks	4 weeks	6 months	6 months[3]
Haemophilus influenzae type b[5]	6 weeks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose) if first dose administered at age 12 through 14 months No further doses needed if first dose administered at age 15 months or older	4 weeks[5] if current age is younger than 12 months and first dose administered at < 7 months old 8 weeks and age 12 months through 59 months (as final dose)[5] if current age is younger than 12 months and first dose administered between 7 through 11 months (regardless of Hib vaccine [PRP-T or PRP-OMP] used for first dose); OR if current age is 12 through 59 months and first dose administered at younger than age 12 months; OR first 2 doses were PRP-OMP and administered at younger than 12 months. No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 through 59 months who received 3 (PRP-T) doses before age 12 months and started the primary series before age 7 months	
Pneumococcal[6]	6 weeks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 through 59 months who received 3 doses before age 12 months or for children at high risk who received 3 doses at any age	
Inactivated poliovirus[7]	6 weeks	4 weeks[7]	4 weeks[7]	6 months[7] minimum age 4 years for final dose	
Meningococcal[13]	6 weeks	8 weeks[13]	See footnote 13	See footnote 13	
Measles, mumps, rubella[9]	12 months	4 weeks			
Varicella[10]	12 months	3 months			
Hepatitis A[11]	12 months	6 months			
Persons aged 7 through 18 years					
Tetanus, diphtheria; tetanus, diphtheria, & acellular pertussis[4]	7 years[4]	4 weeks	4 weeks if first dose of DTaP/DT administered at younger than age 12 months 6 months if first dose of DTaP/DT administered at age 12 months or older and then no further doses needed for catch-up	6 months if first dose of DTaP/DT administered at younger than age 12 months	
Human papillomavirus[12]	9 years	Routine dosing intervals are recommended[12]			
Hepatitis A[11]	12 months	6 months			
Hepatitis B[1]	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Inactivated poliovirus[7]	6 weeks	4 weeks	4 weeks[7]	6 months[7]	
Meningococcal[13]	6 weeks	8 weeks[13]			
Measles, mumps, rubella[9]	12 months	4 weeks			
Varicella[10]	12 months	3 months if person is younger than age 13 years 4 weeks if person is aged 13 years or older			

NOTE: The above recommendations must be read along with the footnotes of this schedule.

Footnotes — Recommended immunization schedule for persons aged 0 through 18 years—United States, 2014

For further guidance on the use of the vaccines mentioned below, see: http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.
For vaccine recommendations for persons 19 years of age and older, see the adult immunization schedule.

Additional information

- For contraindications and precautions to use of a vaccine and for additional information regarding that vaccine, vaccination providers should consult the relevant ACIP statement available online at http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.
- For purposes of calculating intervals between doses, 4 weeks = 28 days. Intervals of 4 months or greater are determined by calendar months.
- Vaccine doses administered 4 days or less before the minimum interval are considered valid. Doses of any vaccine administered ≥5 days earlier than the minimum interval or minimum age should not be counted as valid doses and should be repeated as age-appropriate. The repeat dose should be spaced after the invalid dose by the recommended minimum interval. For further details, see *MMWR, General Recommendations on Immunization and Reports* / Vol. 60 / No. 2; Table 2. *Recommended and minimum ages and intervals between vaccine doses* available online at http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf.
- Information on travel vaccine requirements and recommendations is available at http://wwwnc.cdc.gov/travel/page/vaccinations.htm.
- For vaccination of persons with primary and secondary immunodeficiencies, see Table 13, "*Vaccination of persons with primary and secondary immunodeficiencies*," in General Recommendations on Immunization (ACIP), available at http://www.cdc.gov/mmwr/pdf/rr/rr6002.pdf.; and American Academy of Pediatrics. Immunization in Special Clinical Circumstances, in Pickering LK, Baker CJ, Kimberlin DW, Long SS eds. *Red Book: 2012 report of the Committee on Infectious Diseases. 29th ed.* Elk Grove Village, IL: American Academy of Pediatrics.

1. Hepatitis B (HepB) vaccine. (Minimum age: birth)

Routine vaccination:

At birth

- Administer monovalent HepB vaccine to all newborns before hospital discharge.
- For infants born to hepatitis B surface antigen (HBsAg)-positive mothers, administer HepB vaccine and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth. These infants should be tested for HBsAg and antibody to HBsAg (anti-HBs) 1 to 2 months after completion of the HepB series, at age 9 through 18 months (preferably at the next well-child visit).
- If mother's HBsAg status is unknown, within 12 hours of birth administer HepB vaccine regardless of birth weight. For infants weighing less than 2,000 grams, administer HBIG in addition to HepB vaccine within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if mother is HBsAg-positive, also administer HBIG for infants weighing 2,000 grams or more as soon as possible, but no later than age 7 days.

Doses following the birth dose

- The second dose should be administered at age 1 or 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks.
- Infants who did not receive a birth dose should receive 3 doses of a HepB-containing vaccine on a schedule of 0, 1 to 2 months, and 6 months starting as soon as feasible. See Figure 2.
- Administer the second dose 1 to 2 months after the first dose (minimum interval of 4 weeks), administer the third dose at least 8 weeks after the second dose AND at least 16 weeks after the **first** dose. The final (third or fourth) dose in the HepB vaccine series should be administered no earlier than age 24 weeks.
- Administration of a total of 4 doses of HepB vaccine is permitted when a combination vaccine containing HepB is administered after the birth dose.

Catch-up vaccination:

- Unvaccinated persons should complete a 3-dose series.
- A 2-dose series (doses separated by at least 4 months) of adult formulation Recombivax HB is licensed for use in children aged 11 through 15 years.
- For other catch-up guidance, see Figure 2.

2. Rotavirus (RV) vaccines. (Minimum age: 6 weeks for both RV1 [Rotarix] and RV5 [RotaTeq])

Routine vaccination:

Administer a series of RV vaccine to all infants as follows:

1. If Rotarix is used, administer a 2-dose series at 2 and 4 months of age.
2. If RotaTeq is used, administer a 3-dose series at ages 2, 4, and 6 months.
3. If any dose in the series was RotaTeq or vaccine product is unknown for any dose in the series, a total of 3 doses of RV vaccine should be administered.

Catch-up vaccination:

- The maximum age for the first dose in the series is 14 weeks, 6 days; vaccination should not be initiated for infants aged 15 weeks, 0 days or older.
- The maximum age for the final dose in the series is 8 months, 0 days.
- For other catch-up guidance, see Figure 2.

3. Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine. (Minimum age: 6 weeks. Exception: DTaP-IPV [Kinrix]: 4 years)

Routine vaccination:

- Administer a 5-dose series of DTaP vaccine at ages 2, 4, 6, 15 through 18 months, and 4 through 6 years. The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.

Catch-up vaccination:

- The fifth dose of DTaP vaccine is not necessary if the fourth dose was administered at age 4 years or older.
- For other catch-up guidance, see Figure 2.

4. Tetanus and diphtheria toxoids and acellular pertussis (Tdap) vaccine. (Minimum age: 10 years for Boostrix, 11 years for Adacel)

Routine vaccination:

- Administer 1 dose of Tdap vaccine to all adolescents aged 11 through 12 years.
- Tdap may be administered regardless of the interval since the last tetanus and diphtheria toxoid-containing vaccine.
- Administer 1 dose of Tdap vaccine to pregnant adolescents during each pregnancy (preferred during 27 through 36 weeks gestation) regardless of time since prior Td or Tdap vaccination.

Catch-up vaccination:

- Persons aged 7 years and older who are not fully immunized with DTaP vaccine should receive Tdap vaccine as 1 (preferably the first) dose in the catch-up series; if additional doses are needed, use Td vaccine. For children 7 through 10 years who receive a dose of Tdap as part of the catch-up series, an adolescent Tdap vaccine dose at age 11 through 12 years should NOT be administered. Td should be administered instead 10 years after the Tdap dose.
- Persons aged 11 through 18 years who have not received Tdap vaccine should receive a dose followed by tetanus and diphtheria toxoids (Td) booster doses every 10 years thereafter.
- Inadvertent doses of DTaP vaccine:
  - If administered inadvertently to a child aged 7 through 10 years may count as part of the catch-up series. This dose may count as the adolescent Tdap dose, or the child can later receive a Tdap booster dose at age 11 through 12 years.
  - If administered inadvertently to an adolescent aged 11 through 18 years, the dose should be counted as the adolescent Tdap booster.
- For other catch-up guidance, see Figure 2.

5. *Haemophilus influenzae* type b (Hib) conjugate vaccine. (Minimum age: 6 weeks for PRP-T [ACTHIB, DTaP-IPV/Hib (Pentacel) and Hib-MenCY (MenHibrix)], PRP-OMP [PedvaxHIB or COMVAX], 12 months for PRP-T [Hiberix])

Routine vaccination:

- Administer a 2- or 3-dose Hib vaccine primary series and a booster dose (dose 3 or 4 depending on vaccine used in primary series) at age 12 through 15 months to complete a full Hib vaccine series.
- The primary series with ActHIB, MenHibrix, or Pentacel consists of 3 doses and should be administered at 2, 4, and 6 months of age. The primary series with PedvaxHib or COMVAX consists of 2 doses and should be administered at 2 and 4 months of age; a dose at age 6 months is not indicated.
- One booster dose (dose 3 or 4 depending on vaccine used in primary series) of any Hib vaccine should be administered at age 12 through 15 months. An exception is Hiberix vaccine. Hiberix should only be used for the booster (final) dose in children aged 12 months through 4 years who have received at least 1 prior dose of Hib-containing vaccine.

For further guidance on the use of the vaccines mentioned below, see: http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.

5. ***Haemophilus influenzae* type b (Hib) conjugate vaccine (cont'd)**
   - For recommendations on the use of MenHibrix in patients at increased risk for meningococcal disease, please refer to the meningococcal vaccine footnotes and also to *MMWR* March 22, 2013 / 62(RR02); 1-22, available at http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf.

   Catch-up vaccination:
   - If dose 1 was administered at ages 12 through 14 months, administer a second (final) dose at least 8 weeks after dose 1, regardless of Hib vaccine used in the primary series.
   - If the first 2 doses were PRP-OMP (PedvaxHIB or COMVAX), and were administered at age 11 months or younger, the third (and final) dose should be administered at age 12 through 15 months and at least 8 weeks after the second dose.
   - If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a third (and final) dose at age 12 through 15 months or 8 weeks after second dose, whichever is later, regardless of Hib vaccine used for first dose.
   - If first dose is administered at younger than 12 months of age and second dose is given between 12 through 14 months of age, a third (and final) dose should be given 8 weeks later.
   - For unvaccinated children aged 15 months or older, administer only 1 dose.
   - For other catch-up guidance, see Figure 2. For catch-up guidance related to MenHibrix, please see the meningococcal vaccine footnotes and also *MMWR* March 22, 2013 / 62(RR02); 1-22, available at http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf.

   Vaccination of persons with high-risk conditions:
   - Children aged 12 through 59 months who are at increased risk for Hib disease, including chemotherapy recipients and those with anatomic or functional asplenia (including sickle cell disease), human immunodeficiency virus (HIV) infection, immunoglobulin deficiency, or early component complement deficiency, who have received either no doses or only 1 dose of Hib vaccine before 12 months of age, should receive 2 additional doses of Hib vaccine 8 weeks apart; children who received 2 or more doses of Hib vaccine before 12 months of age should receive 1 additional dose.
   - For patients younger than 5 years of age undergoing chemotherapy or radiation treatment who received a Hib vaccine dose(s) within 14 days of starting therapy or during therapy, repeat the dose(s) at least 3 months following therapy completion.
   - Recipients of hematopoietic stem cell transplant (HSCT) should be revaccinated with a 3-dose regimen of Hib vaccine starting 6 to 12 months after successful transplant, regardless of vaccination history; doses should be administered at least 4 weeks apart.
   - A single dose of any Hib-containing vaccine should be administered to unimmunized* children and adolescents 15 months of age and older undergoing an elective splenectomy; if possible, vaccine should be administered at least 14 days before procedure.
   - Hib vaccine is not routinely recommended for patients 5 years or older. However, 1 dose of Hib vaccine should be administered to unimmunized* persons aged 5 years or older who have anatomic or functional asplenia (including sickle cell disease) and unvaccinated persons 5 through 18 years of age with human immunodeficiency virus (HIV) infection.

   ** Patients who have not received a primary series and booster dose or at least 1 dose of Hib vaccine after 14 months of age are considered unimmunized.*

6. **Pneumococcal vaccines. (Minimum age: 6 weeks for PCV13, 2 years for PPSV23)**

   Routine vaccination with PCV13:
   - Administer a 4-dose series of PCV13 vaccine at ages 2, 4, and 6 months and at age 12 through 15 months.
   - For children aged 14 through 59 months who have received an age-appropriate series of 7-valent PCV (PCV7), administer a single supplemental dose of 13-valent PCV (PCV13).

   Catch-up vaccination with PCV13:
   - Administer 1 dose of PCV13 to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
   - For other catch-up guidance, see Figure 2.

   Vaccination of persons with high-risk conditions with PCV13 and PPSV23:
   - All recommended PCV13 doses should be administered prior to PPSV23 vaccination if possible.
   - For children 2 through 5 years of age with any of the following conditions: chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure); chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy); diabetes mellitus; cerebrospinal fluid leak; cochlear implant; sickle cell disease and other hemoglobinopathies; anatomic or functional asplenia; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; solid organ transplantation; or congenital immunodeficiency:
     1. Administer 1 dose of PCV13 if 3 doses of PCV (PCV7 and/or PCV13) were received previously.
     2. Administer 2 doses of PCV13 at least 8 weeks apart if fewer than 3 doses of PCV (PCV7 and/or PCV13) were received previously.
     3. Administer 1 supplemental dose of PCV13 if 4 doses of PCV7 or other age-appropriate complete PCV7 series was received previously.
     4. The minimum interval between doses of PCV (PCV7 or PCV13) is 8 weeks.
     5. For children with no history of PPSV23 vaccination, administer PPSV23 at least 8 weeks after the most recent dose of PCV13.
   - For children aged 6 through 18 years who have cerebrospinal fluid leak; cochlear implant; sickle cell disease and other hemoglobinopathies; anatomic or functional asplenia; congenital or acquired immunodeficiencies; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; generalized malignancy; solid organ transplantation; or multiple myeloma:
     1. If neither PCV13 nor PPSV23 has been received previously, administer 1 dose of PCV13 now and 1 dose of PPSV23 at least 8 weeks later.
     2. If PCV13 has been received previously but PPSV23 has not, administer 1 dose of PPSV23 at least 8 weeks after the most recent dose of PCV13.
     3. If PPSV23 has been received but PCV13 has not, administer 1 dose of PCV13 at least 8 weeks after the most recent dose of PPSV23.
   - For children aged 6 through 18 years with chronic heart disease (particularly cyanotic congenital heart disease and cardiac failure), chronic lung disease (including asthma if treated with high-dose oral corticosteroid therapy), diabetes mellitus, alcoholism, or chronic liver disease, who have not received PPSV23, administer 1 dose of PPSV23. If PCV13 has been received previously, then PPSV23 should be administered at least 8 weeks after any prior PCV13 dose.
   - A single revaccination with PPSV23 should be administered 5 years after the first dose to children with sickle cell disease or other hemoglobinopathies; anatomic or functional asplenia; congenital or acquired immunodeficiencies; HIV infection; chronic renal failure; nephrotic syndrome; diseases associated with treatment with immunosuppressive drugs or radiation therapy, including malignant neoplasms, leukemias, lymphomas, and Hodgkin disease; generalized malignancy; solid organ transplantation; or multiple myeloma.

7. **Inactivated poliovirus vaccine (IPV). (Minimum age: 6 weeks)**

   Routine vaccination:
   - Administer a 4-dose series of IPV at ages 2, 4, 6 through 18 months, and 4 through 6 years. The final dose in the series should be administered on or after the fourth birthday and at least 6 months after the previous dose.

   Catch-up vaccination:
   - In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk for imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
   - If 4 or more doses are administered before age 4 years, an additional dose should be administered at age 4 through 6 years and at least 6 months after the previous dose.
   - A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months after the previous dose.
   - If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age. IPV is not routinely recommended for U.S. residents aged 18 years or older.
   - For other catch-up guidance, see Figure 2.

8. **Influenza vaccines. (Minimum age: 6 months for inactivated influenza vaccine [IIV], 2 years for live, attenuated influenza vaccine [LAIV])**

   Routine vaccination:
   - Administer influenza vaccine annually to all children beginning at age 6 months. For most healthy, nonpregnant persons aged 2 through 49 years, either LAIV or IIV may be used. However, LAIV should NOT be administered to some persons, including 1) those with asthma, 2) children 2 through 4 years who had wheezing in the past 12 months, or 3) those who have any other underlying medical conditions that predispose them to influenza complications. For all other contraindications to use of LAIV, see *MMWR* 2013; 62 (No. RR-7):1-43, available at http://www.cdc.gov/mmwr/pdf/rr/rr6207.pdf.

   For children aged 6 months through 8 years:
   - For the 2013–14 season, administer 2 doses (separated by at least 4 weeks) to children who are receiving influenza vaccine for the first time. Some children in this age group who have been vaccinated previously will also need 2 doses. For additional guidance, follow dosing guidelines in the 2013-14 ACIP influenza vaccine recommendations, *MMWR* 2013; 62 (No. RR-7):1-43, available at http://www.cdc.gov/mmwr/pdf/rr/rr6207.pdf.
   - For the 2014–15 season, follow dosing guidelines in the 2014 ACIP influenza vaccine recommendations.

   For persons aged 9 years and older:
   - Administer 1 dose.

For further guidance on the use of the vaccines mentioned below, see: http://www.cdc.gov/vaccines/hcp/acip-recs/index.html.

9. Measles, mumps, and rubella (MMR) vaccine. (Minimum age: 12 months for routine vaccination)

Routine vaccination:

- Administer a 2-dose series of MMR vaccine at ages12 through 15 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 4 weeks have elapsed since the first dose.
- Administer 1 dose of MMR vaccine to infants aged 6 through 11 months before departure from the United States for international travel. These children should be revaccinated with 2 doses of MMR vaccine, the first at age 12 through 15 months (12 months if the child remains in an area where disease risk is high), and the second dose at least 4 weeks later.
- Administer 2 doses of MMR vaccine to children aged 12 months and older before departure from the United States for international travel. The first dose should be administered on or after age 12 months and the second dose at least 4 weeks later.

Catch-up vaccination:

- Ensure that all school-aged children and adolescents have had 2 doses of MMR vaccine; the minimum interval between the 2 doses is 4 weeks.

10. Varicella (VAR) vaccine. (Minimum age: 12 months)

Routine vaccination:

- Administer a 2-dose series of VAR vaccine at ages 12 through 15 months and 4 through 6 years. The second dose may be administered before age 4 years, provided at least 3 months have elapsed since the first dose. If the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.

Catch-up vaccination:

- Ensure that all persons aged 7 through 18 years without evidence of immunity (see *MMWR* 2007; 56 [No. RR-4], available at http://www.cdc.gov/mmwr/pdf/rr/rr5604.pdf) have 2 doses of varicella vaccine. For children aged 7 through 12 years, the recommended minimum interval between doses is 3 months (if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid); for persons aged 13 years and older, the minimum interval between doses is 4 weeks.

11. Hepatitis A (HepA) vaccine. (Minimum age: 12 months)

Routine vaccination:

- Initiate the 2-dose HepA vaccine series at 12 through 23 months; separate the 2 doses by 6 to 18 months.
- Children who have received 1 dose of HepA vaccine before age 24 months should receive a second dose 6 to 18 months after the first dose.
- For any person aged 2 years and older who has not already received the HepA vaccine series, 2 doses of HepA vaccine separated by 6 to 18 months may be administered if immunity against hepatitis A virus infection is desired.

Catch-up vaccination:

- The minimum interval between the two doses is 6 months.

Special populations:

- Administer 2 doses of HepA vaccine at least 6 months apart to previously unvaccinated persons who live in areas where vaccination programs target older children, or who are at increased risk for infection. This includes persons traveling to or working in countries that have high or intermediate endemicity of infection; men having sex with men; users of injection and non-injection illicit drugs; persons who work with HAV-infected primates or with HAV in a research laboratory; persons with clotting-factor disorders; persons with chronic liver disease; and persons who anticipate close, personal contact (e.g., household or regular babysitting) with an international adoptee during the first 60 days after arrival in the United States from a country with high or intermediate endemicity. The first dose should be administered as soon as the adoption is planned, ideally 2 or more weeks before the arrival of the adoptee.

12. Human papillomavirus (HPV) vaccines. (Minimum age: 9 years for HPV2 [Cervarix] and HPV4 [Gardisil])

Routine vaccination:

- Administer a 3-dose series of HPV vaccine on a schedule of 0, 1-2, and 6 months to all adolescents aged 11 through 12 years. Either HPV4 or HPV2 may be used for females, and only HPV4 may be used for males.
- The vaccine series may be started at age 9 years.
- Administer the second dose 1 to 2 months after the first dose (minimum interval of 4 weeks), administer the third dose 24 weeks after the first dose and 16 weeks after the second dose (minimum interval of 12 weeks).

Catch-up vaccination:

- Administer the vaccine series to females (either HPV2 or HPV4) and males (HPV4) at age 13 through 18 years if not previously vaccinated.
- Use recommended routine dosing intervals (see above) for vaccine series catch-up.

13. Meningococcal conjugate vaccines. (Minimum age: 6 weeks for Hib-MenCY [MenHibrix], 9 months for MenACWY-D [Menactra], 2 months for MenACWY-CRM [Menveo])

Routine vaccination:

- Administer a single dose of Menactra or Menveo vaccine at age 11 through 12 years, with a booster dose at age 16 years.
- Adolescents aged 11 through 18 years with human immunodeficiency virus (HIV) infection should receive a 2-dose primary series of Menactra or Menveo with at least 8 weeks between doses.
- For children aged 2 months through 18 years with high-risk conditions, see below.

Catch-up vaccination:

- Administer Menactra or Menveo vaccine at age 13 through 18 years if not previously vaccinated.
- If the first dose is administered at age 13 through 15 years, a booster dose should be administered at age 16 through 18 years with a minimum interval of at least 8 weeks between doses.
- If the first dose is administered at age 16 years or older, a booster dose is not needed.
- For other catch-up guidance, see Figure 2.

Vaccination of persons with high-risk conditions and other persons at increased risk of disease:

- Children with anatomic or functional asplenia (including sickle cell disease):
  1. For children younger than 19 months of age, administer a 4-dose infant series of MenHibrix or Menveo at 2, 4, 6, and 12 through 15 months of age.
  2. For children aged 19 through 23 months who have not completed a series of MenHibrix or Menveo, administer 2 primary doses of Menveo at least 3 months apart.
  3. For children aged 24 months and older who have not received a complete series of MenHibrix or Menveo or Menactra, administer 2 primary doses of either Menactra or Menveo at least 2 months apart. If Menactra is administered to a child with asplenia (including sickle cell disease), do not administer Menactra until 2 years of age and at least 4 weeks after the completion of all PCV13 doses.
- Children with persistent complement component deficiency:
  1. For children younger than 19 months of age, administer a 4-dose infant series of either MenHibrix or Menveo at 2, 4, 6, and 12 through 15 months of age.
  2. For children 7 through 23 months who have not initiated vaccination, two options exist depending on age and vaccine brand:
     a. For children who initiate vaccination with Menveo at 7 months through 23 months of age, a 2-dose series should be administered with the second dose after 12 months of age and at least 3 months after the first dose.
     b. For children who initiate vaccination with Menactra at 9 months through 23 months of age, a 2-dose series of Menactra should be administered at least 3 months apart.
     c. For children aged 24 months and older who have not received a complete series of MenHibrix, Menveo, or Menactra, administer 2 primary doses of either Menactra or Menveo at least 2 months apart.
- For children who travel to or reside in countries in which meningococcal disease is hyperendemic or epidemic, including countries in the African meningitis belt or the Hajj, administer an age-appropriate formulation and series of Menactra or Menveo for protection against serogroups A and W meningococcal disease. Prior receipt of MenHibrix is not sufficient for children traveling to the meningitis belt or the Hajj because it does not contain serogroups A or W.
- For children at risk during a community outbreak attributable to a vaccine serogroup, administer or complete an age- and formulation-appropriate series of MenHibrix, Menactra, or Menveo.
- For booster doses among persons with high-risk conditions, refer to *MMWR* 2013 62(RR02); 1-22, available at http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6202a1.htm.

Catch-up recommendations for persons with high-risk conditions:

1. If MenHibrix is administered to achieve protection against meningococcal disease, a complete age-appropriate series of MenHibrix should be administered.
2. If the first dose of MenHibrix is given at or after 12 months of age, a total of 2 doses should be given at least 8 weeks apart to ensure protection against serogroups C and Y meningococcal disease.
3. For children who initiate vaccination with Menveo at 7 months through 9 months of age, a 2-dose series should be administered with the second dose after 12 months of age and at least 3 months after the first dose.
4. For other catch-up recommendations for these persons, refer to *MMWR* 2013 62(RR02); 1-22, available at http://www.cdc.gov/mmwr/preview/mmwrhtml/rr6202a1.htm.

For complete information on use of meningococcal vaccines, including guidance related to vaccination of persons at increased risk of infection, see *MMWR* March 22, 2013 / 62(RR02);1-22, available at http://www.cdc.gov/mmwr/pdf/rr/rr6202.pdf.

Current practice guidelines recommend administration of surfactant at or soon after birth in preterm infants with respiratory distress syndrome. However, recent multicenter randomized controlled trials indicate that early use of continuous positive airway pressure with subsequent selective surfactant administration in extremely preterm infants results in lower rates of bronchopulmonary dysplasia/death when compared with treatment with prophylactic or early surfactant therapy. Continuous positive airway pressure started at or soon after birth with subsequent selective surfactant administration may be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants. *Pediatrics* 2014;133:171–174

BACKGROUND

Current practice guidelines in neonatology recommend administration of surfactant at or soon after birth in preterm infants with respiratory distress syndrome (RDS).[1] However, recent multicenter randomized controlled trials indicate that nasal continuous positive airway pressure (CPAP) may be an effective alternative to prophylactic or early surfactant administration.[2–8] Respiratory support is being achieved more frequently with CPAP and other less invasive approaches, such as the technique of intubation, surfactant, and extubation (INSURE).[9]

Experimental evidence documents that mechanical ventilation, particularly in the presence of surfactant deficiency, results in lung injury. Early randomized clinical trials demonstrated that surfactant administration in infants with established RDS decreased mortality, bronchopulmonary dysplasia (BPD), and pneumothorax.[10] Subsequent trials indicated that early selective administration of surfactant results in fewer pneumothoraces, less pulmonary interstitial emphysema, less BPD, and lower mortality compared with delayed selective surfactant therapy.[11] Trials of prophylactic administration of surfactant demonstrated decreased air leaks and mortality compared with selective surfactant therapy.[12] However, infants enrolled in these trials did not consistently receive early CPAP, an alternative therapy for the maintenance of functional residual capacity. Furthermore, control infants were intubated and mechanically ventilated without exogenous surfactant.

The INSURE strategy also resulted in fewer air leaks and shorter duration of ventilation when compared with later selective surfactant administration with continued ventilation. However, oxygen need and survival at 36 weeks' postmenstrual age or longer-term outcomes were not assessed in these trials.[13] It is also worth noting that the INSURE studies did not consistently use early CPAP in the control group. In fact, a recent large trial not included in this meta-analysis did not show a benefit of the INSURE strategy when compared with early CPAP.[7] The INSURE strategy may be more efficacious if an infant can be rapidly extubated. Studies in baboons have demonstrated an increase in the severity of pulmonary injury when extubation to CPAP is delayed, thus reducing the benefits of surfactant administration.[14] Decisions on extubation may have to be individualized, because some critically ill infants may not benefit from rapid extubation. Further research is needed to test the potential benefits of the INSURE strategy on important long-term outcomes. However, rapid extubation after surfactant administration may not be achievable or desirable in the most immature infants, and decisions to extubate should be individualized.

CPAP can be delivered by several noninvasive techniques such as nasal prongs, nasopharyngeal tube, or mask by using a water-bubbling system (bubble CPAP) or a ventilator. Although physician preference for bubble or ventilator CPAP is common, physiologic and clinical studies have been inconclusive. It is feasible to provide noninvasive nasal CPAP starting in the delivery room, even in extremely preterm infants (24–27 weeks' gestation), but the most immature infants had the highest risk of failure.[6] Noninvasive modes of ventilation, such as nasal intermittent ventilation, do not appear to provide further benefits compared with CPAP.[15]

RANDOMIZED CONTROLLED TRIALS OF NASAL CPAP STARTING AT BIRTH

Recently published large, multicenter randomized controlled trials of prophylactic or early CPAP have enrolled very immature infants, a group that, in previous trials, benefited from surfactant treatment. The COIN (CPAP or INtubation) Trial of the Australasian Trial Network compared the effectiveness of nasal CPAP (8 cm of water pressure) to intubation and mechanical ventilation in preterm infants who were breathing spontaneously at 5 minutes after birth.[4] There was a trend for a lower rate of death or BPD in infants who received CPAP and used fewer corticosteroids postnatally. The mean duration of ventilation was shorter in the CPAP group (3 days in the CPAP group and 4 days in the ventilator group). However, the CPAP group had a higher rate of pneumothorax than the ventilator group (9% vs 3%; $P < .001$). Although surfactant therapy was not required for intubated infants, three-quarters of the intubation cohort received surfactant. Similarly, 46% of infants in the CPAP group required ventilator support, and 50% received surfactant. Therefore, the comparison was between early CPAP (with 50% of infants ultimately receiving surfactant) and intubation and ventilation, mostly but not always with surfactant administration.

The largest CPAP trial ($N = 1310$), the Surfactant Positive Pressure and Pulse Oximetry Randomized Trial (SUPPORT) conducted by the *Eunice Kennedy Shriver* National Institutes of Health and Human Development Neonatal Research Network investigators, was designed to evaluate nasal CPAP started immediately after birth by using a limited-ventilation strategy compared with prophylactic surfactant therapy and ventilator support started within 60 minutes after birth by using a limited ventilation strategy in infants born at 24 to 27 weeks' gestation.[5] This trial used prospectively defined criteria for intubation and extubation. The rate of death or BPD in the CPAP group was 48% compared with 51% in the surfactant group (relative risk [RR]: 0.91; 95% confidence interval [CI]: 0.83–1.01; $P = .07$). Among infants born at 24 and 25 weeks' gestation, the death rate was lower in the CPAP group than in the surfactant group (20% vs 29%; RR: 0.68; 95% CI: 0.5–0.92; $P = .01$). Two-thirds of the infants in the CPAP group ultimately received surfactant. In addition, duration of mechanical ventilation was shorter (25 vs 28 days), and use of postnatal corticosteroid therapy was reduced in the CPAP group (7% vs 13%). The rate of air leaks did not differ between the groups, and there were no adverse effects of the CPAP strategy despite a reduction in the use of surfactant. This trial demonstrated that nasal CPAP started immediately after birth is an effective and safe alternative to prophylactic or early surfactant administration and may be superior. A follow-up study at 18 to 22 months' corrected age showed that death or neurodevelopmental impairment occurred in 28% of the infants in the CPAP group compared with 30% of those in the surfactant/ventilation group (RR: 0.93; 95% CI: 0.78–1.10; $P = .38$).[16] CPAP and the limited-ventilation strategy, rather than intubation and surfactant, resulted in less respiratory morbidity by 18 to 22 months' corrected age.[17]

The Vermont Oxford Network Delivery Room Management Trial randomly assigned infants born at 26 to 29 weeks' gestation to 1 of 3 treatment groups: prophylactic surfactant and

continued ventilation, prophylactic surfactant and extubation to CPAP, or CPAP (without surfactant).[7] There were no statistically significant differences between the 3 groups, but when compared with the prophylactic surfactant group, the RR of BPD or death was 0.83 (95% CI: 0.64–1.09) for the CPAP group and 0.78 (95% CI: 0.59–1.03) for the INSURE group.

Other trials have compared early CPAP with prophylactic or early surfactant administration. The CURPAP[2] and Colombian Network[3] trials did not demonstrate a difference in the rate of BPD between the 2 treatment strategies. Moreover, in the Columbian Network trial,[3] infants randomly assigned to prophylactic CPAP had a higher risk of pneumothorax (9%) than infants randomly assigned to INSURE (2%). Infants in the South American Neocosur Network trial were randomly assigned to early CPAP (with rescue using an INSURE strategy) or oxygen hood (with rescue using mechanical ventilation).[8] The early CPAP strategy (and selective of INSURE, if needed) reduced the need for mechanical ventilation and surfactant.

Standard but diverse CPAP systems have been used in these and other large randomized controlled trials reviewed, including bubble CPAP and ventilator CPAP. A detailed description of the practical aspects of using CPAP systems are beyond the scope of this statement but are available in the published literature.[18,19]

Preterm infants are frequently born precipitously in hospitals without the capability of CPAP. CPAP can be provided with a bag and mask or other comparable devices in these circumstances. However, special expertise is necessary because CPAP may not be easy to use without specific training. Safe transport before delivery may be preferable depending on clinical circumstances. Thus, care should be individualized on the basis of the capabilities of health workers in addition to the patient's condition.

A meta-analysis of prophylactic surfactant versus prophylactic stabilization with CPAP and subsequent selective surfactant administration in preterm infants showed that prophylactic administration of surfactant compared with stabilization with CPAP and selective surfactant administration was associated with a higher risk of death or BPD (RR: 1.12; 95% CI: 1.02–1.24; $P < .05$).[11] The previously reported benefits of prophylactic surfactant could no longer be demonstrated.

It is notable that infants as immature as 24 weeks' gestational age were enrolled in many of the trials. In a subgroup analysis in the SUPPORT trial, the most immature infants (born at 24 and 25 weeks' gestation) benefited the most from the CPAP strategy. Many extremely preterm infants can be managed with CPAP only; early application of nasal CPAP (without surfactant administration) was successful in 50% of infants weighing ≤750 g at birth in 1 retrospective review.[20]

Surfactant administration can be expensive, particularly in low-resource settings. Additionally, intubation and mechanical ventilation may not be possible or desirable in institutions with limited resources. CPAP provides an alternative for early respiratory support in resource-limited settings. Emerging evidence indicates that early CPAP is an effective strategy for respiratory support in extremely preterm infants, including very immature infants. CPAP appears to be at least as safe and effective as early surfactant therapy with mechanical ventilation.[9]

CONCLUSIONS

1. Based on a meta-analysis of prophylactic surfactant versus CPAP as well as on other trials of more selective early use of surfactant versus CPAP not included in the meta-analysis, the early use of CPAP with subsequent selective surfactant administration in extremely preterm infants results in lower rates of BPD/death when compared with treatment with prophylactic or early surfactant therapy (Level of Evidence: 1).
2. Preterm infants treated with early CPAP alone are not at increased risk of adverse outcomes if treatment with surfactant is delayed or not given (Level of Evidence: 1).
3. Early initiation of CPAP may lead to a reduction in duration of mechanical ventilation and postnatal corticosteroid therapy (Level of Evidence: 1).
4. Infants with RDS may vary markedly in the severity of the respiratory disease, maturity, and presence of other complications, and thus it is necessary to individualize patient care. Care for these infants is provided in a variety of care settings, and thus the capabilities of the health care team need to be considered.

RECOMMENDATION

1. Using CPAP immediately after birth with subsequent selective surfactant administration may be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants (Level of Evidence: 1, Strong Recommendation).[21] If it is likely that respiratory support with a ventilator will be needed, early administration of surfactant followed by rapid extubation is preferable to prolonged ventilation (Level of Evidence: 1, Strong Recommendation).[21]

Returning to Learning Following a Concussion

- *Clinical Report*

CLINICAL REPORT

Returning to Learning Following a Concussion

abstract

FREE

Following a concussion, it is common for children and adolescents to experience difficulties in the school setting. Cognitive difficulties, such as learning new tasks or remembering previously learned material, may pose challenges in the classroom. The school environment may also increase symptoms with exposure to bright lights and screens or noisy cafeterias and hallways. Unfortunately, because most children and adolescents look physically normal after a concussion, school officials often fail to recognize the need for academic or environmental adjustments. Appropriate guidance and recommendations from the pediatrician may ease the transition back to the school environment and facilitate the recovery of the child or adolescent. This report serves to provide a better understanding of possible factors that may contribute to difficulties in a school environment after a concussion and serves as a framework for the medical home, the educational home, and the family home to guide the student to a successful and safe return to learning. *Pediatrics* 2013;132:948–957

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

DEFINITIONS

- Individualized education plan (IEP): a formalized educational plan protected under the Individuals with Disabilities Education Act (IDEA; Pub L No. 101-476, 1990), known commonly as special education, that provides for classification or coding of a student under 1 of 13 federally designated categories and allowances for modification of regular education without penalty to the student.
- 504 plan: under Section 504 of the Rehabilitation Act (Pub L No. 93-112, 1973) and the Americans with Disabilities Act (Pub L No. 101-336, 1990), provides for a student who is not eligible for special education under an IEP but who requires accommodations in regular education on the basis of bona fide medical need, as documented by a physician and validation by the educational home.
- Individualized health care plan: a written document created by a school nurse on the basis of information provided by the student's pediatrician to document specific health care needs in the school setting with a plan for addressing each documented need.
- Family Educational Rights and Privacy Act (FERPA): a federal law established in 1974 (Pub L No. 93-380) that protects the privacy of students' "education records," including school health records, and applies to educational agencies and institutions that receive funds under any program administered by the US Department of

Education. Schools require FERPA permission from parents to release any information to any entity, including physicians. FERPA does not cover requirements of the Health Insurance Portability and Accountability Act (HIPAA). Other details can be found at: http://www.ed.gov/policy/gen/guid/fpco/index.html.

- Health Insurance Portability and Accountability Act (HIPAA): the Privacy Rule of HIPAA (Pub L No. 104-191, 1996) requires "covered entities," including physicians, to protect individuals' health records and other identifiable health information with appropriate safeguards to protect privacy and sets limits and conditions on the uses and disclosures that may be made of such information without patient authorization. HIPAA covers FERPA requirements. More information is available at http://www.hhs.gov/ocr/privacy.
- Child Find: Child Find is a continuous process of public awareness activities, screening, and evaluation designed to locate, identify, and refer as early as possible all young children with disabilities and their families who are in need of Early Intervention Program (Part C) or Preschool Special Education (Part B/619) services of the IDEA.

INTRODUCTION

Much attention has been paid to concussions in children and adolescents, particularly concussions resulting from sports. The majority of the focus on concussions has been centered on diagnosis, education of key stakeholders regarding the problem, and the timing of safe return to play (that is, to sports and other physical activity). Unfortunately, little attention has been given to academics and learning and how a concussion may affect the young student learner. Developing appropriate guidance and evidence-based recommendations for a "return to learn" (RTL) for a student following a concussion is a challenge, given the limited research that exists in this area of concussion and its management. Because of this shortage of research, the guidance provided in this clinical report is based primarily on expert opinion and adapted from a program developed in Colorado to address the issue of RTL.[1] Data are currently insufficient to advocate the ideal way to manage the RTL in the pediatric population.

Pediatricians report that inadequate training on concussion management is among the most significant barriers to effectively counseling patients on returning to school following a concussion.[2] There are many published statements that discuss the importance of "cognitive rest" following a concussion.[3–5] Cognitive rest refers to avoiding potential cognitive stressors, such as texting, video games, TV exposure, and schoolwork, as examples. However, to date, there is no research documenting the benefits or harm of these methods in either the prolongation of symptoms or the ultimate outcome for the student following a concussion. Given the disruptive nature that concussion symptoms may pose for the student and his or her family, adding additional restrictions that may not be needed has the potential to create further emotional stress during the recovery. This calls for an individualized approach for the student when a pediatrician is making recommendations for cognitive rest and the student's RTL in the school setting.

BACKGROUND

With an estimated 1.7 million traumatic brain injuries occurring annually, many of them concussions, the need for specific recommendations for returning a student to learning after concussion is necessary.[6] Given that students typically appear well physically after a concussion, it may be difficult for educators, school administrators, and peers of the student to fully understand the extent of deficits experienced by a student with a concussion. This lack of outward physical appearance of illness may also make it difficult for school officials to accept the need for adjustments for a student with a concussion.

Cognitive difficulties following a concussion have long been recognized and can clearly affect a student's learning capabilities. With recent increased attention to concussions, more focus has been placed on appropriate management for this specific injury. Neurocognitive testing, particularly the commercially available computerized versions, and its use after concussion has become more widespread, but the focus has been primarily on sports-related concussions. Although these neurocognitive tests may be helpful as a tool in assessing a student after a concussion, they have not been applied systematically to determine when and how a student is ready to take on the typical cognitive demands in a school setting.

Although a concussion can have obvious direct effects on learning, there is also increasing evidence that using a concussed brain to learn may worsen concussion symptoms and perhaps even prolong recovery.[7,8] Increasing cognitive activities are hypothesized to add additional stress to an energy-deprived brain, which may worsen symptoms. The goal during concussion recovery is to avoid overexerting the brain to the level of worsening or reproducing symptoms. Determining the appropriate balance between how much cognitive exertion and rest is needed is the hallmark of the management plan during cognitive recovery.

There is insufficient research on the role of cognitive rest, although recent research suggests benefit to the concept of cognitive rest both early and late in the recovery of the student.[9]

SIGNS AND SYMPTOMS OF CONCUSSION AFFECTING STUDENTS

Many aspects of a concussion can affect the student in the classroom. The common signs and symptoms the student may experience can be physical, cognitive, emotional, or related to sleep. Fortunately, research has demonstrated that recovery for the school-age student occurs usually within 3 weeks from the injury, but school adjustments during this recovery period may be necessary.[10]

When evaluating the student, recognizing the common signs and symptoms of a concussion and how they may affect the student in the school setting is important (Table 1). A thorough understanding of potential problems the student can encounter will help the pediatrician make appropriate recommendations to the school, the student, and the student's family. Allowing adequate cognitive rest may help minimize a worsening of symptoms and potentially facilitate a quicker recovery without significant disruption to the student's life.

Use of symptom checklists may help not only in evaluating what symptoms the student may be experiencing but also in rating them in severity (Figs 1 and 2). These checklists can also be used serially to follow the student through his or her recovery and identify areas that may need more targeted interventions.[11] Because the diagnosis of concussion is largely symptom driven, it is important not only to recognize but also to inquire further about the specific nature of the symptoms reported by the student or observed by the parent because many of the symptoms reported after a concussion may not be unique to a concussion. For example, some students may have preexisting depression, chronic daily or intermittent headaches, learning disabilities, or attention-deficit/hyperactivity disorder, which can affect reporting on a symptom checklist.

TABLE 1 Signs and Symptoms of a Concussion and the Potential Problems They May Pose to the Student

Sign/Symptom	Potential Implications in School
Headache	Most common symptom reported in concussions
	Can distract the student from concentration
	Can vary throughout the day and may be triggered by various exposures, such as fluorescent lighting, loud noises, and focusing on tasks
Dizziness/lightheadedness	May be an indication of injury to vestibular system
	May make standing quickly or walking in crowded environment challenging
	Often provoked by visual stimulus (rapid movements, videos, etc)
Visual symptoms: light sensitivity, double vision, blurry vision	Troubles with various aspects of the school building
	Slide presentations
	Movies
	Smart boards
	Computers
	Handheld computers (tablets)
	Artificial lighting
	Difficulty reading and copying
	Difficulty paying attention to visual tasks
Noise sensitivity	Troubles with various aspects of the school building
	Lunchroom
	Shop classes
	Music classes (band/choir)
	Physical education classes
	Hallways
	Organized sports practices
Difficulty concentrating or remembering	Challenges learning new tasks and comprehending new materials
	Difficulty with recalling and applying previously learned material
	Lack of focus in the classroom
	Troubles with test taking
	Troubles with standardized testing
	Reduced ability to take drivers education classes safely
Sleep disturbances	Excessive fatigue can hamper memory for new or past learning or ability to attend and focus
	Insufficient sleep can lead to tardiness or excessive absences
	Difficulty getting to sleep or frequent waking at night may lead to sleeping in class
	Excessive napping due to fatigue may lead to further disruptions of the sleep cycle

Careful history taking to account for any possible preinjury conditions is useful in assessing the student with concussion, especially one with protracted postconcussive symptoms. The pediatrician should account for these preexisting conditions and continue to manage the concussion and as well as the preexisting problems concurrently. It is also worthwhile to discuss other potential stressors that may affect symptom reporting, such as family or relationship problems, pressures from coaches and teammates if the child is involved in organized sports, and the restriction from participation in important upcoming life events. Symptom checklists and their scores may help in determining what symptoms may need to be addressed when returning to the school environment but should not be the sole determining factor in deciding when to return a child to school after a concussion.

THE RETURN TO LEARNING TEAM

A student returning to school after a concussion may benefit from a multidisciplinary team to maximize his or her recovery (Table 2).[1] Because state laws differ, the accessibility for some

CIRCLE ONE FOR EACH LISTED	NONE	MILD		MODERATE		SEVERE

Nervous or anxious	0	1	2	3	4	5	6

FIGURE 1
Example postconcussion symptom score checklist (recommended for seventh grade and up).[5] Use of the postconcussion symptom scale: the student should complete the form, on his or her own, by circling a subjective value for each symptom. This form can be used with each encounter to track progress toward symptom resolution. Many students may have some of these reported symptoms at a baseline, such as concentration difficulties in the patient with attention-deficit disorder or sadness in a student with underlying depression. This must be taken into consideration when interpreting the score. Students do not need a total score of 0 to return to play if they had symptoms before their concussion. This scale has not been validated to determine concussion severity.

CIRCLE ONE FOR EACH LISTED	NONE	RARELY	SOMETIMES	OFTEN

I get tired easily	0	1	2	3

FIGURE 2
Example of postconcussion symptom score checklist (recommended for kindergarten to sixth grade).[5]

students to a school physician or a school nurse may be less likely in some communities. It remains essential that all schools recognize the importance of team management for a student after concussion and ensure that all students recovering from concussion have assigned staff who will be responsible for smooth reentry to school. Yet in the ideal situation, there is a school physician in every district and a school nurse in every school, so that a medical team in the educational home can readily work with the student's medical home toward a child or adolescent's optimal benefit and outcome.[12,13]

Even though a student may be having symptoms, ultimately, the goal is to keep disruptions to the student's life to a minimum and to return the recovering student to school as soon as possible. The challenge of the multidisciplinary team is to balance the need for the student to be at school with the appropriate adjustments for the cognitive demands at school that have the potential for increasing symptoms. To reach the right balance at home and school, the multidisciplinary teams should be well versed in their roles and responsibilities in concussion management and keep communication open among all parties regarding decisions to progress, regress, or hold steady during the RTL process.

After a concussion, the student already has individuals in place for each of the teams described (Table 2). Ideally, at least 1 person from each team is involved in the concussion management and communicating with each other to help facilitate the recovery. The pediatrician does not need to create the teams or roles, but it will help to understand what roles and responsibilities each team has in the recovery of the student.

The role and responsibility of the family team is to enforce rest and to reduce stimulation to the student during recovery. In the early phases of a concussion,

TABLE 2 Multidisciplinary Team to Facilitate "Return to Learning"[1]

Team	Members of the Team
Family team	Student, parents, guardians, grandparents, peers, teammates, and family friends
Medical team	Emergency department, primary care provider, concussion specialist (primary care sports medicine physicians, neurologists, neurosurgeons, as examples), clinical psychologist, neuropsychologist, team and/or school physician
School academic team	Teacher, school counselor, school psychologist, social worker, school nurse, school administrator, school physician
School physical activity team	School nurse, athletic trainer, coach, physical education teacher, playground supervisor, school physician

All members listed for a team do not need to be involved for successful concussion management. An individual, such as an emergency department physician, may only be involved in the initial assessment and suggestion for initiating academic adjustments. Some members may serve roles on various teams. Some schools may have access to only certain individuals suggested for a team. This list is meant to serve as a framework to help pediatricians and others involved with concussion management, possible roles they can serve for a student with a concussion.

TABLE 3 Sample Approach for Determining a Students' Readiness to Return to Learning Following a Concussion[17]

If a student/athlete experiences symptoms enough to affect his or her ability to concentrate or tolerate stimulation for even up to 30 minutes, the student should likely remain at home. The student may consider light mental activities, such as watching TV, light reading, and interaction with the family, until they provoke symptoms. Computer use, texting, and video games should remain at a minimum.

When the student/athlete is able to tolerate symptoms comfortably for up to 30 to 45 minutes, the parent may consider returning him or her back to learning, either through home tutoring or in-school instruction with programming adjustment as needed. However, it is the parent who should communicate with the school about the concussion and sign a release of information for school personnel to coordinate adjustments that may be needed as recommended by the primary care provider. The level of adjustments are decided collectively by the parent, school, and primary care provider based on severity, type, and duration of symptoms present.

symptoms may be so severe that they may prevent the student from attending school or even accepting home tutoring. However, as symptoms become tolerable, short-lived, and/or amenable to rest and intervention, the student may return to school, often with the use of supplemental academic adjustments. Therefore, it is the parent who will ultimately make the decision when the student should return to school. It is not unusual for a student to be extremely symptomatic in the doctor's office initially but minimally symptomatic at home within several days. Some guidance to help decision making for return to school can be found in Table 3.

The role and responsibility of the medical team is to evaluate the concussion, assess for a more serious structural or neurologic injury, and prescribe physical and cognitive rest, as appropriate, until symptoms improve. As recovery continues, the medical team should gather data from the family and from the school teams to aid in the decision of when to start to allow safe progression back to increasing physical activity.

Two school teams are involved in the recovery process for the student with a concussion, the school physical activity team and the school academic team. The roles and responsibilities of the 2 school teams are extensive and varied. In the early stages of the concussion, the primary goal of the school physical activity team is to safeguard the student from any further potential injury to the brain. If a concussion has been suspected, it is recommended that the student be removed from physical activity and be evaluated by his or her pediatrician or other appropriate health care professionals for further diagnosis and management before returning to physical activity. Pediatricians should counsel patients on the current recommended return to activity progressions, as outlined in the clinical report from the American Academy of Pediatrics titled "Sport-Related Concussion in Children and Adolescents," which may be applied to both athletes and nonathletes.[3]

Similarly, in the early phases of a concussion, the school academic team must coordinate the return of the student to cognitive exertion and help to facilitate the appropriate level of academic adjustments necessary to reduce or eliminate symptoms. Whether communication occurs directly with a single teacher or is coordinated across all teachers via the designated case manager, such as the school nurse, counselor, or school psychologist, it is essential for all adults working with the student to understand the effects of a concussion on learning and how best to reduce cognitive demands during this period of recovery. The parent is encouraged to return the student to school, even if the day is shortened, when the student can tolerate cognitive activity or stimulation for approximately 30 to 45 minutes. This arbitrary cutoff is based on the observation that a good amount of learning takes place in 30- to 45-minute increments. High schools with 7 to 8 consecutive classes often schedule periods at 30- to 45-minute intervals. A student with a concussion can benefit from 30 minutes of instruction and a 15-minute "rest period" before changing classes. High schools on a "block schedule" usually run 90-minute blocks (two 45-minute periods), which may require allowances for a planned rest midway through the block. The concussed student may maximize learning in 30- to 45-minute increments before needing to take a rest (Table 3). Missing instruction, however, may necessitate the need for the provision of class notes, supplemental tutoring, or an easing of assignments or course expectations.

When the student returns to school, observing which classes exacerbate

symptoms will allow for further adjustments to be made to help reduce symptom provocation. Students may be able to tolerate some classes better than others, and consideration should be given for reduced exposure for those classes that the student cannot tolerate as well by substituting a study hall period, allowing for rest periods, or making adjustments to class schedules.

As the concussion symptoms improve, the school academic team and the family team should feel comfortable increasing mental and social activities, as tolerated by the student, and involving the medical team only as needed, apart from preplanned follow-up visits. This may translate into parents allowing their child to attend a social gathering, watch a game, or return to driving. At school, this should translate into a teacher requiring more work from a student who is obviously feeling better and able to tolerate longer periods of time of mental exertion without provoking symptoms.

Pediatricians should encourage teachers to pick and choose the academic adjustments most amenable to their class teaching style and content and most appropriate for the phase of recovery of the concussion on the basis of a child's tolerance. Teachers and those on the school academic team should reassess progress at weekly intervals to determine the effectiveness and continued need of adjustments. Direct communication and attention to symptoms with the student is helpful, because the student may not be willing to mention problems specifically to the teacher. Communication with a student should be conducted in a private setting, because many students prefer not to be singled out or draw additional attention to themselves following the injury. Younger students may be apprehensive or not know how to effectively express their academic struggles. High-achieving students may also be unwilling to "give in" to adjustments that are offered.

STRATEGIES TO RETURN TO LEARN IN THE CLASSROOM

Returning a student to the classroom while symptomatic from a concussion requires an individualized approach. Most students will likely return to the classroom while symptomatic from their concussion. Each concussion is unique and may encompass a different constellation and severity of symptoms. Concussion symptoms may vary from student to student and even from concussion to concussion in the same individual who may sustain more than one concussion. Therefore, a "cookie-cutter" approach to managing a concussion and a return to the classroom cannot be applied. However, most of the difficulties that arise in students can be handled with similar adjustments, depending on the signs or symptoms they are experiencing.

In the first few weeks after a concussion, most interventions can be made in the general education classroom, by the general education teacher, with minimal support and check-ins with the school physician, school nurse, school counselor, school psychologist, school social worker, or certified athletic trainer (AT).[14,15] Parents should be encouraged to follow up with the school and student to assess whether academic adjustments are occurring to minimize worsening of students' symptoms during their early recovery.

Physicians should learn educational terminology to assist them in being precise in what they are requesting of schools. The term "academic adjustment" is used intentionally to refer to nonformalized adjustments made to the student's environment during the typical 1- to 3-week recovery period that do not jeopardize the curriculum or require alterations in standardized testing. The term "academic accommodations" is used to address longer-term needs, beyond 3 weeks, which may include standardized testing arrangement, extra time on work, changes in class schedule, for example, and access to the grade-level curriculum but still within the context of regular education and may be formalized in a 504 plan. The term "academic modification" is used when considering more prolonged and more permanent changes to an educational plan, necessitating special education with needs specified in an IEP. Teachers' understanding and putting a few reasonable adjustments in place in the early stages of the concussion will often help bring the student through recovery in the typical, expected timeframe of 1 to 3 weeks. The type of academic adjustments put in place should depend on the severity of the symptoms, the type of symptom, specific teaching styles used by a teacher in the classroom, and pattern of the symptoms (Table 4).

Concussion education can be conducted by the pediatrician via direct communication with school personnel on a case-by-case basis to facilitate better understanding among appropriate school personnel during the RTL process; restrictions and adjustments should be specifically listed on a school note at each visit and during the interim, if needed. Unfortunately, simply requesting this in written form does not guarantee the school can or will comply. It would be helpful for the pediatrician if the school could identify a "point person" or case manager to contact at the school and likewise for the school to be given a "point person" in the pediatrician's office who will communicate with each other during the RTL process. FERPA permission is needed by educational agencies, and HIPAA permission is required by medical personnel; therefore, a signed parent permission on a document that satisfies both is required for communication among team members. The school point person is often a member of the school academic team. The

medical home point person is someone with enough knowledge of the situation and of the child to communicate concerns back to the pediatrician. Parents should also be involved with this communication.

The team approach between the medical home and a school staff member is helpful in assisting the school with problems it encounters in the process and identifying solutions to these problems. A team approach also can reduce the likelihood of a pediatrician's office from receiving frequent phone calls from many individuals about the same situation. For many schools, the point person would be a guidance counselor, school psychologist, school physician, or school nurse. In schools in which a AT is present, the AT can help reinforce communication of any school or sports restrictions to safeguard against the student-athlete beginning a return to play protocol but still having academic adjustments.[15] For this reason, communication with the AT by the treating physician or a representative of the school who has been communicating with the physician is also encouraged.[16] In some circumstances, the AT may be limited to support only the students in organized sports for the school rather than the student body as a whole. It would be helpful to the pediatrician to understand how ATs can assist the pediatrician with the management of their patients.

Encouraging parents to communicate with the school, especially the designated case manager, about how recommended adjustments are being applied can be helpful. Pediatricians should also encourage parents to communicate with their child to make sure any adjustments that are being offered are also being used, as needed, and are helping.

TABLE 4 Signs and Symptoms of a Concussion and the Strategies to Help in the School Setting

Sign/Symptom	Potential Adjustments in School Setting
Headache	Frequent breaks
	Identifying aggravators and reducing exposure to them
	Rests, planned or as needed, in nurses office or quiet area
Dizziness	Allow student to put head down if symptoms worsen
	Give student early dismissal from class and extra time to get from class to class to avoid crowded hallways
Visual symptoms: light sensitivity, double vision, blurry vision	Reduce exposure to computers, smart boards, videos
	Reduce brightness on the screens
	Allow the student to wear a hat or sunglasses in school
	Consider use of audiotapes of books
	Turn off fluorescent lights as needed
	Seat student closer to the center of classroom activities (blurry vision)
	Cover 1 eye with patch/tape 1 lens if glasses are worn (double vision)
Noise sensitivity	Allow the student to have lunch in quiet area with a classmate
	Limit or avoid band, choir, or shop classes
	Avoid noisy gyms and organized sports practices/games
	Consideration of the use of earplugs
	Give student early dismissal from class and extra time to get from class to class to avoid crowded hallways during pass time
Difficulty concentrating or remembering	Avoid testing or completion of major projects during recovery when possible
	Provide extra time to complete nonstandardized tests
	Postpone standardized testing (may require that 504 plan is in place)
	Consider 1 test per day during exam periods
	Consider the use of preprinted notes, notetaker, scribe, or reader for oral test taking
Sleep disturbances	Allow for late start or shortened school day to catch up on sleep
	Allow rest breaks

PROLONGED SYMPTOMS

Fortunately, most students with a concussion will recover within the first 3 weeks from their injury.[10] For students with symptoms lasting longer than 3 weeks, further medical management considerations and accommodations, rather than academic adjustments, may be needed. Schools currently have in place a system for accommodations (504 plan) for students expected to have temporary interference with learning or modifications (IEP) for students with a classifiable chronic condition. However, applying these systems to concussions, in some schools, may be a newer concept. Although healing may be considered "protracted" with some concussions, the expectation is still for a full recovery that no longer would require academic adjustments, accommodations, or modifications. Referral to a concussion specialist (licensed physician, such as a pediatrician, neurologist, primary care sports medicine specialist, or neurosurgeon with expanded knowledge and experience in pediatric concussion management) should also be considered, if not already initiated, for the student with prolonged symptoms.

Because laws, regulations, policies, and practices vary among states, districts, and schools, it is important that the pediatrician be familiar with the level of flexibility and creativity that a particular school will provide or permit. Differences also exist among long-term modifications, midterm accommodations, and short-term adjustments. Pediatricians should understand that the IDEA provides for longer-term accommodations. For example, there are provisions for school-based problem-solving teams to determine the appropriateness of an IEP for a child in need of long-term modifications through special education on the basis of a given classification.

In addition, a 504 plan is available through the Rehabilitation Act of 1973 and Americans with Disabilities Act of 1990 for a child who needs longer-term academic accommodations in regular education but does not qualify for special education through 1 of the 13 classifications available via an IEP. Most adjustments can and should be short term and through the child's educational team, with guidance from the medical home and approval by the principal and family team. The key to this process is that the pediatrician provides the school with medical documentation based on persisting signs and symptoms that might significantly limit a child's ability to access full instruction. It is also helpful for the pediatrician to realize that, often, schools will not allow a child to participate in extracurricular activities until he or she is fully participating in curricular activities.

Early in the recovery, a student may need simple academic adjustments in the classroom. Students who do not respond in the first few months may need a more targeted level of intervention. At this level, school teams may need to brainstorm and problem solve what other interventions may be helpful and decide whether more formalized assessments need to occur. Often, the family team is a critical part of the problem-solving process, as is the medical team. All 3 teams must be actively involved in managing the concussion on behalf of the recovering student. At this level, some of the interventions can no longer be easily applied in the general education classroom without formal intervention. For example, students may require some amount of pullout from the regular classroom for a small-group intervention, tutoring, or 1-on-1 instruction. Customized plans at this point may be more formalized into an Individualized Health Plan, a learning plan, or a 504 plan. Interventions at this level are usually accommodations to the environment (ie, large-print books, extra set of books at home, audio books, extended time on tests, note takers).

If symptoms remain severe or prolonged, typically longer than 5 to 6 months, more intensive intervention may be needed. In these cases, a potentially more permanent disability is considered, necessitating most school districts to trigger their Child Find (a component of IDEA) obligations, provide appropriate testing, and develop an IEP. The family team and medical team should continue to be involved and consulted during the development of the IEP. Interventions at this level are often considered modifications of the curriculum, implying that the student may not be held responsible for the regular education curriculum required of all other same-age peers. Instead, the student may be taught without penalty on a level appropriate for him or her, often at a level lower than peers, and will only be held accountable for his or her own personal academic growth rather than being compared with typical grade-level peers.[17,18] In addition, the concussion would be so severe at this level as to potentially necessitate specialized instruction and/or specialized programming. It is uncommon, however, for the student with a concussion to need an IEP.

When considering the implementation of a 504 plan or IEP, involving the school academic teams or special education teams is beneficial and necessary. The school academic team, including the school psychologist, can provide formal recommendations to the school to make the creation of the 504 plan or IEP that is most relevant to the particular student's greatest needs in the academic setting. Regardless of the problems, it is essential the medical team, the school team, and the family team work together, if further testing seems indicated to help in the development of an educational program through an IEP or 504 plan. In the majority of these assessments, the recommendations and development of an IEP or 504 plan will be developed by the schools. A medical diagnosis of concussion can prompt the school academic team to collect other sources of information and consider developing a 504 plan or IEP. Importantly, 504 plans and IEPs are governed by different laws. A 504 plan can be provided when a school determines the concussion to substantially limit one or more major life activities, such as learning. On the other hand, an IEP can be provided if it is determined that the concussion results in total or partial impairment that adversely affects educational performance such that a student cannot benefit from regular education alone and requires modification of curriculum, specialized instruction, programming, and/or placement.

Although not expected or common after a concussion, a student with prolonged symptoms who does not seem to be responding to various interventions should also be evaluated for issues related to anxiety about school or school avoidance. This may be more likely in the child who sustained a concussion from an incidence of bullying or assault. Keeping a child out of school and away from friends for extended periods also may risk development of fear and isolation in a child or adolescent on attempting to return to school and might require the assistance of a mental health specialist in extreme cases.

EDUCATION

Given the large number of concussions occurring each year, both in and out of formal sport activities, most schools will encounter a child who is dealing with symptoms from a concussion. Education of all individuals involved is paramount to helping students who may need assistance in the school setting.

Education regarding concussion, generally, and the role of cognitive and

physical rest and return to school, specifically, is essential for the teams of individuals helping a student with concussion during assessment, management, and recovery. This education should extend to both school personnel (eg, administrators, athletic directors, teachers, guidance counselors, school psychologists, coaches, school physicians, school nurses, ATs) and individuals likely not employed by the school (eg, primary physicians, sports/team physicians, emergency department physicians, parents, and other caregivers). Even in states with legislation for concussion education and management, nonathletic personnel in schools are often left out of concussion education efforts. However, a comprehensive team approach to care may help reduce mistakes in management, which could potentially risk reinjury during the healing phase, lengthen recovery, or result in untoward long-term outcomes.

Education, on a larger scale, should be conducted to instruct school groups on the concepts of concussion management, particularly when introducing models of cognitive rest. Education can be tailored to various school personnel as needed. Education sessions are especially helpful as sport seasons begin in the fall, winter, and spring. Several groups have developed educational materials, such as online tutorials, relevant to this topic and provide excellent resources for schools, parents, students, and health care providers (see Resources).

FUTURE DIRECTIONS

Given the paucity of studies that have been conducted thus far regarding the effects and role of cognitive rest after concussion, further research is needed. Future research is also needed to clarify best practices for RTL. Developing a better understanding of the best methods to assist a student in the school environment, determining whether cognitive rest can assist in speed of recovery, and evaluating written and educational resources on this topic are all areas that require additional research and review. Studies comparing outcomes in school settings that have concussion management teams with case management versus those that do not would also be of value.

Continued education of all individuals involved with a student with a concussion should help facilitate better outcomes and less resistance to developing appropriate concussion management guidelines and programs.

CONCLUSIONS AND GUIDANCE FOR PHYSICIANS

1. Students with a concussion may need academic adjustments in school to help minimize a worsening of symptoms.
2. Given that most concussions resolve within 3 weeks of the injury, adjustments may often be made in the individual classroom setting without formal written plans, such as a 504 plan or IEP.
3. Students with symptoms lasting longer than 3 to 4 weeks may benefit from a more detailed assessment by a concussion specialist (licensed physician, such as a pediatrician, neurologist, primary care sports medicine specialist, or neurosurgeon with expanded knowledge and experience in pediatric concussion management) and recommendations specific to the educational environment. Considerations should be given to developing a 504 plan or, subsequently, but unlikely, an IEP, in the student with a lengthy recovery.
4. A team approach consisting of the medical team, the school team, and the family team to assist the student in his or her return to learning is ideal.
5. Students should be performing at their academic "baseline" before returning to sports, full physical activity, or other extracurricular activities following a concussion.
6. Education of all individuals involved with students who sustain a concussion is necessary to provide adequate adjustments, accommodations, and long-term program modifications for the students.
7. Additional research is necessary to strengthen and provide more evidence-based recommendations for appropriate adjustments for students following a concussion.

FREE

The American Academy of Pediatrics (AAP) believes that optimal pediatric health care depends on a team-based approach with supervision by a physician leader, preferably a pediatrician. The pediatrician, here defined to include not only pediatric generalists but all pediatric medical subspecialists, all surgical specialists, and internal medicine/pediatric physicians, is uniquely qualified to manage, coordinate, and supervise the entire spectrum of pediatric care, from diagnosis through all stages of treatment, in all practice settings. The AAP recognizes the valuable contributions of nonphysician clinicians, including nurse practitioners and physician assistants, in delivering optimal pediatric care. However, the expansion of the scope of practice of nonphysician pediatric clinicians raises critical public policy and child health advocacy concerns. Pediatricians should serve as advocates for optimal pediatric care in state legislatures, public policy forums, and the media and should pursue opportunities to resolve scope of practice conflicts outside state legislatures. The AAP affirms the importance of appropriate documentation and standards in pediatric education, training, skills, clinical competencies, examination, regulation, and patient care to ensure safety and quality health care for all infants, children, adolescents, and young adults. *Pediatrics* 2013;131:1211–1216

INTRODUCTION

The American Academy of Pediatrics (AAP) advocates that every child receive high-quality, accessible, family-centered, continuous, coordinated, comprehensive care in a medical home. To this end, optimal pediatric care is best delivered in a team-based approach that is led by a primary physician, ideally a pediatrician, who assumes responsibility for managing the patient's care. All professionals who provide pediatric care must hold to the highest standards of education and training and continually demonstrate their skills and competencies.

COMPREHENSIVE TEAM-BASED CARE WITH PHYSICIAN LEADERSHIP

The provision of optimal pediatric care depends on a team-based approach to health care that is ideally led by a pediatrician. In this team-based model of pediatric care, the physician assumes overall responsibility for the care of the patient. As leader of the pediatric

health care team, the physician oversees the delivery of care and, when appropriate, delegates patient care responsibilities to nurse practitioners (NPs), physician assistants (PAs), and other valued members of the heath care team. The pediatrician who leads the health care team also determines when referral to other physicians is warranted. When patient care responsibilities must be shared by multiple providers, the pediatrician should assume primary responsibility for managing the full range of health care services to ensure continuity of care within the child's medical home.[1] For some children, a general pediatrician and a pediatric medical subspecialist or surgical specialist may decide to comanage care. The medical home's team-based model of pediatric care provides high-quality, cost-effective care by minimizing duplication of clinical effort, promoting the appropriate and timely use of all health care providers on the team, and ensuring that the care provided is accessible, continuous, comprehensive, family-centered, coordinated, compassionate, and culturally effective.[2]

UNIQUE QUALIFICATIONS OF PEDIATRICIANS

As a direct result of their extensive training and experience, pediatricians possess the broad range of competencies required to best assess and manage health issues in children. Pediatric illness runs the gamut from basic to complex, from common behavioral disorders to rare metabolic and genetic diseases. In addition, diseases that present initially as a common condition such as a cold may sometimes progress to a severe and complex illness such as pneumonia or respiratory failure. The pediatrician is the clinician most extensively educated in pediatric health care and has the depth and breadth of knowledge, skills, and experience to deliver optimal care to children.

PROFESSIONAL STANDARDS TO ENSURE SAFETY AND QUALITY CARE

The AAP supports safe, quality care for all children and their families and believes that any health care professional who wishes to actively participate in the care of children must demonstrate appropriate education, training, skills, and ongoing competencies in pediatric health within his or her scope of practice to ensure the highest standards of care. All members of the health care team should provide care consistent with their education, training, and licensure.

In recent years, the health care market has seen a significant increase in the number of nonphysician clinicians who seek to care for children. Professional associations for psychologists, pharmacists, massage therapists, physical therapists, occupational therapists, optometrists, acupuncturists, naturopaths, homeopaths, and chiropractors have actively sought expanded scopes of practice in the care of children. In an evergrowing and more complicated health care delivery system, patients and families need to know what services these clinicians are licensed and trained to provide and understand the differences in education and skills among them.

Support for such transparency is increasing and resulting in requirements that medical and health professionals be required to display or advertise their degrees, credential(s), or licenses according to a standard that is easier for consumers to understand. In addition, truth-in-advertising laws help patients distinguish between medical doctors and other health professions with doctoral degrees who are licensed to provide care.

KEY MEMBERS OF THE PEDIATRIC HEALTH CARE TEAM

For many years, pediatricians have worked closely with physicians in disciplines across the field of medicine to optimize the care of children. The AAP specifically acknowledges the key role that family physicians have played in providing care to children and the importance of their continuing collaboration with pediatricians. Pediatricians need to collaborate closely with family physicians in practice to provide pediatric support and consultation.

Nonphysician clinicians play an invaluable role in the provision of health care to infants, children, adolescents, and young adults as part of the physician-led team that provides pediatric health care. Learning to work in teams should begin in pediatric residency training, where collaborative learning with nonphysician clinicians can expose future pediatricians to the benefits of team-based care. In particular, the AAP also affirms that these nonphysician clinicians have been important participants in the care of children in the United States for many years.

PAs are educated in the medical model to provide medical care specifically under the direction and supervision of a physician. PAs must graduate from an accredited master's-level educational program that includes didactic education and clinical rotations in pediatrics and must also pass the national certifying examination administered by the National Commission on Certification of Physician Assistants. The AAP is involved in the development of educational standards and national certification for PAs through appointed representatives on the boards of the Accreditation Review Commission on Education for the Physician Assistant and the National Commission on Certification of Physician Assistants. PAs support the

concept of physician-directed, team-based care.

NPs are educated in graduate-level training programs, and the majority of NPs are certified by either the American Nurses Credentialing Center or the American Academy of Nurse Practitioners. In 7 states, national board certification is not required for licensing. The care provided by NPs can vary considerably on the basis of the laws in the state in which they practice. States may limit or deny NPs the authority to prescribe medications, to admit patients to the hospital, or to practice independently. As of 2012, more than half of the states required physician involvement (eg, collaborative practice agreement, physician delegation and supervision) for NPs to practice diagnosis and treatment and for prescriptive authority (for information on current state laws, please contact the AAP Division of State Government Affairs at stgov@aap.org).[3] Full admitting privileges for NPs would allow them to admit, provide care for, and discharge patients without physician supervision. Although NPs are rarely granted full admitting privileges, it is not uncommon for them to obtain associate privileges that permit them to admit a patient to a supervising physician. NPs can play an important role in the inpatient setting, but the AAP believes that a pediatrician should lead the health care team that is providing pediatric inpatient care.

In states that do not allow independent practice, a structured agreement with a physician is required. Recent studies have shown that even in states which allow independent practice for NPs, fewer than 15% of pediatric NPs actually choose to practice independently.[4] Regardless of the state in which they practice, the vast majority of pediatric NPs choose to practice under the supervision of general pediatricians, pediatric medical subspecialists, or pediatric surgical specialists. The AAP endorses this collaborative and structured relationship and believes this choice reflects both a shared commitment to patient safety and the positive nature of current pediatrician–NP relationships in US health care.

Of note, some reports have called for changes in the education of NPs so that they might spend additional time in clinical training and increase their likelihood of independent practice. These reports have also called for changes in the scope of practice for NPs in efforts to meet a workforce demand in areas with physician shortages.[5–7]

Considering the educational aspect, NPs generally receive a master's degree or postmaster's certificate. These NP training programs provide 500 to 720 hours of clinical training.[8] However, in 2004, the American Association of Colleges of Nursing endorsed a position statement calling for NP training programs to move the current level of preparation necessary for advanced nursing practice from a master's-level to a doctorate-level degree (eg, Doctor of Nursing Practice [DNP] or Doctor of Philosophy [PhD] in Nursing) by 2015.[9] The American Association of Colleges of Nursing's *The Essentials of Doctoral Education for Advanced Nursing Practice* (2006) recommends that programs—designed for individuals who have already acquired the competencies in *The Essentials of Baccalaureate Education for Professional Nursing Practice* (1998)—be "three calendar years, or 36 months of full-time study (including summers) or four years on a traditional academic calendar."[10] This requirement is equivalent to the currently required 3 years of graduate training for the master's degree program. Subsequently, the number of doctorate-level nursing programs in the United States has grown from 20 in 2006 to 182 in 2011.[9]

Increases in the duration of education or the final degree (eg, a DNP or PhD in Nursing) will not achieve educational parity with physicians. In comparison, with 4 years of medical school and 3 years of pediatric residency at a minimum, the pediatrician has invested between 12 000 and 14 000 clinical hours at the completion of basic pediatric training alone. Therefore, the AAP believes that pediatricians and NPs are not interchangeable in the delivery of pediatric health care.

A recent study of the geographic distribution of pediatric NPs found that the majority of states have fewer than 25 pediatric NPs per 100 000 children and that a state's independent practice laws are not related to its density of pediatric NPs.[11] In 2010, almost 85% of all NPs reported practicing in urban areas.[12] Furthermore, a recent study from the University of Washington Rural Health Research Center found no statistically significant link between states that allow NPs greater practice autonomy and higher rates of NP practice in rural areas.

Because a greater supply of NPs in a state does not necessarily lead to an equitable distribution to areas that are underserved, the AAP does not support changes in scope of practice for NPs in these areas and believes it is ill-advised to create a system of care based on independent practice without any supervision or oversight by a physician. Rather, the AAP recommends incentives for physician relocation, including loan forgiveness, payment reform, and expanded health insurance coverage for children.[13]

Some have called for an expansion of retail-based clinics as a means to increase the provision of care for children in underserved areas. However, retail-based clinics are not staffed by

physicians, and the nonphysician clinicians that are staffing these clinics often work without supervision or oversight by a physician (ie, independent practice). Also, a recent study of more than 900 retail clinics throughout the United States found that "retail clinics are currently located in more advantaged neighborhoods, which may make them less accessible for those most in need."[14] In light of its commitment to comprehensive team-based care, the AAP does not support the use of retail-based clinics for the medical care of infants, children, and adolescents.[15] Because retail-based clinics are not founded on a medical home model, use of these clinics as a source of care for children poses a significant risk for fragmentation of care, limited follow-up, missed diagnoses, and decreased quality of care overall.

SCOPE OF PRACTICE LEGISLATION

Scope of practice legislation falls under the jurisdiction of individual states. State legislatures are therefore the loci of deliberations on these issues. The competing political agendas and perspectives expressed during these deliberations often generate highly charged debates. To bring a uniformity of approach and an essential level of civility to this discourse, the AAP endorses the 2005 recommendations of the Federation of State Medical Boards regarding the approach to scope of practice legislation.[16] A portion of the Federation of State Medical Boards statement follows:

> "Changing or creating a new scope of practice for a health profession necessitates establishment of a legitimate need for the change, along with a systematic review of the impact of the proposed change on public health, safety, and welfare. Patient safety and public protection must be the primary objectives in making decisions on scope of practice. It is important for boards and legislatures to recognize that there are often significant differences in the prerequisites, the scope, and the duration of education provided to other health care practitioners when compared with that provided to physicians. Policy makers must ensure that all practitioners are prepared, by virtue of education and training, to provide the services authorized in their scope of practice in a safe, effective, and economical manner."

LIABILITY

The expansion of the scope of practice of NPs, PAs, and other nonphysician clinicians has created new challenges for physicians in all specialties in addressing professional and medical liability issues. Specific areas of risk for physicians when supervising nonphysician clinicians include improper delegation of authority, vicarious liability for medical care provided by nonphysician clinicians, and liability for nonmedical acts committed by nonphysician clinicians in which the physician is responsible for the negligent hiring, training, supervising, or retaining of the nonphysician clinicians. When delegating authority to nonphysician clinicians, physicians should consider the proper method of delegation and their oversight responsibilities for the delegated duties.

It is important that lawmakers and regulators remain attentive to the fact that a physician's ability to delegate authority is often governed by contractual limitations as well as by statutes that govern health care facilities. Moreover, health care entities, such as hospitals or managed care organizations, may not authorize the delegation of more authority than is permitted by state statutes or regulations, but they may impose limitations on the delegation of authority that are more restrictive than state laws. These policies may also be admissible in a medical liability lawsuit as evidence of the standard of care. Physicians violating such policies may risk loss of employment or revocation of privileges. Physicians and health care entities must therefore be knowledgeable about the terms of these state statutes and regulations, as well as health care entity policies, and should seek advice from a qualified attorney.

For nonphysician clinicians who practice independently of a physician, public policy should require both exclusive professional responsibility for the care they provide and adequate liability insurance to allow for appropriate financial remedy for adverse settlements or decisions. States that license nonphysician clinicians should therefore require that these nonphysician clinicians abide by the same rules regarding liability insurance as do physicians. Because physicians can be held accountable for clinicians acting under their supervision, a pediatrician should consider potential professional or medical liability issues before establishing a supervisory relationship.

CONCLUSIONS

The AAP believes that optimal pediatric care is best rendered by using a team-based approach led by a pediatrician. As the clinician most extensively educated in pediatric health care, the pediatrician has the depth and breadth of knowledge, skills, and experience to assume this role and should be held to the highest standards. Collaboration with family physicians is an important component of pediatric health care delivery, as are partnerships with nonphysician clinicians in an effort to provide safe and effective quality health care for all infants, children, adolescents, and young adults in the United States. The AAP recognizes the importance of team-based education and training. Furthermore, the AAP maintains that to ensure safe and effective care, all members of the health care team must be required to demonstrate

adequate education, training, skills, and competencies in pediatric health within their scope of practice, and all members of the health care team must provide care that is consistent with their education, training, and licensure. Patient safety and public protection must be the primary benchmarks in making any decision on changes involving the scope of practice of those who care for children.

The AAP affirms the following policy recommendations:

1. A pediatrician should serve as the leader of the pediatric health care team. This leadership role is based on the pediatrician's ability to manage, coordinate, and supervise the entire spectrum of pediatric care, from diagnosis through all stages of treatment and in all practice settings.
2. Pediatricians must assume responsibility for educating patients, families, health care purchasers, policy makers, the media, and the public about scope of practice issues.
3. Pediatricians should participate in the training and educational experiences of nonphysician pediatric clinicians, using evidenced-based and best-practice sources whenever possible. Similarly, training of pediatricians should include collaborative learning experiences in team care.
4. The AAP supports limitations on the scope of practice of nonphysician clinicians and opposes legislation that expands their scope of practice, including independent practice, hospital admitting privileges, and independent prescriptive authority.
5. Although the AAP opposes independent practice for nonphysician clinicians, in states that do allow independent practice, nonphysician clinicians acting independently of physicians should be held to the equivalent degree of professional and medical liability and abide by the same rules regarding liability insurance as would physicians.
6. To promote the highest standards of care in each state, scope of practice issues should be resolved according to the current guidelines developed by the Federation of State Medical Boards. These guidelines were designed to assist policy makers in ensuring that all practitioners are prepared, by virtue of education, training, and ongoing evaluation of competency, to provide services authorized in their scopes of practice in a safe, effective, and cost-efficient manner.
7. AAP chapters should encourage, recruit, and train their members to serve as advocates of optimal pediatric health care in state-level policy initiatives concerning nonphysician scope of practice. Such activities depend on physicians who are knowledgeable about lawmaking and policy-making processes and who have the skills necessary to be effective advocates in legislative deliberations.
8. AAP chapters and state medical and specialty societies, as well as national medical and specialty societies, should be proactive in scope of practice advocacy and should partner in informing policy makers, health care purchasers, the media, and the public about the differences in the education, skills, and knowledge of various health care professionals.

Surfactant Replacement Therapy for Preterm and Term Neonates With Respiratory Distress

- *Clinical Report*

CLINICAL REPORT

Surfactant Replacement Therapy for Preterm and Term Neonates With Respiratory Distress

abstract

FREE

Respiratory failure secondary to surfactant deficiency is a major cause of morbidity and mortality in preterm infants. Surfactant therapy substantially reduces mortality and respiratory morbidity for this population. Secondary surfactant deficiency also contributes to acute respiratory morbidity in late-preterm and term neonates with meconium aspiration syndrome, pneumonia/sepsis, and perhaps pulmonary hemorrhage; surfactant replacement may be beneficial for these infants. This statement summarizes the evidence regarding indications, administration, formulations, and outcomes for surfactant-replacement therapy. The clinical strategy of intubation, surfactant administration, and extubation to continuous positive airway pressure and the effect of continuous positive airway pressure on outcomes and surfactant use in preterm infants are also reviewed. *Pediatrics* 2014;133:156–163

INTRODUCTION

Surfactant replacement was established as an effective and safe therapy for immaturity-related surfactant deficiency by the early 1990s.[1] Systematic reviews of randomized, controlled trials confirmed that surfactant administration in preterm infants with established respiratory distress syndrome (RDS) reduces mortality, decreases the incidence of pulmonary air leak (pneumothoraces and pulmonary interstitial emphysema), and lowers the risk of chronic lung disease or death at 28 days of age (Table 1).[2–11] Subsequent trials indicated that prophylactic or early administration of surfactant resulted in fewer pneumothoraces, less pulmonary interstitial emphysema, and improved survival without bronchopulmonary dysplasia (BPD). However, recent randomized clinical trials indicate that the benefits of prophylactic surfactant are no longer evident in groups of infants when continuous positive airway pressure (CPAP) is used routinely.[5]

This clinical report updates a 2008 report from the American Academy of Pediatrics.[1] As in the previous report, a number of clinically important topics are reviewed surrounding use of surfactant, including prophylactic versus rescue replacement, preparations and administration techniques, the synergistic effects of surfactant and antenatal steroids, and surfactant therapy for respiratory disorders other than RDS. In addition, the effect of CPAP on RDS and surfactant replacement and the

efficacy of the INSURE approach (intubation, surfactant administration, and extubation to CPAP) are reviewed.

PRETERM INFANTS AND SURFACTANT EFFECTIVENESS IN CLINICAL TRIALS

Surfactant trials have included infants born between 23 and 34 weeks' gestation and/or with birth weight between 500 and 2000 g.[1–12] The results of subgroup analyses from such studies indicated that surfactant therapy decreased mortality rates most effectively in infants born at less than 30 weeks' gestation or with birth weight <1250 g.[12] In addition, surfactant replacement reduced the incidence of pneumothorax, pulmonary interstitial emphysema, and the combined outcome of death or BPD, compared with no surfactant replacement[12]; these findings suggest that lung injury is mitigated after surfactant replacement. The incidence of other medical morbidities, such as BPD, intraventricular hemorrhage, necrotizing enterocolitis, health care–associated infections, retinopathy of prematurity, and patent ductus arteriosus, has not changed with surfactant replacement, but this may be attributable, in part, to the large reduction in mortality with surfactant replacement therapy.[13] The onset of clinical signs of patent ductus arteriosus may occur earlier, and the incidence of pulmonary hemorrhage, especially in infants born at less than 27 weeks' gestation, may be increased with surfactant therapy. Surfactant replacement is effective for larger and more mature preterm infants with established RDS.

PROPHYLACTIC VERSUS RESCUE SURFACTANT

A prophylactic, or preventive, surfactant strategy is defined as intubation and surfactant administration to infants at high risk of developing RDS for the primary purpose of preventing worsening RDS rather than treatment of established RDS; this has been operationalized in clinical studies as surfactant administration in the delivery room before initial resuscitation efforts or the onset of respiratory distress or, most commonly, after initial resuscitation but within 10 to 30 minutes after birth. This contrasts with a rescue or treatment surfactant strategy, in which surfactant is given only to preterm infants with established RDS. Rescue surfactant is most often administered within the first 12 hours after birth, when specified threshold criteria of severity of RDS are met.

The meta-analysis of studies conducted before routine application of CPAP demonstrated a lower mortality rate (relative risk [RR] 0.69; 95% confidence interval [CI] 0.56–0.85; number needed to benefit [NNTB] 20) and a decrease in the risk of air leak (RR 0.79; 95% CI 0.63–0.98) in preterm infants receiving prophylactic surfactant versus rescue surfactant.[14] However, when the studies that allowed for routine application of CPAP were included in the meta-analysis (National Institute of Child Health and Human Development SUPPORT Trial and Vermont Oxford Network Delivery Room Management Trial), the benefits of prophylactic surfactant on mortality (RR 0.89; 95% CI 0.76–1.04) and air leak (RR 0.86; 95% CI 0.71–1.04) could no longer be demonstrated.[5] Furthermore, infants receiving prophylactic surfactant had a higher incidence of BPD or death than did infants stabilized on CPAP (RR 1.12; 95% CI 1.02–1.24). Secondary analyses of studies that did or did not use CPAP to stabilize infants demonstrated a trend to a lower risk of intraventricular hemorrhage (RR 0.91; 95% CI 0.82–1.00) and severe intraventricular hemorrhage (RR 0.87; 95% CI 0.70–1.04) with prophylactic surfactant. That finding cannot be explained; however, there was considerable heterogeneity in the trials included in the meta-analysis. The risks of developing other complications of prematurity, such as retinopathy of prematurity, patent ductus arteriosus, and periventricular leukomalacia, were not significantly different.

When studies investigating infants born at <30 weeks' gestation were analyzed separately,[5] similar findings were noted. However, there was a trend for an increased risk of chronic lung disease in infants born at <30 weeks' gestation who received prophylactic surfactant (RR 1.13; 95% CI 1.00–1.28) and a significant increase in death or chronic lung disease (RR 1.13; 95% CI 1.02–1.25) with use of prophylactic surfactant.

EARLY VERSUS DELAYED SELECTIVE SURFACTANT TREATMENT OF RDS

Although there are no statistically significant benefits to prophylactic use of surfactant when compared with

prophylactic CPAP, several studies have investigated whether administration of surfactant early in the course of respiratory insufficiency improves clinical outcomes. Early rescue is defined as surfactant treatment within 1 to 2 hours of birth, and late rescue is defined as surfactant treatment 2 or more hours after birth. A recent meta-analysis of early (within 2 hours) versus delayed surfactant treatment concluded that the risks of mortality (RR 0.84; 95% CI 0.74–0.95), air leak (RR 0.61; 95% CI 0.48–0.78), chronic lung disease (RR 0.69; 95% CI 0.55–0.86), and chronic lung disease or death (RR 0.83; 95% CI 0.75–0.91) were significantly decreased. There were no differences in other complications of prematurity.[7]

EARLY ADMINISTRATION OF SURFACTANT FOLLOWED BY BRIEF VENTILATION AND EXTUBATION TO CPAP (INSURE STRATEGY)

The INSURE strategy is widely used throughout the world. In randomized clinical trials performed before 2008, the INSURE approach, compared with rescue surfactant administration in infants with RDS, was associated with a significantly reduced need for mechanical ventilation (RR 0.67; 95% CI 0.57–0.79) and a reduced need for oxygen at 28 days.[6] In an analysis stratified by fraction of inspired oxygen requirement at study entry, a significantly higher frequency of patent ductus arteriosus was observed among infants in the rescue surfactant group, who required a fraction of inspired oxygen greater than 0.45 (RR 2.15; 95% CI 1.09–4.23). The Vermont Oxford Network Delivery Room Management Trial (n = 648) randomly assigned infants born at 26 to 29 weeks' gestation to 1 of 3 treatment groups: prophylactic surfactant and continued ventilation, prophylactic surfactant and rapid extubation to CPAP (INSURE), or nasal CPAP without surfactant.[15] When compared with the group of infants receiving prophylactic surfactant and continued ventilation, the RR of death or BPD was 0.78 (95% CI 0.59–1.03) for the INSURE group and 0.83 (95% CI 0.64–1.09) for the CPAP group. However, in the nasal CPAP group, 48% were managed without intubation and 54% without surfactant treatment. A recent meta-analysis demonstrated that prophylactic surfactant (with rapid extubation to CPAP) was associated with a higher risk of death or BPD (RR 1.12; 95% CI 1.02–1.24; number needed to harm of 17) when compared with early stabilization with CPAP and selective surfactant administration.[5] In infants with birth weight ≥1250 g and mild to moderate RDS, elective intubation and administration of surfactant decreased the need for mechanical ventilation but had no effect on the duration of oxygen therapy, ventilator therapy, or hospital stay.[16]

ANIMAL-DERIVED VERSUS SYNTHETIC SURFACTANT

A wide variety of animal-derived and synthetic surfactants are available commercially (Table 2); both are beneficial as therapy for RDS in preterm infants. Animal-derived surfactants are modified or purified from bovine or porcine lungs. Treatment with animal-derived surfactants (beractant [Survanta; Abbvie Inc, North Chicago, IL], calfactant [Infasurf; ONY Inc, Amherst, NY], and poractant [Curosurf; Chiesi Farmaceutici, Parma, Italy]) has several advantages over first-generation, protein-free synthetic surfactants (eg, colfosceril palmitate [Exosurf; GlaxoSmithKline, Middlesex, UK]).[3] These include lower mortality rates (RR 0.86; 95% CI 0.76–0.98; number needed to harm of 40) and fewer pneumothoraces (RR 0.63; 95% CI 0.53–0.75; NNTB 22).[4] Animal-derived surfactants contain variable amounts of surfactant protein B (SP-B). SP-B enhances the rate of adsorption of phospholipids at the air-water interface, is involved in the formation of tubular myelin, and has antiinflammatory properties. However, it is unclear whether significant differences in clinical outcomes exist among the available animal-derived products.

A synthetic surfactant (lucinactant) that contains a 21-amino acid peptide that mimics SP-B activity has recently been approved for the prevention and treatment of RDS in preterm infants.[18,19] When compared with animal-derived surfactant (beractant or poractant), lucinactant was shown to be equivalent.[18,19] Neonatal morbidities (intraventricular hemorrhage, periventricular leukomalacia, pulmonary hemorrhage, sepsis, patent ductus arteriosus, retinopathy of prematurity, necrotizing enterocolitis, and BPD) were not significantly different between preterm infants treated with animal-derived surfactants and those treated with synthetic surfactants.

SURFACTANT ADMINISTRATION

Surfactant administration strategies have been based on manufacturer guidelines for individual surfactants.[1] The dose of surfactant, frequency of administration, and treatment procedures have been modeled after research protocols. Furthermore, repeated doses of surfactants given at intervals for predetermined indications have decreased mortality and morbidity compared with placebo or single surfactant doses.[10] However, given the long half-life for surfactant in preterm infants with RDS,[20] redosing should not be needed more often than every 12 hours, unless surfactant is being inactivated by an infectious process, meconium, or blood. Dosing intervals shorter than 12 hours recommended by some manufacturers are not based on human pharmacokinetic data.

TABLE 2 Composition and Dosage of Surfactants[17]

Surfactant	Main Phospholipids	Proteins	Phospholipid Concentration	Suggested Dose	Phospholipid per Dose
Animal-derived					
Beractant (Survanta[a]) minced bovine lung extract	DPPC and PG	(<0.1%) SP-B and (1%) SP-C	25 mg/mL	4 mL/kg	100 mg/kg
Calfactant (Infasurf[b]) bovine calf lung lavage	DPPC and PG	(0.7%) SP-B and (1%) SP-C	35 mg/mL	3 mL/kg	105 mg/kg
Poractant (Curosurf[c]) minced porcine lung extract	DPPC and PG	(0.6%)SP-B and (1%) SP-C	80 mg/mL	2.5 mL/kg and	100-200 mg/kg
				1.25 mL/kg	100 mg/kg
Synthetic					
Colfosceril (Exosurf[d])	DPPC (100%)	None	13.5 mg/mL	5 mL/kg	67.5 mg/kg
Synthetic, protein analog					
Lucinactant (Surfaxin[e])	DPPC and POPG	KL4 peptide as SP-B	30 mg/mL	5.8 mL/kg	175 mg/kg

DPPC, dipalmitoyl phosphatidylcholine; PG, phosphatidylglycerol; POPG, palmitoyloleyl phosphatidylglycerol; SP-C, surfactant protein C.

Surfactant administration procedures may be complicated by transient airway obstruction, oxygen desaturation, bradycardia, and alterations in cerebral blood flow and brain electrical activity. The delivery of surfactant can also result in rapid improvement in lung volume, functional residual capacity, and compliance. Thus, expeditious changes in mechanical ventilator settings may be necessary to minimize the risks of lung injury and air leak. Clinicians with expertise in these procedures should be responsible for surfactant administration whenever surfactant is given.

Surfactant has traditionally been administered through an endotracheal tube either as bolus, in smaller aliquots,[21] or by infusion through an adaptor port on the proximal end of the endotracheal tube.[19] In an animal model, administration of surfactant as an intratracheal bolus while disconnected from the mechanical ventilator resulted in more uniform distribution than an infusion administered over 30 minutes through a side-hole adapter.[22] However, a small clinical trial of human preterm infants showed no significant differences in clinical outcomes between methods.[23] During surfactant administration, reflux into the endotracheal tube occurred more often when the infusion technique was used. Similar clinical outcomes were also found when surfactant was administered as a bolus or as a 1-minute infusion through a side-hole adapter.[24] Because data are conflicting and limited, the optimal method of surfactant administration in preterm infants has yet to be clearly proven. Additionally, there is insufficient evidence to recommend the optimal number of fractional doses of surfactant or what body position is best when surfactant is administered.

A number of alternatives to intratracheal administration of surfactant have been evaluated in clinical trials.[25–32] These include use of aerosolized surfactant preparations, laryngeal mask airway-aided delivery of surfactant, instillation of pharyngeal surfactant, and administration of surfactant using thin intratracheal catheters. Theoretically, each of these methods could allow administration of surfactant without intubation in spontaneously breathing infants. In a recent study, Göpel et al[25] randomized 220 preterm infants born at 26 to 28 weeks' gestation to receive either surfactant administered via a thin plastic catheter (using laryngoscopy) or surfactant administered as a rescue therapy. All infants were maintained on CPAP. The administration of surfactant through a thin plastic catheter significantly reduced the need for mechanical ventilation and decreased the need for oxygen therapy at 28 days. More data are needed to recommend any of the alternative techniques for surfactant administration.

SURFACTANT REPLACEMENT THERAPY FOR RESPIRATORY DISORDERS OTHER THAN RDS

Surfactant inactivation and secondary dysfunction may occur with conditions such as meconium aspiration syndrome, persistent pulmonary hypertension of the newborn, neonatal pneumonia, and pulmonary hemorrhage.[33,34] Surfactant administration techniques, surfactant dosage, patient populations, entry criteria, and study outcomes in the small randomized trials and case series of surfactant replacement in neonates with secondary surfactant deficiency vary considerably.[35–42]

Meconium aspiration syndrome with severe respiratory failure and persistent pulmonary hypertension may be complicated by surfactant inactivation. Surfactant replacement by bolus or slow infusion in infants with severe

meconium aspiration syndrome improved oxygenation and reduced the need for extracorporeal membrane oxygenation (ECMO) (RR 0.64; 95% CI 0.46–0.91; NNTB 6).[35] Surfactant did not reduce mortality or decrease the frequency of air leaks (pneumothoraces or pulmonary interstitial emphysema). In a blinded randomized clinical trial of infants receiving ECMO, administration of surfactant shortened the duration of the ECMO. Notably, there were no infants with congenital diaphragmatic hernia in that study.[36]

Surfactant inactivation may be associated with pneumonia.[37,38] In a small randomized trial of surfactant rescue therapy, the subgroup of infants with sepsis showed improved oxygenation and a reduced need for ECMO compared with a similar group of control infants.[37] Newborn infants with pneumonia or sepsis receiving rescue surfactant also demonstrated improved gas exchange compared with infants without surfactant treatment. The number of neonates who received surfactant for sepsis and pneumonia in these clinical reports is small, and no recommendation can be made.

Surfactant treatment of pulmonary hemorrhage is plausible, because blood inhibits surfactant function. However, only a few retrospective and observational reports have documented the benefits of such therapy, and the magnitude of benefit remains to be established.[39]

Congenital diaphragmatic hernia may be associated with surfactant insufficiency.[40] Although measurements of disaturated phosphatidylcholine from lungs of infants with congenital diaphragmatic hernia show synthetic rates similar to those from infants without diaphragmatic hernia, pool sizes and kinetics are altered.[40] However, surfactant treatment of a large series of infants with congenital diaphragmatic hernia did not improve outcomes. In fact, the need for ECMO, the incidence of chronic lung disease, and mortality rate were increased with surfactant administration.[41,42]

ANTENATAL STEROIDS AND SURFACTANT REPLACEMENT

Surfactant trials that proved efficacy were performed at a time when antenatal steroid therapy was given infrequently.[43] By the late 1990s, most mothers of preterm infants born at less than 30 weeks' gestation had received antenatal steroids (58% to 92%).[44–46] Antenatal steroids significantly reduce mortality (RR 0.62; 95% CI 0.51–0.77; NNTB 23), RDS (RR 0.65; 95% CI 0.47–0.75; NNTB 12), and surfactant use in preterm infants (RR 0.45; 95% CI 0.22–0.93; NNTB 9),[47] most consistently in those born between 28 and 34 weeks' gestation.

Results of observational studies and clinical trials have inferred that antenatal steroids may reduce the need for prophylactic and early rescue surfactant replacement in infants born after 27 to 28 weeks' gestation,[16,48] but no randomized, controlled trials have addressed this issue. In infants born at or earlier than 27 weeks' gestation, the incidence of RDS is not reduced after exposure to antenatal steroids; however, in a recently published study, death or neurodevelopment impairment at 18 to 22 months was significantly lower for infants who had been exposed to antenatal steroids at 23 to 25 weeks' gestation.[49] Infants born before 32 weeks' gestation who received both antenatal steroids and postnatal surfactant were found on subgroup analyses to have significant reductions in mortality, severity of respiratory distress, and air leaks when compared with subgroups that received neither steroids nor surfactant, antenatal steroids only, or surfactant only.[50–52] This finding corroborates evidence from animal models of RDS that the combination of antenatal steroids and postnatal surfactant improves lung function more than either treatment alone.[53–55]

An important additional benefit of antenatal steroids is a reduction in risk of intraventricular hemorrhage, an advantage not found with surfactant replacement alone.[56] The effects of antenatal steroids on other neonatal morbidities, such as necrotizing enterocolitis and patent ductus arteriosus, have been inconsistent. However, antenatal steroids have not significantly decreased the incidence of BPD.[50,51]

CPAP AND SURFACTANT

Randomized clinical trials suggest that nasal CPAP is acceptable as an alternative to surfactant administration in preterm infants with RDS. A clinical report from the American Academy of Pediatrics, "Respiratory Support of the Preterm Infant," is forthcoming.[57]

TABLE 3 Levels of Evidence[59]

Recommendation LOE	LOE	Grade of Recommendation
Preterm infants born at <30 wk of gestation who need mechanical ventilation because of severe RDS should be given surfactant after initial stabilization.	1	Strong Recommendation
Using CPAP immediately after birth with subsequent selective surfactant administration should be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants.	1	Strong Recommendation
Rescue surfactant may be considered for infants with hypoxic respiratory failure attributable to secondary surfactant deficiency (eg, meconium aspiration syndrome or sepsis/pneumonia).	2	Recommendation

SUMMARY OF SCIENCE

1. Surfactant replacement, given as prophylaxis or rescue treatment, reduces the incidence of RDS, air leaks, and mortality in preterm infants with RDS (level of evidence [LOE] 1).
2. Both animal-derived and newer synthetic surfactants with SP-B–like activity decrease acute respiratory morbidity and mortality in preterm infants with RDS (LOE 1).
3. Early rescue surfactant treatment (<2 hours of age) in infants with RDS decreases the risk of mortality, air leak, and chronic lung disease in preterm infants (LOE 1).
4. Early initiation of CPAP with subsequent selective surfactant administration in extremely preterm infants results in lower rates of BPD/death when compared with treatment with prophylactic surfactant therapy (LOE 1).
5. Surfactant replacement has not been shown to affect the incidence of neurologic, developmental, behavioral, medical, or educational outcomes in preterm infants (LOE 2).
6. Surfactant treatment improves oxygenation and reduces the need for ECMO without an increase in morbidity in neonates with meconium aspiration syndrome (LOE 2).
7. Surfactant treatment of infants with congenital diaphragmatic hernia does not improve clinical outcomes (LOE 2).
8. Antenatal steroids and postnatal surfactant replacement independently and additively reduce mortality, the severity of RDS, and air leaks in preterm infants (LOE 2).

CLINICAL IMPLICATIONS (TABLE 3)

1. Preterm infants born at <30 weeks' gestation who need mechanical ventilation because of severe RDS should be given surfactant after initial stabilization (Strong Recommendation).
2. Using CPAP immediately after birth with subsequent selective surfactant administration should be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants (Strong Recommendation).
3. Rescue surfactant may be considered for infants with hypoxic respiratory failure attributable to secondary surfactant deficiency (eg, pulmonary hemorrhage, meconium aspiration syndrome, or sepsis/pneumonia) (Recommendation).
4. Preterm and term neonates who are receiving surfactant should be managed by nursery and transport personnel with the technical and clinical expertise to administer surfactant safely and deal with multisystem illness. Therefore, pediatric providers who are without expertise, or who are inexperienced or uncomfortable with surfactant administration or managing an infant who has received surfactant should wait for the transport team to arrive.

The Transfer of Drugs and Therapeutics Into Human Breast Milk: An Update on Selected Topics

• *Clinical Report*

CLINICAL REPORT

The Transfer of Drugs and Therapeutics Into Human Breast Milk: An Update on Selected Topics

abstract

FREE

Many mothers are inappropriately advised to discontinue breastfeeding or avoid taking essential medications because of fears of adverse effects on their infants. This cautious approach may be unnecessary in many cases, because only a small proportion of medications are contraindicated in breastfeeding mothers or associated with adverse effects on their infants. Information to inform physicians about the extent of excretion for a particular drug into human milk is needed but may not be available. Previous statements on this topic from the American Academy of Pediatrics provided physicians with data concerning the known excretion of specific medications into breast milk. More current and comprehensive information is now available on the Internet, as well as an application for mobile devices, at LactMed (http://toxnet.nlm.nih.gov). Therefore, with the exception of radioactive compounds requiring temporary cessation of breastfeeding, the reader will be referred to LactMed to obtain the most current data on an individual medication. This report discusses several topics of interest surrounding lactation, such as the use of psychotropic therapies, drugs to treat substance abuse, narcotics, galactagogues, and herbal products, as well as immunization of breastfeeding women. A discussion regarding the global implications of maternal medications and lactation in the developing world is beyond the scope of this report. The World Health Organization offers several programs and resources that address the importance of breastfeeding (see http://www.who.int/topics/breastfeeding/en/). *Pediatrics* 2013;132:e796–e809

INTRODUCTION

Lactating women can be exposed to medications or other therapeutics, either on a limited or long-term basis, depending on the need to treat acute or chronic conditions. Many women are advised to discontinue nursing or avoid taking necessary medications because of concerns about possible adverse effects in their infants.[1] Such advice is often not based on evidence, because information about the extent of drug excretion into human milk may be unavailable, and for many drugs, information is limited to data from animal studies, which may not correlate with human experience. In addition, not all drugs are excreted in clinically significant amounts into human milk, and the presence of a drug in human milk may not pose a risk for the infant. To weigh the risks and benefits of breastfeeding, physicians need to consider multiple factors. These factors include the need for the drug by the mother, the potential effects of

www.pediatrics.org/cgi/doi/10.1542/peds.2013-1985

doi:10.1542/peds.2013-1985

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

the drug on milk production, the amount of the drug excreted into human milk, the extent of oral absorption by the breastfeeding infant, and potential adverse effects on the breastfeeding infant. The age of the infant is also an important factor in the decision-making process, because adverse events associated with drug exposure via lactation occur most often in neonates younger than 2 months and rarely in infants older than 6 months.[2] In the near future, pharmacogenetics may also provide important guidance for individualized decisions.

In large part because of efforts by Cheston Berlin, Jr, MD, a statement by the American Academy of Pediatrics (AAP) on the transfer of drugs and chemicals into human milk was first published in 1983[3] and underwent several subsequent revisions,[4,5] the most recent of which was published in 2001.[6] Previous editions were intended to list drugs potentially used during lactation and to describe possible effects on the infant and/or on lactation. Revisions for the statement can no longer keep pace with the rapidly changing information available via the Internet, published studies, and new drug approvals. A more comprehensive and current database is available at LactMed (http://toxnet.nlm.nih.gov). LactMed includes up-to-date information on drug levels in human milk and infant serum, possible adverse effects on breastfeeding infants, potential effects on lactation, and recommendations for possible alternative drugs to consider. Common herbal products are also included. For this reason, with the exception of radioactive compounds that require temporary or permanent cessation of breastfeeding, the reader will be referred to LactMed to obtain the most current data on an individual medication.

This statement reviews proposed changes in US Food and Drug Administration (FDA) labeling that are designed to provide useful information to the physician and to outline general

LactMed is part of the National Library of Medicine's Toxicology Data Network (TOXNET)

Each record includes the following information:

- Generic name: refers to US-adopted name of active portion of the drug
- Scientific name: genus and species of botanical products (when applicable)
- Summary of use during lactation (includes discussion of conflicting recommendations and citations)
- Drug levels
  - Maternal levels: based on studies that measure concentration in breast milk; includes relative infant dose (weight-adjusted percentage of maternal dose) when possible
  - Infant levels: serum or urine concentrations from the literature
- Effects in breastfed infants: adverse events with Naranjo* assessment of causality (definite, probably, possibly, unlikely)
- Possible effects on lactation: if known, including effects on infants that may interfere with nursing (eg, sedation)
- Alternative drugs to consider: may not be comprehensive
- References
- Chemical Abstracts Service Registry Number
- Drug class
- LactMed record number
- Last revision date

* The Naranjo probability scale is a method used to estimate the probability that an adverse event is caused by a drug.[7]

considerations for individual risk/benefit counseling. An update regarding the use of antidepressants, anxiolytics, and antipsychotics in the lactating woman is also provided, because the use of psychotropic agents during lactation is still debated. Since publication of the last statement, numerous questions have been raised regarding the use of methadone in the lactating woman. For this reason, therapies for substance abuse and smoking cessation are discussed. Given the finding that codeine use may be associated with toxicity in patients, including neonates with ultrarapid metabolism, a brief review of alternative agents to treat pain in the lactating woman is provided. The use of galactagogues is also reviewed because more women now endeavor to breastfeed adopted infants or preterm neonates. The increasing use of herbal products has invited a discussion of the merits of these alternative therapies in the nursing woman. Finally, immunization of breastfeeding women and their infants will be reviewed to assist pediatricians in encouraging immunization when needed in lactating women and addressing parental reluctance to immunize breastfed infants.

GENERAL CONSIDERATIONS

Several factors should be considered when advising a woman regarding a decision to breastfeed her infant while she is on drug therapy. The benefits of breastfeeding for both the infant and mother need to be weighed against the risks of drug exposure to the infant (or to the mother, in the case of agents intended to induce lactation). Many factors affect the individual risk/benefit decision, including specific information about chemical and pharmacologic properties of the drug, which may be available from resources such as LactMed and in product labeling. In general, chemical properties of a drug, such as lack of ionization, small molecular weight, low volume of distribution, low maternal serum protein binding, and high lipid solubility, facilitate drug excretion into human milk. Drugs with long half-lives are more likely to accumulate in human milk, and drugs with high oral bioavailability are more easily absorbed by the infant.[8] The adverse event profile of the drug is another property that affects the individual risk/benefit ratio. Use of a drug with a significant adverse effect in a lactating woman (such as an arrhythmia) may be acceptable to treat a serious illness in the mother; however, use of the same drug to increase milk production would not be acceptable. For drugs with an adverse event profile that correlates with increasing dosage, higher maternal doses may be associated with greater neonatal toxicity. In addition, the timing of exposure and the duration of therapy are other important considerations. A decision to breastfeed when continuing treatment with an agent for which in utero exposure also has occurred differs from a decision to initiate a novel therapy in the early postpartum period. Similarly, the risks of a single-dose therapy or short-term treatment may differ from those of a chronic therapy.

In addition to pharmacokinetic or chemical properties of the drug, the infant's expected drug exposure is influenced by infant and maternal factors beyond basic known pharmacokinetic and chemical properties of the drug itself. For example, the risk of adverse reactions in a preterm infant or an infant with underlying chronic medical conditions may be higher than that for a more mature or healthier infant. Certain drugs may accumulate in the breastfed infant because of reduced clearance or immaturity of metabolic pathways. However, for other drugs (eg, acetaminophen), the immaturity of these same pathways may protect an infant from toxic drug metabolites. Similarly, patients with specific genotypes may experience drug toxicity, as evidenced by fatalities observed in individuals who demonstrate ultrarapid metabolism of codeine.[9] Finally, certain infant conditions, such as metabolic diseases, and maternal health conditions may preclude nursing (eg, HIV) or require multiple therapies that are particularly toxic (eg, cancer treatment).

CHANGES IN DRUG LABELING

In the past, the lactation section in FDA-approved labeling was often limited to statements that advise caution or contain an admonition to discontinue breastfeeding or discontinue therapy, depending on the importance to the mother. In 2008, the FDA published a proposed revision to the regulations, which affects the pregnancy and lactation sections of labeling. The agency is currently working on the final rule, which is intended to provide a clinically oriented framework for placement of pregnancy and lactation information into drug labeling and to permit the patient and physician to explore the risk/benefit on the basis of the best available data. Under the proposed rule, the current Nursing Mothers section is replaced by a section called Lactation. The Lactation section of labeling will contain 3 subsections: Risk Summary, Clinical Considerations, and Data. The Risk Summary section will include a summary of what is known about the excretion of the drug into human milk and potential effects on the breastfed infant, as well as maternal milk production. The Clinical Considerations section will include methods to minimize exposure of the breastfed infant to the drug when applicable, as well as information about monitoring for

expected adverse drug effects on the infant. The Data component will provide a detailed overview of the existing data that forms the evidence base for the other 2 sections.

In addition to the proposed rule, the FDA published "Guidance for Industry: Clinical Lactation Studies: Study Design, Data Analysis, and Recommendations for Labeling."[10]

Along with outlining recommendations regarding lactation study design as well as the timing and indications for these studies, this draft guidance includes advice on parameters (several of which are used in LactMed) that can be used to inform physicians about the extent of drug exposure. Using these parameters, drug exposure to the infant may be measured directly in infant serum or estimated on the basis of pharmacokinetic parameters. These estimates of infant exposure (for example, relative infant dose) can be expressed as a percent of weight-adjusted maternal or, when known, weight-adjusted pediatric dose.

ESTIMATES OF DRUG EXPOSURE

Daily Infant Dosage (mg/day)=

$\sum$(drug concentration in each milk collection × expreesed volume in each milk collection)

OR

C_{milk}[average drug concentration in milk(mg/mL)] × V_{milk}(volume in mL of milk ingested in 24 hours)

Note: V_{milk} is typically estimated to be 150 mL/kg/day

Relative Infant Dose

% Maternal Dose= [Daily Infant Dosage (mg/kg/day) ÷ Maternal Dose (mg/kg/day)] × 100

% Infant or Pediatric Dose= [Daily Infant Dosage (mg/kg/day) ÷ Infant or Pediatric dose(mg/kg/day)] × 100

ANTIDEPRESSANTS, ANXIOLYTICS, AND ANTIPSYCHOTICS

Previous statements from the AAP categorized the effect of psychoactive drugs on the nursing infant as "unknown but may be of concern." Although new data have been published since 2001, information on the long-term effects of these compounds is still limited. Most publications regarding psychoactive drugs describe the pharmacokinetics in small numbers of lactating women with short-term observational studies of their infants. In addition, interpretation of the effects on the infant from the small number of longer-term studies is confounded by prenatal treatment or exposure to multiple therapies. For these reasons, the long-term effect on the developing infant is still largely unknown.[11,12]

Many antianxiety drugs, antidepressants, and mood stabilizers appear in low concentrations in human milk, with estimated relative infant doses less than 2% of weight-adjusted maternal dose and/or milk-plasma ratios less than 1.[13] However, the percentage of maternal doses that approach clinically significant levels (10% or more) have been reported for bupropion,[14] diazepam,[13] fluoxetine,[15] citalopram,[16] lithium,[17] lamotrigine,[18] and venlafaxine.[19] Data on drug excretion in human milk are not available for up to one-third of psychoactive therapies.[13]

Because of the long half-life of some of these compounds and/or their metabolites, coupled with an infant's immature hepatic and renal function, nursing infants may have measurable amounts of the drug or its metabolites in plasma and potentially in neural tissue. Infant plasma concentrations that exceed 10% of therapeutic maternal plasma concentrations have been reported for a number of selective serotonin reuptake inhibitors, antipsychotics, anxiolytics, and mood stabilizers (see Table 1).

[a] Based on individual maternal-infant pair(s); may include active metabolites.

Mothers who desire to breastfeed their infant(s) while taking these agents should be counseled about the benefits of breastfeeding as well as the potential risk that the infant may be exposed to clinically significant levels and that the long-term effects of this exposure are unknown. Consideration should be given to monitoring growth and neurodevelopment of the infant.

DRUGS FOR SMOKING CESSATION OR TO TREAT SUBSTANCE ABUSE/ ALCOHOL DEPENDENCE

Although many women are appropriately advised to refrain from smoking, drinking, and using recreational drugs during and after pregnancy, in part because of adverse effects on their infants (see Table 2), some are unable to do so and may seek assistance after delivery. Maternal smoking is not an absolute contraindication to breastfeeding.[31] Nonetheless, for multiple reasons, including the association of sudden infant death syndrome with

TABLE 2 Drugs of Abuse for Which Adverse Effects on the Breastfeeding Infant Have Been Reported[a]

Drug	Reported Effect or Reason for Concern	Reference
Alcohol	Impaired motor development or postnatal growth, decreased milk consumption, sleep disturbances.	Koren 2002,[34] Backstrand 2004,[35] Mennella 2007[36]
	Note: Although binge drinking should be avoided, occasional, limited ingestion (0.5 g of alcohol/kg/d; equivalent to 8 oz wine or 2 cans of beer per day) may be acceptable.	National Academy of Sciences 1991[37]
Amphetamines	Hypertension, tachycardia, and seizures.	Product labeling
	In animal studies of postnatal exposure, long-term behavioral effects, including learning and memory deficits and altered locomotor activity, were observed.	
Benzodiazepines	Accumulation of metabolite, prolonged half-life in neonate or preterm infant is noted; chronic use not recommended.	Jain 2005,[38] Malone 2004[39]
	Apnea, cyanosis, withdrawal, sedation, cyanosis, and seizures.	
Cocaine	Intoxication, seizures, irritability, vomiting, diarrhea, tremulousness.	Chasnoff 1987,[40] Winecker 2001[41]
Heroin	Withdrawal symptoms, tremors, restlessness, vomiting, poor feeding.	vandeVelde 2007[42]
LSD	Potent hallucinogen.	
Methamphetamine	Fatality, persists in breast milk for 48 h.	Ariagno 1995,[43] Bartu 2009[44]
Methylene dioxy-methamphetamine (ecstasy)	Closely related products (amphetamines) are concentrated in human milk.	
Marijuana (cannabis)	Neurodevelopmental effects, delayed motor development at 1 y, lethargy, less frequent and shorter feedings, high milk-plasma ratios in heavy users.	Djulus 2005,[45] Campolongo 2009,[46] Garry 2010[47]
Phencyclidine	Potent hallucinogen, infant intoxication.	AAP 2001,[6] Academy of Breastfeeding Medicine[48]

[a] Effect on maternal judgment or mood may affect ability to care for infant.

tobacco exposure,[32,33] lactating women should be strongly encouraged to stop smoking and to minimize secondhand exposure. Exposure to alcohol or recreational drugs may impair a mother's judgment and interfere with her care of the infant and can cause toxicity to the breastfeeding infant (see Table 2).

Limited information is available regarding the use of medications in lactating women to treat substance abuse or alcohol dependence or for smoking cessation. However, the presence of behaviors, such as continued ingestion of illicit drugs or alcohol, and underlying conditions, such as HIV infection, are not compatible with breastfeeding.[49,50] Patients also require ongoing psychosocial support to maintain abstinence.[48]

Methadone, buprenorphine, and naltrexone are 3 agents approved by the FDA for use in the treatment of opioid dependence. Continued breastfeeding by women undergoing such treatment presumes that the patient remains abstinent, is HIV negative, and is enrolled in and closely monitored by an appropriate drug treatment program with significant social support.[48,51]

Potential adverse effects on breastfeeding infants from methadone (according to product labeling) and buprenorphine include lethargy, respiratory difficulty, and poor weight gain.[52] The long-term effects of methadone in humans are unknown. Nonetheless, methadone levels in human milk are low, with calculated infant exposures less than 3% of the maternal weight-adjusted dose.[53,54] Plasma concentrations in infants are also low (less than 3% of maternal trough concentrations) during the neonatal period and up to 6 months postpartum.[55,56] For these reasons, guidelines from the Academy of Breastfeeding Medicine encourage breastfeeding for women treated with methadone who are enrolled in methadone-maintenance programs.[48]

Buprenorphine is excreted into human milk and achieves a level similar to that in maternal plasma.[57] Infant exposure appears to be up to 2.4% of the maternal weight-adjusted dose.[55,56,58] However, buprenorphine can be abused, and although the significance in humans is unknown, labeling for buprenorphine and buprenorphine/naloxone combinations states that use is not advised by lactating women, because animal lactation studies have shown decreased milk production and viability of the offspring. FDA labeling also advises caution for use of naltrexone in nursing infants of opioid-dependent women. Of note, published information on naltrexone is limited to 1 case report that estimates infant exposure to be low (7 μg/kg/d, or 0.86% of the maternal weight-adjusted dose).[59]

Transferred amounts of methadone or buprenorphine are insufficient to prevent symptoms of neonatal abstinence syndrome.[49,60] Neonatal abstinence syndrome can occur after abrupt discontinuation of methadone.[51,61] Thus, breastfeeding should not be stopped abruptly, and gradual

weaning is advised if a decision is made to discontinue breastfeeding.

Limited information is available for disulfiram and naltrexone, agents that are used to treat alcohol dependence. As noted previously, a low relative infant dose (<1%) was observed in a single case report of naltrexone exposure in a 6-week-old breastfed infant.[59] FDA labeling discourages use of disulfiram and both the injectable and oral form of naltrexone in lactating women.

Only one-third of women successfully discontinue smoking without pharmacologic aids.[62] Nicotine replacement therapy, bupropion, and varenicline are agents indicated for use as aids to smoking cessation treatment. Nicotine replacement therapy is compatible with breastfeeding as long as the dose (assuming a cigarette delivers ~1 mg of nicotine) is less than the number of cigarettes typically smoked, because nicotine passes freely into human milk and is orally absorbed as nicotine. Cotinine concentrations are lower than those related to tobacco use. Short-acting products (eg, gum or lozenges) are recommended.[62] Infant exposure decreases proportionally with maternal patch doses.[63]

In contrast, bupropion is excreted into human milk with exposures that may exceed 10% (range, 1.4%–10.6%) of the maternal dose.[14] Although infant levels were not measured, there is a case report of a seizure in a 6-month-old breastfed infant potentially related to bupropion.[64] Limited published information is available for varenicline, but the varenicline label includes a boxed warning for serious neuropsychiatric adverse events, including suicidal ideation or behavior. FDA labeling discourages use of both these agents in lactating women.

PAIN MEDICATIONS

Rarely, normal doses of codeine given to lactating women may result in dangerously high levels of its active metabolite morphine in breastfeeding infants. A fatality has been noted in an infant of a mother with ultrarapid metabolism.[65] In this infant, the postmortem level of morphine (87 ng/mL) greatly exceeded a typical level in a breastfeeding infant (2.2 ng/mL), as well as the therapeutic range for neonates (10–12 ng/mL). In addition, unexplained apnea, bradycardia, cyanosis, and sedation have been reported in nursing infants of mothers receiving codeine.[2,66] Hydrocodone is also metabolized via the CYP2D6 pathway. On the basis of pharmacokinetic data, infants exposed to hydrocodone through human milk may receive up to 9% of the relative maternal dose.[67] Given the reduced clearance of hydrocodone in neonates and the adverse events observed in ultrarapid metabolizers of codeine, caution is advised for use of codeine and hydrocodone in both the mother and nursing infant. Close monitoring for signs and symptoms of neonatal as well as maternal toxicity is recommended. A commercial test to identify ultrarapid metabolizers is not yet widely available. The incidence of this specific CYP2D6 genotype varies with racial and ethnic group as follows: Chinese, Japanese, or Hispanic, 0.5% to 1.0%; Caucasian, 1.0% to 10.0%; African American, 3.0%; and North African, Ethiopian, and Saudi Arabian, 16.0% to 28.0%.[68]

For these reasons, when narcotic agents are needed to treat pain in the breastfeeding woman, agents other than codeine (eg, butorphanol, morphine, or hydromorphone) are preferred. Clinically insignificant levels of butorphanol are excreted into human milk. Morphine appears to be tolerated by the breastfeeding infant, although there is 1 case report of an infant with plasma concentrations within the therapeutic range.[69] Clearance of morphine is decreased in infants younger than 1 month and approaches 80% of adult values by 6 months of age.[70] Limited data suggest that use of hydromorphone for brief periods may be compatible with breastfeeding[71,72]; however, FDA labeling discourages use. Regardless of the choice of therapy, to minimize adverse events for both the mother and her nursing infant, the lowest dose and shortest duration of therapy should be prescribed. Drug delivery via patient-controlled anesthesia or administration by the epidural route may also minimize infant exposure.

Other narcotic agents, such as oxycodone, pentazocine, propoxyphene, and meperidine, are not recommended in the lactating mother. Relatively high amounts of oxycodone are excreted into human milk, and therapeutic concentrations have been detected in the plasma of a nursing infant.[73] Central nervous system depression was noted in 20% of infants exposed to oxycodone during breastfeeding.[74] Thus, use of oxycodone should be discouraged. Limited published data are available about pentazocine. However, respiratory depression and apnea occur frequently in infants, particularly in neonates or in preterm infants, who are treated with pentazocine. Propoxyphene has been associated with unexplained apnea, bradycardia, and cyanosis, as well as hypotonia in nursing infants.[75,76] Moreover, propoxyphene was withdrawn from the market because significant QT prolongation occurred at therapeutic doses.[77] Meperidine use is associated with decreased alertness of the infant and is likely to interfere with breastfeeding.[71] Although estimates of meperidine exposure are low (approximately 2% to 3% of the maternal weight-adjusted dose), the half-life of the active metabolite for meperidine is prolonged, and it may accumulate in infant blood or tissue.[71,72]

When narcotics are not required to relieve mild to moderate pain, other analgesic agents can be used. Presuming that pain relief is adequate, short-acting agents, such as ibuprofen and acetaminophen, are acceptable.[78] Although the half-life of ibuprofen may be prolonged in neonates, particularly in preterm infants (according to product labeling), minimal amounts of ibuprofen are excreted into human milk.[72] Despite reduced clearance of acetaminophen,[79] hepatotoxicity is less common in neonates than in older infants, in part because of low levels of certain cytochrome P-450 enzymes, which convert acetaminophen into toxic metabolites.[80] Acetaminophen is available for both oral and intravenous administration.

Although all nonsteroidal antiinflammatory drugs (NSAIDs) carry a boxed warning regarding gastrointestinal bleeding and potential long-term cardiac toxicity, according to their product labeling and Gardiner et al,[81] celecoxib, flurbiprofen, and naproxen are considered to be compatible with breastfeeding, because less than 1% is excreted into human milk. In addition, a breastfeeding infant would receive less than 1% of the relative pediatric dose of celecoxib prescribed for a 2-year-old (according to product labeling). However, long-term use of naproxen is not recommended because of the drug's long half-life and case reports of gastrointestinal tract bleeding and emesis. Avoiding NSAIDs in breastfeeding infants with ductal-dependent cardiac lesions may be prudent.

Limited published data on other NSAIDs (etodolac, fenoprofen, meloxicam, oxaprozin, piroxicam, sulindac, and tolmetin) are available, and FDA labeling discourages their use for a variety of reasons. Although the implications for humans are unknown, meloxicam concentrations in milk of lactating animals exceed plasma concentrations. Diflunisal has a long half-life and is not recommended because of potential adverse events, including cataracts and fatality, in neonatal animals. Similarly, mefenamic acid has a prolonged half-life in preterm infants. Injectable and oral forms of ketorolac are contraindicated in nursing women, according to product labeling, because of potential adverse effects related to closure of the ductus arteriosus in neonates. Less than 1% of ketorolac nasal spray is excreted into human milk, and unlike the oral and intravenous forms of ketorolac, use is not contraindicated (product labeling).

Carisoprodol and its active metabolite, meprobamate, are concentrated in human milk (2–4 times maternal plasma concentrations). Impaired milk production has been observed, and animal studies suggest maternal use may lead to less effective infant feeding (because of sedation) and/or decreased milk production (according to product labeling).

Low doses (75–162 mg/d) of aspirin may be acceptable[82]; however, use of high-dose aspirin therapy during breastfeeding is not advised, because the serum concentration of salicylate in breastfeeding infants has been reported to reach approximately 40% of therapeutic concentrations. Adverse events, such as rash, platelet abnormalities, bleeding, and metabolic acidosis have also been reported.[71]

GALACTAGOGUES

Galactagogues, or agents to stimulate lactation, are often used to facilitate lactation, particularly for mothers of preterm infants. They also may be used to induce lactation in an adoptive mother. However, evidence to support these agents, including use of dopamine antagonists, such as domperidone and metoclopramide; herbal treatments; and hormonal manipulation, is lacking.[83]

Although a placebo-controlled study (n = 42) suggested that domperidone may increase milk volume in mothers of preterm infants,[84] maternal safety has not been established. The FDA issued a warning in June 2004 regarding use of domperidone in breastfeeding women because of safety concerns based on published reports of arrhythmia, cardiac arrest, and sudden death associated with intravenous therapy. Furthermore, treatment with oral domperidone is associated with QT prolongation in children and infants.[85,86] Domperidone is not an approved product in the United States, and labeling for oral formulations marketed outside the United States do not recommend use during lactation.

Several small trials (each with fewer than 25 subjects) published before 1990 suggested that metoclopramide increases prolactin concentrations and/or milk production in mothers of both term and preterm infants.[87] However, more recent controlled studies do not replicate this finding.[88,89] Human milk concentrations of metoclopramide are similar to therapeutic concentrations in adult plasma,[88] and measurable amounts can be detected in breastfeeding infants.[90] Clearance of metoclopramide in neonates is prolonged, which may result in excessive serum concentrations and the risk of conditions associated with overdose, such as methemoglobinemia. Of concern, prolactin concentrations were increased in 4 of 7 infants exposed to metoclopramide via human milk.[90] The safety profile for metoclopramide includes adverse reactions, such as dystonia, depression, suicidal ideation, and gastrointestinal tract disturbances, as well as a boxed warning about the risk of tardive dyskinesia. These risks to the mother limit the usefulness of this therapy.

Although a pilot study in 8 lactating women performed decades ago suggested that oxytocin nasal spray

increased human milk production, a larger placebo-controlled trial in 51 women has not confirmed that observation.[91] Oxytocin nasal spray is no longer marketed in the United States. Similarly, anecdotal reports supporting the use of the herb fenugreek to facilitate lactation have not been confirmed by controlled studies.[92,93] Fenugreek contains coumarin, which may interact with NSAIDs.[94] Use of fenugreek in lactating women also is associated with maple-syrup odor in infants.[95] Available data do not support the routine use of other herbal products, such as fennel, to facilitate lactation.[96]

In summary, galactagogues have a limited role in facilitating lactation and have not been subject to full assessments of safety for the nursing infant. Nursing mothers should seek consultation with a lactation specialist and use nonpharmacologic measures to increase milk supply, such as ensuring proper technique, using massage therapy, increasing the frequency of milk expression, prolonging the duration of pumping, and maximizing emotional support.

COMMONLY USED HERBAL PRODUCTS

Despite the frequent use of herbal products in breastfeeding women (up to 43% of lactating mothers in a 2004 survey),[97] reliable information on the safety of many herbal products is lacking. Herbal products are not subject to the same standards for manufacturing and proven effectiveness and safety as are drug products before they are marketed.[98] In fact, the use of several herbal products may be harmful, including kava and yohimbe. For example, the FDA has issued a warning that links kava supplementation to severe liver damage.[99] Breastfeeding mothers should not use yohimbe because of reports of associated fatalities in children.[100] In addition, from 2008 through 2010, the FDA recalled 10 or more dietary supplements each year because of the presence of potentially toxic undeclared ingredients in the supplement.[101] Similarly, the US Government Accountability Office found that 16 of 40 common herbal dietary supplements obtained from retail stores contained pesticide residues.[102]

Safety data are lacking for many herbs commonly used during breastfeeding, such as chamomile,[103] black cohosh,[104] blue cohosh,[105] chastetree,[106] echinacea,[107] ginseng,[108] gingko,[109] *Hypericum* (St John's wort),[110,111] and valerian.[112] Adverse events have been reported in both breastfeeding infants and mothers. For example, St John's wort may cause colic, drowsiness, or lethargy in the breastfed infant even though milk production and infant weight do not appear to be adversely affected[110] and relative maternal dose and infant plasma concentrations are low.[113] Prolonged use of fenugreek may require monitoring of coagulation status and serum glucose concentrations.[114] For these reasons, these aforementioned herbal products are not recommended for use by nursing women.

Although supplementation of nursing mothers with iron and vitamins is safe as long as recommended daily allowances are not exceeded, the use of other nutritional supplements may not be. For instance, L-tryptophan has been associated with eosinophilic myositis.[115] Therefore, physicians should inquire about the use of herbal products and dietary supplements in lactating women and discuss the need for caution because of the paucity of data available.

DIAGNOSTIC IMAGING

When feasible, elective imaging procedures should be delayed until a woman is no longer breastfeeding. For most radiopharmaceuticals, breastfeeding should be interrupted for a time period based on the rate of decline of the agent and dosimetry to avoid infant exposures greater than 1 mSv (100 mrem). For agents that may be concentrated in breast tissue, close contact of the mother with the infant and, consequently, nursing may need to be avoided for a period of time, although expressed milk that has been refrigerated until the radioactivity has decayed may be safe. General guidelines based on Nuclear Regulatory Commission regulations and International Commission on Radiologic Protection guidelines[116] are cited in Tables 3 and 4. However, because there is considerable variability in milk radioactivity, and close contact with an infant may result in additional exposure, consultation with a radiologist should be sought. If deemed necessary, individualized testing of expressed milk may be performed to ensure that radioactivity has reached background levels before breastfeeding is resumed.[117]

Notably, because radiolabeled iodinated products are concentrated in the developing thyroid and radioactivity persists after imaging with most ^{131}I and ^{125}I radiopharmaceuticals (with the exception of ^{125}I- hippurate), breastfeeding should be interrupted for a minimum of 3 weeks. Similarly, ^{22}Na and ^{67}Ga (gallium) administration also require a prolonged (3-week) interruption in breastfeeding. Because the lactating breast has a greater ^{131}I affinity than does the nonlactating breast, women should cease breastfeeding at least 4 weeks before whole-body procedures with ^{131}I and should discontinue breastfeeding thereafter. Doing so will reduce the radiation dose and potential cancer risk to maternal breast tissue.

Traditionally, lactating women receiving intravascular gadolinium or iodinated contrast (as opposed to radiolabeled iodine) are advised to discontinue nursing for 24 hours. However, a minimal amount (0.04%) of the intravenous dose reaches human milk, and, of that, less than 1% to

TABLE 3 Radioactive Compounds That May Require Temporary Cessation of Breastfeeding: Recommendations of the International Commission on Radiologic Protection

Compound	Examples	Example of Procedures	Recommended Time for Cessation of Breastfeeding	Comments
^{14}C-labeled	Triolein, glycocholic acid, urea	*Helicobacter pylori* breath test	None	No approved US products
^{99m}Tc-labeled	DMSA, DTPA, phosphonates (MDP), PYP, tetrofosmin	Multiple: imaging of kidney, bone, lung, heart, tumors	0 to 4 h, as long as no free pertechnetate	Consider discarding at least 1 meal after procedure
	Microspheres, pertechnetate, WBC		12–24 h	Range depends on dose
	Sulfur-colloids, RBC in vivo		6 h	
I-labeled	^{123}I, ^{125}I or ^{131}I-iodo hippurate	Thyroid imaging	12 h	Note: whole-body irradiation with ^{131}I requires prolonged cessation
Others	^{11}C- ^{11}N or ^{11}O-labeled	PET scans	None	Short physical half-life
	^{57}Co-labeled vitamin B_{12}	Schilling test	24 h	Pomeroy 2005[119]
	^{18}F-FDG	PET scans	None, first feeding should be expressed breast milk to avoid direct contact[120]	Use alternatives for 10 half-lives (10×109 min= 18 h)[a]
	^{51}Cr-EDTA	Renal imaging	None	
	^{81m}Kr-gas	Pulmonary imaging	None	No approved US products
	^{82}Rb chloride	PET scan of myocardium	May resume 1 h after last infusion	Half-life 75 s[a]
	^{111}In-octreotide	SPECT, neuroendocrine tumors	None	
	^{111}In -WBC		1 wk	Depends on dose
	^{133}Xe	Cardiac, pulmonary, and cerebral imaging	None	Half-life 5 d[a]

DMSA, dimercaptosuccinic acid; DTPA, diethylenetriaminepentaacetate; EDTA, ethylenediaminetetraacetic acid; FDG, fludeoxyglucose; PET, positron emission tomography; PYP, pyrophosphate; RBC, red blood cell; SPECT, single-photon emission computed tomography; WBC, white blood cell.
[a] FDA-approved drug labeling.

TABLE 4 Radioactive Compounds Requiring Prolonged Cessation of Breastfeeding

Compound	Examples	Example of Procedures	Recommended Time for Cessation of Breastfeeding	Comments
I-labled	^{123}I- BMIPP, -HSA, -IPPA, -MIBG, -NaI, or -HSA	Imaging of tumors	Greater than 3 wk	Essentially need to stop breastfeeding
	^{131}I-MIBG or -NaI			
Others	^{201}Tl-chloride	Cardiac imaging	48 h to 2 wk	Half-life 73 h[a]
	^{67}Ga-citrate	Imaging of tumors	1 wk to 1 mo	Depends on dose
	^{22}Na, ^{75}Se		Greater than 3 wk	Essentially need to stop breastfeeding

Use of expressed human milk recommended because of exposure via direct contact.[120] BMIPP, β-methyl-p-iodophenyl-pentadecanoic acid; HSA, human serum albumin; IPPA, iodophenylpentadecanoic; MIBG, metaiodobenzylguanidine; NaI, sodium iodide.
[a] FDA-approved drug labeling.

2% is absorbed by the infant. Therefore, breastfeeding can be continued without interruption after the use of iodinated contrast or gadolinium.[118]

BREASTFEEDING AND VACCINES

With rare exceptions, maternal immunization does not create any problems for breastfeeding infants, although questions concerning 2 topics often arise regarding lactation and immunization: the effect of lactation on the infant's immune response to a vaccine and a potential adverse effect on the infant from maternal immunization. Breastfeeding does not interfere with the infant's immune response to most routine immunizations (eg, diphtheria and tetanus toxoids and acellular pertussis vaccine, inactivated poliovirus vaccine, and hepatitis B vaccine [HBV]),[121] despite the presence of maternal antibodies in human milk. Seroconversion rates are also similar between breastfed and formula-fed infants receiving rotavirus vaccine; however, vaccine efficacy for severe rotavirus gastroenteritis appears to be higher in formula-fed infants compared with exclusively breastfed infants, particularly during the second season (98% vs 88%) when breastfeeding has been discontinued.[122] Nonetheless, protection during the first year is similar. Moreover, breastfeeding enhances the antibody response to pneumococcal and *Haemophilus influenzae* type b vaccines.[123] Breastfeeding may also decrease the incidence of fever after infant immunization.[124] Therefore, the timing of infant feeding (including human milk) relative to immunization is not restricted, even for live vaccines, such as rotavirus.

Lactating women may need to be immunized. Inactivated vaccines (such as tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine; inactivated poliovirus vaccine; influenza; hepatitis A vaccine; HBV; or human papillomavirus vaccine [HPV]) given to

a nursing mother do not pose a risk to the breastfeeding infant. Several vaccines, such as tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine and influenza vaccine, are recommended for the mother during the postpartum period to protect the infant as well as the mother. Other routine or catch-up vaccines, such as HPV, hepatitis A vaccine, and HBV, can be given to the lactating mother. HPV immunization is recommended for women younger than 27 years. The incidence of adverse reactions in nursing infants within 30 days of maternal immunization with HPV was similar to nursing infants of women receiving the control except for acute respiratory illness (according to Gardasil labeling). Hence, caution is warranted when immunizing mothers of infants who are vulnerable to respiratory illnesses (eg, preterm infants, infants with congenital heart disease or chronic respiratory problems).

Most live vaccines are not associated with virus secretion in human milk. For example, despite maternal seroconversion, neither the varicella virus nor antibody to varicella DNA has been detected in breastfeeding infants.[125] Although attenuated rubella can be secreted into human milk and transmitted to breastfed infants, infections are usually asymptomatic or mild. Consequently, postpartum immunization with measles-mumps-rubella vaccine is recommended for women who lack immunity, especially to rubella.[126] In contrast, infants are considered to be at high risk of developing vaccinia after exposure to smallpox vaccine or encephalitis after yellow fever vaccine. Two cases of meningoencephalitis in nursing infants whose mothers had been immunized against yellow fever are documented in the literature.[127,128] Therefore, most vaccines, with the exception of smallpox or yellow-fever vaccine, which are contraindicated in nonemergency situations, may be administered during lactation.

SUMMARY

The benefits of breastfeeding outweigh the risk of exposure to most therapeutic agents via human milk. Although most drugs and therapeutic agents do not pose a risk to the mother or nursing infant, careful consideration of the individual risk/benefit ratio is necessary for certain agents, particularly those that are concentrated in human milk or result in exposures in the infant that may be clinically significant on the basis of relative infant dose or detectable serum concentrations. Caution is also advised for drugs and agents with unproven benefits, with long half-lives that may lead to drug accumulation, or with known toxicity to the mother or infant. In addition, specific infants may be more vulnerable to adverse events because of immature organ function (eg, preterm infants or neonates) or underlying medical conditions. Several excellent resources are available for the pediatrician, including product labeling and the peer-reviewed database, LactMed. Consultation with a specialist may be indicated, particularly when the use of radiopharmaceuticals, oncologic drugs, or other therapies not addressed by LactMed is contemplated. Additional information about topics outside the scope of this report, such as environmental agents, can be obtained from the third edition of the AAP textbook *Pediatric Environmental Health*.[129]

Transitioning HIV-Infected Youth Into Adult Health Care

- *Policy Statement*

POLICY STATEMENT

Transitioning HIV-Infected Youth Into Adult Health Care

abstract

FREE

With advances in antiretroviral therapy, most HIV-infected children survive into adulthood. Optimal health care for these youth includes a formal plan for the transition of care from primary and/or subspecialty pediatric/adolescent/family medicine health care providers (medical home) to adult health care provider(s). Successful transition involves the early engagement and participation of the youth and his or her family with the pediatric medical home and adult health care teams in developing a formal plan. Referring providers should have a written policy for the transfer of HIV-infected youth to adult care, which will guide in the development of an individualized plan for each youth. The plan should be introduced to the youth in early adolescence and modified as the youth approaches transition. Assessment of developmental milestones is important to define the readiness of the youth in assuming responsibility for his or her own care before initiating the transfer. Communication among all providers is essential and should include both personal contact and a written medical summary. Progress toward the transition should be tracked and, once completed, should be documented and assessed. *Pediatrics* 2013;132:192–197

INTRODUCTION

In the United States, the prevalence of HIV infection in adolescents and young adults continues to increase as a result of the improved survival of perinatally infected youth as well as those horizontally infected through adult risk behaviors.[1] The Centers for Disease Control and Prevention estimated that in 2009, there were approximately 77 000 HIV-infected youth between 13 and 24 years of age in the United States. Currently, HIV infection is the seventh leading cause of death in this age group. Youths accounted for 12 200 (25.7%) of all new HIV infections in 2010. More than one-half (59.5%) were unaware of their infection, the highest for any age group.[2]

The rate of new HIV infections is highest in African-American youth, including males who have sex with men (MSM) and females with heterosexual contact. HIV infection rates are sevenfold higher among non-Hispanic African Americans and 2.5-fold higher among Hispanic Americans than among non-Hispanic white Americans.[3] AIDS rates nearly doubled from 1997 to 2006 in male subjects between 15 and 19 years of age, largely because of the dramatic increase in HIV infection among MSM from lower socioeconomic classes.[4] In addition, female subjects between 10 and 14 years of age are at a higher risk of

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

infection than similarly aged male subjects.[2] The disease disproportionately affects minorities and individuals residing in the South and the Northeast regions of the United States. Risk factors include sex with older men, lack of access to HIV prevention services, and lack of perceived personal risk despite frequent anonymous sexual encounters and unprotected anal intercourse. The HIV incidence rate for African-American women is nearly 15 times that of white women and nearly 4 times that of Hispanic/Latina women.[5] Risk factors among these groups include poverty, stigma, limited access to health care, higher rates of concurrent sexually transmitted infections, and drug use.[2]

Adolescence is a developmental stage characterized by immature concrete reasoning often manifested by denial of illness, a sense of invulnerability reflected by risk taking, and behaviors that are strongly influenced by peer norms. These characteristics all have a direct negative effect on the ability to adhere to complex medical regimens. With the dramatic improvement in HIV care over the past 3 decades, the infected adolescent and his or her caregivers are now faced with managing a chronic illness. In addition to caring for the physical needs of the HIV-infected adolescent, it is important to recognize and address the psychosocial barriers to optimal health and enable delivery of uninterrupted, high-quality medically and developmentally appropriate health care as the individual transitions from adolescence to adulthood.[6]

The increasing incidence and prevalence of HIV infection affect the nation's youth at an age when individual psychosocial and physical developmental processes are evolving and maturing. Physically, the pubertal growth spurt is associated with hormonal and bodily changes reflected in secondary sexual characteristics that influence adolescents' long-term self-image and self-esteem. Furthermore, the social environment and responses of peers and significant others have to be constantly integrated into an evolving identity. Among HIV-infected adolescents and young adults, these changes often occur on a background of denial, depression, marginalization and stigmatization, and medical comorbidities associated with HIV infection.[6] Accompanying psychosocial stressors include parental loss, placement in foster care, poverty, homelessness, unemployment, discrimination, and abuse. HIV-infected youth may have less social support because of stigmatization associated with their infection and/or their sexual orientation. Planning for the transition to adult health care should consider potential cultural differences in different populations of infected youth.

HIV-infected youth consist of 2 distinct populations: those who acquired HIV infection perinatally and those infected horizontally through risk behaviors including consensual or nonconsensual sex. Although the course of the infections in these populations may differ, the challenges faced can be similar, including the stigma of HIV infection and the resulting need for confidentiality, which conflicts with the need for disclosure of their infection status to sexual partners.[7] Youth with horizontal acquisition of HIV may be reluctant to disclose an abusive relationship or sexual exploitation to parents and authorities. Differences between the clinical and psychosocial presentations of youth with perinatally and horizontally acquired HIV infection influence the acceptance of illness, self-efficacy, and antiretroviral treatment (ART) adherence. Among young MSM, unique stressors include homophobia and discrimination, which can lead to a cascade of adverse outcomes, including homelessness and unemployment, and directly affect clinical follow-up and adherence to life-saving medications. Adolescents with newly diagnosed infection may present with an opportunistic and/or sexually transmitted infection associated with advanced immunosuppression. The development of individual disease management skills may be essential for adherence to ART and treatment of associated comorbidities. However, these expectations may be incongruous with the developmental stage of the individual newly diagnosed with HIV along with the complex social situations in which these teenagers may find themselves. Many perinatally infected children have survived into adolescence with multiple courses of combination ART not infrequently associated with periods of poor adherence, often reflecting treatment fatigue, leading to viral resistance.[8] With HIV resistance, therapeutic options become limited, necessitating increasingly more complex treatment regimens. Such regimens can be particularly difficult to implement in treatment-weary adolescents with challenges such as stunted growth, delayed puberty, and physical disabilities arising from earlier complications of perinatal HIV infection or from long-term ART.

Adolescents who have chronic health conditions are often followed up in pediatric or adolescent clinics through adolescence or into young adulthood, although the upper age limit varies. Seamless and successful transition from pediatric- to adult-oriented health care is dependent on these youth acquiring skills to allow them to be responsible for the management of their own health care.[9–12] In situations in which youth have both a primary care provider (medical home) and a subspecialty HIV care provider, both primary care and HIV care will need to be transitioned to adult providers. This situation could allow for the transition of

primary care and subspecialty care at different times. With good communication and careful planning, this strategy could help smooth the transition and improve retention in care.

HIV-infected youth face many of the same challenges in transitioning to adult health care as do individuals with other chronic health conditions.[10] These include the loss of close and supportive relationships with their individual pediatric/adolescent/family medicine providers. The neurocognitive delay and behavioral problems commonly experienced by HIV-infected youth may pose additional challenges for the adult health care provider.[6,13,14] The adult care site may not provide the level of support and encouragement to which the youth is accustomed in his or her pediatric medical home. At 1 site, HIV-infected youth aged 17 to 24 years who received care in an adult health clinic had poorer outcomes than did older adults in the same clinic, with lower rates of viral suppression and nearly 4 times the rate of loss to follow-up.[15] However, increases in CD4+ T-lymphocyte counts were similar in the 2 groups. High rates of substance use and mental health problems, difficulties in adjustment, and reduced emotional support may lead to loss to follow-up and disease progression.[15,16] In addition, in many states, youth who have received public health insurance coverage become ineligible at 18 to 21 years of age, limiting their access to care and medications. Among HIV-infected youth older than 18 years who transitioned from National Institutes of Health clinical research protocols to adult care, 15% reported not having health insurance.[16] Protocols and linkages to care in anticipation of the transition can help avert such consequences.

Several models of transition to adult health care have been proposed, with considerable variability among institutions and individual providers. This variability is reflected in differences in addressing comprehensive care needs as part of the transition, including medical, psychosocial, and financial aspects of transitioning.[17–21] In a survey of providers of pediatric HIV care in the United States, 81% had designated a transition coordinator, but few had established policies to define the details of the transition.[22] One university-based program elected to begin the process at 23 years of age because of a high failure rate when initiated at 21 years of age.[20] Results of this strategy are not yet available. Most models are characterized by flexibility, allowing youth to move back and forth between stages of the transition with the anticipation of completing the process by 25 years of age.

Data are limited regarding the outcomes of HIV-infected youth after transition to adult health care.[23,24] Fewer than one-half of children with congenital heart disease at 1 large pediatric center successfully transitioned to adult health care.[25] Qualitative studies emphasize the importance of an adult-based case manager and mental health providers to assist in the transition as well as an individualized approach to the transition process, including addressing health insurance, alcohol and drug treatment, housing, transportation, education, training, and employment needs.[16,26] Predictors of a successful transition included good adherence to care[24] and effective management of psychiatric comorbidities[6,27] before transition. Further studies to define the outcome of transition and identify the determinants of a successful transfer of care are urgently needed.

RECOMMENDATIONS

Guidelines for transitioning youth with chronic diseases to adult health care have been published by the Society for Adolescent Health and Medicine (formerly known as the Society for Adolescent Medicine)[28] and the American Academy of Pediatrics (AAP [with endorsement by the American Academy of Family Physicians and the American College of Physicians]).[10,29] Broad recommendations include the development of a formal, multidisciplinary, transitional program that involves individual youths and their families and the identification of an adult health care provider before the transition. These guidelines provide guidance on care planning and the transfer of medical information. Their conclusions remain widely accepted as a gold standard that can serve as a framework for the transition of HIV-infected youth. However, a national survey of AAP members revealed that pediatricians remain poorly informed about the conclusions of the AAP consensus statement and that most pediatric practices neither initiate transition planning early in adolescence nor offer transition support services.[30] Identified gaps included limited personnel and training of staff, limited time and workforce shortages, inadequate reimbursement, and anxiety on the part of treating clinicians, adolescents, and their parents about planning for future health care. Guidelines specific to transitioning HIV-infected youth are also available.[20,21]

There are 4 major steps in the transition process:

1. The primary and/or subspecialty pediatric, adolescent, or family medicine HIV care team, in collaboration with adult HIV care providers, develops a formal written policy for transition of youth to adult health care. Written supporting documents, such as brochures and Web-based information, can be helpful in implementing the policy. The transition policy should describe the goals and timeline of transition and explain how the practice evaluates this process.

The policy should be shared with all members of the health care team and implemented with appropriate staff training. An important component of the plan is to establish a system, such as a registry, to identify and track youth as they approach and progress through the transition process because these youth may frequently change where they are living.

2. The patient and his or her family should be introduced to the concept of transition to adult health care early in adolescence, well in anticipation of the actual transfer of care. Although opinions differ regarding the appropriate age to first introduce the transition process, early adolescence is generally regarded as the most appropriate time. Many recommend beginning the discussion of transition by 12 years of age or at an appropriate time after the initial diagnosis, if it occurs at an older age.[10] HIV infection status must be fully disclosed to the patient and explained before introducing the plan. Factors to consider in choosing the age to introduce the plan include individual developmental stage and neurocognitive abilities. Providers may use a readiness assessment tool to reveal areas of strength and weakness to which patient education can be focused to achieve self-management. Specific tools are available for downloading from the Internet, such as the New York State guidelines.[21] It is important to encourage independence through personal ownership and management of health care. Particular attention should be paid to identifying and addressing behavioral, emotional, and mental health problems. In conjunction with the patient and family, the referring provider develops an individualized written transition plan with realistic goals to delineate the process of transition to adult health care. The plan should emphasize education of all involved parties and empowerment of the HIV-infected youth to assume responsibility for his or her own health care. The plan should anticipate and address challenges that patients, parents, and caregivers encounter during transition, including the loss of an established provider. Patient education during office visits and peer group sessions can reinforce the value of independence and decision-making as part of the transition. The creation of a portable medical summary and an emergency care plan is an important component of the plan.

   Ongoing discussions of the transition plan should occur at least annually at subsequent visits, with modification of the plan as appropriate. The health care coverage of the youth should be evaluated regularly to ensure that health care coverage and access to medications remains uninterrupted during the transition. The 2010 Patient Protection and Affordable Care Act health care reform legislation includes provision for children to remain on their parents' insurance until 26 years of age and eliminates insurers' ability to exclude coverage on the basis of preexisting conditions.
3. The actual transition to adult health care is initiated. The age at which this transition is initiated is generally between 18 and 25 years and can be influenced by the upper age at which health care is provided by the referring team and the comfort of the adult health care provider in caring for younger adults. Once a suitable adult HIV medicine provider is identified, a pretransfer visit to meet the adult health care provider can help to establish a successful long-term relationship. The pediatric, adolescent, or family medicine provider should communicate directly with the adult health care provider and supply appropriate documentation, including a transfer letter, the portable medical summary, and/or electronic health record (EHR), before the initial encounter between the adult health care provider and the patient. The portable medical summary and/or EHR should address all medical and psychosocial needs, including advance directives. Ideally, the youth would be introduced to the adult health care provider personally by the pediatric, adolescent, or family medicine provider, either in the referring or adult clinic. It is likely that most youth will need ongoing support from the pediatric adolescent or family medicine health care team during the process for transition to be successful. This support could consist of periodic contact by a member of the referring health care team, such as a nurse or social worker. A peer support group may assist youth with dealing with anxiety resulting from the transition process.
4. The final step in the transition process is to document the completion of the transition and evaluate the outcome of the process. The referring health care provider should document that the young adult has established his or her care in the adult clinic and should be available to provide ongoing encouragement to maintain the youth in adult health care. The referring team should be available to the adult health care provider to serve as a resource during the immediate posttransfer period. However, once the youth has established ongoing care with the adult health care provider, it is appropriate for the

pediatric, adolescent, or family medicine provider to withdraw from providing care to prevent confusion in the patient and to reinforce the role of the adult health care provider.

CONCLUSIONS

A well-planned transition of HIV-infected youth from pediatric, adolescent, or family medicine clinics, often from a medical home to adult health care, enables them to optimize their ability to assume adult roles and activities. Transition planning should be a standard part of providing health care for all HIV-infected youth. Pediatricians and adolescent and family medicine providers have a pivotal role in facilitating seamless and effective transition at a very vulnerable and anxious time of life for both HIV-infected youth and their families. These essential transitional activities can improve health outcomes for HIV-infected adolescents.

Specific Recommendations

1. Pediatric, adolescent, and family medicine HIV care providers, in collaboration with suitable adult HIV care providers, should develop a formal process for transition of youth to adult health care.
2. The patient and his or her family should be introduced to the concept of transition to adult health care early in adolescence well in anticipation of the actual transfer of care. The youth should be informed of his or her HIV status before initiating the process.
3. There are 4 key steps in the transition process:
   a. The referring provider should develop written policies to define the process of transition of HIV-infected youth to adult health care. The plan should be shared with all pediatric/adolescent or family medicine providers, staff, and patients and their families with appropriate staff training. Written documents, such as brochures and Web-based information, can be helpful in implementing the policy. Providers should establish a system to identify and track youth as they progress through the transition process.
   b. The provider, the youth, and the family should jointly create an individualized transition plan well in anticipation of transition, which should include creation of a portable medical summary and/or EHR and an emergency care plan. Providers may use a readiness assessment tool, and the transition plan should be revised on the basis of these assessments.
   c. Transition to the adult HIV care provider should be initiated with appropriate communication, including a transfer letter and portable medical summary. A pretransfer visit by the patient to meet the adult health care provider can assist in establishing a successful long-term relationship.
   d. Completion of the transition should be documented, and the outcome of the process should be evaluated. The referring health care team should be available to the adult health care provider to serve as a resource during the immediate posttransfer period.
4. The health care coverage of the youth should be evaluated regularly to ensure that health care coverage and access to medications remains uninterrupted during transition.
5. The transition process should ensure that the youth's health care, educational, vocational, and social service needs are discussed and addressed.

CLINICAL REPORT

Use of Inhaled Nitric Oxide in Preterm Infants

Praveen Kumar MD, FAAP, and COMMITTEE ON FETUS AND NEWBORN

abstract

FREE

Nitric oxide, an important signaling molecule with multiple regulatory effects throughout the body, is an important tool for the treatment of full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure. Several randomized controlled trials have evaluated its role in the management of preterm infants ≤34 weeks' gestational age with varying results. The purpose of this clinical report is to summarize the existing evidence for the use of inhaled nitric oxide in preterm infants and provide guidance regarding its use in this population. *Pediatrics* 2014;133:164–170

INTRODUCTION

Nitric oxide (NO) is an important signaling molecule with multiple regulatory effects throughout the body. In perinatal medicine, inhaled nitric oxide (iNO) was initially studied for its pulmonary vasodilating effects in infants with pulmonary hypertension and has since become an important tool for the treatment of full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure.[1] Inhaled NO also has multiple and complex systemic and pulmonary effects. In animal models of neonatal chronic lung disease, iNO stimulates angiogenesis, augments alveolarization, improves surfactant function, and inhibits proliferation of smooth muscle cells and abnormal elastin deposition.[2–6] Although the evidence for similar benefits in preterm infants is lacking, the off-label use of iNO in this population has escalated.[7] A study published in 2010 reported a sixfold increase (from 0.3% to 1.8%) in the use of iNO among infants born at less than 34 weeks' gestation between 2000 and 2008.[7] The greatest increase occurred among infants who were born at 23 to 26 weeks' gestation (0.8% to 6.6%). The National Institutes of Health convened a consensus panel in October 2010 to evaluate the evidence for safety and efficacy of iNO therapy in preterm infants. After reviewing the published evidence, the panel concluded that the available evidence does not support the use of iNO in early routine, early rescue, or later rescue regimens in the care of infants born at less than 34 weeks' gestation and that hospitals, clinicians, and the pharmaceutical industry should avoid marketing iNO for this group of infants.[8] An individual-patient data meta-analysis of 14 randomized controlled trials reached similar conclusions.[9] The purpose of this clinical report is to summarize the

existing evidence for the use of iNO in preterm infants and provide guidance regarding its use in this population.

LITERATURE REVIEW

Use of iNO in Preterm Infants With Respiratory Failure

The benefits associated with iNO therapy in full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure initiated interest in exploring whether iNO could reduce the rates of death and neonatal morbidities in more immature infants. Pilot studies reported short-term improvement in oxygenation with iNO, but no significant benefit was observed in mortality or other morbidities.[10–15] Subsequently, several randomized clinical trials were undertaken.[16–23] Table 1 outlines the study population, entry criteria, and dose and duration of iNO treatment and summarizes the outcomes for all published randomized controlled trials. Only 1 small trial of 40 patients reported a beneficial effect on survival (Table 1). Subgroup analyses of secondary outcomes have provided conflicting results. Post hoc analysis of the Neonatal Research Network study suggested that iNO therapy was associated with reduced rates of death and bronchopulmonary dysplasia (BPD) in infants with a birth weight greater than 1000 g, but higher mortality and increased risk of severe intracranial hemorrhage in infants weighing 1000 g or less at birth.[17] In contrast, another large multicenter US trial reported no significant difference in the primary outcome of death or BPD between treated and control groups; however, infants treated with iNO had fewer brain lesions (eg, grade 3 or 4 intracranial hemorrhage, periventricular leukomalacia, and/or ventriculomegaly) noted on cranial ultrasonography.[20] A European multicenter study reported that infants randomized to iNO treatment had longer duration of ventilation, time on oxygen therapy, and length of hospital stay compared with the placebo group, although none of these results were statistically significant.[19]

Use of iNO in Preterm Infants to Improve the Rate of Survival Without BPD

Lung pathology in preterm infants with BPD is characterized by reduced numbers of large alveoli and abnormal pulmonary vasculature development. Surfactant deficiency, ventilator-induced lung injury, oxygen toxicity, and inflammation appear to play important roles in its pathogenesis.[26,27] In animal models of neonatal lung injury, iNO promotes angiogenesis, decreases apoptosis, and reduces lung inflammation and oxidant injury.[28–30] In an early study of iNO use in preterm infants, the incidence of BPD was reduced in treated infants who required ventilator support.[16] Of 3 subsequent large randomized trials designed to evaluate the effect of iNO therapy on survival without BPD,[20,24,25] 2 found no significant benefit[20,25] (Table 1). A third trial, which featured late treatment (7–21 days of age), a longer duration of drug exposure (25 days), and a higher cumulative dose, demonstrated a modest but statistically significant beneficial effect (44% iNO vs 37% placebo; P = .042).[24] A subgroup analysis showed that the beneficial effect was seen in infants enrolled between 7 and 14 days of age but not those enrolled between the ages of 15 and 21 days.[24]

EFFECTS OF INO THERAPY ON NEURODEVELOPMENTAL OUTCOME

Studies in animal models suggest that iNO may have direct beneficial effects on the brain through mechanisms involving the cerebral vasculature and/or neuronal maturation.[31,32] Other investigators have described a possible role for intravascular NO-derived molecules in conserving and stabilizing NO bioactivity that may contribute to the regulation of regional blood flow and oxygen delivery.[33,34] Neurodevelopmental outcome has been reported for 6 clinical trials,[35–40] and of these, 1 noted a more favorable neurodevelopmental outcome at 1 year of age among the preterm cohort treated with iNO but no difference in the rate of cerebral palsy.[36]

EFFECTS OF INO THERAPY ON LONG-TERM PULMONARY OUTCOME OF SURVIVORS

In animal models, iNO decreases baseline airway resistance and may increase the rate of alveolarization.[2–6] To date, only 2 studies have reported respiratory outcomes of preterm infants treated with iNO.[41,42] In a telephone survey that included 456 infants in the Nitric Oxide Chronic Lung Disease (NOCLD) study group, the use of bronchodilators, inhaled steroids, systemic steroids, diuretics, and supplemental oxygen during the first year of life was less in the iNO-treated group, but there were no significant differences in the frequency of wheezing or the rate of rehospitalization. In the Inhaled Nitric Oxide Versus Ventilatory Support Without Inhaled Nitric Oxide multicenter trial, follow-up at 1 year of age showed no difference in maximal expiratory flow at functional residual capacity, wheezing, readmission rate, or use of respiratory medications.[42]

RESULTS OF META-ANALYSES OF STUDIES EVALUATING THE USE OF INO IN PRETERM INFANTS

Two published meta-analyses found no overall significant effect of iNO on the rate of mortality, BPD, intraventricular hemorrhage, or neurodevelopmental impairment.[43,44] In view of the limitations

TABLE 1 Randomized Controlled Trials of iNO in Preterm Infants

Author, Year	*n*	Gestational Age, wk	Birth Weight, g	Age at Enrollment	Entry Criteria	iNO Protocol	Primary Outcome	Study Results
Subhedar, 1997[11]	42	<32	—	96 h	Need for mechanical ventilation and high risk of developing CLD	20 ppm for at least first 2 h and then 5 ppm for 3–4 d	Death and/or CLD before discharge	No difference in primary outcome
Kinsella, 1999[12]	80	≤34	—	≤7 d	aAO_2 ratio <0.1 on 2 consecutive blood gases in first 7 d of life	5 ppm for 7–14 d	Survival	No difference in primary outcome; no difference in rate of IVH or CLD
The French-Belgian iNO Trial, 1999[13]	85	<33	—	<7 d	OI between 12.5 and 30.0 on 2 consecutive blood gases at least 1 h apart	10–20 ppm for a minimum of 2 h	OI reduction of ≥33% or at least 10 points	More treated infants achieved primary outcome; no difference in median OI at 2 h; no difference in survival or other outcomes
Srisuparp, 2002[15]	34	—	<2000	<72 h	OI ranging from >4 to >12 based on birth wt	20 ppm for 24–48 h and then 5 ppm for maximum of 7 d	Change in oxygenation	Improved oxygenation with treatment but no difference in survival or IVH
Schreiber, 2003[16]	207	<34	<2000	<72 h	Need for mechanical ventilation	10 ppm for first day then 5 ppm for 6 d	Death and survival without BPD at 36 wk postmenstrual age	Treatment associated with a decrease in the combined incidence of BPD and death; no difference in mortality alone
Van Meurs, 2005[17]	420	<34	401–1500	4–120 h; mean 26–28 h	OI ≥10 on 2 consecutive blood gases between 30 min and 12 h apart	5–10 ppm for maximum of 14 d	Incidence of death or BPD	No difference in primary outcome; no difference in rate of BPD, severe IVH, or PVL. Post hoc analyses: Decrease in primary outcome in cohort with birth weight >1000 g; higher rate of mortality and severe IVH in cohort with birth wt <1000 g
Hascoet, 2005[18]	145	<32	—	6–48 h	aAO_2 ratio <0.22	5 ppm for first h of treatment and further dosage were adjusted based on response; total duration of treatment not clearly defined but varied from 4 h in nonresponders to few days in responders	Intact survival at 28 d	No difference in primary outcome; iNO was an independent risk factor for the combined risk of death or brain lesion
Field, 2005[19]	108	<34	—	<28 d; median 1 d	Severe respiratory failure requiring assisted ventilation	5–40 ppm depending on patient response; total duration of treatment not clearly defined	Death or severe disability at 1 y corrected age; death or CLD	No difference in primary outcome
Kinsella, 2006[20]	793	≤34	500–1250	<48 h	Need for mechanical ventilation	5 ppm for maximum of 21 d	Death or BPD at 36 wk postmenstrual age	No difference in primary outcome but had a decreased risk of brain injury; decreased incidence of BPD in cohort with birth weight ≤1000 g
Dani, 2006[21]	40	<30	—	≤7 d	aAO_2 ratio <0.15	10 ppm for 4 h then 6 ppm until extubation	Death and BPD	Primary outcome less with iNO treatment

TABLE 1 Continued

Author, Year	*n*	Gestational Age, wk	Birth Weight, g	Age at Enrollment	Entry Criteria	iNO Protocol	Primary Outcome	Study Results
Ballard, 2006[24]	582	≤32	500–1250	7–21 d	Need for mechanical ventilation for lung disease between 7 and 21 d; infants with birth weight 500–799 g were eligible if requiring nasal CPAP	20 ppm for 48–96 h followed by 10, 5, and 2 ppm at weekly intervals, with a minimum treatment duration of 24 d	Survival without BPD at 36 wk of postmenstrual age	Improved survival without BPD at 36 wk postmenstrual age; post hoc analysis showed most benefit when iNO treatment was started between 7–14 d of age
Van Meurs, 2007[23]	29	<34	>1500	4–120 h; mean 24–25 h	OI ≥15 on 2 consecutive blood gases between 30 min and 12 h apart	5–10 ppm for maximum of 14 d	Incidence of death or BPD	No difference in primary outcome
Su and Chen, 2008[22]	65	<32	≤1500	Mean 2.5 d	OI ≥25	5–20 ppm based on patient response; treatment duration at physician discretion (mean duration 4.9 ± 2.3 d)	OI at 24 h after randomization	Improved oxygenation with iNO treatment; no difference in survival, CLD, IVH, PDA, ROP, or duration of intubation
Mercier, 2010[25]	800	<29	>500	First day of life	Need for surfactant or CPAP within 24 h of birth	5 ppm for minimum of 7 d and maximum of 21 d	Survival without BPD at 36 wk postmenstrual age	No difference in primary outcome; no difference in survival alone; no difference in BPD; no difference in brain injury

Dash indicates not part of enrollment criteria.
aAO_2, arterial-alveolar oxygen ratio; CLD, chronic lung disease; CPAP, continuous positive airway pressure; IVH, intraventricular hemorrhage; OI, oxygenation index; PDA, patent ductus arteriosus; PVL, periventricular leukomalacia; ROP, retinopathy of prematurity.

of meta-analysis using aggregate data from different trials and to identify any patient or treatment characteristics that might predict benefit, Askie et al[9] conducted an individual-patient data meta-analysis. Data from 3298 infants in 11 trials that included 96% of published data showed no statistically significant effect of iNO on the rate of death or chronic lung disease (relative risk 0.96; 95% confidence interval 0.92–1.01) or severe brain lesions on cranial imaging (relative risk 1.12; 95% confidence interval 0.98–1.28). There were no statistically significant differences in iNO effect according to any of the patient-level characteristics tested; however, the authors cautioned that they could not exclude the possibility of a small reduction in the combined outcome of death or chronic lung disease if a higher dose of iNO (20 ppm) was used after >7 days of age, as observed in the NOCLD study.[9,24]

COST-BENEFIT ANALYSES OF ROUTINE USE OF INO IN PRETERM INFANTS

Treatment with iNO is expensive and can add significantly to health care costs.[8] A retrospective economic evaluation using patient-level data from the NOCLD trial (the only trial showing clinical benefit) reported that the overall mean cost per infant for the initial hospitalization was similar in the treated and placebo groups; however, when iNO therapy was initiated between 7 and 14 days of age, there was a 71% probability that the treatment decreased costs and improved outcomes.[45] Cost-benefit analysis from 2 other studies failed to show any cost-benefit.[37,39] Among preterm infants in the Inhaled Nitric Oxide Versus Ventilatory Support Without Inhaled Nitric Oxide trial, there was no difference in resource use and cost of care through the 4-year assessment.[37] Using more robust research methodology, including

data on postdischarge resource utilization and health-related quality of life evaluations, Watson et al[39] found that costs of care did not vary significantly by treatment arm through 1 year of age. Although quality-adjusted survival was slightly better with iNO therapy, the estimated incremental cost-effectiveness ratio was $2.25 million per quality-adjusted life year, with only a 12.9% probability that the incremental cost-effectiveness ratio would be less than $500 000 per quality-adjusted life year. Additionally, in subgroup analysis, total costs were significantly higher for the iNO-treated group in the smallest birth weight stratum (500–749 g).

SAFETY OF INO USE IN PRETERM INFANTS

The only information regarding the safety of iNO use in preterm infants is derived from the NOCLD trial.[46–49] The limited data suggest that iNO is safe and does not increase lung inflammation or oxidative stress.[46,48]

SUMMARY

1. The results of randomized controlled trials, traditional meta-analyses, and an individualized patient data meta-analysis study indicate that neither rescue nor routine use of iNO improves survival in preterm infants with respiratory failure (Evidence quality, A; Grade of recommendation, strong).[50]
2. The preponderance of evidence does not support treating preterm infants who have respiratory failure with iNO for the purpose of preventing/ameliorating BPD, severe intraventricular hemorrhage, or other neonatal morbidities (Evidence quality, A; Grade of recommendation, strong).
3. The incidence of cerebral palsy, neurodevelopmental impairment, or cognitive impairment in preterm infants treated with iNO is similar to that of control infants (Evidence quality, A).
4. The results of 1 multicenter, randomized controlled trial suggest that treatment with a high dose of iNO (20 ppm) beginning in the second postnatal week may provide a small reduction in the rate of BPD. However, these results need to be confirmed by other trials.
5. An individual-patient data meta-analysis that included 96% of preterm infants enrolled in all published iNO trials found no statistically significant differences in iNO effect according to any of the patient-level characteristics, including gestational age, race, oxygenation index, postnatal age at enrollment, evidence of pulmonary hypertension, and mode of ventilation.
6. There are limited data and inconsistent results regarding the effects of iNO treatment on pulmonary outcomes of preterm infants in early childhood.

AAP PRINCIPLES CONCERNING RETAIL-BASED CLINICS

Retail-Based Clinic Policy Work Group (12/06, reaffirmed 1/11)

ABUSIVE HEAD TRAUMA IN INFANTS AND CHILDREN

Cindy W. Christian, MD; Robert Block, MD; and Committee on Child Abuse and Neglect

ABSTRACT. Shaken baby syndrome is a term often used by physicians and the public to describe abusive head trauma inflicted on infants and young children. Although the term is well known and has been used for a number of decades, advances in the understanding of the mechanisms and clinical spectrum of injury associated with abusive head trauma compel us to modify our terminology to keep pace with our understanding of pathologic mechanisms. Although shaking an infant has the potential to cause neurologic injury, blunt impact or a combination of shaking and blunt impact cause injury as well. Spinal cord injury and secondary hypoxic ischemic injury can contribute to poor outcomes of victims. The use of broad medical terminology that is inclusive of all mechanisms of injury, including shaking, is required. The American Academy of Pediatrics recommends that pediatricians develop skills in the recognition of signs and symptoms of abusive head injury, including those caused by both shaking and blunt impact, consult with pediatric subspecialists when necessary, and embrace a less mechanistic term, abusive head trauma, when describing an inflicted injury to the head and its contents. (4/09, reaffirmed 3/13)

ACCESS TO OPTIMAL EMERGENCY CARE FOR CHILDREN

Committee on Pediatric Emergency Medicine

ABSTRACT. Millions of pediatric patients require some level of emergency care annually, and significant barriers limit access to appropriate services for large numbers of children. The American Academy of Pediatrics has a strong commitment to identifying barriers to access to emergency care, working to surmount these obstacles, and encouraging, through education and system changes, improved levels of emergency care available to all children. (1/07, reaffirmed 8/10)

ACCF/AHA/AAP RECOMMENDATIONS FOR TRAINING IN PEDIATRIC CARDIOLOGY

American College of Cardiology Foundation, American Heart Association, and American Academy of Pediatrics (12/05, reaffirmed 1/09)

ACHIEVING QUALITY HEALTH SERVICES FOR ADOLESCENTS

Committee on Adolescence

ABSTRACT. In recent years, there has been an increased national focus on assessing and improving the quality of health care. This statement provides recommendations and criteria for assessment of the quality of primary care delivered to adolescents in the United States. Consistent implementation of American Academy of Pediatrics recommendations (periodicity of visits and confidentiality issues), renewed attention to professional quality-improvement activities (access and immunizations) and public education, and modification of existing quality-measurement activities to ensure that quality is delivered are proposed as strategies that would lead to improved care for youth. (6/08, reaffirmed 3/13)

ACTIVE HEALTHY LIVING: PREVENTION OF CHILDHOOD OBESITY THROUGH INCREASED PHYSICAL ACTIVITY

Council on Sports Medicine and Fitness and Council on School Health

ABSTRACT. The current epidemic of inactivity and the associated epidemic of obesity are being driven by multiple factors (societal, technologic, industrial, commercial, financial) and must be addressed likewise on several fronts. Foremost among these are the expansion of school physical education, dissuading children from pursuing sedentary activities, providing suitable role models for physical activity, and making activity-promoting changes in the environment. This statement outlines ways that pediatric health care providers and public health officials can encourage, monitor, and advocate for increased physical activity for children and teenagers. (5/06, reaffirmed 5/09, 8/12)

ADDITIONAL RECOMMENDATIONS FOR USE OF TETANUS TOXOID, REDUCED-CONTENT DIPHTHERIA TOXOID, AND ACELLULAR PERTUSSIS VACCINE (TDAP)

Committee on Infectious Diseases

ABSTRACT. The American Academy of Pediatrics and the Centers for Disease Control and Prevention are amending previous recommendations and making additional recommendations for the use of tetanus toxoid, reduced-content diphtheria toxoid, and acellular pertussis vaccine (Tdap). Review of the results from clinical trials and other studies has revealed no excess reactogenicity when Tdap is given within a short interval after other tetanus- or diphtheria-containing toxoid products, and accrual of postmarketing adverse-events reports reveals an excellent safety record for Tdap. Thus, the recommendation for caution regarding Tdap use within any interval after a tetanus- or

diphtheria-containing toxoid product is removed. Tdap should be given when it is indicated and when no contraindication exists. In further efforts to protect people who are susceptible to pertussis, the American Academy of Pediatrics and Centers for Disease Control and Prevention recommend a single dose of Tdap for children 7 through 10 years of age who were underimmunized with diphtheria-tetanus-acellular pertussis (DTaP). Also, the age for recommendation for Tdap is extended to those aged 65 years and older who have or are likely to have contact with an infant younger than 12 months (eg, health care personnel, grandparents, and other caregivers). (9/11)

ADMISSION AND DISCHARGE GUIDELINES FOR THE PEDIATRIC PATIENT REQUIRING INTERMEDIATE CARE (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine)

ABSTRACT. During the past 3 decades, the specialty of pediatric critical care medicine has grown rapidly, leading to a number of pediatric intensive care units opening across the country. Many patients who are admitted to the hospital require a higher level of care than routine inpatient general pediatric care, yet not to the degree of intensity of pediatric critical care; therefore, an intermediate care level has been developed in institutions providing multidisciplinary subspecialty pediatric care. These patients may require frequent monitoring of vital signs and nursing interventions, but usually they do not require invasive monitoring. The admission of the pediatric intermediate care patient is guided by physiologic parameters depending on the respective organ system involved relative to an institution's resources and capacity to care for a patient in a general care environment. This report provides admission and discharge guidelines for intermediate pediatric care. Intermediate care promotes greater flexibility in patient triage and provides a cost-effective alternative to admission to a pediatric intensive care unit. This level of care may enhance the efficiency of care and make health care more affordable for patients receiving intermediate care. (5/04, reaffirmed 2/08, 1/13)

ADOLESCENT PREGNANCY: CURRENT TRENDS AND ISSUES (CLINICAL REPORT)

Jonathan D. Klein, MD, MPH, and Committee on Adolescence

ABSTRACT. The prevention of unintended adolescent pregnancy is an important goal of the American Academy of Pediatrics and our society. Although adolescent pregnancy and birth rates have been steadily decreasing, many adolescents still become pregnant. Since the last statement on adolescent pregnancy was issued by the Academy in 1998, efforts to prevent adolescent pregnancy have increased, and new observations, technologies, and prevention effectiveness data have emerged. The purpose of this clinical report is to review current trends and issues related to adolescent pregnancy, update practitioners on this topic, and review legal and policy implications of concern to pediatricians. (7/05)

ADOLESCENTS AND HIV INFECTION: THE PEDIATRICIAN'S ROLE IN PROMOTING ROUTINE TESTING

Committee on Pediatric AIDS

ABSTRACT. Pediatricians can play a key role in preventing and controlling HIV infection by promoting risk-reduction counseling and offering routine HIV testing to adolescent and young adult patients. Most sexually active youth do not feel that they are at risk of contracting HIV and have never been tested. Obtaining a sexual history and creating an atmosphere that promotes nonjudgmental risk counseling is a key component of the adolescent visit. In light of increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the Centers for Disease Control and Prevention recommends universal and routine HIV testing for all patients seen in health care settings who are 13 to 64 years of age. There are advances in diagnostics and treatment that help support this recommendation. This policy statement reviews the epidemiologic data and recommends that routine screening be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV. This statement addresses many of the real and perceived barriers that pediatricians face in promoting routine HIV testing for their patients. (10/11)

ADOLESCENTS AND HUMAN IMMUNODEFICIENCY VIRUS INFECTION: THE ROLE OF THE PEDIATRICIAN IN PREVENTION AND INTERVENTION

Committee on Pediatric AIDS and Committee on Adolescence

ABSTRACT. Half of all new human immunodeficiency virus (HIV) infections in the United States occur among young people between the ages of 13 and 24. Sexual transmission accounts for most cases of HIV during adolescence. Pediatricians can play an important role in educating adolescents about HIV prevention, transmission, and testing, with an emphasis on risk reduction, and in advocating for the special needs of adolescents for access to information about HIV. (1/01, reaffirmed 10/03, 1/05)

THE ADOLESCENT'S RIGHT TO CONFIDENTIAL CARE WHEN CONSIDERING ABORTION

Committee on Adolescence

ABSTRACT. In this statement, the American Academy of Pediatrics (AAP) reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. The AAP supports the recommendations presented in the report on mandatory parental consent to abortion by the Council on Ethical and Judicial Affairs of the American Medical Association. Adolescents should be strongly encouraged to involve their parents and other trusted adults in decisions regarding pregnancy termination, and the majority of them voluntarily do so. Legislation mandating parental involvement does not achieve the intended benefit of promoting family communication, but it does increase the risk of harm to the adolescent by delaying access to appropriate medical care.

The statement presents a summary of pertinent current information related to the benefits and risks of legislation requiring mandatory parental involvement in an adolescent's decision to obtain an abortion. The AAP acknowledges and respects the diversity of beliefs about abortion and affirms the value of voluntary parental involvement in decision making by adolescents. (5/96, reaffirmed 5/99, 11/02)

ADVANCED PRACTICE IN NEONATAL NURSING

Committee on Fetus and Newborn

ABSTRACT. The participation of advanced practice registered nurses in neonatal care continues to be accepted and supported by the American Academy of Pediatrics. Recognized categories of advanced practice neonatal nursing are the neonatal clinical nurse specialist and the neonatal nurse practitioner. (5/09)

AGE LIMITS OF PEDIATRICS

Child and Adolescent Health Action Group (5/88, reaffirmed 9/92, 1/97, 3/02, 1/06, 10/11)

AGE TERMINOLOGY DURING THE PERINATAL PERIOD

Committee on Fetus and Newborn

ABSTRACT. Consistent definitions to describe the length of gestation and age in neonates are needed to compare neurodevelopmental, medical, and growth outcomes. The purposes of this policy statement are to review conventional definitions of age during the perinatal period and to recommend use of standard terminology including gestational age, postmenstrual age, chronological age, corrected age, adjusted age, and estimated date of delivery. (11/04, reaffirmed 10/07, 11/08, 1/09)

ALCOHOL USE BY YOUTH AND ADOLESCENTS: A PEDIATRIC CONCERN

Committee on Substance Abuse

ABSTRACT. Alcohol use continues to be a major problem from preadolescence through young adulthood in the United States. Results of recent neuroscience research have substantiated the deleterious effects of alcohol on adolescent brain development and added even more evidence to support the call to prevent and reduce underaged drinking. Pediatricians should be knowledgeable about substance abuse to be able to recognize risk factors for alcohol and other substance abuse among youth, screen for use, provide appropriate brief interventions, and refer to treatment. The integration of alcohol use prevention programs in the community and our educational system from elementary school through college should be promoted by pediatricians and the health care community. Promotion of media responsibility to connect alcohol consumption with realistic consequences should be supported by pediatricians. Additional research into the prevention, screening and identification, brief intervention, and management and treatment of alcohol and other substance use by adolescents continues to be needed to improve evidence-based practices. (4/10)

ALLERGY TESTING IN CHILDHOOD: USING ALLERGEN-SPECIFIC IGE TESTS (CLINICAL REPORT)

Scott H. Sicherer, MD; Robert A. Wood, MD; and Section on Allergy and Immunology

ABSTRACT. A variety of triggers can induce common pediatric allergic diseases which include asthma, allergic rhinitis, atopic dermatitis, food allergy, and anaphylaxis. Allergy testing serves to confirm an allergic trigger suspected on the basis of history. Tests for allergen-specific immunoglobulin E (IgE) are performed by in vitro assays or skin tests. The tests are excellent for identifying a sensitized state in which allergen-specific IgE is present, and may identify triggers to be eliminated and help guide immunotherapy treatment. However, a positive test result does not always equate with clinical allergy. Newer enzymatic assays based on anti-IgE antibodies have supplanted the radioallergosorbent test (RAST). This clinical report focuses on allergen-specific IgE testing, emphasizing that the medical history and knowledge of disease characteristics are crucial for rational test selection and interpretation. (12/11)

ALL-TERRAIN VEHICLE INJURY PREVENTION: TWO-, THREE-, AND FOUR-WHEELED UNLICENSED MOTOR VEHICLES

Committee on Injury and Poison Prevention

ABSTRACT. Since 1987, the American Academy of Pediatrics (AAP) has had a policy about the use of motorized cycles and all-terrain vehicles (ATVs) by children. The purpose of this policy statement is to update and strengthen previous policy. This statement describes the various kinds of motorized cycles and ATVs and outlines the epidemiologic characteristics of deaths and injuries related to their use by children in light of the 1987 consent decrees entered into by the US Consumer Product Safety Commission and the manufacturers of ATVs. Recommendations are made for public, patient, and parent education by pediatricians; equipment modifications; the use of safety equipment; and the development and improvement of safer off-road trails and responsive emergency medical systems. In addition, the AAP strengthens its recommendation for passage of legislation in all states prohibiting the use of 2- and 4-wheeled off-road vehicles by children younger than 16 years, as well as a ban on the sale of new and used 3-wheeled ATVs, with a recall of all used 3-wheeled ATVs. (6/00, reaffirmed 5/04, 1/07)

AMBIENT AIR POLLUTION: HEALTH HAZARDS TO CHILDREN

Committee on Environmental Health

ABSTRACT. Ambient (outdoor) air pollution is now recognized as an important problem, both nationally and worldwide. Our scientific understanding of the spectrum of health effects of air pollution has increased, and numerous studies are finding important health effects from air pollution at levels once considered safe. Children and infants are among the most susceptible to many of the air pollutants. In addition to associations between air pollution and respiratory symptoms, asthma exacerbations, and asthma hospitalizations, recent studies have found links between air pollution and preterm birth, infant mortality, deficits in lung growth, and possibly, develop-

ment of asthma. This policy statement summarizes the recent literature linking ambient air pollution to adverse health outcomes in children and includes a perspective on the current regulatory process. The statement provides advice to pediatricians on how to integrate issues regarding air quality and health into patient education and children's environmental health advocacy and concludes with recommendations to the government on promotion of effective air-pollution policies to ensure protection of children's health. (12/04, reaffirmed 4/09)

ANTENATAL COUNSELING REGARDING RESUSCITATION AT AN EXTREMELY LOW GESTATIONAL AGE (CLINICAL REPORT)

Daniel G. Batton, MD, and Committee on Fetus and Newborn

ABSTRACT. The anticipated delivery of an extremely low gestational age infant raises difficult questions for all involved, including whether to initiate resuscitation after delivery. Each institution caring for women at risk of delivering extremely preterm infants should provide comprehensive and consistent guidelines for antenatal counseling. Parents should be provided the most accurate prognosis possible on the basis of all the factors known to affect outcome for a particular case. Although it is not feasible to have specific criteria for when the initiation of resuscitation should or should not be offered, the following general guidelines are suggested. If the physicians involved believe there is no chance for survival, resuscitation is not indicated and should not be initiated. When a good outcome is considered very unlikely, the parents should be given the choice of whether resuscitation should be initiated, and clinicians should respect their preference. Finally, if a good outcome is considered reasonably likely, clinicians should initiate resuscitation and, together with the parents, continually reevaluate whether intensive care should be continued. Whenever resuscitation is considered an option, a qualified individual, preferably a neonatologist, should be involved and should be present in the delivery room to manage this complex situation. Comfort care should be provided for all infants for whom resuscitation is not initiated or is not successful. (6/09)

ANTIVIRAL THERAPY AND PROPHYLAXIS FOR INFLUENZA IN CHILDREN (CLINICAL REPORT)

Committee on Infectious Diseases

ABSTRACT. Antiviral agents are available that are safe and effective for the treatment and prophylaxis of influenza virus infections in children. The neuraminidase inhibitors (oseltamivir [Tamiflu] and zanamivir [Relenza]) are preferred agents because of current widespread resistance to the adamantanes (amantadine [Symmetrel] and rimantadine [Flumadine]). Therapy should be provided to children with influenza infection who are at high risk of severe infection and to children with moderate-to-severe influenza infection who may benefit from a decrease in the duration of symptoms. Prophylaxis should be provided (1) to high-risk children who have not yet received immunization and during the 2 weeks after immunization, (2) to unimmunized family members and health care professionals with close contact with high-risk unimmunized children or infants who are younger than 6 months, and (3) for control of influenza outbreaks in unimmunized staff and children in an institutional setting. Testing of current H5N1 avian influenza virus isolates, the potential agents of pandemic influenza, suggests susceptibility to oseltamivir and zanamivir. Because no prospective data exist on the efficacy of these agents in humans for H5N1 strains, the dosage and duration of therapy in adults and children may differ from those documented to be effective for epidemic influenza strains. (4/07, reaffirmed 7/10)

THE APGAR SCORE

Committee on Fetus and Newborn (joint with American College of Obstetricians and Gynecologists)

ABSTRACT. The Apgar score provides a convenient shorthand for reporting the status of the newborn infant and the response to resuscitation. The Apgar score has been used inappropriately to predict specific neurologic outcome in the term infant. There are no consistent data on the significance of the Apgar score in preterm infants. The Apgar score has limitations, and it is inappropriate to use it alone to establish the diagnosis of asphyxia. An Apgar score assigned during resuscitation is not equivalent to a score assigned to a spontaneously breathing infant. An expanded Apgar score reporting form will account for concurrent resuscitative interventions and provide information to improve systems of perinatal and neonatal care. (4/06, reaffirmed 1/09)

APPLICATION OF THE RESOURCE-BASED RELATIVE VALUE SCALE SYSTEM TO PEDIATRICS

Committee on Coding and Nomenclature

ABSTRACT. With an increased focus on payment and productivity measurement in health care, it is essential to understand the genesis and principles behind the Medicare Resource-Based Relative Value Scale (RBRVS) physician fee schedule. The majority of third-party payers, including a growing number of Medicaid programs and commercial payers, use variations of the Medicare RBRVS as their basis for physician payment. Many group practices have also adopted this system to benchmark physician productivity and determine variable compensation and bonus payments. Because pediatric care is underrepresented in any Medicare-based payment system analysis, unique aspects of physician work and practice expense may not be accurately reflected in the total relative value units (RVUs) for certain pediatric services. Despite this potential limitation, the American Academy of Pediatrics supports the use of *Current Procedural Terminology* (CPT) codes to report unique physician work and the RBRVS physician fee schedule as a uniform payment system. The American Academy of Pediatrics will continue to work to rectify perceived inequities of the RBRVS system as they pertain to pediatrics. (12/08)

ASSESSMENT AND MANAGEMENT OF INGUINAL HERNIA IN INFANTS (CLINICAL REPORT)

Kasper S. Wang, MD; Committee on Fetus and Newborn; and Section on Surgery

ABSTRACT. Inguinal hernia repair in infants is a routine surgical procedure. However, numerous issues, including timing of the repair, the need to explore the contralateral groin, use of laparoscopy, and anesthetic approach, remain unsettled. Given the lack of compelling data, con-

sideration should be given to large, prospective, randomized controlled trials to determine best practices for the management of inguinal hernias in infants. (9/12)

ATHLETIC PARTICIPATION BY CHILDREN AND ADOLESCENTS WHO HAVE SYSTEMIC HYPERTENSION

Rebecca A. Demorest, MD; Reginald L. Washington, MD; and Council on Sports Medicine and Fitness

ABSTRACT. Children and adolescents who have hypertension may be at risk for complications when exercise causes their blood pressure to rise even higher. The purpose of this statement is to update recommendations concerning the athletic participation of individuals with hypertension, including special populations such as those with spinal cord injuries or obesity, by using the guidelines from "The 36th Bethesda Conference: Eligibility Recommendations for Competitive Athletes with Cardiovascular Abnormalities"; "The Fourth Report on the Diagnosis, Evaluation, and Treatment of High Blood Pressure in Children and Adolescents"; and "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure." (5/10, reaffirmed 5/13)

AUDITORY INTEGRATION TRAINING AND FACILITATED COMMUNICATION FOR AUTISM

Committee on Children With Disabilities

ABSTRACT. This statement reviews the basis for two new therapies for autism—auditory integration training and facilitative communication. Both therapies seek to improve communication skills. Currently available information does not support the claims of proponents that these treatments are efficacious. Their use does not appear warranted at this time, except within research protocols. (8/98, reaffirmed 5/02, 1/06, 12/09)

BASEBALL AND SOFTBALL

Council on Sports Medicine and Fitness

ABSTRACT. Baseball and softball are among the most popular and safest sports in which children and adolescents participate. Nevertheless, traumatic and overuse injuries occur regularly, including occasional catastrophic injury and even death. Safety of the athlete is a constant focus of attention among those responsible for modifying rules. Understanding the stresses placed on the arm, especially while pitching, led to the institution of rules controlling the quantity of pitches thrown in youth baseball and established rest periods between pitching assignments. Similarly, field maintenance and awareness of environmental conditions as well as equipment maintenance and creative prevention strategies are critically important in minimizing the risk of injury. This statement serves as a basis for encouraging safe participation in baseball and softball. This statement has been endorsed by the Canadian Paediatric Society. (2/12)

BICYCLE HELMETS

Committee on Injury and Poison Prevention

ABSTRACT. Bicycling remains one of the most popular recreational sports among children in America and is the leading cause of recreational sports injuries treated in emergency departments. An estimated 23 000 children younger than 21 years sustained head injuries (excluding the face) while bicycling in 1998. The bicycle helmet is a very effective device that can prevent the occurrence of up to 88% of serious brain injuries. Despite this, most children do not wear a helmet each time they ride a bicycle, and adolescents are particularly resistant to helmet use. Recently, a group of national experts and government agencies renewed the call for all bicyclists to wear helmets. This policy statement describes the role of the pediatrician in helping attain universal helmet use among children and teens for each bicycle ride. (10/01, reaffirmed 1/05, 2/08, 11/11)

BONE DENSITOMETRY IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Laura K. Bachrach, MD; Irene N. Sills, MD; and Section on Endocrinology

ABSTRACT. Concern for bone fragility in children and adolescents has led to increased interest in bone densitometry. Pediatric patients with genetic and acquired chronic diseases, immobility, and inadequate nutrition may fail to achieve the expected gains in bone size, mass, and strength, which leaves them vulnerable to fracture. In older adults, bone densitometry has been shown to predict fracture risk and reflect response to therapy. The role of densitometry in the management of children at risk of bone fragility is less certain. This clinical report summarizes the current knowledge about bone densitometry in the pediatric population, including indications for its use, interpretation of results, and its risks and costs. This report emphasizes consensus statements generated at the 2007 Pediatric Position Development Conference of the International Society of Clinical Densitometry by an international panel of bone experts. Some of these recommendations are evidence-based, and others reflect expert opinion, because the available data are inadequate. The statements from this and other expert panels have provided general guidance to the pediatrician, but decisions about ordering and interpreting bone densitometry still require clinical judgment. Ongoing studies will help to better define the indications and best methods for assessing bone strength in children and the clinical factors that contribute to fracture risk. (12/10)

BOXING PARTICIPATION BY CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness (joint with Canadian Paediatric Society Healthy Active Living and Sports Medicine Committee)

ABSTRACT. Thousands of boys and girls younger than 19 years participate in boxing in North America. Although boxing provides benefits for participants, including exercise, self-discipline, and self-confidence, the sport of boxing encourages and rewards deliberate blows to the head and face. Participants in boxing are at risk of head, face, and neck injuries, including chronic and even fatal neurologic injuries. Concussions are one of the most common injuries that occur with boxing. Because of the risk of head and facial injuries, the American Academy of Pediatrics and the Canadian Paediatric Society oppose boxing as a sport for children and adolescents. These organizations recommend that physicians vigorously oppose boxing in youth and encourage patients to participate in

alternative sports in which intentional head blows are not central to the sport. (8/11)

BREASTFEEDING AND THE USE OF HUMAN MILK

Section on Breastfeeding

ABSTRACT. Breastfeeding and human milk are the normative standards for infant feeding and nutrition. Given the documented short- and long-term medical and neurodevelopmental advantages of breastfeeding, infant nutrition should be considered a public health issue and not only a lifestyle choice. The American Academy of Pediatrics reaffirms its recommendation of exclusive breastfeeding for about 6 months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for 1 year or longer as mutually desired by mother and infant. Medical contraindications to breastfeeding are rare. Infant growth should be monitored with the World Health Organization (WHO) Growth Curve Standards to avoid mislabeling infants as underweight or failing to thrive. Hospital routines to encourage and support the initiation and sustaining of exclusive breastfeeding should be based on the American Academy of Pediatrics-endorsed WHO/UNICEF "Ten Steps to Successful Breastfeeding." National strategies supported by the US Surgeon General's Call to Action, the Centers for Disease Control and Prevention, and The Joint Commission are involved to facilitate breastfeeding practices in US hospitals and communities. Pediatricians play a critical role in their practices and communities as advocates of breastfeeding and thus should be knowledgeable about the health risks of not breastfeeding, the economic benefits to society of breastfeeding, and the techniques for managing and supporting the breastfeeding dyad. The "Business Case for Breastfeeding" details how mothers can maintain lactation in the workplace and the benefits to employers who facilitate this practice. (2/12)

THE BUILT ENVIRONMENT: DESIGNING COMMUNITIES TO PROMOTE PHYSICAL ACTIVITY IN CHILDREN

Committee on Environmental Health

ABSTRACT. An estimated 32% of American children are overweight, and physical inactivity contributes to this high prevalence of overweight. This policy statement highlights how the built environment of a community affects children's opportunities for physical activity. Neighborhoods and communities can provide opportunities for recreational physical activity with parks and open spaces, and policies must support this capacity. Children can engage in physical activity as a part of their daily lives, such as on their travel to school. Factors such as school location have played a significant role in the decreased rates of walking to school, and changes in policy may help to increase the number of children who are able to walk to school. Environment modification that addresses risks associated with automobile traffic is likely to be conducive to more walking and biking among children. Actions that reduce parental perception and fear of crime may promote outdoor physical activity. Policies that promote more active lifestyles among children and adolescents will enable them to achieve the recommended 60 minutes of daily physical activity. By working with community partners, pediatricians can participate in establishing communities designed for activity and health. (5/09, reaffirmed 1/13)

CALCIUM AND VITAMIN D REQUIREMENTS OF ENTERALLY FED PRETERM INFANTS (CLINICAL REPORT)

Steven A. Abrams, MD, and Committee on Nutrition

ABSTRACT. Bone health is a critical concern in managing preterm infants. Key nutrients of importance are calcium, vitamin D, and phosphorus. Although human milk is critical for the health of preterm infants, it is low in these nutrients relative to the needs of the infants during growth. Strategies should be in place to fortify human milk for preterm infants with birth weight <1800 to 2000 g and to ensure adequate mineral intake during hospitalization and after hospital discharge. Biochemical monitoring of very low birth weight infants should be performed during their hospitalization. Vitamin D should be provided at 200 to 400 IU/day both during hospitalization and after discharge from the hospital. Infants with radiologic evidence of rickets should have efforts made to maximize calcium and phosphorus intake by using available commercial products and, if needed, direct supplementation with these minerals. (4/13)

CARDIOVASCULAR HEALTH SUPERVISION FOR INDIVIDUALS AFFECTED BY DUCHENNE OR BECKER MUSCULAR DYSTROPHY (CLINICAL REPORT)

Section on Cardiology and Cardiac Surgery

ABSTRACT. Duchenne muscular dystrophy is the most common and severe form of the childhood muscular dystrophies. The disease is typically diagnosed between 3 and 7 years of age and follows a predictable clinical course marked by progressive skeletal muscle weakness with loss of ambulation by 12 years of age. Death occurs in early adulthood secondary to respiratory or cardiac failure. Becker muscular dystrophy is less common and has a milder clinical course but also results in respiratory and cardiac failure. The natural history of the cardiomyopathy in these diseases has not been well established. As a result, patients traditionally present for cardiac evaluation only after clinical symptoms become evident. The purpose of this policy statement is to provide recommendations for optimal cardiovascular evaluation to health care specialists caring for individuals in whom the diagnosis of Duchenne or Becker muscular dystrophy has been confirmed. (12/05, reaffirmed 1/09)

CARDIOVASCULAR MONITORING AND STIMULANT DRUGS FOR ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

James M. Perrin, MD; Richard A. Friedman, MD; Timothy K. Knilans, MD; Black Box Working Group; and Section on Cardiology and Cardiac Surgery

ABSTRACT. A recent American Heart Association (AHA) statement recommended electrocardiograms (ECGs) routinely for children before they start medications to treat attention-deficit/hyperactivity disorder (ADHD). The AHA statement reflected the thoughtful work of a group committed to improving the health of children with heart disease. However, the recommendation to obtain

an ECG before starting medications for treating ADHD contradicts the carefully considered and evidence-based recommendations of the American Academy of Child and Adolescent Psychiatry and the American Academy of Pediatrics (AAP). These organizations have concluded that sudden cardiac death (SCD) in persons taking medications for ADHD is a very rare event, occurring at rates no higher than those in the general population of children and adolescents. Both of these groups also noted the lack of any evidence that the routine use of ECG screening before beginning medication for ADHD treatment would prevent sudden death. The AHA statement pointed out the importance of detecting silent but clinically important cardiac conditions in children and adolescents, which is a goal that the AAP shares. The primary purpose of the AHA statement is to prevent cases of SCD that may be related to stimulant medications. The recommendations of the AAP and the rationale for these recommendations are the subject of this statement. (8/08)

CARE OF ADOLESCENT PARENTS AND THEIR CHILDREN (CLINICAL REPORT)

Jorge L. Pinzon, MD; Veronnie F. Jones, MD; Committee on Adolescence; and Committee on Early Childhood

ABSTRACT. Teen pregnancy and parenting remain an important public health issue in the United States and the world, and many children live with their adolescent parents alone or as part of an extended family. A significant proportion of teen parents reside with their family of origin, significantly affecting the multigenerational family structure. Repeated births to teen parents are also common. This clinical report updates a previous policy statement on care of the adolescent parent and their children and addresses medical and psychosocial risks specific to this population. Challenges unique to teen parents and their children are reviewed, along with suggestions for the pediatrician on models for intervention and care. (11/12)

CARE OF THE ADOLESCENT SEXUAL ASSAULT VICTIM (CLINICAL REPORT)

Miriam Kaufman, MD, and Committee on Adolescence

ABSTRACT. Sexual assault is a broad-based term that encompasses a wide range of sexual victimizations including rape. Since the American Academy of Pediatrics published its last policy statement on sexual assault in 2001, additional information and data have emerged about sexual assault and rape in adolescents and the treatment and management of the adolescent who has been a victim of sexual assault. This report provides new information to update physicians and focuses on assessment and care of sexual assault victims in the adolescent population. (8/08)

CARE COORDINATION IN THE MEDICAL HOME: INTEGRATING HEALTH AND RELATED SYSTEMS OF CARE FOR CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Council on Children With Disabilities

ABSTRACT. Care coordination is a process that facilitates the linkage of children and their families with appropriate services and resources in a coordinated effort to achieve good health. Care coordination for children with special health care needs often is complicated because there is no single point of entry into the multiple systems of care, and complex criteria frequently determine the availability of funding and services among public and private payers. Economic and sociocultural barriers to coordination of care exist and affect families and health care professionals. In their important role of providing a medical home for all children, primary care physicians have a vital role in the process of care coordination, in concert with the family. (11/05)

CAREGIVER-FABRICATED ILLNESS IN A CHILD: A MANIFESTATION OF CHILD MALTREATMENT (CLINICAL REPORT)

Emalee G. Flaherty, MD; Harriet L. MacMillan, MD; and Committee on Child Abuse and Neglect

ABSTRACT. Caregiver-fabricated illness in a child is a form of child maltreatment caused by a caregiver who falsifies and/or induces a child's illness, leading to unnecessary and potentially harmful medical investigations and/or treatment. This condition can result in significant morbidity and mortality. Although caregiver-fabricated illness in a child has been widely known as Munchausen syndrome by proxy, there is ongoing discussion about alternative names, including pediatric condition falsification, factitious disorder (illness) by proxy, child abuse in the medical setting, and medical child abuse. Because it is a relatively uncommon form of maltreatment, pediatricians need to have a high index of suspicion when faced with a persistent or recurrent illness that cannot be explained and that results in multiple medical procedures or when there are discrepancies between the history, physical examination, and health of a child. This report updates the previous clinical report "Beyond Munchausen Syndrome by Proxy: Identification and Treatment of Child Abuse in the Medical Setting." The authors discuss the need to agree on appropriate terminology, provide an update on published reports of new manifestations of fabricated medical conditions, and discuss approaches to assessment, diagnosis, and management, including how best to protect the child from further harm. (8/13)

See full text on page 471.

THE CHANGING CONCEPT OF SUDDEN INFANT DEATH SYNDROME: DIAGNOSTIC CODING SHIFTS, CONTROVERSIES REGARDING THE SLEEPING ENVIRONMENT, AND NEW VARIABLES TO CONSIDER IN REDUCING RISK

Task Force on Sudden Infant Death Syndrome

ABSTRACT. There has been a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed down for sleep in a nonprone position. Although the SIDS rate continues to fall, some of the recent decrease of the last several years may be a result of coding shifts to other causes of unexpected infant deaths. Since the AAP published its last statement on SIDS in 2000, several issues have become relevant, including the significant risk of side sleeping position; the AAP no longer recognizes side sleeping as a reasonable alternative to fully supine sleeping. The AAP also stresses the need to avoid redundant soft bedding and soft objects in the infant's sleeping environment, the hazards of adults sleeping with an infant in the same bed, the SIDS risk reduction associated with having infants sleep

in the same room as adults and with using pacifiers at the time of sleep, the importance of educating secondary caregivers and neonatology practitioners on the importance of "back to sleep," and strategies to reduce the incidence of positional plagiocephaly associated with supine positioning. This statement reviews the evidence associated with these and other SIDS-related issues and proposes new recommendations for further reducing SIDS risk. (11/05, reaffirmed 5/08)

CHEERLEADING INJURIES: EPIDEMIOLOGY AND RECOMMENDATIONS FOR PREVENTION

Council on Sports Medicine and Fitness

ABSTRACT. Over the last 30 years, cheerleading has increased dramatically in popularity and has evolved from leading the crowd in cheers at sporting events into a competitive, year-round sport involving complex acrobatic stunts and tumbling. Consequently, cheerleading injuries have steadily increased over the years in both number and severity. Sprains and strains to the lower extremities are the most common injuries. Although the overall injury rate remains relatively low, cheerleading has accounted for approximately 66% of all catastrophic injuries in high school girl athletes over the past 25 years. Risk factors for injuries in cheerleading include higher BMI, previous injury, cheering on harder surfaces, performing stunts, and supervision by a coach with low level of training and experience. This policy statement describes the epidemiology of cheerleading injuries and provides recommendations for injury prevention. (10/12)

CHEMICAL-BIOLOGICAL TERRORISM AND ITS IMPACT ON CHILDREN

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT. Children remain potential victims of chemical or biological terrorism. In recent years, children have even been specific targets of terrorist acts. Consequently, it is necessary to address the needs that children would face after a terrorist incident. A broad range of public health initiatives have occurred since September 11, 2001. Although the needs of children have been addressed in many of them, in many cases, these initiatives have been inadequate in ensuring the protection of children. In addition, public health and health care system preparedness for terrorism has been broadened to the so-called all-hazards approach, in which response plans for terrorism are blended with plans for a public health or health care system response to unintentional disasters (eg, natural events such as earthquakes or pandemic flu or manmade catastrophes such as a hazardous-materials spill). In response to new principles and programs that have appeared over the last 5 years, this policy statement provides an update of the 2000 policy statement. The roles of both the pediatrician and public health agencies continue to be emphasized; only a coordinated effort by pediatricians and public health can ensure that the needs of children, including emergency protocols in schools or child care centers, decontamination protocols, and mental health interventions, will be successful. (9/06, reaffirmed 1/11)

CHEMICAL-MANAGEMENT POLICY: PRIORITIZING CHILDREN'S HEALTH

Council on Environmental Health

ABSTRACT. The American Academy of Pediatrics recommends that chemical-management policy in the United States be revised to protect children and pregnant women and to better protect other populations. The Toxic Substance Control Act (TSCA) was passed in 1976. It is widely recognized to have been ineffective in protecting children, pregnant women, and the general population from hazardous chemicals in the marketplace. It does not take into account the special vulnerabilities of children in attempting to protect the population from chemical hazards. Its processes are so cumbersome that in its more than 30 years of existence, the TSCA has been used to regulate only 5 chemicals or chemical classes of the tens of thousands of chemicals that are in commerce. Under the TSCA, chemical companies have no responsibility to perform premarket testing or postmarket follow-up of the products that they produce; in fact, the TSCA contains disincentives for the companies to produce such data. Voluntary programs have been inadequate in resolving problems. Therefore, chemical-management policy needs to be rewritten in the United States. Manufacturers must be responsible for developing information about chemicals before marketing. The US Environmental Protection Agency must have the authority to demand additional safety data about a chemical and to limit or stop the marketing of a chemical when there is a high degree of suspicion that the chemical might be harmful to children, pregnant women, or other populations. (4/11)

CHILD ABUSE, CONFIDENTIALITY, AND THE HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT

Committee on Child Abuse and Neglect

ABSTRACT. The federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 has significantly affected clinical practice, particularly with regard to how patient information is shared. HIPAA addresses the security and privacy of patient health data, ensuring that information is released appropriately with patient or guardian consent and knowledge. However, when child abuse or neglect is suspected in a clinical setting, the physician may determine that release of information without consent is necessary to ensure the health and safety of the child. This policy statement provides an overview of HIPAA regulations with regard to the role of the pediatrician in releasing or reviewing patient health information when the patient is a child who is a suspected victim of abuse or neglect. This statement is based on the most current regulations provided by the US Department of Health and Human Services and is subject to future changes and clarifications as updates are provided. (12/09)

THE CHILD IN COURT: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. When children come to court as witnesses, or when their needs are decided in a courtroom, they face unique stressors from the legal proceeding and from the social predicament that resulted in court action. Effective

pediatric support and intervention requires an understanding of the situations that bring children to court and the issues that will confront children and child advocates in different court settings. (11/99, reaffirmed 11/02)

CHILD FATALITY REVIEW

Cindy W. Christian, MD; Robert D. Sege, MD, PhD; Committee on Child Abuse and Neglect; Committee on Injury, Violence, and Poison Prevention; and Council on Community Pediatrics

ABSTRACT. Injury remains the leading cause of pediatric mortality and requires public health approaches to reduce preventable deaths. Child fatality review teams, first established to review suspicious child deaths involving abuse or neglect, have expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence. Approximately half of all states report reviewing child deaths from all causes, and the process of fatality review has identified effective local and state prevention strategies for reducing child deaths. This expanded approach can be a powerful tool in understanding the epidemiology and preventability of child death locally, regionally, and nationally; improving accuracy of vital statistics data; and identifying public health and legislative strategies for reducing preventable child fatalities. The American Academy of Pediatrics supports the development of federal and state legislation to enhance the child fatality review process and recommends that pediatricians become involved in local and state child death reviews. (8/10)

CHILD LIFE SERVICES

Committee on Hospital Care and Child Life Council

ABSTRACT. Child life programs have become standard in most large pediatric centers and even on some smaller pediatric inpatient units to address the psychosocial concerns that accompany hospitalization and other health care experiences. The child life specialist focuses on the strengths and sense of well-being of children while promoting their optimal development and minimizing the adverse effects of children's experiences in health care or other potentially stressful settings. Using play and psychological preparation as primary tools, child life interventions facilitate coping and adjustment at times and under circumstances that might prove overwhelming otherwise. Play and age-appropriate communication may be used to (1) promote optimal development, (2) present information, (3) plan and rehearse useful coping strategies for medical events or procedures, (4) work through feelings about past or impending experiences, and (5) establish therapeutic relationships with children and parents to support family involvement in each child's care, with continuity across the care continuum. The benefits of this collaborative work with the family and health care team are not limited to the health care setting; it may also optimize reintegration into schools and the community. (10/06, reaffirmed 2/12)

CHILD PASSENGER SAFETY

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Child passenger safety has dramatically evolved over the past decade; however, motor vehicle crashes continue to be the leading cause of death of children 4 years and older. This policy statement provides 4 evidence-based recommendations for best practices in the choice of a child restraint system to optimize safety in passenger vehicles for children from birth through adolescence: (1) rear-facing car safety seats for most infants up to 2 years of age; (2) forward-facing car safety seats for most children through 4 years of age; (3) belt-positioning booster seats for most children through 8 years of age; and (4) lap-and-shoulder seat belts for all who have outgrown booster seats. In addition, a fifth evidence-based recommendation is for all children younger than 13 years to ride in the rear seats of vehicles. It is important to note that every transition is associated with some decrease in protection; therefore, parents should be encouraged to delay these transitions for as long as possible. These recommendations are presented in the form of an algorithm that is intended to facilitate implementation of the recommendations by pediatricians to their patients and families and should cover most situations that pediatricians will encounter in practice. The American Academy of Pediatrics urges all pediatricians to know and promote these recommendations as part of child passenger safety anticipatory guidance at every health-supervision visit. (3/11)

CHILD PASSENGER SAFETY (TECHNICAL REPORT)

Dennis R. Durbin, MD, MSCE, and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Despite significant reductions in the number of children killed in motor vehicle crashes over the past decade, crashes continue to be the leading cause of death for children 4 years and older. Therefore, the American Academy of Pediatrics continues to recommend inclusion of child passenger safety anticipatory guidance at every health-supervision visit. This technical report provides a summary of the evidence in support of 5 recommendations for best practices to optimize safety in passenger vehicles for children from birth through adolescence that all pediatricians should know and promote in their routine practice. These recommendations are presented in the revised policy statement on child passenger safety in the form of an algorithm that is intended to facilitate their implementation by pediatricians with their patients and families. The algorithm is designed to cover the majority of situations that pediatricians will encounter in practice. In addition, a summary of evidence on a number of additional issues that affect the safety of children in motor vehicles, including the proper use and installation of child restraints, exposure to air bags, travel in pickup trucks, children left in or around vehicles, and the importance of restraint laws, is provided. Finally, this technical report provides pediatricians with a number of resources for additional information to use when providing anticipatory guidance to families. (3/11)

CHILDREN, ADOLESCENTS, AND ADVERTISING
Committee on Communications
ABSTRACT. Advertising is a pervasive influence on children and adolescents. Young people view more than 40 000 ads per year on television alone and increasingly are being exposed to advertising on the Internet, in magazines, and in schools. This exposure may contribute significantly to childhood and adolescent obesity, poor nutrition, and cigarette and alcohol use. Media education has been shown to be effective in mitigating some of the negative effects of advertising on children and adolescents. (12/06, reaffirmed 3/10)

CHILDREN, ADOLESCENTS, AND THE MEDIA
Council on Communications and Media
ABSTRACT. Media, from television to the "new media" (including cell phones, iPads, and social media), are a dominant force in children's lives. Although television is still the predominant medium for children and adolescents, new technologies are increasingly popular. The American Academy of Pediatrics continues to be concerned by evidence about the potential harmful effects of media messages and images; however, important positive and prosocial effects of media use should also be recognized. Pediatricians are encouraged to take a media history and ask 2 media questions at every well-child visit: How much recreational screen time does your child or teenager consume daily? Is there a television set or Internet-connected device in the child's bedroom? Parents are encouraged to establish a family home use plan for all media. Media influences on children and teenagers should be recognized by schools, policymakers, product advertisers, and entertainment producers. (10/13)
See full text on page 481.

CHILDREN, ADOLESCENTS, OBESITY, AND THE MEDIA
Council on Communications and Media
ABSTRACT. Obesity has become a worldwide public health problem. Considerable research has shown that the media contribute to the development of child and adolescent obesity, although the exact mechanism remains unclear. Screen time may displace more active pursuits, advertising of junk food and fast food increases children's requests for those particular foods and products, snacking increases while watching TV or movies, and late-night screen time may interfere with getting adequate amounts of sleep, which is a known risk factor for obesity. Sufficient evidence exists to warrant a ban on junk-food or fast-food advertising in children's TV programming. Pediatricians need to ask 2 questions about media use at every well-child or well-adolescent visit: (1) How much screen time is being spent per day? and (2) Is there a TV set or Internet connection in the child's bedroom? (7/11)

CHILDREN, ADOLESCENTS, SUBSTANCE ABUSE, AND THE MEDIA
Victor C. Strasburger, MD, and Council on Communications and Media
ABSTRACT. The causes of adolescent substance use are multifactorial, but the media can play a key role. Tobacco and alcohol represent the 2 most significant drug threats to adolescents. More than $25 billion per year is spent on advertising for tobacco, alcohol, and prescription drugs, and such advertising has been shown to be effective. Digital media are increasingly being used to advertise drugs. In addition, exposure to PG-13– and R-rated movies at an early age may be a major factor in the onset of adolescent tobacco and alcohol use. The American Academy of Pediatrics recommends a ban on all tobacco advertising in all media, limitations on alcohol advertising, avoiding exposure of young children to substance-related (tobacco, alcohol, prescription drugs, illegal drugs) content on television and in PG-13– and R-rated movies, incorporating the topic of advertising and media into all substance abuse–prevention programs, and implementing media education programs in the classroom. (9/10)

CHILDREN, ADOLESCENTS, AND TELEVISION
Committee on Public Education
ABSTRACT. This statement describes the possible negative health effects of television viewing on children and adolescents, such as violent or aggressive behavior, substance use, sexual activity, obesity, poor body image, and decreased school performance. In addition to the television ratings system and the v-chip (electronic device to block programming), media education is an effective approach to mitigating these potential problems. The American Academy of Pediatrics offers a list of recommendations on this issue for pediatricians and for parents, the federal government, and the entertainment industry. (2/01)

CHILDREN AS HEMATOPOIETIC STEM CELL DONORS
Committee on Bioethics
ABSTRACT. In the past half-century, hematopoietic stem cell transplantation has become standard treatment for a variety of diseases in children and adults, including selected hematologic malignancies, immunodeficiencies, hemoglobinopathies, bone marrow failure syndromes, and congenital metabolic disorders. There are 3 sources of allogeneic hematopoietic stem cells: bone marrow, peripheral blood, and umbilical cord blood; each has its own benefits and risks. Children often serve as hematopoietic stem cell donors, most commonly for their siblings. HLA-matched biological siblings are generally preferred as donors because of reduced risks of transplant-related complications as compared with unrelated donors. This statement includes a discussion of the ethical considerations regarding minors serving as stem cell donors, using the traditional benefit/burden calculation from the perspectives of both the donor and the recipient. The statement also includes an examination of the circumstances under which a minor may ethically participate as a hematopoietic stem cell donor, how the risks can be minimized, what the informed-consent process should entail, the role for a donor advocate (or some similar mechanism), and other ethical concerns. The American Academy of Pediatrics holds that minors can ethically serve as stem cell donors when specific criteria are fulfilled. (1/10)

CHILDREN IN PICKUP TRUCKS

Committee on Injury and Poison Prevention

ABSTRACT. Pickup trucks have become increasingly popular in the United States. A recent study found that in crashes involving fatalities, cargo area passengers were 3 times more likely to die than were occupants in the cab. Compared with restrained cab occupants, the risk of death for those in the cargo area was 8 times higher. Furthermore, the increased use of extended-cab pickup trucks and air bag-equipped front passenger compartments creates concerns about the safe transport of children. The most effective preventive strategies are the legislative prohibition of travel in the cargo area and requirements for age-appropriate restraint use and seat selection in the cab. Parents should select vehicles that are appropriate for the safe transportation needs of the family. Physicians have an important role in counseling families and advocating public policy measures to reduce the number of deaths and injuries to occupants of pickup trucks. (10/00, reaffirmed 5/04, 1/07)

CHRONIC ABDOMINAL PAIN IN CHILDREN (CLINICAL REPORT)

Subcommittee on Chronic Abdominal Pain (joint with North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition)

ABSTRACT. Children and adolescents with chronic abdominal pain pose unique challenges to their caregivers. Affected children and their families experience distress and anxiety that can interfere with their ability to perform regular daily activities. Although chronic abdominal pain in children is usually attributable to a functional disorder rather than organic disease, numerous misconceptions, insufficient knowledge among health care professionals, and inadequate application of knowledge may contribute to a lack of effective management. This clinical report accompanies a technical report (see page e370 in this issue) on childhood chronic abdominal pain and provides guidance for the clinician in the evaluation and treatment of children with chronic abdominal pain. The recommendations are based on the evidence reviewed in the technical report and on consensus achieved among subcommittee members. (3/05)

CHRONIC ABDOMINAL PAIN IN CHILDREN (TECHNICAL REPORT)

Subcommittee on Chronic Abdominal Pain (joint with North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition)

ABSTRACT. Chronic abdominal pain, defined as long-lasting intermittent or constant abdominal pain, is a common pediatric problem encountered by primary care physicians, medical subspecialists, and surgical specialists. Chronic abdominal pain in children is usually functional, that is, without objective evidence of an underlying organic disorder. The Subcommittee on Chronic Abdominal Pain of the American Academy of Pediatrics and the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition has prepared this report based on a comprehensive, systematic review and rating of the medical literature. This report accompanies a clinical report based on the literature review and expert opinion.

The subcommittee examined the diagnostic and therapeutic value of a medical and psychological history, diagnostic tests, and pharmacologic and behavioral therapy. The presence of alarm symptoms or signs (such as weight loss, gastrointestinal bleeding, persistent fever, chronic severe diarrhea, and significant vomiting) is associated with a higher prevalence of organic disease. There was insufficient evidence to state that the nature of the abdominal pain or the presence of associated symptoms (such as anorexia, nausea, headache, and joint pain) can discriminate between functional and organic disorders. Although children with chronic abdominal pain and their parents are more often anxious or depressed, the presence of anxiety, depression, behavior problems, or recent negative life events does not distinguish between functional and organic abdominal pain. Most children who are brought to the primary care physician's office for chronic abdominal pain are unlikely to require diagnostic testing. Pediatric studies of therapeutic interventions were examined and found to be limited or inconclusive. (3/05)

CIRCUMCISION POLICY STATEMENT

Task Force on Circumcision

ABSTRACT. Male circumcision is a common procedure, generally performed during the newborn period in the United States. In 2007, the American Academy of Pediatrics (AAP) formed a multidisciplinary task force of AAP members and other stakeholders to evaluate the recent evidence on male circumcision and update the Academy's 1999 recommendations in this area. Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks and that the procedure's benefits justify access to this procedure for families who choose it. Specific benefits identified included prevention of urinary tract infections, penile cancer, and transmission of some sexually transmitted infections, including HIV. The American College of Obstetricians and Gynecologists has endorsed this statement. (8/12)

CLASSIFYING RECOMMENDATIONS FOR CLINICAL PRACTICE GUIDELINES

Steering Committee on Quality Improvement and Management

ABSTRACT. Clinical practice guidelines are intended to improve the quality of clinical care by reducing inappropriate variations, producing optimal outcomes for patients, minimizing harm, and promoting cost-effective practices. This statement proposes an explicit classification of recommendations for clinical practice guidelines of the American Academy of Pediatrics (AAP) to promote communication among guideline developers, implementers, and other users of guideline knowledge, to improve consistency, and to facilitate user understanding. The statement describes 3 sequential activities in developing evidence-based clinical practice guidelines and related policies: 1) determination of the aggregate evidence quality in support of a proposed recommendation; 2) evaluation of the anticipated balance between benefits and harms when the recommendation is carried out; and

3) designation of recommendation strength. An individual policy can be reported as a "strong recommendation," "recommendation," "option," or "no recommendation." Use of this classification is intended to improve consistency and increase the transparency of the guideline-development process, facilitate understanding of AAP clinical practice guidelines, and enhance both the utility and credibility of AAP clinical practice guidelines. (9/04)

CLIMATIC HEAT STRESS AND EXERCISING CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness and Council on School Health

ABSTRACT. Results of new research indicate that, contrary to previous thinking, youth do not have less effective thermoregulatory ability, insufficient cardiovascular capacity, or lower physical exertion tolerance compared with adults during exercise in the heat when adequate hydration is maintained. Accordingly, besides poor hydration status, the primary determinants of reduced performance and exertional heat-illness risk in youth during sports and other physical activities in a hot environment include undue physical exertion, insufficient recovery between repeated exercise bouts or closely scheduled same-day training sessions or rounds of sports competition, and inappropriately wearing clothing, uniforms, and protective equipment that play a role in excessive heat retention. Because these known contributing risk factors are modifiable, exertional heat illness is usually preventable. With appropriate preparation, modifications, and monitoring, most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. (8/11)

CLINICAL GENETIC EVALUATION OF THE CHILD WITH MENTAL RETARDATION OR DEVELOPMENTAL DELAYS (CLINICAL REPORT)

John B. Moeschler, MD; Michael Shevell, MD; and Committee on Genetics

ABSTRACT. This clinical report describes the clinical genetic evaluation of the child with developmental delays or mental retardation. The purpose of this report is to describe the optimal clinical genetics diagnostic evaluation to assist pediatricians in providing a medical home for children with developmental delays or mental retardation and their families. The literature supports the benefit of expert clinical judgment by a consulting clinical geneticist in the diagnostic evaluation. However, it is recognized that local factors may preclude this particular option. No single approach to the diagnostic process is supported by the literature. This report addresses the diagnostic importance of clinical history, 3-generation family history, dysmorphologic examination, neurologic examination, chromosome analysis (≥650 bands), fragile X molecular genetic testing, fluorescence in situ hybridization studies for subtelomere chromosome rearrangements, molecular genetic testing for typical and atypical presentations of known syndromes, computed tomography and/or magnetic resonance brain imaging, and targeted studies for metabolic disorders. (6/06, reaffirmed 5/12)

***CLOSTRIDIUM DIFFICILE* INFECTION IN INFANTS AND CHILDREN**

Committee on Infectious Diseases

ABSTRACT. Infections caused by *Clostridium difficile* in hospitalized children are increasing. The recent publication of clinical practice guidelines for *C difficile* infection in adults did not address issues that are specific to children. The purpose of this policy statement is to provide the pediatrician with updated information and recommendations about *C difficile* infections affecting pediatric patients. (12/12)

COCHLEAR IMPLANTS IN CHILDREN: SURGICAL SITE INFECTIONS AND PREVENTION AND TREATMENT OF ACUTE OTITIS MEDIA AND MENINGITIS

Lorry G. Rubin, MD; Blake Papsin, MD; Committee on Infectious Diseases; and Section on Otolaryngology–Head and Neck Surgery

ABSTRACT. The use of cochlear implants is increasingly common, particularly in children younger than 3 years. Bacterial meningitis, often with associated acute otitis media, is more common in children with cochlear implants than in groups of control children. Children with profound deafness who are candidates for cochlear implants should receive all age-appropriate doses of pneumococcal conjugate and *Haemophilus influenzae* type b conjugate vaccines and appropriate annual immunization against influenza. In addition, starting at 24 months of age, a single dose of 23-valent pneumococcal polysaccharide vaccine should be administered. Before implant surgery, primary care providers and cochlear implant teams should ensure that immunizations are up-to-date, preferably with completion of indicated vaccines at least 2 weeks before implant surgery. Imaging of the temporal bone/inner ear should be performed before cochlear implantation in all children with congenital deafness and all patients with profound hearing impairment and a history of bacterial meningitis to identify those with inner-ear malformations/cerebrospinal fluid fistulas or ossification of the cochlea. During the initial months after cochlear implantation, the risk of complications of acute otitis media may be higher than during subsequent time periods. Therefore, it is recommended that acute otitis media diagnosed during the first 2 months after implantation be initially treated with a parenteral antibiotic (eg, ceftriaxone or cefotaxime). Episodes occurring 2 months or longer after implantation can be treated with a trial of an oral antimicrobial agent (eg, amoxicillin or amoxicillin/clavulanate at a dose of approximately 90 mg/kg per day of amoxicillin component), provided the child does not appear toxic and the implant does not have a spacer/positioner, a wedge that rests in the cochlea next to the electrodes present in certain implant models available between 1999 and 2002. "Watchful waiting" without antimicrobial therapy is inappropriate for children with implants with acute otitis media. If feasible, tympanocentesis should be performed for acute otitis media, and the material should be sent for culture, but performance of this procedure should not result in an undue delay in initiating antimicrobial therapy. For patients with suspected meningitis, cerebrospinal fluid as well as middle-ear fluid, if present, should be sent for culture. Empiric antimicrobial therapy for meningitis

occurring within 2 months of implantation should include an agent with broad activity against Gram-negative bacilli (eg, meropenem) plus vancomycin. For meningitis occurring 2 months or longer after implantation, standard empiric antimicrobial therapy for meningitis (eg, ceftriaxone plus vancomycin) is indicated. For patients with meningitis, urgent evaluation by an otolaryngologist is indicated for consideration of imaging and surgical exploration. (7/10)

COLLABORATIVE ROLE OF THE PEDIATRICIAN IN THE DIAGNOSIS AND MANAGEMENT OF BIPOLAR DISORDER IN ADOLESCENTS (CLINICAL REPORT)

Benjamin N. Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Despite the complexity of diagnosis and management, pediatricians have an important collaborative role in referring and partnering in the management of adolescents with bipolar disorder. This report presents the classification of bipolar disorder as well as interviewing and diagnostic guidelines. Treatment options are described, particularly focusing on medication management and rationale for the common practice of multiple, simultaneous medications. Medication adverse effects may be problematic and better managed with collaboration between mental health professionals and pediatricians. Case examples illustrate a number of common diagnostic and management issues. (11/12)

COMMUNICATING WITH CHILDREN AND FAMILIES: FROM EVERYDAY INTERACTIONS TO SKILL IN CONVEYING DISTRESSING INFORMATION (TECHNICAL REPORT)

Marcia Levetown, MD, and Committee on Bioethics

ABSTRACT. Health care communication is a skill that is critical to safe and effective medical practice; it can and must be taught. Communication skill influences patient disclosure, treatment adherence and outcome, adaptation to illness, and bereavement. This article provides a review of the evidence regarding clinical communication in the pediatric setting, covering the spectrum from outpatient primary care consultation to death notification, and provides practical suggestions to improve communication with patients and families, enabling more effective, efficient, and empathic pediatric health care. (5/08, reaffirmed 5/11)

COMMUNITY PEDIATRICS: NAVIGATING THE INTERSECTION OF MEDICINE, PUBLIC HEALTH, AND SOCIAL DETERMINANTS OF CHILDREN'S HEALTH

Council on Community Pediatrics

ABSTRACT. This policy statement provides a framework for the pediatrician's role in promoting the health and well-being of all children in the context of their families and communities. It offers pediatricians a definition of community pediatrics, emphasizes the importance of recognizing social determinants of health, and delineates the need to partner with public health to address population-based child health issues. It also recognizes the importance of pediatric involvement in child advocacy at local, state, and federal levels to ensure all children have access to a high-quality medical home and to eliminate child health disparities. This statement provides a set of specific recommendations that underscore the critical nature of this dimension of pediatric practice, teaching, and research. (2/13)

See full text on page 487.

COMPREHENSIVE HEALTH EVALUATION OF THE NEWLY ADOPTED CHILD (CLINICAL REPORT)

Veronnie F. Jones, MD, PhD, MSPH, and Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Children who join families through the process of adoption often have multiple health care needs. After placement in an adoptive home, it is essential that these children have a timely comprehensive health evaluation. This evaluation should include a review of all available medical records and a complete physical examination. Evaluation should also include diagnostic testing based on the findings from the history and physical examination as well as the risks presented by the child's previous living conditions. Age-appropriate screens should be performed, including, for example, newborn screening panels, hearing, vision, dental, and formal behavioral/developmental screens. The comprehensive assessment can occur at the time of the initial visit to the physician after adoptive placement or can take place over several visits. Adopted children should be referred to other medical specialists as deemed appropriate. The Section on Adoption and Foster Care is a resource within the American Academy of Pediatrics for physicians providing care for children who are being adopted. (12/11)

CONDOM USE BY ADOLESCENTS

Committee on Adolescence

ABSTRACT. Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). This policy statement has been developed to assist the pediatrician in understanding and supporting the use of condoms by their patients to prevent unintended pregnancies and STIs and address barriers to their use. When used consistently and correctly, male latex condoms reduce the risk of pregnancy and many STIs, including HIV. Since the last policy statement published 12 years ago, there is an increased evidence base supporting the protection provided by condoms against STIs. Rates of acquisition of STIs/HIV among adolescents remain unacceptably high. Interventions that increase availability or accessibility to condoms are most efficacious when combined with additional individual, small-group, or community-level activities that include messages about safer sex. Continued research is needed to inform public health interventions for adolescents that increase the consistent and correct use of condoms and promote dual protection of condoms for STI prevention with other effective methods of contraception. (10/13)

See full text on page 495.

CONFIDENTIALITY IN ADOLESCENT HEALTH CARE
Committee on Adolescence (4/89, reaffirmed 1/93, 11/97, 5/00, 5/04)

CONFLICTS BETWEEN RELIGIOUS OR SPIRITUAL BELIEFS AND PEDIATRIC CARE: INFORMED REFUSAL, EXEMPTIONS, AND PUBLIC FUNDING
Committee on Bioethics
ABSTRACT. Although respect for parents' decision-making authority is an important principle, pediatricians should report suspected cases of medical neglect, and the state should, at times, intervene to require medical treatment of children. Some parents' reasons for refusing medical treatment are based on their religious or spiritual beliefs. In cases in which treatment is likely to prevent death or serious disability or relieve severe pain, children's health and future autonomy should be protected. Because religious exemptions to child abuse and neglect laws do not equally protect all children and may harm some children by causing confusion about the duty to provide medical treatment, these exemptions should be repealed. Furthermore, public health care funds should not cover alternative unproven religious or spiritual healing practices. Such payments may inappropriately legitimize these practices as appropriate medical treatment. (10/13)
See full text on page 507.

CONGENITAL ADRENAL HYPERPLASIA (TECHNICAL REPORT)
Section on Endocrinology and Committee on Genetics
ABSTRACT. The Section on Endocrinology and the Committee on Genetics of the American Academy of Pediatrics, in collaboration with experts from the field of pediatric endocrinology and genetics, developed this policy statement as a means of providing up-to-date information for the practicing pediatrician about current practice and controversial issues in congenital adrenal hyperplasia (CAH), including the current status of prenatal diagnosis and treatment, the benefits and problem areas of neonatal screening programs, and the management of children with nonclassic CAH. The reference list is designed to allow physicians who wish more information to research the topic more thoroughly. (12/00, reaffirmed 10/04)

A CONSENSUS STATEMENT ON HEALTH CARE TRANSITIONS FOR YOUNG ADULTS WITH SPECIAL HEALTH CARE NEEDS
American Academy of Pediatrics, American Academy of Family Physicians, and American College of Physicians-American Society of Internal Medicine
ABSTRACT. This policy statement represents a consensus on the critical first steps that the medical profession needs to take to realize the vision of a family-centered, continuous, comprehensive, coordinated, compassionate, and culturally competent health care system that is as developmentally appropriate as it is technically sophisticated. The goal of transition in health care for young adults with special health care needs is to maximize lifelong functioning and potential through the provision of high-quality, developmentally appropriate health care services that continue uninterrupted as the individual moves from adolescence to adulthood. This consensus document has now been approved as policy by the boards of the American Academy of Pediatrics, the American Academy of Family Physicians, and the American College of Physicians-American Society of Internal Medicine. (12/02)

CONSENT FOR EMERGENCY MEDICAL SERVICES FOR CHILDREN AND ADOLESCENTS
Committee on Pediatric Emergency Medicine and Committee on Bioethics
ABSTRACT. Parental consent generally is required for the medical evaluation and treatment of minor children. However, children and adolescents might require evaluation of and treatment for emergency medical conditions in situations in which a parent or legal guardian is not available to provide consent or conditions under which an adolescent patient might possess the legal authority to provide consent. In general, a medical screening examination and any medical care necessary and likely to prevent imminent and significant harm to the pediatric patient with an emergency medical condition should not be withheld or delayed because of problems obtaining consent. The purpose of this policy statement is to provide guidance in those situations in which parental consent is not readily available, in which parental consent is not necessary, or in which parental refusal of consent places a child at risk of significant harm. (7/11)

CONSENT BY PROXY FOR NONURGENT PEDIATRIC CARE (CLINICAL REPORT)
Gary N. McAbee, DO, JD, and Committee on Medical Liability and Risk Management
ABSTRACT. Minor-aged patients are often brought to the pediatrician for nonurgent acute medical care, physical examinations, or health supervision visits by someone other than their legally authorized representative, which, in most situations, is a parent. These surrogates or proxies can be members of the child's extended family, such as a grandparent, adult sibling, or aunt/uncle; a noncustodial parent or stepparent in cases of divorce and remarriage; an adult who lives in the home but is not biologically or legally related to the child; or even a child care professional (eg, au pair, nanny). This report identifies common situations in which pediatricians may encounter "consent by proxy" for nonurgent medical care for minors, including physical examinations, and explains the potential for liability exposure associated with these circumstances. The report suggests practical steps that balance the need to minimize the physician's liability exposure with the patient's access to health care. Key issues to be considered when creating or updating office policies for obtaining and documenting consent by proxy are offered. (10/10)

CONSUMPTION OF RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS BY PREGNANT WOMEN AND CHILDREN
Committee on Infectious Diseases and Committee on Nutrition
ABSTRACT. Sales of raw or unpasteurized milk and milk products are still legal in at least 30 states in the United States. Raw milk and milk products from cows, goats, and sheep continue to be a source of bacterial infections

attributable to a number of virulent pathogens, including *Listeria monocytogenes, Campylobacter jejuni, Salmonella* species, *Brucella* species, and *Escherichia coli* O157. These infections can occur in both healthy and immunocompromised individuals, including older adults, infants, young children, and pregnant women and their unborn fetuses, in whom life-threatening infections and fetal miscarriage can occur. Efforts to limit the sale of raw milk products have met with opposition from those who are proponents of the purported health benefits of consuming raw milk products, which contain natural or unprocessed factors not inactivated by pasteurization. However, the benefits of these natural factors have not been clearly demonstrated in evidence-based studies and, therefore, do not outweigh the risks of raw milk consumption. Substantial data suggest that pasteurized milk confers equivalent health benefits compared with raw milk, without the additional risk of bacterial infections. The purpose of this policy statement was to review the risks of raw milk consumption in the United States and to provide evidence of the risks of infectious complications associated with consumption of unpasteurized milk and milk products, especially among pregnant women, infants, and children. (12/13)

See full text on page 513.

CONTRACEPTION AND ADOLESCENTS

Committee on Adolescence

ABSTRACT. Although adolescent pregnancy rates in the United States have decreased significantly over the past decade, births to adolescents remain both an individual and public health issue. As advocates for the health and well-being of all young people, the American Academy of Pediatrics strongly supports the recommendation that adolescents postpone consensual sexual activity until they are fully ready for the emotional, physical, and financial consequences of sex. The academy recognizes, however, that some young people will choose not to postpone sexual activity, and as health care providers, the responsibility of pediatricians includes helping teens reduce risks and negative health consequences associated with adolescent sexual behaviors, including unintended pregnancies and sexually transmitted infections. This policy statement provides the pediatrician with updated information on contraception methods and guidelines for counseling adolescents. (11/07)

CONTROVERSIES CONCERNING VITAMIN K AND THE NEWBORN

Committee on Fetus and Newborn

ABSTRACT. Prevention of early vitamin K deficiency bleeding (VKDB) of the newborn, with onset at birth to 2 weeks of age (formerly known as classic hemorrhagic disease of the newborn), by oral or parenteral administration of vitamin K is accepted practice. In contrast, late VKDB, with onset from 2 to 12 weeks of age, is most effectively prevented by parenteral administration of vitamin K. Earlier concern regarding a possible causal association between parenteral vitamin K and childhood cancer has not been substantiated. This revised statement presents updated recommendations for the use of vitamin K in the prevention of early and late VKDB. (7/03, reaffirmed 5/06, 5/09)

COPARENT OR SECOND-PARENT ADOPTION BY SAME-SEX PARENTS

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Children who are born to or adopted by 1 member of a same-sex couple deserve the security of 2 legally recognized parents. Therefore, the American Academy of Pediatrics supports legislative and legal efforts to provide the possibility of adoption of the child by the second parent or coparent in these families. (2/02, reaffirmed 5/09)

COPARENT OR SECOND-PARENT ADOPTION BY SAME-SEX PARENTS (TECHNICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. A growing body of scientific literature demonstrates that children who grow up with 1 or 2 gay and/or lesbian parents fare as well in emotional, cognitive, social, and sexual functioning as do children whose parents are heterosexual. Children's optimal development seems to be influenced more by the nature of the relationships and interactions within the family unit than by the particular structural form it takes. (2/02, reaffirmed 5/09)

CORPORAL PUNISHMENT IN SCHOOLS

Committee on School Health

ABSTRACT. The American Academy of Pediatrics recommends that corporal punishment in schools be abolished in all states by law and that alternative forms of student behavior management be used. (8/00, reaffirmed 6/03, 5/06, 2/12)

COUNSELING THE ADOLESCENT ABOUT PREGNANCY OPTIONS

Committee on Adolescence

ABSTRACT. When consulted by a pregnant adolescent, pediatricians should be able to make a timely diagnosis and to help the adolescent understand her options and act on her decision to continue or terminate her pregnancy. Pediatricians may not impose their values on the decision-making process and should be prepared to support the adolescent in her decision or refer her to a physician who can. (5/98, reaffirmed 1/01, 1/06)

COUNSELING FAMILIES WHO CHOOSE COMPLEMENTARY AND ALTERNATIVE MEDICINE FOR THEIR CHILD WITH CHRONIC ILLNESS OR DISABILITY

Committee on Children With Disabilities

ABSTRACT. The use of complementary and alternative medicine (CAM) to treat chronic illness or disability is increasing in the United States. This is especially evident among children with autism and related disorders. It may be challenging to the practicing pediatrician to distinguish among accepted biomedical treatments, unproven therapies, and alternative therapies. Moreover, there are no published guidelines regarding the use of CAM in the care of children with chronic illness or disability. To best serve the interests of children, it is important to maintain a scientific perspective, to provide balanced advice about therapeutic options, to guard against bias, and to establish and maintain a trusting relationship with families. This

statement provides information and guidance for pediatricians when counseling families about CAM. (3/01, reaffirmed 1/05, 5/10)

CREATING HEALTHY CAMP EXPERIENCES
Council on School Health
ABSTRACT. The American Academy of Pediatrics has created recommendations for health appraisal and preparation of young people before participation in day or resident camps and to guide health and safety practices for children at camp. These recommendations are intended for parents, primary health care providers, and camp administration and health center staff. Although camps have diverse environments, there are general guidelines that apply to all situations and specific recommendations that are appropriate under special conditions. This policy statement has been reviewed and is supported by the American Camp Association. (3/11)

THE CRUCIAL ROLE OF RECESS IN SCHOOL
Council on School Health
ABSTRACT. Recess is at the heart of a vigorous debate over the role of schools in promoting the optimal development of the whole child. A growing trend toward reallocating time in school to accentuate the more academic subjects has put this important facet of a child's school day at risk. Recess serves as a necessary break from the rigors of concentrated, academic challenges in the classroom. But equally important is the fact that safe and well-supervised recess offers cognitive, social, emotional, and physical benefits that may not be fully appreciated when a decision is made to diminish it. Recess is unique from, and a complement to, physical education—not a substitute for it. The American Academy of Pediatrics believes that recess is a crucial and necessary component of a child's development and, as such, it should not be withheld for punitive or academic reasons. (12/12)

DEALING WITH THE PARENT WHOSE JUDGMENT IS IMPAIRED BY ALCOHOL OR DRUGS: LEGAL AND ETHICAL CONSIDERATIONS (CLINICAL REPORT)
Committee on Medical Liability
ABSTRACT. An estimated 11 to 17.5 million children are being raised by a substance-abusing parent or guardian. The importance of this statistic is undeniable, particularly when a patient is brought to a pediatric office by a parent or guardian exhibiting symptoms of judgment impairment. Although the physician-patient relationship exists between the pediatrician and the minor patient, other obligations (some perceived and some real) should be considered as well. In managing encounters with impaired parents who may become disruptive or dangerous, pediatricians should be aware of their responsibilities before acting. In addition to fulfilling the duty involved with an established physician-patient relationship, the pediatrician should take reasonable care to safeguard patient confidentiality; protect the safety of the patient and other patients, visitors, and employees; and comply with reporting mandates. This clinical report identifies and discusses the legal and ethical concepts related to these circumstances. The report offers implementation suggestions when establishing anticipatory office procedures and training programs for staff on what to do (and not do) in such situations to maximize the patient's well-being and safety and minimize the liability of the pediatrician. (9/04, reaffirmed 9/10)

DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)
Jane Knapp, MD; Deborah Mulligan-Smith, MD; and Committee on Pediatric Emergency Medicine
ABSTRACT. Of the estimated 40000 American children ≤14 years old who die each year, approximately 20% die or are pronounced dead in outpatient sites, primarily the emergency department (ED). The ED is distinguishable from other sites at which children die, because the death is often sudden, unexpected, and without a previously established physician-patient care relationship. Despite these difficult circumstances and potentially limited professional experience with the death of a child, the emergency physician must be prepared to respond to the emotional, cultural, procedural, and legal issues that are an inevitable part of caring for ill and injured children who die. All of this must be accomplished while supporting a grieving family. There is also a responsibility to inform the child's pediatrician of the death, who in turn also must be prepared to counsel and support bereaved families. The American Academy of Pediatrics and American College of Emergency Physicians collaborated on the joint policy statement, "Death of a Child in the Emergency Department," agreeing on recommendations on the principles of care after the death of a child in the ED. This technical report provides the background information, consensus opinion, and evidence, where available, used to support the recommendations found in the policy statement. Important among these are the pediatrician's role as an advocate to advise in the formulation of ED policy and procedure that facilitate identification and management of medical examiners' cases, identification and reporting of child maltreatment, requests for postmortem examinations, and procurement of organ donations. (5/05, reaffirmed 8/13)

DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT: JOINT STATEMENT OF THE AMERICAN ACADEMY OF PEDIATRICS AND THE AMERICAN COLLEGE OF EMERGENCY PHYSICIANS
Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians) (10/02, reaffirmed 1/06, 1/09, 8/13)

DEVELOPMENTAL DYSPLASIA OF THE HIP PRACTICE GUIDELINE (TECHNICAL REPORT)
Harold P. Lehmann, MD, PhD; Richard Hinton, MD, MPH; Paola Morello, MD; Jeanne Santoli, MD; in conjunction with Committee on Quality Improvement and Subcommittee on Developmental Dysplasia of the Hip
ABSTRACT. *Objective.* To create a recommendation for pediatricians and other primary care providers about their role as screeners for detecting developmental dysplasia of the hip (DDH) in children.

Patients. Theoretical cohorts of newborns.

Method. Model-based approach using decision analysis as the foundation. Components of the approach include the following:

Perspective: Primary care provider.

Outcomes: DDH, avascular necrosis of the hip (AVN).

Options: Newborn screening by pediatric examination; orthopaedic examination; ultrasonographic examination; orthopaedic or ultrasonographic examination by risk factors. Intercurrent health supervision-based screening.

Preferences: 0 for bad outcomes, 1 for best outcomes.

Model: Influence diagram assessed by the Subcommittee and by the methodology team, with critical feedback from the Subcommittee.

Evidence Sources: Medline and EMBASE search of the research literature through June 1996. Hand search of sentinel journals from June 1996 through March 1997. Ancestor search of accepted articles.

Evidence Quality: Assessed on a custom subjective scale, based primarily on the fit of the evidence to the decision model.

Results. After discussion, explicit modeling, and critique, an influence diagram of 31 nodes was created. The computer-based and the hand literature searches found 534 articles, 101 of which were reviewed by 2 or more readers. Ancestor searches of these yielded a further 17 articles for evidence abstraction. Articles came from around the globe, although primarily Europe, British Isles, Scandinavia, and their descendants. There were 5 controlled trials, each with a sample size less than 40. The remainder were case series. Evidence was available for 17 of the desired 30 probabilities. Evidence quality ranged primarily between one third and two thirds of the maximum attainable score (median: 10–21; interquartile range: 8–14).Based on the raw evidence and Bayesian hierarchical meta-analyses, our estimate for the incidence of DDH revealed by physical examination performed by pediatricians is 8.6 per 1000; for orthopaedic screening, 11.5; for ultrasonography, 25. The odds ratio for DDH, given breech delivery, is 5.5; for female sex, 4.1; for positive family history, 1.7, although this last factor is not statistically significant. Postneonatal cases of DDH were divided into mid-term (younger than 6 months of age) and late-term (older than 6 months of age). Our estimates for the mid-term rate for screening by pediatricians is 0.34/1000 children screened; for orthopaedists, 0.1; and for ultrasonography, 0.28. Our estimates for late-term DDH rates are 0.21/1000 newborns screened by pediatricians; 0.08, by orthopaedists; and 0.2 for ultrasonography. The rates of AVN for children referred before 6 months of age is estimated at 2.5/1000 infants referred. For those referred after 6 months of age, our estimate is 109/1000 referred infants. The decision model (reduced, based on available evidence) suggests that orthopaedic screening is optimal, but because orthopaedists in the published studies and in practice would differ, the supply of orthopaedists is relatively limited, and the difference between orthopaedists and pediatricians is statistically insignificant, we conclude that pediatric screening is to be recommended. The place of ultrasonography in the screening process remains to be defined because there are too few data about postneonatal diagnosis by ultrasonographic screening to permit definitive recommendations. These data could be used by others to refine the conclusions based on costs, parental preferences, or physician style. Areas for research are well defined by our model-based approach. (4/00)

DIAGNOSIS OF HIV-1 INFECTION IN CHILDREN YOUNGER THAN 18 MONTHS IN THE UNITED STATES (TECHNICAL REPORT)

Jennifer S. Read, MD, MS, MPH, DTM&H, and Committee on Pediatric AIDS

ABSTRACT. The objectives of this technical report are to describe methods of diagnosis of HIV-1 infection in children younger than 18 months in the United States and to review important issues that must be considered by clinicians who care for infants and young children born to HIV-1–infected women. Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be detectable in the child's bloodstream until 18 months of age. Therefore, routine serologic testing of these infants and young children is generally only informative before the age of 18 months if the test result is negative. Virologic assays, including HIV-1 DNA or RNA assays, represent the gold standard for diagnostic testing of infants and children younger than 18 months. With such testing, the diagnosis of HIV-1 infection (as well as the presumptive exclusion of HIV-1 infection) can be established within the first several weeks of life among nonbreastfed infants. Important factors that must be considered when selecting HIV-1 diagnostic assays for pediatric patients and when choosing the timing of such assays include the age of the child, potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and of the child, and characteristics of the virus. If the mother's HIV-1 serostatus is unknown, rapid HIV-1 antibody testing of the newborn infant to identify HIV-1 exposure is essential so that antiretroviral prophylaxis can be initiated within the first 12 hours of life if test results are positive. For HIV-1–exposed infants (identified by positive maternal test results or positive antibody results for the infant shortly after birth), it has been recommended that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. If any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection can be made on the basis of 2 positive HIV-1 DNA or RNA assay results. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 antibody test result obtained at ≥6 months of age. Alternatively, presumptive exclusion of HIV-1 infection can be based on 1 positive HIV-1 virologic test with at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age) or negative HIV-1 antibody test results (at least 1 of

which is performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative virologic test results, 1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age, or 2 negative HIV-1 antibody test results from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection. Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age. For breastfeeding infants, a similar testing algorithm can be followed, with timing of testing starting from the date of complete cessation of breastfeeding instead of the date of birth. (12/07, reaffirmed 4/10)

DIAGNOSIS AND MANAGEMENT OF CHILDHOOD OBSTRUCTIVE SLEEP APNEA SYNDROME (TECHNICAL REPORT)

Carole L. Marcus, MBBCh; Lee J. Brooks, MD; Sally Davidson Ward, MD; Kari A. Draper, MD; David Gozal, MD; Ann C. Halbower, MD; Jacqueline Jones, MD; Christopher Lehmann, MD; Michael S. Schechter, MD, MPH; Stephen Sheldon, MD; Richard N. Shiffman, MD, MCIS; and Karen Spruyt, PhD

ABSTRACT. *Objective.* This technical report describes the procedures involved in developing recommendations on the management of childhood obstructive sleep apnea syndrome (OSAS).

Methods. The literature from 1999 through 2011 was evaluated.

Results and Conclusions. A total of 3166 titles were reviewed, of which 350 provided relevant data. Most articles were level II through IV. The prevalence of OSAS ranged from 0% to 5.7%, with obesity being an independent risk factor. OSAS was associated with cardiovascular, growth, and neurobehavioral abnormalities and possibly inflammation. Most diagnostic screening tests had low sensitivity and specificity. Treatment of OSAS resulted in improvements in behavior and attention and likely improvement in cognitive abilities. Primary treatment is adenotonsillectomy (AT). Data were insufficient to recommend specific surgical techniques; however, children undergoing partial tonsillectomy should be monitored for possible recurrence of OSAS. Although OSAS improved postoperatively, the proportion of patients who had residual OSAS ranged from 13% to 29% in low-risk populations to 73% when obese children were included and stricter polysomnographic criteria were used. Nevertheless, OSAS may improve after AT even in obese children, thus supporting surgery as a reasonable initial treatment. A significant number of obese patients required intubation or continuous positive airway pressure (CPAP) postoperatively, which reinforces the need for inpatient observation. CPAP was effective in the treatment of OSAS, but adherence is a major barrier. For this reason, CPAP is not recommended as first-line therapy for OSAS when AT is an option. Intranasal steroids may ameliorate mild OSAS, but follow-up is needed. Data were insufficient to recommend rapid maxillary expansion. (8/12)

DIAGNOSIS AND MANAGEMEN OF AN INITIAL UTI IN FEBRILE INFANTS AND YOUNG CHILDREN (TECHNICAL REPORT)

S. Maria E. Finnell, MD, MS; Aaron E. Carroll, MD, MS; Stephen M. Downs, MD, MS; and Subcommittee on Urinary Tract Infection

ABSTRACT. *Objectives.* The diagnosis and management of urinary tract infections (UTIs) in young children are clinically challenging. This report was developed to inform the revised, evidence-based, clinical guideline regarding the diagnosis and management of initial UTIs in febrile infants and young children, 2 to 24 months of age, from the American Academy of Pediatrics Subcommittee on Urinary Tract Infection.

Methods. The conceptual model presented in the 1999 technical report was updated after a comprehensive review of published literature. Studies with potentially new information or with evidence that reinforced the 1999 technical report were retained. Meta-analyses on the effectiveness of antimicrobial prophylaxis to prevent recurrent UTI were performed.

Results. Review of recent literature revealed new evidence in the following areas. Certain clinical findings and new urinalysis methods can help clinicians identify febrile children at very low risk of UTI. Oral antimicrobial therapy is as effective as parenteral therapy in treating UTI. Data from published, randomized controlled trials do not support antimicrobial prophylaxis to prevent febrile UTI when vesicoureteral reflux is found through voiding cystourethrography. Ultrasonography of the urinary tract after the first UTI has poor sensitivity. Early antimicrobial treatment may decrease the risk of renal damage from UTI.

Conclusions. Recent literature agrees with most of the evidence presented in the 1999 technical report, but meta-analyses of data from recent, randomized controlled trials do not support antimicrobial prophylaxis to prevent febrile UTI. This finding argues against voiding cystourethrography after the first UTI. (8/11)

DIAGNOSIS AND PREVENTION OF IRON DEFICIENCY AND IRON-DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN (0–3 YEARS OF AGE) (CLINICAL REPORT)

Robert D. Baker, MD, PhD; Frank R. Greer, MD; and Committee on Nutrition

ABSTRACT. This clinical report covers diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants (both breastfed and formula fed) and toddlers from birth through 3 years of age. Results of recent basic research support the concerns that iron-deficiency anemia and iron deficiency without anemia during infancy and childhood can have long-lasting detrimental effects on neurodevelopment. Therefore, pediatricians and other health care providers should strive to eliminate iron deficiency and iron-deficiency anemia. Appropriate iron intakes for infants and toddlers as well as methods for screening for iron deficiency and iron-deficiency anemia are presented. (10/10)

DIAGNOSTIC IMAGING OF CHILD ABUSE
Section on Radiology
ABSTRACT. The role of imaging in cases of child abuse is to identify the extent of physical injury when abuse is present and to elucidate all imaging findings that point to alternative diagnoses. Effective diagnostic imaging of child abuse rests on high-quality technology as well as a full appreciation of the clinical and pathologic alterations occurring in abused children. This statement is a revision of the previous policy published in 2000. (4/09)

DISASTER PLANNING FOR SCHOOLS
Council on School Health
ABSTRACT. Community awareness of the school district's disaster plan will optimize a community's capacity to maintain the safety of its school-aged population in the event of a school-based or greater community crisis. This statement is intended to stimulate awareness of the disaster-preparedness process in schools as a part of a global, community-wide preparedness plan. Pediatricians, other health care professionals, first responders, public health officials, the media, school nurses, school staff, and parents all need to be unified in their efforts to support schools in the prevention of, preparedness for, response to, and recovery from a disaster. (10/08, reaffirmed 9/11)

DISCLOSURE OF ILLNESS STATUS TO CHILDREN AND ADOLESCENTS WITH HIV INFECTION
Committee on Pediatric AIDS
ABSTRACT. Many children with human immunodeficiency virus (HIV) infection and acquired immunodeficiency syndrome are surviving to middle childhood and adolescence. Studies suggest that children who know their HIV status have higher self-esteem than children who are unaware of their status. Parents who have disclosed the status to their children experience less depression than those who do not. This statement addresses our current knowledge and recommendations for disclosure of HIV infection status to children and adolescents. (1/99, reaffirmed 2/02, 5/05, 1/09, 1/12)

DISPENSING MEDICATIONS AT THE HOSPITAL UPON DISCHARGE FROM AN EMERGENCY DEPARTMENT (TECHNICAL REPORT)
Loren G. Yamamoto, MD, MPH, MBA; Shannon Manzi, PharmD; and Committee on Pediatric Emergency Medicine
ABSTRACT. Although most health care services can and should be provided by their medical home, children will be referred or require visits to the emergency department (ED) for emergent clinical conditions or injuries. Continuation of medical care after discharge from an ED is dependent on parents or caregivers' understanding of and compliance with follow-up instructions and on adherence to medication recommendations. ED visits often occur at times when the majority of pharmacies are not open and caregivers are concerned with getting their ill or injured child directly home. Approximately one-third of patients fail to obtain priority medications from a pharmacy after discharge from an ED. The option of judiciously dispensing ED discharge medications from the ED's outpatient pharmacy within the facility is a major convenience that overcomes this obstacle, improving the likelihood of medication adherence. Emergency care encounters should be routinely followed up with primary care provider medical homes to ensure complete and comprehensive care. (1/12)

DISTINGUISHING SUDDEN INFANT DEATH SYNDROME FROM CHILD ABUSE FATALITIES (CLINICAL REPORT)
Kent P. Hymel, MD, and Committee on Child Abuse and Neglect (joint with National Association of Medical Examiners)
ABSTRACT. Fatal child abuse has been mistaken for sudden infant death syndrome. When a healthy infant younger than 1 year dies suddenly and unexpectedly, the cause of death may be certified as sudden infant death syndrome. Sudden infant death syndrome is more common than infanticide. Parents of sudden infant death syndrome victims typically are anxious to provide unlimited information to professionals involved in death investigation or research. They also want and deserve to be approached in a nonaccusatory manner. This clinical report provides professionals with information and suggestions for procedures to help avoid stigmatizing families of sudden infant death syndrome victims while allowing accumulation of appropriate evidence in potential cases of infanticide. This clinical report addresses deficiencies and updates recommendations in the 2001 American Academy of Pediatrics policy statement of the same name. (7/06, reaffirmed 4/09, 3/13)

DO-NOT-RESUSCITATE ORDERS FOR PEDIATRIC PATIENTS WHO REQUIRE ANESTHESIA AND SURGERY (CLINICAL REPORT)
Section on Surgery, Section on Anesthesia and Pain Medicine, and Committee on Bioethics
ABSTRACT. This clinical report addresses the topic of preexisting do-not-resuscitate (DNR) orders for children undergoing anesthesia and surgery. Pertinent issues addressed include the rights of children, surrogate decision-making, the process of informed consent, and the roles of surgeons and anesthesiologists. The reevaluation process of DNR orders called "required reconsideration" can be incorporated into the process of informed consent for surgery and anesthesia. Care should be taken to distinguish between goal-directed and procedure-directed approaches to DNR orders. By giving parents or other surrogates and clinicians the option of deciding from among full resuscitation, limitations based on procedures, or limitations based on goals, the child's needs are individualized and better served. (12/04, reaffirmed 1/09, 10/12)

DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN
Committee on Environmental Health and Committee on Infectious Diseases
ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms and cause illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation. With few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when

traveling. Illness resulting from children's ingestion of contaminated water can be severe. This policy statement provides recommendations for inspection, testing, and remediation for wells providing drinking water for children. (5/09, reaffirmed 1/13)

DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN (TECHNICAL REPORT)

Walter J. Rogan, MD; Michael T. Brady, MD; Committee on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms, leading to significant illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation, and with few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This report reviews relevant aspects of groundwater and wells; describes the common chemical and microbiologic contaminants; gives an algorithm with recommendations for inspection, testing, and remediation for wells providing drinking water for children; reviews the definitions and uses of various bottled waters; provides current estimates of costs for well testing; and provides federal, national, state, and, where appropriate, tribal contacts for more information. (5/09, reaffirmed 1/13)

EARLY CHILDHOOD ADVERSITY, TOXIC STRESS, AND THE ROLE OF THE PEDIATRICIAN: TRANSLATING DEVELOPMENTAL SCIENCE INTO LIFELONG HEALTH

Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in a wide range of biological, behavioral, and social sciences are expanding our understanding of how early environmental influences (the ecology) and genetic predispositions (the biologic program) affect learning capacities, adaptive behaviors, lifelong physical and mental health, and adult productivity. A supporting technical report from the American Academy of Pediatrics (AAP) presents an integrated ecobiodevelopmental framework to assist in translating these dramatic advances in developmental science into improved health across the life span. Pediatricians are now armed with new information about the adverse effects of toxic stress on brain development, as well as a deeper understanding of the early life origins of many adult diseases. As trusted authorities in child health and development, pediatric providers must now complement the early identification of developmental concerns with a greater focus on those interventions and community investments that reduce external threats to healthy brain growth. To this end, AAP endorses a developing leadership role for the entire pediatric community—one that mobilizes the scientific expertise of both basic and clinical researchers, the family-centered care of the pediatric medical home, and the public influence of AAP and its state chapters—to catalyze fundamental change in early childhood policy and services. AAP is committed to leveraging science to inform the development of innovative strategies to reduce the precipitants of toxic stress in young children and to mitigate their negative effects on the course of development and health across the life span. (12/11)

EARLY CHILDHOOD CARIES IN INDIGENOUS COMMUNITIES

Committee on Native American Child Health (joint with Canadian Paediatric Society First Nations, Inuit, and Métis Committee)

ABSTRACT. The oral health of Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian, Alaska Native) is a major child health issue: there is a high prevalence of early childhood caries (ECC) and resulting adverse health effects in this community, as well as high rates and costs of restorative and surgical treatments under general anesthesia. ECC is an infectious disease that is influenced by multiple factors, including socioeconomic determinants, and requires a combination of approaches for improvement. This statement includes recommendations for preventive oral health and clinical care for young infants and pregnant women by primary health care providers, community-based health-promotion initiatives, oral health workforce and access issues, and advocacy for community water fluoridation and fluoride-varnish program access. Further community-based research on the epidemiology, prevention, management, and microbiology of ECC in Indigenous communities would be beneficial. (5/11)

EARLY INTERVENTION, IDEA PART C SERVICES, AND THE MEDICAL HOME: COLLABORATION FOR BEST PRACTICE AND BEST OUTCOMES (CLINICAL REPORT)

Richard C. Adams, MD; Carl Tapia, MD; and Council on Children With Disabilities

ABSTRACT. The medical home and the Individuals With Disabilities Education Act Part C Early Intervention Program share many common purposes for infants and children ages 0 to 3 years, not the least of which is a family-centered focus. Professionals in pediatric medical home practices see substantial numbers of infants and toddlers with developmental delays and/or complex chronic conditions. Economic, health, and family-focused data each underscore the critical role of timely referral for relationship-based, individualized, accessible early intervention services and the need for collaborative partnerships in care. The medical home process and Individuals With Disabilities Education Act Part C policy both support nurturing relationships and family-centered care; both offer clear value in terms of economic and health outcomes. Best practice models for early intervention services incorporate learning in the natural environment and coaching models. Proactive medical homes provide strategies for effective developmental surveillance, family-centered resources, and tools to support high-risk groups, and comanagement of infants with special health care needs, including the monitoring of services provided and outcomes achieved. (9/13)

ECHOCARDIOGRAPHY IN INFANTS AND CHILDREN
Section on Cardiology
ABSTRACT. It is the intent of this statement to inform pediatric providers on the appropriate use of echocardiography. Although on-site consultation may be impossible, methods should be established to ensure timely review of echocardiograms by a pediatric cardiologist. With advances in data transmission, echocardiography information can be exchanged, in some cases eliminating the need for a costly patient transfer. By cooperating through training, education, and referral, complete and cost-effective echocardiographic services can be provided to all children. (6/97, reaffirmed 3/03, 3/07)

EDUCATION OF CHILDREN WITH HUMAN IMMUNODEFICIENCY VIRUS INFECTION
Committee on Pediatric AIDS
ABSTRACT. Treatment for human immunodeficiency virus (HIV) infection has enabled more children and youths to attend school and participate in school activities. Children and youths with HIV infection should receive the same education as those with other chronic illnesses. They may require special services, including home instruction, to provide continuity of education. Confidentiality about HIV infection status should be maintained with parental consent required for disclosure. Youths also should assent or consent as is appropriate for disclosure of their diagnosis. (6/00, reaffirmed 3/03, 10/06, 4/10, 3/13)

EFFECTS OF EARLY NUTRITIONAL INTERVENTIONS ON THE DEVELOPMENT OF ATOPIC DISEASE IN INFANTS AND CHILDREN: THE ROLE OF MATERNAL DIETARY RESTRICTION, BREASTFEEDING, TIMING OF INTRODUCTION OF COMPLEMENTARY FOODS, AND HYDROLYZED FORMULAS (CLINICAL REPORT)
Frank R. Greer, MD; Scott H. Sicherer, MD; A. Wesley Burks, MD; Committee on Nutrition; and Section on Allergy and Immunology
ABSTRACT. This clinical report reviews the nutritional options during pregnancy, lactation, and the first year of life that may affect the development of atopic disease (atopic dermatitis, asthma, food allergy) in early life. It replaces an earlier policy statement from the American Academy of Pediatrics that addressed the use of hypoallergenic infant formulas and included provisional recommendations for dietary management for the prevention of atopic disease. The documented benefits of nutritional intervention that may prevent or delay the onset of atopic disease are largely limited to infants at high risk of developing allergy (ie, infants with at least 1 first-degree relative [parent or sibling] with allergic disease). Current evidence does not support a major role for maternal dietary restrictions during pregnancy or lactation. There is evidence that breastfeeding for at least 4 months, compared with feeding formula made with intact cow milk protein, prevents or delays the occurrence of atopic dermatitis, cow milk allergy, and wheezing in early childhood. In studies of infants at high risk of atopy and who are not exclusively breastfed for 4 to 6 months, there is modest evidence that the onset of atopic disease may be delayed or prevented by the use of hydrolyzed formulas compared with formula made with intact cow milk protein, particularly for atopic dermatitis. Comparative studies of the various hydrolyzed formulas also indicate that not all formulas have the same protective benefit. There is also little evidence that delaying the timing of the introduction of complementary foods beyond 4 to 6 months of age prevents the occurrence of atopic disease. At present, there are insufficient data to document a protective effect of any dietary intervention beyond 4 to 6 months of age for the development of atopic disease. (1/08)

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT
Council on Clinical Information Technology
ABSTRACT. This policy statement identifies the potential value of electronic prescribing (e-prescribing) systems in improving quality and reducing harm in pediatric health care. On the basis of limited but positive pediatric data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. The American Academy of Pediatrics also recommends a set of functions that technology vendors should provide when e-prescribing systems are used in environments in which children receive care. (3/13)
See full text on page 537.

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT (TECHNICAL REPORT)
Kevin B. Johnson, MD, MS; Christoph U. Lehmann, MD; and Council on Clinical Information Technology
ABSRACT. This technical report discusses recent advances in electronic prescribing (e-prescribing) systems, including the evidence base supporting their limitations and potential benefits. Specifically, this report acknowledges that there are limited but positive pediatric data supporting the role of e-prescribing in mitigating medication errors, improving communication with dispensing pharmacists, and improving medication adherence. On the basis of these data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. This report supports the accompanying policy statement from the American Academy of Pediatrics recommending the adoption of e-prescribing by pediatric health care providers. (3/13)
See full text on page 537.

ELECTRONIC PRESCRIBING SYSTEMS IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS
Council on Clinical Information Technology
ABSTRACT. The use of electronic prescribing applications in pediatric practice, as recommended by the federal government and other national health care improvement organizations, should be encouraged. Legislation and policies that foster adoption of electronic prescribing systems by pediatricians should recognize both specific pediatric requirements and general economic incentives required to speed the adoption of these systems. Continued research into improving the effectiveness of these systems,

recognizing the unique challenges of providing care to the pediatric population, should be promoted. (6/07)

ELECTRONIC PRESCRIBING SYSTEMS IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS (TECHNICAL REPORT)

Robert S. Gerstle, MD; Christoph U. Lehmann, MD; and Council on Clinical Information Technology

ABSTRACT. This technical report discusses electronic prescribing systems and their limitations and potential benefits, particularly to the pediatrician in the ambulatory setting. In the report we acknowledge the benefits of integrating these systems with electronic health records and practice-management systems and recommend that the adoption of electronic prescribing systems be done in the context of ultimately moving toward an electronic health record. This technical report supports the accompanying American Academy of Pediatrics policy-statement recommendations on the adoption of electronic prescribing systems by pediatricians. (6/07)

E-MAIL COMMUNICATION BETWEEN PEDIATRICIANS AND THEIR PATIENTS (CLINICAL REPORT)

Steering Committee on Clinical Information Technology

ABSTRACT. This report addresses specific e-mail patient communication issues relevant to pediatricians and their appropriate use of e-mail in the office setting. The report briefly reviews: 1) e-mail privacy and security concerns; 2) e-mail in the office environment; 3) the legal status of e-mail; and 4) available e-mail technologic solutions. (7/04, reaffirmed 2/08)

EMERGENCY CONTRACEPTION

Committee on Adolescence

ABSTRACT. Despite significant declines over the past 2 decades, the United States continues to have teen birth rates that are significantly higher than other industrialized nations. Use of emergency contraception can reduce the risk of pregnancy if used up to 120 hours after unprotected intercourse or contraceptive failure and is most effective if used in the first 24 hours. Indications for the use of emergency contraception include sexual assault, unprotected intercourse, condom breakage or slippage, and missed or late doses of hormonal contraceptives, including the oral contraceptive pill, contraceptive patch, contraceptive ring (ie, improper placement or loss/expulsion), and injectable contraception. Adolescents younger than 17 years must obtain a prescription from a physician to access emergency contraception in most states. In all states, both males and females 17 years or older can obtain emergency contraception without a prescription. Adolescents are more likely to use emergency contraception if it has been prescribed in advance of need. The aim of this updated policy statement is to (1) educate pediatricians and other physicians on available emergency contraceptive methods; (2) provide current data on safety, efficacy, and use of emergency contraception in teenagers; and (3) encourage routine counseling and advance emergency-contraception prescription as 1 part of a public health strategy to reduce teen pregnancy. This policy focuses on pharmacologic methods of emergency contraception used within 120 hours of unprotected or underprotected coitus for the prevention of unintended pregnancy. Emergency contraceptive medications include products labeled and dedicated for use as emergency contraception by the US Food and Drug Administration (levonorgestrel and ulipristal) and the "off-label" use of combination oral contraceptives. (11/12)

EMERGENCY INFORMATION FORMS AND EMERGENCY PREPAREDNESS FOR CHILDREN WITH SPECIAL HEALTH CARE NEEDS

*Committee on Pediatric Emergency Medicine and Council on Clinical Information Technology (*joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. Children with chronic medical conditions rely on complex management plans for problems that cause them to be at increased risk for suboptimal outcomes in emergency situations. The emergency information form (EIF) is a medical summary that describes medical condition(s), medications, and special health care needs to inform health care providers of a child's special health conditions and needs so that optimal emergency medical care can be provided. This statement describes updates to EIFs, including computerization of the EIF, expanding the potential benefits of the EIF, quality-improvement programs using the EIF, the EIF as a central repository, and facilitating emergency preparedness in disaster management and drills by using the EIF. (3/10)

ENDORSEMENT OF HEALTH AND HUMAN SERVICES RECOMMENDATION FOR PULSE OXIMETRY SCREENING FOR CRITICAL CONGENITAL HEART DISEASE

Section on Cardiology and Cardiac Surgery Executive Committee

ABSTRACT. Incorporation of pulse oximetry to the assessment of the newborn infant can enhance detection of critical congenital heart disease (CCHD). Recently, the Secretary of Health and Human Services (HHS) recommended that screening for CCHD be added to the uniform screening panel. The American Academy of Pediatrics (AAP) has been a strong advocate of early detection of CCHD and fully supports the decision of the Secretary of HHS.

The AAP has published strategies for the implementation of pulse oximetry screening, which addressed critical issues such as necessary equipment, personnel, and training, and also provided specific recommendations for assessment of saturation by using pulse oximetry as well as appropriate management of a positive screening result. The AAP is committed to the safe and effective implementation of pulse oximetry screening and is working with other advocacy groups and governmental agencies to promote pulse oximetry and to support widespread surveillance for CCHD.

Going forward, AAP chapters will partner with state health departments to implement the new screening strategy for CCHD and will work to ensure that there is an adequate system for referral for echocardiographic/pediatric cardiac evaluation after a positive screening result. It is imperative that AAP members engage their respective

policy makers in adopting and funding the recommendations made by the Secretary of HHS. (12/11)

ENHANCING PEDIATRIC WORKFORCE DIVERSITY AND PROVIDING CULTURALLY EFFECTIVE PEDIATRIC CARE: IMPLICATIONS FOR PRACTICE, EDUCATION, AND POLICY MAKING

Committee on Pediatric Workforce

ABSTRACT. This policy statement serves to combine and update 2 previously independent but overlapping statements from the American Academy of Pediatrics (AAP) on culturally effective health care (CEHC) and workforce diversity. The AAP has long recognized that with the ever-increasing diversity of the pediatric population in the United States, the health of all children depends on the ability of all pediatricians to practice culturally effective care. CEHC can be defined as the delivery of care within the context of appropriate physician knowledge, understanding, and appreciation of all cultural distinctions, leading to optimal health outcomes. The AAP believes that CEHC is a critical social value and that the knowledge and skills necessary for providing CEHC can be taught and acquired through focused curricula across the spectrum of lifelong learning.

This statement also addresses workforce diversity, health disparities, and affirmative action. The discussion of diversity is broadened to include not only race, ethnicity, and language but also cultural attributes such as gender, religious beliefs, sexual orientation, and disability, which may affect the quality of health care. The AAP believes that efforts must be supported through health policy and advocacy initiatives to promote the delivery of CEHC and to overcome educational, organizational, and other barriers to improving workforce diversity. (9/13)

See full text on page 553.

EPIDEMIOLOGY AND DIAGNOSIS OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (TECHNICAL REPORT)

Committee on Fetus and Newborn and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU are a major clinical problem resulting in increased morbidity and mortality, prolonged length of hospital stays, and increased medical costs. Neonates are at high risk for health care–associated infections because of impaired host defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of neonatal skin, the use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotics. This statement will review the epidemiology and diagnosis of health care–associated infections in newborn infants. (3/12)

EQUIPMENT FOR AMBULANCES

American College of Surgeons Committee on Trauma, American College of Emergency Physicians, National Association of EMS Physicians, Pediatric Equipment Guidelines Committee—Emergency Medical Services for Children (EMSC) Partnership for Children Stakeholder Group, and American Academy of Pediatrics

INTRODUCTION (EXCERPT). Almost 4 decades ago, the Committee on Trauma of the American College of Surgeons (ACS) developed a list of standardized equipment for ambulances. Beginning in 1988, the American College of Emergency Physicians (ACEP) published a similar list. The 2 organizations collaborated on a joint document published in 2000, and the National Association of EMS Physicians (NAEMSP) participated in the 2005 revision. The 2005 revision included resources needed on ambulances for appropriate homeland security. All 3 organizations adhere to the principle that emergency medical services (EMS) providers at all levels must have the appropriate equipment and supplies to optimize prehospital delivery of care. The document was written to serve as a standard for the equipment needs of emergency ambulance services in both the United States and Canada.

EMS providers care for patients of all ages, who have a wide variety of medical and traumatic conditions. With permission from the ACS Committee on Trauma, ACEP, and NAEMSP, the current revision includes updated pediatric recommendations developed by members of the federal Emergency Medical Services for Children (EMSC) Stakeholder Group. The EMSC Program has developed several performance measures for the program's state partnership grantees. One of the performance measures evaluates the availability of essential pediatric equipment and supplies for basic life support (BLS) and advanced life support (ALS) patient care units. This document will be used as the standard for this performance measure. The American Academy of Pediatrics (AAP) has also officially endorsed this list. (6/09)

ESSENTIAL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY IN CHILDREN

Committee on Child Health Financing

ABSTRACT. The previous policy statement from the American Academy of Pediatrics, "Model Language for Medical Necessity in Children," was published in July 2005. Since that time, there have been new and emerging delivery and payment models. The relationship established between health care providers and health plans should promote arrangements that are beneficial to all who are affected by these contractual arrangements. Pediatricians play an important role in ensuring that the needs of children are addressed in these emerging systems. It is important to recognize that health care plans designed for adults may not meet the needs of children. Language in health care contracts should reflect the health care needs of children and families. Informed pediatricians can make a difference in the care of children and influence the role of primary care physicians in the new paradigms. This policy highlights many of the important elements pediatricians should assess as providers develop a role in emerging care models. (7/13)

ETHICAL CONSIDERATIONS IN RESEARCH WITH SOCIALLY IDENTIFIABLE POPULATIONS

Committee on Native American Child Health and Committee on Community Health Services

ABSTRACT. Community-based research raises ethical issues not normally encountered in research conducted in academic settings. In particular, conventional risk-benefits assessments frequently fail to recognize harms that can occur in socially identifiable populations as a result of research participation. Furthermore, many such communities require more stringent measures of beneficence that must be applied directly to the participating communities. In this statement, the American Academy of Pediatrics sets forth recommendations for minimizing harms that may result from community-based research by emphasizing community involvement in the research process. (1/04, reaffirmed 10/07, 1/13)

ETHICAL CONTROVERSIES IN ORGAN DONATION AFTER CIRCULATORY DEATH

Committee on Bioethics

ABSTRACT. The persistent mismatch between the supply of and need for transplantable organs has led to efforts to increase the supply, including controlled donation after circulatory death (DCD). Controlled DCD involves organ recovery after the planned withdrawal of life-sustaining treatment and the declaration of death according to the cardiorespiratory criteria. Two central ethical issues in DCD are when organ recovery can begin and how to manage conflicts of interests. The "dead donor rule" should be maintained, and donors in cases of DCD should only be declared dead after the permanent cessation of circulatory function. Permanence is generally established by a 2- to 5-minute waiting period. Given ongoing controversy over whether the cessation must also be irreversible, physicians should not be required to participate in DCD. Because the preparation for organ recovery in DCD begins before the declaration of death, there are potential conflicts between the donor's and recipient's interests. These conflicts can be managed in a variety of ways, including informed consent and separating the various participants' roles. For example, informed consent should be sought for premortem interventions to improve organ viability, and organ procurement organization personnel and members of the transplant team should not be involved in the discontinuation of life-sustaining treatment or the declaration of death. It is also important to emphasize that potential donors in cases of DCD should receive integrated interdisciplinary palliative care, including sedation and analgesia. (4/13)

ETHICAL ISSUES WITH GENETIC TESTING IN PEDIATRICS

Committee on Bioethics

ABSTRACT. Advances in genetic research promise great strides in the diagnosis and treatment of many childhood diseases. However, emerging genetic technology often enables testing and screening before the development of definitive treatment or preventive measures. In these circumstances, careful consideration must be given to testing and screening of children to ensure that use of this technology promotes the best interest of the child. This statement reviews considerations for the use of genetic technology for newborn screening, carrier testing, and testing for susceptibility to late-onset conditions. Recommendations are made promoting informed participation by parents for newborn screening and limited use of carrier testing and testing for late-onset conditions in the pediatric population. Additional research and education in this developing area of medicine are encouraged. (6/01, reaffirmed 1/05, 1/09)

ETHICAL AND POLICY ISSUES IN GENETIC TESTING AND SCREENING OF CHILDREN

Committee on Bioethics and Committee on Genetics (joint with American College of Medical Genetics and Genomics)

ABSTRACT. The genetic testing and genetic screening of children are commonplace. Decisions about whether to offer genetic testing and screening should be driven by the best interest of the child. The growing literature on the psychosocial and clinical effects of such testing and screening can help inform best practices. This policy statement represents recommendations developed collaboratively by the American Academy of Pediatrics and the American College of Medical Genetics and Genomics with respect to many of the scenarios in which genetic testing and screening can occur. (2/13)

ETHICS AND THE CARE OF CRITICALLY ILL INFANTS AND CHILDREN

Committee on Bioethics

ABSTRACT. The ability to provide life support to ill children who, not long ago, would have died despite medicine's best efforts challenges pediatricians and families to address profound moral questions. Our society has been divided about extending the life of some patients, especially newborns and older infants with severe disabilities. The American Academy of Pediatrics (AAP) supports individualized decision making about life-sustaining medical treatment for all children, regardless of age. These decisions should be jointly made by physicians and parents, unless good reasons require invoking established child protective services to contravene parental authority. At this time, resource allocation (rationing) decisions about which children should receive intensive care resources should be made clear and explicit in public policy, rather than be made at the bedside. (7/96, reaffirmed 10/99, 6/03)

EVALUATING INFANTS AND YOUNG CHILDREN WITH MULTIPLE FRACTURES (CLINICAL REPORT)

Carole Jenny, MD, MBA, FAAP, for Committee on Child Abuse and Neglect

ABSTRACT. Infants and toddlers with multiple unexplained fractures are often victims of inflicted injury. However, several medical conditions can also cause multiple fractures in children in this age group. In this report, the differential diagnosis of multiple fractures is presented, and diagnostic testing available to the clinician is discussed. The hypothetical entity "temporary brittle-bone disease" is examined also. Although frequently offered in

court cases as a cause of multiple infant fractures, there is no evidence that this condition actually exists. (9/06)

EVALUATING FOR SUSPECTED CHILD ABUSE: CONDITIONS THAT PREDISPOSE TO BLEEDING (TECHNICAL REPORT)

Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; James D. Anderst, MD, MS; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Child abuse might be suspected when children present with cutaneous bruising, intracranial hemorrhage, or other manifestations of bleeding. In these cases, it is necessary to consider medical conditions that predispose to easy bleeding/bruising. When evaluating for the possibility of bleeding disorders and other conditions that predispose to hemorrhage, the pediatrician must consider the child's presenting history, medical history, and physical examination findings before initiating a laboratory investigation. Many medical conditions can predispose to easy bleeding. Before ordering laboratory tests for a disease, it is useful to understand the biochemical basis and clinical presentation of the disorder, condition prevalence, and test characteristics. This technical report reviews the major medical conditions that predispose to bruising/bleeding and should be considered when evaluating for abusive injury. (3/13)

See full text on page 587.

EVALUATION FOR BLEEDING DISORDERS IN SUSPECTED CHILD ABUSE (CLINICAL REPORT)

James D. Anderst, MD, MS; Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Bruising or bleeding in a child can raise the concern for child abuse. Assessing whether the findings are the result of trauma and/or whether the child has a bleeding disorder is critical. Many bleeding disorders are rare, and not every child with bruising/bleeding concerning for abuse requires an evaluation for bleeding disorders. In some instances, however, bleeding disorders can present in a manner similar to child abuse. The history and clinical evaluation can be used to determine the necessity of an evaluation for a possible bleeding disorder, and prevalence and known clinical presentations of individual bleeding disorders can be used to guide the extent of the laboratory testing. This clinical report provides guidance to pediatricians and other clinicians regarding the evaluation for bleeding disorders when child abuse is suspected. (3/13)

See full text on page 607.

THE EVALUATION OF CHILDREN IN THE PRIMARY CARE SETTING WHEN SEXUAL ABUSE IS SUSPECTED (CLINICAL REPORT)

Carole Jenny, MD, MBA; James E. Crawford-Jakubiak, MD; and Committee on Child Abuse and Neglect

ABSTRACT. This clinical report updates a 2005 report from the American Academy of Pediatrics on the evaluation of sexual abuse in children. The medical assessment of suspected child sexual abuse should include obtaining a history, performing a physical examination, and obtaining appropriate laboratory tests. The role of the physician includes determining the need to report suspected sexual abuse; assessing the physical, emotional, and behavioral consequences of sexual abuse; providing information to parents about how to support their child; and coordinating with other professionals to provide comprehensive treatment and follow-up of children exposed to child sexual abuse. (7/13)

See full text on page 619.

EVALUATION AND MANAGEMENT OF THE INFANT EXPOSED TO HIV-1 IN THE UNITED STATES (CLINICAL REPORT)

Peter L. Havens, MD; Lynne M. Mofenson, MD; and Committee on Pediatric AIDS

ABSTRACT. The pediatrician plays a key role in the prevention of mother-to-child transmission of HIV-1 infection. For infants born to women with HIV-1 infection identified during pregnancy, the pediatrician ensures that antiretroviral prophylaxis is provided to the infant to decrease the risk of acquiring HIV-1 infection and promotes avoidance of postnatal HIV-1 transmission by advising HIV-1–infected women not to breastfeed. The pediatrician should perform HIV-1 antibody testing for infants born to women whose HIV-1 infection status was not determined during pregnancy or labor. For HIV-1–exposed infants, the pediatrician monitors the infant for early determination of HIV-1 infection status and for possible short- and long-term toxicity from antiretroviral exposures. Provision of chemoprophylaxis for *Pneumocystis jiroveci* pneumonia and support of families living with HIV-1 by providing counseling to parents or caregivers are also important components of care. (12/08)

THE EVALUATION OF SEXUAL BEHAVIORS IN CHILDREN (CLINICAL REPORT)

Nancy D. Kellogg, MD, and Committee on Child Abuse and Neglect

ABSTRACT. Most children will engage in sexual behaviors at some time during childhood. These behaviors may be normal but can be confusing and concerning to parents or disruptive or intrusive to others. Knowledge of age-appropriate sexual behaviors that vary with situational and environmental factors can assist the clinician in differentiating normal sexual behaviors from sexual behavior problems. Most situations that involve sexual behaviors in young children do not require child protective services intervention; for behaviors that are age-appropriate and transient, the pediatrician may provide guidance in supervision and monitoring of the behavior. If the behavior is intrusive, hurtful, and/or age-inappropriate, a more comprehensive assessment is warranted. Some children with sexual behavior problems may reside or have resided in homes characterized by inconsistent parenting, violence, abuse, or neglect and may require more immediate intervention and referrals. (8/09, reaffirmed 3/13)

EVALUATION OF SUSPECTED CHILD PHYSICAL ABUSE (CLINICAL REPORT)

Nancy D. Kellogg, MD, and Committee on Child Abuse and Neglect

ABSTRACT. This report provides guidance in the clinical approach to the evaluation of suspected physical abuse in children. The medical assessment is outlined with respect to obtaining a history, physical examination, and

appropriate ancillary testing. The role of the physician may encompass reporting suspected abuse; assessing the consistency of the explanation, the child's developmental capabilities, and the characteristics of the injury or injuries; and coordination with other professionals to provide immediate and long-term treatment and follow-up for victims. Accurate and timely diagnosis of children who are suspected victims of abuse can ensure appropriate evaluation, investigation, and outcomes for these children and their families. (6/07, reaffirmed 5/12)

EVIDENCE FOR THE DIAGNOSIS AND TREATMENT OF ACUTE UNCOMPLICATED SINUSITIS IN CHILDREN: A SYSTEMATIC REVIEW (TECHNICAL REPORT)

Michael J. Smith, MD, MSCE

In 2001, the American Academy of Pediatrics published clinical practice guidelines for the management of acute bacterial sinusitis (ABS) in children. The technical report accompanying those guidelines included 21 studies that assessed the diagnosis and management of ABS in children. This update to that report incorporates studies of pediatric ABS that have been performed since 2001. Overall, 17 randomized controlled trials of the treatment of sinusitis in children were identified and analyzed. Four randomized, double-blind, placebo-controlled trials of antimicrobial therapy have been published. The results of these studies varied, likely due to differences in inclusion and exclusion criteria. Because of this heterogeneity, formal meta-analyses were not performed. However, qualitative analysis of these studies suggests that children with greater severity of illness at presentation are more likely to benefit from antimicrobial therapy. An additional 5 trials compared different antimicrobial therapies but did not include placebo groups. Six trials assessed a variety of ancillary treatments for ABS in children, and 3 focused on subacute sinusitis. Although the number of pediatric trials has increased since 2001, there are still limited data to guide the diagnosis and management of ABS in children. Diagnostic and treatment guidelines focusing on severity of illness at the time of presentation have the potential to identify those children most likely to benefit from antimicrobial therapy and at the same time minimize unnecessary use of antibiotics. (6/13)

See full text on page 317.

AN EVIDENCE-BASED REVIEW OF IMPORTANT ISSUES CONCERNING NEONATAL HYPERBILIRUBINEMIA (TECHNICAL REPORT)

Stanley Ip, MD; Mei Chung, MPH; John Kulig, MD, MPH; Rebecca O'Brien, MD; Robert Sege, MD, PhD; Stephan Glicken, MD; M. Jeffrey Maisels, MB, BCh; Joseph Lau, MD; and Subcommittee on Hyperbilirubinemia

ABSTRACT. This article is adapted from a published evidence report concerning neonatal hyperbilirubinemia with an added section on the risk of blood exchange transfusion (BET). Based on a summary of multiple case reports that spanned more than 30 years, we conclude that kernicterus, although infrequent, has at least 10% mortality and at least 70% long-term morbidity. It is evident that the preponderance of kernicterus cases occurred in infants with a bilirubin level higher than 20 mg/dL. Given the diversity of conclusions on the relationship between peak bilirubin levels and behavioral and neurodevelopmental outcomes, it is apparent that the use of a single total serum bilirubin level to predict long-term outcomes is inadequate and will lead to conflicting results. Evidence for efficacy of treatments for neonatal hyperbilirubinemia was limited. Overall, the 4 qualifying studies showed that phototherapy had an absolute risk-reduction rate of 10% to 17% for prevention of serum bilirubin levels higher than 20 mg/dL in healthy infants with jaundice. There is no evidence to suggest that phototherapy for neonatal hyperbilirubinemia has any long-term adverse neurodevelopmental effects. Transcutaneous measurements of bilirubin have a linear correlation to total serum bilirubin and may be useful as screening devices to detect clinically significant jaundice and decrease the need for serum bilirubin determinations. Based on our review of the risks associated with BETs from 15 studies consisting mainly of infants born before 1970, we conclude that the mortality within 6 hours of BET ranged from 3 per 1000 to 4 per 1000 exchanged infants who were term and without serious hemolytic diseases. Regardless of the definitions and rates of BET-associated morbidity and the various pre-exchange clinical states of the exchanged infants, in many cases the morbidity was minor (eg, postexchange anemia). Based on the results from the most recent study to report BET morbidity, the overall risk of permanent sequelae in 25 sick infants who survived BET was from 5% to 10%. (7/04)

EXCESSIVE SLEEPINESS IN ADOLESCENTS AND YOUNG ADULTS: CAUSES, CONSEQUENCES, AND TREATMENT STRATEGIES (TECHNICAL REPORT)

Richard P. Millman, MD; Working Group on Sleepiness in Adolescents/Young Adults; and Committee on Adolescence

ABSTRACT. Adolescents and young adults are often excessively sleepy. This excessive sleepiness can have a profound negative effect on school performance, cognitive function, and mood and has been associated with other serious consequences such as increased incidence of automobile crashes. In this article we review available scientific knowledge about normal sleep changes in adolescents (13–22 years of age), the factors associated with chronic insufficient sleep, the effect of insufficient sleep on a variety of systems and functions, and the primary sleep disorders or organic dysfunctions that, if untreated, can cause excessive daytime sleepiness in this population. (6/05)

EXPERT WITNESS PARTICIPATION IN CIVIL AND CRIMINAL PROCEEDINGS

Committee on Medical Liability and Risk Management

ABSTRACT. The interests of the public and both the medical and legal professions are best served when scientifically sound and unbiased expert witness testimony is readily available in civil and criminal proceedings. As members of the medical community, patient advocates, and private citizens, pediatricians have ethical and professional obligations to assist in the administration of justice. The American Academy of Pediatrics believes that the adoption of the recommendations outlined in this statement will improve the quality of medical expert witness testimony in legal proceedings and, thereby, increase

the probability of achieving outcomes that are fair, honest, and equitable. Strategies for enforcing guidance and promoting oversight of expert witnesses are proposed. (6/09)

EXPOSURE TO NONTRADITIONAL PETS AT HOME AND TO ANIMALS IN PUBLIC SETTINGS: RISKS TO CHILDREN (CLINICAL REPORT)

Larry K. Pickering, MD; Nina Marano, DVM, MPH; Joseph A. Bocchini, MD; Frederick J. Angulo, DVM, PhD; and Committee on Infectious Diseases

ABSTRACT. Exposure to animals can provide many benefits during the growth and development of children. However, there are potential risks associated with animal exposures, including exposure to nontraditional pets in the home and animals in public settings. Educational materials, regulations, and guidelines have been developed to minimize these risks. Pediatricians, veterinarians, and other health care professionals can provide advice on selection of appropriate pets as well as prevention of disease transmission from nontraditional pets and when children contact animals in public settings. (10/08, reaffirmed 12/11)

THE EYE EXAMINATION IN THE EVALUATION OF CHILD ABUSE (CLINICAL REPORT)

Alex V. Levin, MD, MHSc; Cindy W. Christian, MD; Committee on Child Abuse and Neglect; and Section on Ophthalmology

ABSTRACT. Retinal hemorrhage is an important indicator of possible abusive head trauma, but it is also found in a number of other conditions. Distinguishing the type, number, and pattern of retinal hemorrhages may be helpful in establishing a differential diagnosis. Identification of ocular abnormalities requires a full retinal examination by an ophthalmologist using indirect ophthalmoscopy through a pupil that has been pharmacologically dilated. At autopsy, removal of the eyes and orbital tissues may also reveal abnormalities not discovered before death. In previously well young children who experience unexpected apparent life-threatening events with no obvious cause, children with head trauma that results in significant intracranial hemorrhage and brain injury, victims of abusive head trauma, and children with unexplained death, premortem clinical eye examination and postmortem examination of the eyes and orbits may be helpful in detecting abnormalities that can help establish the underlying etiology. (7/10)

EYE EXAMINATION IN INFANTS, CHILDREN, AND YOUNG ADULTS BY PEDIATRICIANS

Committee on Practice and Ambulatory Medicine and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Early detection and prompt treatment of ocular disorders in children is important to avoid lifelong visual impairment. Examination of the eyes should be performed beginning in the newborn period and at all well-child visits. Newborns should be examined for ocular structural abnormalities, such as cataract, corneal opacity, and ptosis, which are known to result in visual problems. Vision assessment beginning at birth has been endorsed by the American Academy of Pediatrics, the American Association for Pediatric Ophthalmology and Strabismus, and the American Academy of Ophthalmology. All children who are found to have an ocular abnormality or who fail vision assessment should be referred to a pediatric ophthalmologist or an eye care specialist appropriately trained to treat pediatric patients. (4/03, reaffirmed 5/07)

FACILITIES AND EQUIPMENT FOR THE CARE OF PEDIATRIC PATIENTS IN A COMMUNITY HOSPITAL (CLINICAL REPORT)

Committee on Hospital Care

ABSTRACT. Many children who require hospitalization are admitted to community hospitals that are more accessible for families and their primary care physicians but vary substantially in their pediatric resources. The intent of this clinical report is to provide basic guidelines for furnishing and equipping a pediatric area in a community hospital. (5/03, reaffirmed 5/07, reaffirmed 8/13)

FAILURE TO THRIVE AS A MANIFESTATION OF CHILD NEGLECT (CLINICAL REPORT)

Robert W. Block, MD; Nancy F. Krebs, MD; Committee on Child Abuse and Neglect; and Committee on Nutrition

ABSTRACT. Failure to thrive is a common problem in infancy and childhood. It is most often multifactorial in origin. Inadequate nutrition and disturbed social interactions contribute to poor weight gain, delayed development, and abnormal behavior. The syndrome develops in a significant number of children as a consequence of child neglect. This clinical report is intended to focus the pediatrician on the consideration, evaluation, and management of failure to thrive when child neglect may be present. Child protective services agencies should be notified when the evaluation leads to a suspicion of abuse or neglect. (11/05, reaffirmed 1/09)

FALLS FROM HEIGHTS: WINDOWS, ROOFS, AND BALCONIES

Committee on Injury and Poison Prevention

ABSTRACT. Falls of all kinds represent an important cause of child injury and death. In the United States, approximately 140 deaths from falls occur annually in children younger than 15 years. Three million children require emergency department care for fall-related injuries. This policy statement examines the epidemiology of falls from heights and recommends preventive strategies for pediatricians and other child health care professionals. Such strategies involve parent counseling, community programs, building code changes, legislation, and environmental modification, such as the installation of window guards and balcony railings. (5/01, reaffirmed 10/04, 5/07, 6/10)

FAMILIES AND ADOPTION: THE PEDIATRICIAN'S ROLE IN SUPPORTING COMMUNICATION (CLINICAL REPORT)

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Each year, more children join families through adoption. Pediatricians have an important role in assisting adoptive families in the various challenges they may face with respect to adoption. The acceptance of the differences between families formed through birth and

those formed through adoption is essential in promoting positive emotional growth within the family. It is important for pediatricians to be informed about adoption and to share this knowledge with adoptive families. Parents need ongoing advice with respect to adoption issues and need to be supported in their communication with their adopted children. (12/03)

FATHERS AND PEDIATRICIANS: ENHANCING MEN'S ROLES IN THE CARE AND DEVELOPMENT OF THEIR CHILDREN (CLINICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Research substantiates that fathers' interactions with their children can exert a positive influence on their children's development. This report suggests ways pediatricians can enhance fathers' caregiving involvement by offering specific, culturally sensitive advice and how pediatricians might change their office practices to support and increase fathers' active involvement in their children's care and development. (5/04, reaffirmed 8/13)

FEVER AND ANTIPYRETIC USE IN CHILDREN (CLINICAL REPORT)

Janice E. Sullivan, MD; Henry C. Farrar, MD; Section on Clinical Pharmacology and Therapeutics; and Committee on Drugs

ABSTRACT. Fever in a child is one of the most common clinical symptoms managed by pediatricians and other health care providers and a frequent cause of parental concern. Many parents administer antipyretics even when there is minimal or no fever, because they are concerned that the child must maintain a "normal" temperature. Fever, however, is not the primary illness but is a physiologic mechanism that has beneficial effects in fighting infection. There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurologic complications. Thus, the primary goal of treating the febrile child should be to improve the child's overall comfort rather than focus on the normalization of body temperature. When counseling the parents or caregivers of a febrile child, the general well-being of the child, the importance of monitoring activity, observing for signs of serious illness, encouraging appropriate fluid intake, and the safe storage of antipyretics should be emphasized. Current evidence suggests that there is no substantial difference in the safety and effectiveness of acetaminophen and ibuprofen in the care of a generally healthy child with fever. There is evidence that combining these 2 products is more effective than the use of a single agent alone; however, there are concerns that combined treatment may be more complicated and contribute to the unsafe use of these drugs. Pediatricians should also promote patient safety by advocating for simplified formulations, dosing instructions, and dosing devices. (2/11)

FINANCING GRADUATE MEDICAL EDUCATION TO MEET THE NEEDS OF CHILDREN AND THE FUTURE PEDIATRICIAN WORKFORCE

Committee on Pediatric Workforce

ABSTRACT. This policy statement articulates the positions of the American Academy of Pediatrics on graduate medical education and the associated costs and funding mechanisms. It reaffirms the policy of the American Academy of Pediatrics that graduate medical education is a public good and is an essential part of maintaining a high-quality physician workforce. The American Academy of Pediatrics advocates for lifelong learning across the continuum of medical education. This policy statement focuses on the financing of one component of this continuum, namely residency education. The statement calls on federal and state governments to continue their support of residency education and advocates for stable means of funding such as the establishment of an all-payer graduate medical education trust fund. It further proposes a portable authorization system that would allocate graduate medical education funds for direct medical education costs to accredited residency programs on the basis of the selection of the program by qualified student or residents. This system allows the funding to follow the residents to their program. Recognizing the critical workforce needs of many pediatric medical subspecialties, pediatric surgical specialties, and other pediatric specialty disciplines, this statement maintains that subspecialty fellowship training and general pediatrics research fellowship training should receive adequate support from the graduate medical education financing system, including funding from the National Institutes of Health and other federal agencies, as appropriate. Furthermore, residency education that is provided in freestanding children's hospitals should receive a level of support equivalent to that of other teaching hospitals. The financing of graduate medical education is an important and effective tool to ensure that the future pediatrician workforce can provide optimal heath care for infants, children, adolescents, and young adults. (4/08, reaffirmed 1/12)

FINANCING OF PEDIATRIC HOME HEALTH CARE

Committee on Child Health Financing and Section on Home Care

ABSTRACT. In certain situations, home health care has been shown to be a cost-effective alternative to inpatient hospital care. National health expenditures reveal that pediatric home health costs totaled $5.3 billion in 2000. Medicaid is the major payer for pediatric home health care (77%), followed by other public sources (22%). Private health insurance and families each paid less than 1% of pediatric home health expenses. The most important factors affecting access to home health care are the inadequate supply of clinicians and ancillary personnel, shortages of home health nurses with pediatric expertise, inadequate payment, and restrictive insurance and managed care policies. Many children must stay in the NICU, PICU, and other pediatric wards and intermediate care areas at a much higher cost because of inadequate pediatric home health care services. The main financing problem pertaining to Medicaid is low payment to home health agencies at rates that are insufficient to provide beneficiaries access to home health services. Although home care services may be a covered benefit under private health plans, most do not cover private-duty nursing (83%), home health aides (45%), or home physical, occupational, or speech therapy (33%) and/or impose visit or monetary limits or caps. To advocate for improvements in financing of pediatric home health care, the American Academy of Pediatrics has developed several recommendations for

public policy makers, federal and state Medicaid offices, private insurers, managed care plans, Title V officials, and home health care professionals. These recommendations will improve licensing, payment, coverage, and research related to pediatric home health services. (8/06)

FIREARM-RELATED INJURIES AFFECTING THE PEDIATRIC POPULATION

Council on Injury, Violence, and Poison Prevention Executive Committee

ABSTRACT. The absence of guns from children's homes and communities is the most reliable and effective measure to prevent firearm-related injuries in children and adolescents. Adolescent suicide risk is strongly associated with firearm availability. Safe gun storage (guns unloaded and locked, ammunition locked separately) reduces children's risk of injury. Physician counseling of parents about firearm safety appears to be effective, but firearm safety education programs directed at children are ineffective. The American Academy of Pediatrics continues to support a number of specific measures to reduce the destructive effects of guns in the lives of children and adolescents, including the regulation of the manufacture, sale, purchase, ownership, and use of firearms; a ban on semiautomatic assault weapons; and the strongest possible regulations of handguns for civilian use. (10/12)

FIREWORKS-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. An estimated 8500 individuals, approximately 45% of them children younger than 15 years, were treated in US hospital emergency departments during 1999 for fireworks-related injuries. The hands (40%), eyes (20%), and head and face (20%) are the body areas most often involved. Approximately one third of eye injuries from fireworks result in permanent blindness. During 1999, 16 people died as a result of injuries associated with fireworks. Every type of legally available consumer (so-called "safe and sane") firework has been associated with serious injury or death. In 1997, 20 100 fires were caused by fireworks, resulting in $22.7 million in direct property damage. Fireworks typically cause more fires in the United States on the Fourth of July than all other causes of fire combined on that day. Pediatricians should educate parents, children, community leaders, and others about the dangers of fireworks. Fireworks for individual private use should be banned. Children and their families should be encouraged to enjoy fireworks at public fireworks displays conducted by professionals rather than purchase fireworks for home or private use. (7/01, reaffirmed 1/05, 2/08, 10/11)

FOLIC ACID FOR THE PREVENTION OF NEURAL TUBE DEFECTS

Committee on Genetics

ABSTRACT. The American Academy of Pediatrics endorses the US Public Health Service (USPHS) recommendation that all women capable of becoming pregnant consume 400 μg of folic acid daily to prevent neural tube defects (NTDs). Studies have demonstrated that periconceptional folic acid supplementation can prevent 50% or more of NTDs such as spina bifida and anencephaly. For women who have previously had an NTD-affected pregnancy, the Centers for Disease Control and Prevention (CDC) recommends increasing the intake of folic acid to 4000 μg per day beginning at least 1 month before conception and continuing through the first trimester. Implementation of these recommendations is essential for the primary prevention of these serious and disabling birth defects. Because fewer than 1 in 3 women consume the amount of folic acid recommended by the USPHS, the Academy notes that the prevention of NTDs depends on an urgent and effective campaign to close this prevention gap. (8/99, reaffirmed 11/02, 1/07, 5/12)

FOLLOW-UP MANAGEMENT OF CHILDREN WITH TYMPANOSTOMY TUBES

Section on Otolaryngology and Bronchoesophagology

ABSTRACT. The follow-up care of children in whom tympanostomy tubes have been placed is shared by the pediatrician and the otolaryngologist. Guidelines are provided for routine follow-up evaluation, perioperative hearing assessment, and the identification of specific conditions and complications that warrant urgent otolaryngologic consultation. These guidelines have been developed by a consensus of expert opinions. (2/02)

FORGOING LIFE-SUSTAINING MEDICAL TREATMENT IN ABUSED CHILDREN

Committee on Child Abuse and Neglect and Committee on Bioethics

ABSTRACT. A decision to forgo life-sustaining medical treatment (LSMT) for a critically ill child injured as the result of abuse should be made using the same criteria as those used for any critically ill child. The parent or guardian of an abused child may have a conflict of interest when a decision to forgo LSMT risks changing the legal charge faced by a parent, guardian, relative, or acquaintance from assault to manslaughter or homicide. If a physician suspects that a parent or guardian is not acting in a child's best interest, further review and consultation should be sought in hopes of resolving the conflict. A guardian ad litem who will represent the child's interests regarding LSMT should be appointed in all cases in which a parent or guardian may have a conflict of interest. (11/00, reaffirmed 6/03, 10/06, 4/09)

FORGOING MEDICALLY PROVIDED NUTRITION AND HYDRATION IN CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH; Jeffrey R. Botkin, MD, MPH; and Committee on Bioethics

ABSTRACT. There is broad consensus that withholding or withdrawing medical interventions is morally permissible when requested by competent patients or, in the case of patients without decision-making capacity, when the interventions no longer confer a benefit to the patient or when the burdens associated with the interventions outweigh the benefits received. The withdrawal or withholding of measures such as attempted resuscitation, ventilators, and critical care medications is common in the terminal care of adults and children. In the case of adults, a consensus has emerged in law and ethics that the medical administration of fluid and nutrition is not fundamentally different from other medical interventions such

as use of ventilators; therefore, it can be forgone or withdrawn when a competent adult or legally authorized surrogate requests withdrawal or when the intervention no longer provides a net benefit to the patient. In pediatrics, forgoing or withdrawing medically administered fluids and nutrition has been more controversial because of the inability of children to make autonomous decisions and the emotional power of feeding as a basic element of the care of children. This statement reviews the medical, ethical, and legal issues relevant to the withholding or withdrawing of medically provided fluids and nutrition in children. The American Academy of Pediatrics concludes that the withdrawal of medically administered fluids and nutrition for pediatric patients is ethically acceptable in limited circumstances. Ethics consultation is strongly recommended when particularly difficult or controversial decisions are being considered. (7/09)

THE FUTURE OF PEDIATRICS: MENTAL HEALTH COMPETENCIES FOR PEDIATRIC PRIMARY CARE

Committee on Psychosocial Aspects of Child and Family Health and Task Force on Mental Health

ABSTRACT. Pediatric primary care clinicians have unique opportunities and a growing sense of responsibility to prevent and address mental health and substance abuse problems in the medical home. In this report, the American Academy of Pediatrics proposes competencies requisite for providing mental health and substance abuse services in pediatric primary care settings and recommends steps toward achieving them. Achievement of the competencies proposed in this statement is a goal, not a current expectation. It will require innovations in residency training and continuing medical education, as well as a commitment by the individual clinician to pursue, over time, educational strategies suited to his or her learning style and skill level. System enhancements, such as collaborative relationships with mental health specialists and changes in the financing of mental health care, must precede enhancements in clinical practice. For this reason, the proposed competencies begin with knowledge and skills for systems-based practice. The proposed competencies overlap those of mental health specialists in some areas; for example, they include the knowledge and skills to care for children with attention-deficit/hyperactivity disorder, anxiety, depression, and substance abuse and to recognize psychiatric and social emergencies. In other areas, the competencies reflect the uniqueness of the primary care clinician's role: building resilience in all children; promoting healthy lifestyles; preventing or mitigating mental health and substance abuse problems; identifying risk factors and emerging mental health problems in children and their families; and partnering with families, schools, agencies, and mental health specialists to plan assessment and care. Proposed interpersonal and communication skills reflect the primary care clinician's critical role in overcoming barriers (perceived and/or experienced by children and families) to seeking help for mental health and substance abuse concerns. (6/09, reaffirmed 8/13)

GASTROESOPHAGEAL REFLUX: MANAGEMENT GUIDANCE FOR THE PEDIATRICIAN (CLINICAL REPORT)

Jenifer R. Lightdale, MD, MPH; David A. Gremse, MD; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. Recent comprehensive guidelines developed by the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition define the common entities of gastroesophageal reflux (GER) as the physiologic passage of gastric contents into the esophagus and gastroesophageal reflux disease (GERD) as reflux associated with troublesome symptoms or complications. The ability to distinguish between GER and GERD is increasingly important to implement best practices in the management of acid reflux in patients across all pediatric age groups, as children with GERD may benefit from further evaluation and treatment, whereas conservative recommendations are the only indicated therapy in those with uncomplicated physiologic reflux. This clinical report endorses the rigorously developed, well-referenced North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition guidelines and likewise emphasizes important concepts for the general pediatrician. A key issue is distinguishing between clinical manifestations of GER and GERD in term infants, children, and adolescents to identify patients who can be managed with conservative treatment by the pediatrician and to refer patients who require consultation with the gastroenterologist. Accordingly, the evidence basis presented by the guidelines for diagnostic approaches as well as treatments is discussed. Lifestyle changes are emphasized as first-line therapy in both GER and GERD, whereas medications are explicitly indicated only for patients with GERD. Surgical therapies are reserved for children with intractable symptoms or who are at risk for life-threatening complications of GERD. Recent black box warnings from the US Food and Drug Administration are discussed, and caution is underlined when using promoters of gastric emptying and motility. Finally, attention is paid to increasing evidence of inappropriate prescriptions for proton pump inhibitors in the pediatric population. (4/13)

GENERIC PRESCRIBING, GENERIC SUBSTITUTION, AND THERAPEUTIC SUBSTITUTION

Committee on Drugs (5/87, reaffirmed 6/93, 5/96, 6/99, 5/01, 5/05, 10/08, 10/12)

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH

Committee on Environmental Health

ABSTRACT. There is broad scientific consensus that Earth's climate is warming rapidly and at an accelerating rate. Human activities, primarily the burning of fossil fuels, are very likely (>90% probability) to be the main cause of this warming. Climate-sensitive changes in ecosystems are already being observed, and fundamental, potentially irreversible, ecological changes may occur in the coming decades. Conservative environmental estimates of the impact of climate changes that are already in process indicate that they will result in numerous health

effects to children. The nature and extent of these changes will be greatly affected by actions taken or not taken now at the global level.

Physicians have written on the projected effects of climate change on public health, but little has been written specifically on anticipated effects of climate change on children's health. Children represent a particularly vulnerable group that is likely to suffer disproportionately from both direct and indirect adverse health effects of climate change. Pediatric health care professionals should understand these threats, anticipate their effects on children's health, and participate as children's advocates for strong mitigation and adaptation strategies now. Any solutions that address climate change must be developed within the context of overall sustainability (the use of resources by the current generation to meet current needs while ensuring that future generations will be able to meet their needs). Pediatric health care professionals can be leaders in a move away from a traditional focus on disease prevention to a broad, integrated focus on sustainability as synonymous with health.

This policy statement is supported by a technical report that examines in some depth the nature of the problem of climate change, likely effects on children's health as a result of climate change, and the critical importance of responding promptly and aggressively to reduce activities that are contributing to this change. (11/07, reaffirmed 5/12)

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH (TECHNICAL REPORT)

Katherine M. Shea, MD, MPH, and Committee on Environmental Health

ABSTRACT. There is a broad scientific consensus that the global climate is warming, the process is accelerating, and that human activities are very likely (>90% probability) the main cause. This warming will have effects on ecosystems and human health, many of them adverse. Children will experience both the direct and indirect effects of climate change. Actions taken by individuals, communities, businesses, and governments will affect the magnitude and rate of global climate change and resultant health impacts. This technical report reviews the nature of the global problem and anticipated health effects on children and supports the recommendations in the accompanying policy statement on climate change and children's health. (11/07, reaffirmed 5/12)

GRADUATE MEDICAL EDUCATION AND PEDIATRIC WORKFORCE ISSUES AND PRINCIPLES

Task Force on Graduate Medical Education Reform (6/94)

GUIDANCE FOR THE ADMINISTRATION OF MEDICATION IN SCHOOL

Council on School Health

ABSTRACT. Many children who take medications require them during the school day. This policy statement is designed to guide prescribing health care professionals, school physicians, and school health councils on the administration of medications to children at school. All districts and schools need to have policies and plans in place for safe, effective, and efficient administration of medications at school. Having full-time licensed registered nurses administering all routine and emergency medications in schools is the best situation. When a licensed registered nurse is not available, a licensed practical nurse may administer medications. When a nurse cannot administer medication in school, the American Academy of Pediatrics supports appropriate delegation of nursing services in the school setting. Delegation is a tool that may be used by the licensed registered school nurse to allow unlicensed assistive personnel to provide standardized, routine health services under the supervision of the nurse and on the basis of physician guidance and school nursing assessment of the unique needs of the individual child and the suitability of delegation of specific nursing tasks. Any delegation of nursing duties must be consistent with the requirements of state nurse practice acts, state regulations, and guidelines provided by professional nursing organizations. Long-term, emergency, and short-term medications; over-the-counter medications; alternative medications; and experimental drugs that are administered as part of a clinical trial are discussed in this statement. This statement has been endorsed by the American School Health Association. (9/09, reaffirmed 2/13)

GUIDANCE FOR EFFECTIVE DISCIPLINE

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. When advising families about discipline strategies, pediatricians should use a comprehensive approach that includes consideration of the parent-child relationship, reinforcement of desired behaviors, and consequences for negative behaviors. Corporal punishment is of limited effectiveness and has potentially deleterious side effects. The American Academy of Pediatrics recommends that parents be encouraged and assisted in the development of methods other than spanking for managing undesired behavior. (4/98, reaffirmed 3/01, 1/05, 5/12)

GUIDANCE ON MANAGEMENT OF ASYMPTOMATIC NEONATES BORN TO WOMEN WITH ACTIVE GENITAL HERPES LESIONS (CLINICAL REPORT)

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. Herpes simplex virus (HSV) infection of the neonate is uncommon, but genital herpes infections in adults are very common. Thus, although treating an infant with neonatal herpes is a relatively rare occurrence, managing infants potentially exposed to HSV at the time of delivery occurs more frequently. The risk of transmitting HSV to an infant during delivery is determined in part by the mother's previous immunity to HSV. Women with primary genital HSV infections who are shedding HSV at delivery are 10 to 30 times more likely to transmit the virus to their newborn infants than are women with recurrent HSV infection who are shedding virus at delivery. With the availability of commercial serological tests that reliably can distinguish type-specific HSV antibodies, it is now possible to determine the type of maternal infection and, thus, further refine management of infants delivered to women who have active genital HSV lesions. The management algorithm presented herein uses both serologi-

cal and virological studies to determine the risk of HSV transmission to the neonate who is delivered to a mother with active herpetic genital lesions and tailors management accordingly. The algorithm does not address the approach to asymptomatic neonates delivered to women with a history of genital herpes but no active lesions at delivery. (1/13)

See full text on page 645.

GUIDELINES FOR CARE OF CHILDREN IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. Children who require emergency care have unique needs, especially when emergencies are serious or life-threatening. The majority of ill and injured children are brought to community hospital emergency departments (EDs) by virtue of their geography within communities. Similarly, emergency medical services (EMS) agencies provide the bulk of out-of-hospital emergency care to children. It is imperative, therefore, that all hospital EDs have the appropriate resources (medications, equipment, policies, and education) and staff to provide effective emergency care for children. This statement outlines resources necessary to ensure that hospital EDs stand ready to care for children of all ages, from neonates to adolescents. These guidelines are consistent with the recommendations of the Institute of Medicine's report on the future of emergency care in the United States health system. Although resources within emergency and trauma care systems vary locally, regionally, and nationally, it is essential that hospital ED staff and administrators and EMS systems' administrators and medical directors seek to meet or exceed these guidelines in efforts to optimize the emergency care of children they serve. This statement has been endorsed by the Academic Pediatric Association, American Academy of Family Physicians, American Academy of Physician Assistants, American College of Osteopathic Emergency Physicians, American College of Surgeons, American Heart Association, American Medical Association, American Pediatric Surgical Association, Brain Injury Association of America, Child Health Corporation of America, Children's National Medical Center, Family Voices, National Association of Children's Hospitals and Related Institutions, National Association of EMS Physicians, National Association of Emergency Medical Technicians, National Association of State EMS Officials, National Committee for Quality Assurance, National PTA, Safe Kids USA, Society of Trauma Nurses, Society for Academic Emergency Medicine, and The Joint Commission. (9/09, reaffirmed 4/13)

GUIDELINES FOR THE DETERMINATION OF BRAIN DEATH IN INFANTS AND CHILDREN: AN UPDATE OF THE 1987 TASK FORCE RECOMMENDATIONS (CLINICAL REPORT)

Thomas A. Nakagawa, MD; Stephen Ashwal, MD; Mudit Mathur, MD; and Mohan Mysore, MD (joint with Society of Critical Care Medicine Section on Critical Care and Section on Neurology and Child Neurology Society)

ABSTRACT. *Objective.* To review and revise the 1987 pediatric brain death guidelines.

Methods. Relevant literature was reviewed. Recommendations were developed using the GRADE system.

Conclusions and Recommendations.

(1) Determination of brain death in term newborns, infants and children is a clinical diagnosis based on the absence of neurologic function with a known irreversible cause of coma. Because of insufficient data in the literature, recommendations for preterm infants less than 37 weeks gestational age are not included in this guideline.

(2) Hypotension, hypothermia, and metabolic disturbances should be treated and corrected and medications that can interfere with the neurologic examination and apnea testing should be discontinued allowing for adequate clearance before proceeding with these evaluations.

(3) Two examinations including apnea testing with each examination separated by an observation period are required. Examinations should be performed by different attending physicians. Apnea testing may be performed by the same physician. An observation period of 24 hours for term newborns (37 weeks gestational age) to 30 days of age, and 12 hours for infants and chi (> 30 days to 18 years) is recommended. The first examination determines the child has met the accepted neurologic examination criteria for brain death. The second examination confirms brain death based on an unchanged and irreversible condition. Assessment of neurologic function following cardiopulmonary resuscitation or other severe acute brain injuries should be deferred for 24 hours or longer if there are concerns or inconsistencies in the examination.

(4) Apnea testing to support the diagnosis of brain death must be performed safely and requires documentation of an arterial PaCO2 20 mm Hg above the baseline and 60 mm Hg with no respiratory effort during the testing period. If the apnea test cannot be safely completed, an ancillary study should be performed.

(5) Ancillary studies (electroencephalogram and radionuclide cerebral blood flow) are not required to establish brain death and are not a substitute for the neurologic examination. Ancillary studies may be us d to assist the clinician in making the diagnosis of brain death (i) when components of the examination or apnea testing cannot be completed safely due to the underlying medical condition of the patient; (ii) if there is uncertainty about the results of the neurologic examination; (iii) if a medication effect may be present; or (iv) to reduce the inter-examination observation period. When ancillary studies are used, a second clinical examination and apnea test should be performed and components that can be completed must remain consistent with brain death. In this instance the observation interval may be shortened and the second

neurologic examination and apnea test (or all components that are able to be completed safely) can be performed at any time thereafter.

(6) Death is declared when the above criteria are fulfilled. (8/11)

GUIDELINES FOR DEVELOPING ADMISSION AND DISCHARGE POLICIES FOR THE PEDIATRIC INTENSIVE CARE UNIT (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine Pediatric Section Admission Criteria Task Force)

ABSTRACT. These guidelines were developed to provide a reference for preparing policies on admission to and discharge from pediatric intensive care units. They represent a consensus opinion of physicians, nurses, and allied health care professionals. By using this document as a framework for developing multidisciplinary admission and discharge policies, use of pediatric intensive care units can be optimized and patients can receive the level of care appropriate for their condition. (4/99, reaffirmed 5/05, 2/08, 1/13)

GUIDELINES FOR THE ETHICAL CONDUCT OF STUDIES TO EVALUATE DRUGS IN PEDIATRIC POPULATIONS (CLINICAL REPORT)

Robert E. Shaddy, MD; Scott C. Denne, MD; Committee on Drugs; and Committee on Pediatric Research

ABSTRACT. The proper ethical conduct of studies to evaluate drugs in children is of paramount importance to all those involved in these types of studies. This report is an updated revision to the previously published guidelines from the American Academy of Pediatrics in 1995. Since the previous publication, there have been great strides made in the science and ethics of studying drugs in children. There have also been numerous legislative and regulatory advancements that have promoted the study of drugs in children while simultaneously allowing for the protection of this particularly vulnerable group. This report summarizes these changes and advances and provides a framework from which to guide and monitor the ethical conduct of studies to evaluate drugs in children. (3/10)

GUIDELINES ON FORGOING LIFE-SUSTAINING MEDICAL TREATMENT

Committee on Bioethics (3/94, reaffirmed 11/97, 10/00, 1/04, 1/09, 10/12)

GUIDELINES FOR HOME CARE OF INFANTS, CHILDREN, AND ADOLESCENTS WITH CHRONIC DISEASE

Committee on Children With Disabilities (7/95, reaffirmed 4/00, 1/06)

GUIDELINES FOR MONITORING AND MANAGEMENT OF PEDIATRIC PATIENTS DURING AND AFTER SEDATION FOR DIAGNOSTIC AND THERAPEUTIC PROCEDURES: AN UPDATE (CLINICAL REPORT)

American Academy of Pediatrics; American Academy of Pediatric Dentistry; Charles J. Coté, MD; Stephen Wilson, DMD, MA, PhD; and Work Group on Sedation

ABSTRACT. The safe sedation of children for procedures requires a systematic approach that includes the following: no administration of sedating medication without the safety net of medical supervision; careful presedation evaluation for underlying medical or surgical conditions that would place the child at increased risk from sedating medications; appropriate fasting for elective procedures and a balance between depth of sedation and risk for those who are unable to fast because of the urgent nature of the procedure; a focused airway examination for large tonsils or anatomic airway abnormalities that might increase the potential for airway obstruction; a clear understanding of the pharmacokinetic and pharmacodynamic effects of the medications used for sedation, as well as an appreciation for drug interactions; appropriate training and skills in airway management to allow rescue of the patient; age- and size-appropriate equipment for airway management and venous access; appropriate medications and reversal agents; sufficient numbers of people to carry out the procedure and monitor the patient; appropriate physiologic monitoring during and after the procedure; a properly equipped and staffed recovery area; recovery to presedation level of consciousness before discharge from medical supervision; and appropriate discharge instructions. This report was developed through a collaborative effort of the American Academy of Pediatrics and the American Academy of Pediatric Dentistry to offer pediatric providers updated information and guidance in delivering safe sedation to children. (12/06, reaffirmed 3/11)

GUIDELINES FOR PEDIATRIC CANCER CENTERS

Section on Hematology/Oncology

ABSTRACT. Since the American Academy of Pediatrics published guidelines for pediatric cancer centers in 1986 and 1997, significant changes in the delivery of health care have prompted a review of the role of tertiary medical centers in the care of pediatric patients. The potential effect of these changes on the treatment and survival rates of children with cancer led to this revision. The intent of this statement is to delineate personnel and facilities that are essential to provide state-of-the-art care for children and adolescents with cancer. This statement emphasizes the importance of board-certified pediatric hematologists/oncologists, pediatric subspecialty consultants, and appropriately qualified pediatric medical subspecialists and pediatric surgical specialists overseeing the care of all pediatric and adolescent cancer patients and the need for facilities available only at a tertiary center as essential for the initial management and much of the follow-up for pediatric and adolescent cancer patients. (6/04, reaffirmed 10/08)

GUIDELINES FOR PEDIATRIC CARDIOVASCULAR CENTERS

Section on Cardiology and Cardiac Surgery

ABSTRACT. Pediatric cardiovascular centers should aim to provide high-quality therapeutic outcomes for infants and children with congenital and acquired heart diseases. This policy statement describes critical elements and organizational features of centers in which high-quality outcomes have the greatest likelihood of occurring. Center elements include noninvasive diagnostic modalities, cardiac catheterization, cardiovascular surgery, and cardiovascular intensive care. These elements should

be organizationally united in centers in which pediatric cardiac physician specialists and specialized pediatric staff work together to achieve and surpass existing quality-of-care benchmarks. (3/02, reaffirmed 10/07)

GUIDELINES FOR REFERRAL TO PEDIATRIC SURGICAL SPECIALISTS
Surgical Advisory Panel (7/02, reaffirmed 1/07)

GUIDING PRINCIPLES FOR MANAGED CARE ARRANGEMENTS FOR THE HEALTH CARE OF NEWBORNS, INFANTS, CHILDREN, ADOLESCENTS, AND YOUNG ADULTS
Committee on Child Health Financing
ABSTRACT. By including the precepts of primary care and the medical home in the delivery of services, managed care can be effective in increasing access to a full range of health care services and clinicians. A carefully designed and administered managed care plan can minimize patient under- and overutilization of services, as well as enhance quality of care. Therefore, the American Academy of Pediatrics urges the use of the key principles outlined in this statement in designing and implementing managed care programs for newborns, infants, children, adolescents, and young adults to maximize the positive potential of managed care for pediatrics. (10/13)
See full text on page 659.

GUIDING PRINCIPLES FOR PEDIATRIC HOSPITAL MEDICINE PROGRAMS
Section on Hospital Medicine
ABSTRACT. Pediatric hospital medicine programs have an established place in pediatric medicine. This statement speaks to the expanded roles and responsibilities of pediatric hospitalists and their integrated role among the community of pediatricians who care for children within and outside of the hospital setting. (9/13)
See full text on page 673.

GYNECOLOGIC EXAMINATION FOR ADOLESCENTS IN THE PEDIATRIC OFFICE SETTING (CLINICAL REPORT)
Paula K. Braverman, MD; Lesley Breech, MD; and Committee on Adolescence
ABSTRACT. The American Academy of Pediatrics promotes the inclusion of the gynecologic examination in the primary care setting within the medical home. Gynecologic issues are commonly seen by clinicians who provide primary care to adolescents. Some of the most common concerns include questions related to pubertal development; menstrual disorders such as dysmenorrhea, amenorrhea, oligomenorrhea, and abnormal uterine bleeding; contraception; and sexually transmitted and non–sexually transmitted infections. The gynecologic examination is a key element in assessing pubertal status and documenting physical findings. Most adolescents do not need an internal examination involving a speculum or bimanual examination. However, for cases in which more extensive examination is needed, the primary care office with the primary care clinician who has established rapport and trust with the patient is often the best setting for pelvic examination. This report reviews the gynecologic examination, including indications for the pelvic examination in adolescents and the approach to this examination in the office setting. Indications for referral to a gynecologist are included. The pelvic examination may be successfully completed when conducted without pressure and approached as a normal part of routine young women's health care. (8/10, reaffirmed 5/13)

HEAD LICE (CLINICAL REPORT)
Barbara L. Frankowski, MD, MPH; Joseph A. Bocchini, Jr, MD; Council on School Health; and Committee on Infectious Diseases
ABSTRACT. Head lice infestation is associated with limited morbidity but causes a high level of anxiety among parents of school-aged children. Since the 2002 clinical report on head lice was published by the American Academy of Pediatrics, patterns of resistance to products available over-the-counter and by prescription have changed, and additional mechanical means of removing head lice have been explored. This revised clinical report clarifies current diagnosis and treatment protocols and provides guidance for the management of children with head lice in the school setting. (7/10)

HEALTH CARE SUPERVISION FOR CHILDREN WITH WILLIAMS SYNDROME
Committee on Genetics
ABSTRACT. This set of guidelines is designed to assist the pediatrician to care for children with Williams syndrome diagnosed by clinical features and with regional chromosomal microdeletion confirmed by fluorescence in situ hybridization. (5/01, reaffirmed 5/05, 1/09)

HEALTH CARE OF YOUTH AGING OUT OF FOSTER CARE
Council on Foster Care, Adoption, and Kinship Care and Committee on Early Childhood
ABSTRACT. Youth transitioning out of foster care face significant medical and mental health care needs. Unfortunately, these youth rarely receive the services they need because of lack of health insurance. Through many policies and programs, the federal government has taken steps to support older youth in foster care and those aging out. The Fostering Connections to Success and Increasing Adoptions Act of 2008 (Pub L No. 110-354) requires states to work with youth to develop a transition plan that addresses issues such as health insurance. In addition, beginning in 2014, the Patient Protection and Affordable Care Act of 2010 (Pub L No. 111-148) makes youth aging out of foster care eligible for Medicaid coverage until age 26 years, regardless of income. Pediatricians can support youth aging out of foster care by working collaboratively with the child welfare agency in their state to ensure that the ongoing health needs of transitioning youth are met. (11/12)

HEALTH CARE FOR YOUTH IN THE JUVENILE JUSTICE SYSTEM
Committee on Adolescence
ABSTRACT. Youth in the juvenile correctional system are a high-risk population who, in many cases, have unmet physical, developmental, and mental health needs. Multiple studies have found that some of these health issues occur at higher rates than in the general adolescent population. Although some youth in the juvenile

justice system have interfaced with health care providers in their community on a regular basis, others have had inconsistent or nonexistent care. The health needs of these youth are commonly identified when they are admitted to a juvenile custodial facility. Pediatricians and other health care providers play an important role in the care of these youth, and continuity between the community and the correctional facility is crucial. This policy statement provides an overview of the health needs of youth in the juvenile correctional system, including existing resources and standards for care, financing of health care within correctional facilities, and evidence-based interventions. Recommendations are provided for the provision of health care services to youth in the juvenile correctional system as well as specific areas for advocacy efforts. (11/11)

HEALTH EQUITY AND CHILDREN'S RIGHTS

Council on Community Pediatrics and Committee on Native American Child Health

ABSTRACT. Many children in the United States fail to reach their full health and developmental potential. Disparities in their health and well-being result from the complex interplay of multiple social and environmental determinants that are not adequately addressed by current standards of pediatric practice or public policy. Integrating the principles and practice of child health equity—children's rights, social justice, human capital investment, and health equity ethics—into pediatrics will address the root causes of child health disparities.

Promoting the principles and practice of equity-based clinical care, child advocacy, and child- and family-centered public policy will help to ensure that social and environmental determinants contribute positively to the health and well-being of children. The American Academy of Pediatrics and pediatricians can move the national focus from documenting child health disparities to advancing the principles and practice of child health equity and, in so doing, influence the worldwide practice of pediatrics and child health. All pediatricians, including primary care practitioners and medical and surgical subspecialists, can incorporate these principles into their practice of pediatrics and child health. Integration of these principles into competency-based training and board certification will secure their assimilation into all levels of pediatric practice. (3/10, reaffirmed 10/13)

HEALTH INFORMATION TECHNOLOGY AND THE MEDICAL HOME

Council on Clinical Information Technology

ABSTRACT. The American Academy of Pediatrics (AAP) supports development and universal implementation of a comprehensive electronic infrastructure to support pediatric information functions of the medical home. These functions include (1) timely and continuous management and tracking of health data and services over a patient's lifetime for all providers, patients, families, and guardians, (2) comprehensive organization and secure transfer of health data during patient-care transitions between providers, institutions, and practices, (3) establishment and maintenance of central coordination of a patient's health information among multiple repositories (including personal health records and information exchanges), (4) translation of evidence into actionable clinical decision support, and (5) reuse of archived clinical data for continuous quality improvement. The AAP supports universal, secure, and vendor-neutral portability of health information for all patients contained within the medical home across all care settings (ambulatory practices, inpatient settings, emergency departments, pharmacies, consultants, support service providers, and therapists) for multiple purposes including direct care, personal health records, public health, and registries. The AAP also supports financial incentives that promote the development of information tools that meet the needs of pediatric workflows and that appropriately recognize the added value of medical homes to pediatric care. (4/11)

HEALTH AND MENTAL HEALTH NEEDS OF CHILDREN IN US MILITARY FAMILIES (CLINICAL REPORT)

Benjamin S. Siegel, MD; Beth Ellen Davis, MD, MPH; Committee on Psychosocial Aspects of Child and Family Health; and Section on Uniformed Services

ABSTRACT. The wars in Afghanistan and Iraq have been challenging for US uniformed service families and their children. Almost 60% of US service members have family responsibilities. Approximately 2.3 million active duty, National Guard, and Reserve service members have been deployed since the beginning of the wars in Afghanistan and Iraq (2001 and 2003, respectively), and almost half have deployed more than once, some for up to 18 months' duration. Up to 2 million US children have been exposed to a wartime deployment of a loved one in the past 10 years. Many service members have returned from combat deployments with symptoms of posttraumatic stress disorder, depression, anxiety, substance abuse, and traumatic brain injury. The mental health and well-being of spouses, significant others, children (and their friends), and extended family members of deployed service members continues to be significantly challenged by the experiences of wartime deployment as well as by combat mortality and morbidity. The medical system of the Department of Defense provides health and mental health services for active duty service members and their families as well as activated National Guard and Reserve service members and their families. In addition to military pediatricians and civilian pediatricians employed by military treatment facilities, nonmilitary general pediatricians care for >50% of children and family members before, during, and after wartime deployments. This clinical report is for all pediatricians, both active duty and civilian, to aid in caring for children whose loved ones have been, are, or will be deployed. (5/13)

See full text on page 681.

HEALTH SUPERVISION FOR CHILDREN WITH ACHONDROPLASIA (CLINICAL REPORT)

Tracy L. Trotter, MD; Judith G. Hall, OC, MD; and Committee on Genetics

ABSTRACT. Achondroplasia is the most common condition associated with disproportionate short stature. Substantial information is available concerning the natural history and anticipatory health supervision needs in children with this dwarfing disorder. Most children with achondroplasia have delayed motor milestones, problems

with persistent or recurrent middle-ear dysfunction, and bowing of the lower legs. Less often, infants and children may have serious health consequences related to hydrocephalus, craniocervical junction compression, upper-airway obstruction, or thoracolumbar kyphosis. Anticipatory care should be directed at identifying children who are at high risk and intervening to prevent serious sequelae. This report is designed to help the pediatrician care for children with achondroplasia and their families. (9/05, reaffirmed 5/12)

HEALTH SUPERVISION FOR CHILDREN WITH DOWN SYNDROME (CLINICAL REPORT)

Marilyn J. Bull, MD, and Committee on Genetics

ABSTRACT. These guidelines are designed to assist the pediatrician in caring for the child in whom a diagnosis of Down syndrome has been confirmed by chromosome analysis. Although a pediatrician's initial contact with the child is usually during infancy, occasionally the pregnant woman who has been given a prenatal diagnosis of Down syndrome will be referred for review of the condition and the genetic counseling provided. Therefore, this report offers guidance for this situation as well. (7/11)

HEALTH SUPERVISION FOR CHILDREN WITH FRAGILE X SYNDROME (CLINICAL REPORT)

Joseph H. Hersh, MD; Robert A. Saul, MD; and Committee on Genetics

ABSTRACT. Fragile X syndrome (an FMR1–related disorder) is the most commonly inherited form of mental retardation. Early physical recognition is difficult, so boys with developmental delay should be strongly considered for molecular testing. The characteristic adult phenotype usually does not develop until the second decade of life. Girls can also be affected with developmental delay. Because multiple family members can be affected with mental retardation and other conditions (premature ovarian failure and tremor/ataxia), family history information is of critical importance for the diagnosis and management of affected patients and their families. This report summarizes issues for fragile X syndrome regarding clinical diagnosis, laboratory diagnosis, genetic counseling, related health problems, behavior management, and age-related health supervision guidelines. The diagnosis of fragile X syndrome not only involves the affected children but also potentially has significant health consequences for multiple generations in each family. (4/11)

HEALTH SUPERVISION FOR CHILDREN WITH MARFAN SYNDROME (CLINICAL REPORT)

Brad T. Tinkle, MD, PhD; Howard M. Saal, MD; and Committee on Genetics

ABSTRACT. Marfan syndrome is a systemic, heritable connective tissue disorder that affects many different organ systems and is best managed by using a multidisciplinary approach. The guidance in this report is designed to assist the pediatrician in recognizing the features of Marfan syndrome as well as caring for the individual with this disorder. (9/13)

See full text on page 697.

HEALTH SUPERVISION FOR CHILDREN WITH NEUROFIBROMATOSIS (CLINICAL REPORT)

Joseph H. Hersh, MD, and Committee on Genetics

ABSTRACT. Neurofibromatosis 1 is a multisystem disorder that primarily involves the skin and nervous system. Its population prevalence is 1 in 3500. The condition usually is recognized in early childhood, when cutaneous manifestations are apparent. Although neurofibromatosis 1 is associated with marked clinical variability, most affected children do well from the standpoint of their growth and development. Some features of neurofibromatosis 1 are present at birth, and others are age-related abnormalities of tissue proliferation, which necessitate periodic monitoring to address ongoing health and developmental needs and to minimize the risk of serious medical complications. This clinical report provides a review of the clinical criteria needed to establish a diagnosis, the inheritance pattern of neurofibromatosis 1, its major clinical and developmental manifestations, and guidelines for monitoring and providing intervention to maximize the growth, development, and health of an affected child. (3/08)

HEALTH SUPERVISION FOR CHILDREN WITH PRADER-WILLI SYNDROME (CLINICAL REPORT)

Shawn E. McCandless, MD, and Committee on Genetics

ABSTRACT. This set of guidelines was designed to assist the pediatrician in caring for children with Prader-Willi syndrome diagnosed by clinical features and confirmed by molecular testing. Prader-Willi syndrome provides an excellent example of how early diagnosis and management can improve the long-term outcome for some genetic disorders. (12/10)

HEALTH SUPERVISION FOR CHILDREN WITH SICKLE CELL DISEASE

Section on Hematology/Oncology and Committee on Genetics

ABSTRACT. Sickle cell disease (SCD) is a group of complex genetic disorders with multisystem manifestations. This statement provides pediatricians in primary care and subspecialty practice with an overview of the genetics, diagnosis, clinical manifestations, and treatment of SCD. Specialized comprehensive medical care decreases morbidity and mortality during childhood. The provision of comprehensive care is a time-intensive endeavor that includes ongoing patient and family education, periodic comprehensive evaluations and other disease-specific health maintenance services, psychosocial care, and genetic counseling. Timely and appropriate treatment of acute illness is critical, because life-threatening complications develop rapidly. It is essential that every child with SCD receive comprehensive care that is coordinated through a medical home with appropriate expertise. (3/02, reaffirmed 1/06, 1/11)

HEARING ASSESSMENT IN INFANTS AND CHILDREN: RECOMMENDATIONS BEYOND NEONATAL SCREENING (CLINICAL REPORT)

Allen D. "Buz" Harlor Jr, MD; Charles Bower, MD; Committee on Practice and Ambulatory Medicine; and Section on Otolaryngology–Head and Neck Surgery

ABSTRACT. Congenital or acquired hearing loss in infants and children has been linked with lifelong deficits in speech and language acquisition, poor academic performance, personal-social maladjustments, and emotional difficulties. Identification of hearing loss through neonatal hearing screening, regular surveillance of developmental milestones, auditory skills, parental concerns, and middle-ear status and objective hearing screening of all infants and children at critical developmental stages can prevent or reduce many of these adverse consequences. This report promotes a proactive, consistent, and explicit process for the early identification of children with hearing loss in the medical home. An algorithm of the recommended approach has been developed to assist in the detection and documentation of, and intervention for, hearing loss. (9/09)

HELPING CHILDREN AND FAMILIES DEAL WITH DIVORCE AND SEPARATION (CLINICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. More than 1 million children each year experience their parents' divorce. For these children and their parents, this process can be emotionally traumatic from the beginning of parental disagreement and rancor, through the divorce, and often for many years thereafter. Pediatricians are encouraged to be aware of behavioral changes in their patients that might be signals of family dysfunction so they can help parents and children understand and deal more positively with the issue. Age-appropriate explanation and counseling is important so children realize that they are not the cause of, and cannot be the cure for, the divorce. Pediatricians can offer families guidance in dealing with their children through the troubled time as well as appropriate lists of reading material and, if indicated, can refer them to professionals with expertise in the emotional, social, and legal aspects of divorce and its aftermath. (11/02, reaffirmed 1/06)

HIGH-DEDUCTIBLE HEALTH PLANS AND THE NEW RISKS OF CONSUMER-DRIVEN HEALTH INSURANCE PRODUCTS

Committee on Child Health Financing

ABSTRACT. Consumer-driven health care is the most noteworthy development in health insurance since the widespread adoption of health maintenance organizations and preferred provider organizations in the 1980s. The most common consumer-driven health plan is the high-deductible health plan, which is essentially a catastrophic health insurance plan, often linked with tax-advantaged spending accounts, with very high deductibles, fewer benefits, and higher cost-sharing than conventional health maintenance organization or preferred provider organization plans. The financial risks are significant under high-deductible health plans, especially for low- to moderate-income families and for families whose children have special health care needs. Of concern for pediatricians are the potential quality risks that are predictable in high-deductible health plans, in which families are likely to delay or avoid seeking care, especially preventive care (if it is not exempted from the deductible), when they are faced with paying for care before the deductible is met. This policy statement provides background information on the most common consumer-driven health plan model, discusses the implications for pediatricians and families, and offers recommendations pertaining to health plan product design, education, practice administration, and research. (3/07)

HIV TESTING AND PROPHYLAXIS TO PREVENT MOTHER-TO-CHILD TRANSMISSION IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Universal HIV testing of pregnant women in the United States is the key to prevention of mother-to-child transmission of HIV. Repeat testing in the third trimester and rapid HIV testing at labor and delivery are additional strategies to further reduce the rate of perinatal HIV transmission. Prevention of mother-to-child transmission of HIV is most effective when antiretroviral drugs are received by the mother during her pregnancy and continued through delivery and then administered to the infant after birth. Antiretroviral drugs are effective in reducing the risk of mother-to-child transmission of HIV even when prophylaxis is started for the infant soon after birth. New rapid testing methods allow identification of HIV-infected women or HIV-exposed infants in 20 to 60 minutes. The American Academy of Pediatrics recommends documented, routine HIV testing for all pregnant women in the United States after notifying the patient that testing will be performed, unless the patient declines HIV testing ("opt-out" consent or "right of refusal"). For women in labor with undocumented HIV-infection status during the current pregnancy, immediate maternal HIV testing with opt-out consent, using a rapid HIV antibody test, is recommended. Positive HIV antibody screening test results should be confirmed with immunofluorescent antibody or Western blot assay. For women with a positive rapid HIV antibody test result, antiretroviral prophylaxis should be administered promptly to the mother and newborn infant on the basis of the positive result of the rapid antibody test without waiting for results of confirmatory HIV testing. If the confirmatory test result is negative, then prophylaxis should be discontinued. For a newborn infant whose mother's HIV serostatus is unknown, the health care professional should perform rapid HIV antibody testing on the mother or on the newborn infant, with results reported to the health care professional no later than 12 hours after the infant's birth. If the rapid HIV antibody test result is positive, antiretroviral prophylaxis should be instituted as soon as possible after birth but certainly by 12 hours after delivery, pending completion of confirmatory HIV testing. The mother should be counseled not to breastfeed the infant. Assistance with immediate initiation of hand and pump expression to stimulate milk production should be offered to the mother, given the possibility that the confirmatory test result may be negative. If the confirmatory test result is negative, then prophylaxis should be stopped and breastfeeding may be initiated. If the confirmatory

test result is positive, infants should receive antiretroviral prophylaxis for 6 weeks after birth, and the mother should not breastfeed the infant. (11/08, reaffirmed 6/11)

HOME CARE OF CHILDREN AND YOUTH WITH COMPLEX HEALTH CARE NEEDS AND TECHNOLOGY DEPENDENCIES (CLINICAL REPORT)

Ellen Roy Elias, MD; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. Children and youth with complex medical issues, especially those with technology dependencies, experience frequent and often lengthy hospitalizations. Hospital discharges for these children can be a complicated process that requires a deliberate, multistep approach. In addition to successful discharges to home, it is essential that pediatric providers develop and implement an interdisciplinary and coordinated plan of care that addresses the child's ongoing health care needs. The goal is to ensure that each child remains healthy, thrives, and obtains optimal medical home and developmental supports that promote ongoing care at home and minimize recurrent hospitalizations. This clinical report presents an approach to discharging the child with complex medical needs with technology dependencies from hospital to home and then continually addressing the needs of the child and family in the home environment. (4/12)

HOME, HOSPITAL, AND OTHER NON–SCHOOL-BASED INSTRUCTION FOR CHILDREN AND ADOLESCENTS WHO ARE MEDICALLY UNABLE TO ATTEND SCHOOL

Committee on School Health

ABSTRACT. The American Academy of Pediatrics recommends that school-aged children and adolescents obtain their education in school in the least restrictive setting, that is, the setting most conducive to learning for the particular student. However, at times, acute illness or injury and chronic medical conditions preclude school attendance. This statement is meant to assist evaluation and planning for children to receive non–school-based instruction and to return to school at the earliest possible date. (11/00, reaffirmed 6/03, 5/06)

HONORING DO-NOT-ATTEMPT-RESUSCITATION REQUESTS IN SCHOOLS

Council on School Health and Committee on Bioethics

ABSTRACT. Increasingly, children and adolescents with complex chronic conditions are living in the community. Federal legislation and regulations facilitate their participation in school. Some of these children and adolescents and their families may wish to forego life-sustaining medical treatment, including cardiopulmonary resuscitation, because they would be ineffective or because the risks outweigh the benefits. Honoring these requests in the school environment is complex because of the limited availability of school nurses and the frequent lack of supporting state legislation and regulations. Understanding and collaboration on the part of all parties is essential. Pediatricians have an important role in helping school nurses incorporate a specific action plan into the student's individualized health care plan. The action plan should include both communication and comfort-care plans. Pediatricians who work directly with schools can also help implement policies, and professional organizations can advocate for regulations and legislation that enable students and their families to effectuate their preferences. (4/10, reaffirmed 7/13)

HOSPITAL DISCHARGE OF THE HIGH-RISK NEONATE

Committee on Fetus and Newborn

ABSTRACT. This policy statement updates the guidelines on discharge of the high-risk neonate first published by the American Academy of Pediatrics in 1998. As with the earlier document, this statement is based, insofar as possible, on published, scientifically derived information. This updated statement incorporates new knowledge about risks and medical care of the high-risk neonate, the timing of discharge, and planning for care after discharge. It also refers to other American Academy of Pediatrics publications that are relevant to these issues. This statement draws on the previous classification of high-risk infants into 4 categories: (1) the preterm infant; (2) the infant with special health care needs or dependence on technology; (3) the infant at risk because of family issues; and (4) the infant with anticipated early death. The issues of deciding when discharge is appropriate, defining the specific needs for follow-up care, and the process of detailed discharge planning are addressed as they apply in general to all 4 categories; in addition, special attention is directed to the particular issues presented by the 4 individual categories. Recommendations are given to aid in deciding when discharge is appropriate and to ensure that all necessary care will be available and well coordinated after discharge. The need for individualized planning and physician judgment is emphasized. (11/08, reaffirmed 5/11)

THE HOSPITAL RECORD OF THE INJURED CHILD AND THE NEED FOR EXTERNAL CAUSE-OF-INJURY CODES

Committee on Injury and Poison Prevention

ABSTRACT. Proper record-keeping of emergency department visits and hospitalizations of injured children is vital for appropriate patient management. Determination and documentation of the circumstances surrounding the injury event are essential. This information not only is the basis for preventive counseling, but also provides clues about how similar injuries in other youth can be avoided. The hospital records have an important secondary purpose; namely, if sufficient information about the cause and mechanism of injury is documented, it can be subsequently coded, electronically compiled, and retrieved later to provide an epidemiologic profile of the injury, the first step in prevention at the population level. To be of greatest use, hospital records should indicate the "who, what, when, where, why, and how" of the injury occurrence and whether protective equipment (eg, a seat belt) was used. The pediatrician has two important roles in this area: to document fully the injury event and to advocate the use of standardized external cause-of-injury codes, which allow such data to be compiled and analyzed. (2/99, reaffirmed 5/02, 5/05, 10/08)

HOSPITAL STAY FOR HEALTHY TERM NEWBORNS

Committee on Fetus and Newborn

ABSTRACT. The hospital stay of the mother and her healthy term newborn infant should be long enough to allow identification of early problems and to ensure that

the family is able and prepared to care for the infant at home. The length of stay should also accommodate the unique characteristics of each mother-infant dyad, including the health of the mother, the health and stability of the infant, the ability and confidence of the mother to care for her infant, the adequacy of support systems at home, and access to appropriate follow-up care. Input from the mother and her obstetrician should be considered before a decision to discharge a newborn is made, and all efforts should be made to keep mothers and infants together to promote simultaneous discharge. (1/10)

HPV VACCINE RECOMMENDATIONS
Committee on Infectious Diseases
ABSTRACT. On October 25, 2011, the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention recommended that the quadrivalent human papillomavirus vaccine (Gardasil; Merck & Co, Inc, Whitehouse Station, NJ) be used routinely in males. The American Academy of Pediatrics has reviewed updated data provided by the Advisory Committee on Immunization Practices on vaccine efficacy, safety, and cost-effectiveness as well as programmatic considerations and supports this recommendation. This revised statement updates recommendations for human papillomavirus immunization of both males and females. (2/12)

HUMAN EMBRYONIC STEM CELL (HESC) AND HUMAN EMBRYO RESEARCH
Committee on Pediatric Research and Committee on Bioethics
ABSTRACT. Human embryonic stem cell research has emerged as an important platform for the understanding and treatment of pediatric diseases. From its inception, however, it has raised ethical concerns based not on the use of stem cells themselves but on objections to the source of the cells—specifically, the destruction of preimplantation human embryos. Despite differences in public opinion on this issue, a large majority of the public supports continued research using embryonic stem cells. Given the possible substantial benefit of stem cell research on child health and development, the American Academy of Pediatrics believes that funding and oversight for human embryo and embryonic stem cell research should continue. (10/12)

HUMAN IMMUNODEFICIENCY VIRUS AND OTHER BLOOD-BORNE VIRAL PATHOGENS IN THE ATHLETIC SETTING
Committee on Sports Medicine and Fitness
ABSTRACT. Because athletes and the staff of athletic programs can be exposed to blood during athletic activity, they have a very small risk of becoming infected with human immunodeficiency virus, hepatitis B virus, or hepatitis C virus. This statement, which updates a previous position statement of the American Academy of Pediatrics, discusses sports participation for athletes infected with these pathogens and the precautions needed to reduce the risk of infection to others in the athletic setting. Each of the recommendations in this statement is dependent upon and intended to be considered with reference to the other recommendations in this statement and not in isolation. (12/99, reaffirmed 1/05, 1/09, 11/11)

HUMAN IMMUNODEFICIENCY VIRUS SCREENING
Committee on Fetus and Newborn and Committee on Pediatric AIDS (joint with American College of Obstetricians and Gynecologists) (7/99, reaffirmed 6/02, 5/05, 10/08, 5/12)

HUMAN MILK, BREASTFEEDING, AND TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS IN THE UNITED STATES
Committee on Pediatric AIDS (*11/95, reaffirmed 11/99, 11/03, 2/08)*

HUMAN MILK, BREASTFEEDING, AND TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 IN THE UNITED STATES (TECHNICAL REPORT)
Committee on Pediatric AIDS
ABSTRACT. Transmission of human immunodeficiency virus type 1 (HIV-1) through breastfeeding has been conclusively demonstrated. The risk of such transmission has been quantified, the timing has been clarified, and certain risk factors for breastfeeding transmission have been identified. In areas where infant formula is accessible, affordable, safe, and sustainable, avoidance of breastfeeding has represented one of the main components of mother-to-child HIV-1 transmission prevention efforts for many years. In areas where affordable and safe alternatives to breastfeeding may not be available, interventions to prevent breastfeeding transmission are being investigated. Complete avoidance of breastfeeding by HIV-1-infected women has been recommended by the American Academy of Pediatrics and the Centers for Disease Control and Prevention and remains the only means by which prevention of breastfeeding transmission of HIV-1 can be absolutely ensured. This technical report summarizes the information available regarding breastfeeding transmission of HIV-1. (11/03, reaffirmed 1/07)

IDENTIFICATION AND CARE OF HIV-EXPOSED AND HIV-INFECTED INFANTS, CHILDREN, AND ADOLESCENTS IN FOSTER CARE
Committee on Pediatric AIDS
ABSTRACT. As a consequence of the expanding human immunodeficiency virus (HIV) epidemic and major advances in medical management of HIV-exposed and HIV-infected persons, revised recommendations are provided for HIV testing of infants, children, and adolescents in foster care. Updated recommendations also are provided for the care of HIV-exposed and HIV-infected persons who are in foster care. (7/00, reaffirmed 3/03, 2/08, 6/11)

IDENTIFICATION AND EVALUATION OF CHILDREN WITH AUTISM SPECTRUM DISORDERS (CLINICAL REPORT)
Chris Plauché Johnson, MD, MEd; Scott M. Myers, MD; and Council on Children With Disabilities
ABSTRACT. Autism spectrum disorders are not rare; many primary care pediatricians care for several children with autism spectrum disorders. Pediatricians play an important role in early recognition of autism spectrum disorders, because they usually are the first point of contact for parents. Parents are now much more aware of

the early signs of autism spectrum disorders because of frequent coverage in the media; if their child demonstrates any of the published signs, they will most likely raise their concerns to their child's pediatrician. It is important that pediatricians be able to recognize the signs and symptoms of autism spectrum disorders and have a strategy for assessing them systematically. Pediatricians also must be aware of local resources that can assist in making a definitive diagnosis of, and in managing, autism spectrum disorders. The pediatrician must be familiar with developmental, educational, and community resources as well as medical subspecialty clinics. This clinical report is 1 of 2 documents that replace the original American Academy of Pediatrics policy statement and technical report published in 2001. This report addresses background information, including definition, history, epidemiology, diagnostic criteria, early signs, neuropathologic aspects, and etiologic possibilities in autism spectrum disorders. In addition, this report provides an algorithm to help the pediatrician develop a strategy for early identification of children with autism spectrum disorders. The accompanying clinical report addresses the management of children with autism spectrum disorders and follows this report on page 1162 [available at www.pediatrics.org/cgi/content/full/120/5/1162]. Both clinical reports are complemented by the toolkit titled *"Autism: Caring for Children With Autism Spectrum Disorders: A Resource Toolkit for Clinicians,"* which contains screening and surveillance tools, practical forms, tables, and parent handouts to assist the pediatrician in the identification, evaluation, and management of autism spectrum disorders in children. (11/07, reaffirmed 9/10)

IDENTIFICATION AND MANAGEMENT OF EATING DISORDERS IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

David S. Rosen, MD, MPH, and Committee on Adolescence

ABSTRACT. The incidence and prevalence of eating disorders in children and adolescents has increased significantly in recent decades, making it essential for pediatricians to consider these disorders in appropriate clinical settings, to evaluate patients suspected of having these disorders, and to manage (or refer) patients in whom eating disorders are diagnosed. This clinical report includes a discussion of diagnostic criteria and outlines the initial evaluation of the patient with disordered eating. Medical complications of eating disorders may affect any organ system, and careful monitoring for these complications is required. The range of treatment options, including pharmacotherapy, is described in this report. Pediatricians are encouraged to advocate for legislation and policies that ensure appropriate services for patients with eating disorders, including medical care, nutritional intervention, mental health treatment, and care coordination. (11/10)

IDENTIFYING INFANTS AND YOUNG CHILDREN WITH DEVELOPMENTAL DISORDERS IN THE MEDICAL HOME: AN ALGORITHM FOR DEVELOPMENTAL SURVEILLANCE AND SCREENING

Council on Children With Disabilities, Section on Developmental and Behavioral Pediatrics, Bright Futures Steering Committee, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee

ABSTRACT. Early identification of developmental disorders is critical to the well-being of children and their families. It is an integral function of the primary care medical home and an appropriate responsibility of all pediatric health care professionals. This statement provides an algorithm as a strategy to support health care professionals in developing a pattern and practice for addressing developmental concerns in children from birth through 3 years of age. The authors recommend that developmental surveillance be incorporated at every well-child preventive care visit. Any concerns raised during surveillance should be promptly addressed with standardized developmental screening tests. In addition, screening tests should be administered regularly at the 9-, 18-, and 30-month visits. (Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age. In addition, because the frequency of regular pediatric visits decreases after 24 months of age, a pediatrician who expects that his or her patients will have difficulty attending a 30-month visit should conduct screening during the 24-month visit.) The early identification of developmental problems should lead to further developmental and medical evaluation, diagnosis, and treatment, including early developmental intervention. Children diagnosed with developmental disorders should be identified as children with special health care needs, and chronic-condition management should be initiated. Identification of a developmental disorder and its underlying etiology may also drive a range of treatment planning, from medical treatment of the child to family planning for his or her parents. (7/06, reaffirmed 12/09)

IMMUNIZATION INFORMATION SYSTEMS

Committee on Practice and Ambulatory Medicine

ABSTRACT. The American Academy of Pediatrics continues to support the development and implementation of immunization information systems, previously referred to as immunization registries, and other systems for the benefit of children, pediatricians, and their communities. Pediatricians and others must be aware of the value that immunization information systems have for society, the potential fiscal influences on their practice, the costs and benefits, and areas for future improvement. (9/06, reaffirmed 10/11)

IMMUNIZING PARENTS AND OTHER CLOSE FAMILY CONTACTS IN THE PEDIATRIC OFFICE SETTING (TECHNICAL REPORT)

Herschel R. Lessin, MD; Kathryn M. Edwards, MD; Committee on Practice and Ambulatory Medicine; and Committee on Infectious Diseases

ABSTRACT. Additional strategies are needed to protect children from vaccine-preventable diseases. In particular, very young infants, as well as children who are immunocompromised, are at especially high risk for developing the serious consequences of vaccine-preventable diseases and cannot be immunized completely. There is some evidence that children who become infected with these diseases are exposed to pathogens through household contacts, particularly from parents or other close family contacts. Such infections likely are attributable to adults who are not fully protected from these diseases, either because their immunity to vaccine-preventable diseases has waned over time or because they have not received a vaccine. There are many challenges that have added to low adult immunization rates in the United States. One option to increase immunization coverage for parents and close family contacts of infants and vulnerable children is to provide alternative locations for these adults to be immunized, such as the pediatric office setting. Ideally, adults should receive immunizations in their medical homes; however, to provide greater protection to these adults and reduce the exposure of children to pathogens, immunizing parents or other adult family contacts in the pediatric office setting could increase immunization coverage for this population to protect themselves as well as children to whom they provide care. (12/11)

IMPACT OF MUSIC, MUSIC LYRICS, AND MUSIC VIDEOS ON CHILDREN AND YOUTH

Council on Communications and Media

ABSTRACT. Music plays an important role in the socialization of children and adolescents. Popular music is present almost everywhere, and it is easily available through the radio, various recordings, the Internet, and new technologies, allowing adolescents to hear it in diverse settings and situations, alone or shared with friends. Parents often are unaware of the lyrics to which their children are listening because of the increasing use of downloaded music and headphones. Research on popular music has explored its effects on schoolwork, social interactions, mood and affect, and particularly behavior. The effect that popular music has on children's and adolescents' behavior and emotions is of paramount concern. Lyrics have become more explicit in their references to drugs, sex, and violence over the years, particularly in certain genres. A teenager's preference for certain types of music could be correlated or associated with certain behaviors. As with popular music, the perception and the effect of music-video messages are important, because research has reported that exposure to violence, sexual messages, sexual stereotypes, and use of substances of abuse in music videos might produce significant changes in behaviors and attitudes of young viewers. Pediatricians and parents should be aware of this information. Furthermore, with the evidence portrayed in these studies, it is essential for pediatricians and parents to take a stand regarding music lyrics. (10/09)

THE IMPACT OF SOCIAL MEDIA ON CHILDREN, ADOLESCENTS, AND FAMILIES (CLINICAL REPORT)

Gwenn Schurgin O'Keeffe, MD; Kathleen Clarke-Pearson, MD; and Council on Communications and Media

ABSTRACT. Using social media Web sites is among the most common activity of today's children and adolescents. Any Web site that allows social interaction is considered a social media site, including social networking sites such as Facebook, MySpace, and Twitter; gaming sites and virtual worlds such as Club Penguin, Second Life, and the Sims; video sites such as YouTube; and blogs. Such sites offer today's youth a portal for entertainment and communication and have grown exponentially in recent years. For this reason, it is important that parents become aware of the nature of social media sites, given that not all of them are healthy environments for children and adolescents. Pediatricians are in a unique position to help families understand these sites and to encourage healthy use and urge parents to monitor for potential problems with cyberbullying, "Facebook depression," sexting, and exposure to inappropriate content. (3/11)

IMPLEMENTATION PRINCIPLES AND STRATEGIES FOR THE STATE CHILDREN'S HEALTH INSURANCE PROGRAM

Committee on Child Health Financing

ABSTRACT. This policy statement presents principles and implementation and evaluation strategies recommended for the State Children's Health Insurance Program (SCHIP). The statement summarizes the current status of SCHIP, the needs of uninsured children, and the potential benefits of SCHIP programs. Principles and recommended strategies include expanding eligibility, maximizing funding, providing comprehensive benefits, including pediatricians in program design and evaluation, providing adequate reimbursement and access to pediatricians, ensuring choices for families and pediatricians, and establishing simple administrative procedures. (5/01)

THE IMPORTANCE OF PLAY IN PROMOTING HEALTHY CHILD DEVELOPMENT AND MAINTAINING STRONG PARENT-CHILD BONDS (CLINICAL REPORT)

Kenneth R. Ginsburg, MD, MSEd; Committee on Communications; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Play is essential to development because it contributes to the cognitive, physical, social, and emotional well-being of children and youth. Play also offers an ideal opportunity for parents to engage fully with their children. Despite the benefits derived from play for both children and parents, time for free play has been markedly reduced for some children. This report addresses a variety of factors that have reduced play, including a hurried lifestyle, changes in family structure, and increased attention to academics and enrichment activities at the expense of recess or free child-centered play. This report offers guidelines on how pediatricians can advocate for children by helping families, school systems, and communities consider how best to ensure that play is protected as they seek the balance in children's lives to create the optimal developmental milieu. (1/07)

THE IMPORTANCE OF PLAY IN PROMOTING HEALTHY CHILD DEVELOPMENT AND MAINTAINING STRONG PARENT-CHILD BOND: FOCUS ON CHILDREN IN POVERTY (CLINICAL REPORT)

Regina M. Milteer, MD; Kenneth R. Ginsburg, MD, MSEd; Council on Communications and Media; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Play is essential to the social, emotional, cognitive, and physical well-being of children beginning in early childhood. It is a natural tool for children to develop resiliency as they learn to cooperate, overcome challenges, and negotiate with others. Play also allows children to be creative. It provides time for parents to be fully engaged with their children, to bond with their children, and to see the world from the perspective of their child. However, children who live in poverty often face socioeconomic obstacles that impede their rights to have playtime, thus affecting their healthy social-emotional development. For children who are underresourced to reach their highest potential, it is essential that parents, educators, and pediatricians recognize the importance of lifelong benefits that children gain from play. (12/11)

IMPROVING SUBSTANCE ABUSE PREVENTION, ASSESSMENT, AND TREATMENT FINANCING FOR CHILDREN AND ADOLESCENTS

Committee on Child Health Financing and Committee on Substance Abuse

ABSTRACT. The numbers of children, adolescents, and families affected by substance abuse have sharply increased since the early 1990s. The American Academy of Pediatrics recognizes the scope and urgency of this problem and has developed this policy statement for consideration by Congress, federal and state agencies, employers, national organizations, health care professionals, health insurers, managed care organizations, advocacy groups, and families. (10/01)

THE INAPPROPRIATE USE OF SCHOOL "READINESS" TESTS

Committee on Early Childhood, Adoption, and Dependent Care and Committee on School Health (3/95, reaffirmed 4/98, 1/04, 4/10)

INCORPORATING RECOGNITION AND MANAGEMENT OF PERINATAL AND POSTPARTUM DEPRESSION INTO PEDIATRIC PRACTICE (CLINICAL REPORT)

Marian F. Earls, MD, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Every year, more than 400 000 infants are born to mothers who are depressed, which makes perinatal depression the most underdiagnosed obstetric complication in America. Postpartum depression leads to increased costs of medical care, inappropriate medical care, child abuse and neglect, discontinuation of breastfeeding, and family dysfunction and adversely affects early brain development. Pediatric practices, as medical homes, can establish a system to implement postpartum depression screening and to identify and use community resources for the treatment and referral of the depressed mother and support for the mother-child (dyad) relationship. This system would have a positive effect on the health and well-being of the infant and family. State chapters of the American Academy of Pediatrics, working with state Early Periodic Screening, Diagnosis, and Treatment (EPSDT) and maternal and child health programs, can increase awareness of the need for perinatal depression screening in the obstetric and pediatric periodicity of care schedules and ensure payment. Pediatricians must advocate for workforce development for professionals who care for very young children and for promotion of evidence-based interventions focused on healthy attachment and parent-child relationships. (10/10)

INCREASING ANTIRETROVIRAL DRUG ACCESS FOR CHILDREN WITH HIV INFECTION

Committee on Pediatric AIDS and Section on International Child Health

ABSTRACT. Although there have been great gains in the prevention of pediatric HIV infection and provision of antiretroviral therapy for children with HIV infection in resource-rich countries, many barriers remain to scaling up HIV prevention and treatment for children in resource-limited areas of the world. Appropriate testing technologies need to be made more widely available to identify HIV infection in infants. Training of practitioners in the skills required to care for children with HIV infection is required to increase the number of children receiving antiretroviral therapy. Lack of availability of appropriate antiretroviral drug formulations that are easily usable and inexpensive is a major impediment to optimal care for children with HIV. The time and energy spent trying to develop liquid antiretroviral formulations might be better used in the manufacture of smaller pill sizes or crushable tablets, which are easier to dispense, transport, store, and administer to children. (4/07, reaffirmed 4/10)

INCREASING IMMUNIZATION COVERAGE

Committee on Practice and Ambulatory Medicine and Council on Community Pediatrics

ABSTRACT. In 1977, the American Academy of Pediatrics issued a statement calling for universal immunization of all children for whom vaccines are not contraindicated. In 1995, the policy statement "Implementation of the Immunization Policy" was published by the American Academy of Pediatrics, followed in 2003 with publication of the first version of this statement, "Increasing Immunization Coverage." Since 2003, there have continued to be improvements in immunization coverage, with progress toward meeting the goals set forth in *Healthy People 2010.* Data from the 2007 National Immunization Survey showed that 90% of children 19 to 35 months of age have received recommended doses of each of the following vaccines: inactivated poliovirus (IPV), measles-mumps-rubella (MMR), varicella-zoster virus (VZB), hepatitis B virus (HBV), and *Haemophilus influenzae* type b (Hib). For diphtheria and tetanus and acellular pertussis (DTaP) vaccine, 84.5% have received the recommended 4 doses by 35 months of age. Nevertheless, the *Healthy People 2010* goal of at least 80% coverage for the full series (at least 4 doses of DTaP, 3 doses of IPV, 1 dose of MMR, 3 doses of Hib, 3 doses of HBV, and 1 dose of varicella-zoster virus vaccine) has not yet been met, and immunization coverage of adolescents continues to lag behind the goals set forth in *Healthy People 2010.* Despite these

encouraging data, a vast number of new challenges that threaten continued success toward the goal of universal immunization coverage have emerged. These challenges include an increase in new vaccines and new vaccine combinations as well as a significant number of vaccines currently under development; a dramatic increase in the acquisition cost of vaccines, coupled with a lack of adequate payment to practitioners to buy and administer vaccines; unanticipated manufacturing and delivery problems that have caused significant shortages of various vaccine products; and the rise of a public antivaccination movement that uses the Internet as well as standard media outlets to advance a position, wholly unsupported by any scientific evidence, linking vaccines with various childhood conditions, particularly autism. Much remains to be accomplished by physician organizations; vaccine manufacturers; third-party payers; the media; and local, state, and federal governments to ensure dependable vaccine supply and payments that are sufficient to continue to provide immunizations in public and private settings and to promote effective strategies to combat unjustified misstatements by the antivaccination movement.

Pediatricians should work individually and collectively at the local, state, and national levels to ensure that all children without a valid contraindication receive all childhood immunizations on time. Pediatricians and pediatric organizations, in conjunction with government agencies such as the Centers for Disease Control and Prevention, must communicate effectively with parents to maximize their understanding of the overall safety and efficacy of vaccines. Most parents and children have not experienced many of the vaccine-preventable diseases, and the general public is not well informed about the risks and sequelae of these conditions. A number of recommendations are included for pediatricians, individually and collectively, to support further progress toward the goal of universal immunization coverage of all children for whom vaccines are not contraindicated. (5/10)

INDICATIONS FOR MANAGEMENT AND REFERRAL OF PATIENTS INVOLVED IN SUBSTANCE ABUSE

Committee on Substance Abuse

ABSTRACT. This statement addresses the challenge of evaluating and managing the various stages of substance use by children and adolescents in the context of pediatric practice. Approaches are suggested that would assist the pediatrician in differentiating highly prevalent experimental and occasional use from more severe use with adverse consequences that affect emotional, behavioral, educational, or physical health. Comorbid psychiatric conditions are common and should be evaluated and treated simultaneously by child and adolescent mental health specialists. Guidelines for referral based on severity of involvement using established patient treatment-matching criteria are outlined. Pediatricians need to become familiar with treatment professionals and facilities in their communities and to ensure that treatment for adolescent patients is appropriate based on their developmental, psychosocial, medical, and mental health needs. The family should be encouraged to participate actively in the treatment process. (7/00)

INFANT FEEDING AND TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Physicians caring for infants born to women infected with HIV are likely to be involved in providing guidance to HIV-infected mothers on appropriate infant feeding practices. It is critical that physicians are aware of the HIV transmission risk from human milk and the current recommendations for feeding HIV-exposed infants in the United States. Because the only intervention to completely prevent HIV transmission via human milk is not to breastfeed, in the United States, where clean water and affordable replacement feeding are available, the American Academy of Pediatrics recommends that HIV-infected mothers not breastfeed their infants, regardless of maternal viral load and antiretroviral therapy. (1/13)

INFANT METHEMOGLOBINEMIA: THE ROLE OF DIETARY NITRATE IN FOOD AND WATER (CLINICAL REPORT)

Frank R. Greer, MD; Michael Shannon, MD; Committee on Nutrition; and Committee on Environmental Health

ABSTRACT. Infants for whom formula may be prepared with well water remain a high-risk group for nitrate poisoning. This clinical report reinforces the need for testing of well water for nitrate content. There seems to be little or no risk of nitrate poisoning from commercially prepared infant foods in the United States. However, reports of nitrate poisoning from home-prepared vegetable foods for infants continue to occur. Breastfeeding infants are not at risk of methemoglobinemia even when mothers ingest water with very high concentrations of nitrate nitrogen (100 ppm). (9/05, reaffirmed 4/09)

INFECTION PREVENTION AND CONTROL IN PEDIATRIC AMBULATORY SETTINGS

Committee on Infectious Diseases

ABSTRACT. Since the American Academy of Pediatrics published a statement titled "Infection Control in Physicians' Offices" (*Pediatrics.* 2000;105[6]:1361–1369), there have been significant changes that prompted this updated statement. Infection prevention and control is an integral part of pediatric practice in ambulatory medical settings as well as in hospitals. Infection prevention and control practices should begin at the time the ambulatory visit is scheduled. All health care personnel should be educated regarding the routes of transmission and techniques used to prevent transmission of infectious agents. Policies for infection prevention and control should be written, readily available, updated annually, and enforced. The standard precautions for hospitalized patients from the Centers for Disease Control and Prevention, with a modification from the American Academy of Pediatrics exempting the use of gloves for routine diaper changes and wiping a well child's nose or tears, are appropriate for most patient encounters. As employers, pediatricians are required by the Occupational Safety and Health Administration to take precautions to identify and protect employees who are likely to be exposed to blood or other potentially infectious materials while on the job. Key principles of standard precautions include hand hygiene

(ie, use of alcohol-based hand rub or hand-washing with soap [plain or antimicrobial] and water) before and after every patient contact; implementation of respiratory hygiene and cough-etiquette strategies for patients with suspected influenza or infection with another respiratory tract pathogen to the extent feasible; separation of infected, contagious children from uninfected children when feasible; safe handling and disposal of needles and other sharp medical devices and evaluation and implementation of needle-safety devices; appropriate use of personal protective equipment such as gloves, gowns, masks, and eye protection; and appropriate sterilization, disinfection, and antisepsis. (9/07, reaffirmed 8/10)

INFORMED CONSENT, PARENTAL PERMISSION, AND ASSENT IN PEDIATRIC PRACTICE
Committee on Bioethics (2/95, reaffirmed 11/98, 11/02, 10/06, 5/11)

INHALANT ABUSE (CLINICAL REPORT)
Janet F. Williams, MD; Michael Storck, MD; Committee on Substance Abuse; and Committee on Native American Child Health
ABSTRACT. Inhalant abuse is the intentional inhalation of a volatile substance for the purpose of achieving an altered mental state. As an important, yet-underrecognized form of substance abuse, inhalant abuse crosses all demographic, ethnic, and socioeconomic boundaries, causing significant morbidity and mortality in school-aged and older children. This clinical report reviews key aspects of inhalant abuse, emphasizes the need for greater awareness, and offers advice regarding the pediatrician's role in the prevention and management of this substance abuse problem. (5/07)

INJURIES ASSOCIATED WITH INFANT WALKERS
Committee on Injury and Poison Prevention
ABSTRACT. In 1999, an estimated 8800 children younger than 15 months were treated in hospital emergency departments in the United States for injuries associated with infant walkers. Thirty-four infant walker-related deaths were reported from 1973 through 1998. The vast majority of injuries occur from falls down stairs, and head injuries are common. Walkers do not help a child learn to walk; indeed, they can delay normal motor and mental development. The use of warning labels, public education, adult supervision during walker use, and stair gates have all been demonstrated to be insufficient strategies to prevent injuries associated with infant walkers. To comply with the revised voluntary standard (ASTM F977-96), walkers manufactured after June 30, 1997, must be wider than a 36-in doorway or must have a braking mechanism designed to stop the walker if 1 or more wheels drop off the riding surface, such as at the top of a stairway. Because data indicate a considerable risk of major and minor injury and even death from the use of infant walkers, and because there is no clear benefit from their use, the American Academy of Pediatrics recommends a ban on the manufacture and sale of mobile infant walkers. If a parent insists on using a mobile infant walker, it is vital that they choose a walker that meets the performance standards of ASTM F977-96 to prevent falls down stairs. Stationary activity centers should be promoted as a safer alternative to mobile infant walkers. (9/01, reaffirmed 1/05, 2/08, 10/11)

INJURIES IN YOUTH SOCCER (CLINICAL REPORT)
Chris G. Koutures, MD; Andrew J. M. Gregory, MD; and Council on Sports Medicine and Fitness
ABSTRACT. Injury rates in youth soccer, known as football outside the United States, are higher than in many other contact/collision sports and have greater relative numbers in younger, preadolescent players. With regard to musculoskeletal injuries, young females tend to suffer more knee injuries, and young males suffer more ankle injuries. Concussions are fairly prevalent in soccer as a result of contact/collision rather than purposeful attempts at heading the ball. Appropriate rule enforcement and emphasis on safe play can reduce the risk of soccer-related injuries. This report serves as a basis for encouraging safe participation in soccer for children and adolescents. (1/10, reaffirmed 5/13)

INJURY RISK OF NONPOWDER GUNS (TECHNICAL REPORT)
Committee on Injury, Violence, and Poison Prevention
ABSTRACT. Nonpowder guns (ball-bearing [BB] guns, pellet guns, air rifles, paintball guns) continue to cause serious injuries to children and adolescents. The muzzle velocity of these guns can range from approximately 150 ft/second to 1200 ft/second (the muzzle velocities of traditional firearm pistols are 750 ft/second to 1450 ft/second). Both low- and high-velocity nonpowder guns are associated with serious injuries, and fatalities can result from high-velocity guns. A persisting problem is the lack of medical recognition of the severity of injuries that can result from these guns, including penetration of the eye, skin, internal organs, and bone. Nationally, in 2000, there were an estimated 21840 (coefficient of variation: 0.0821) injuries related to nonpowder guns, with approximately 4% resulting in hospitalization. Between 1990 and 2000, the US Consumer Product Safety Commission reported 39 nonpowder gun–related deaths, of which 32 were children younger than 15 years. The introduction of high-powered air rifles in the 1970s has been associated with approximately 4 deaths per year. The advent of war games and the use of paintball guns have resulted in a number of reports of injuries, especially to the eye. Injuries associated with nonpowder guns should receive prompt medical management similar to the management of firearm-related injuries, and nonpowder guns should never be characterized as toys. (11/04, reaffirmed 2/08, 10/11)

IN-LINE SKATING INJURIES IN CHILDREN AND ADOLESCENTS
Committee on Injury and Poison Prevention and Committee on Sports Medicine and Fitness
ABSTRACT. In-line skating has become one of the fastest-growing recreational sports in the United States. Recent studies emphasize the value of protective gear in reducing the incidence of injuries. Recommendations are provided for parents and pediatricians, with special emphasis on the novice or inexperienced skater. (4/98, reaffirmed 1/02, 1/06, 1/09, 11/11)

INSTITUTIONAL ETHICS COMMITTEES
Committee on Bioethics
ABSTRACT. In hospitals throughout the United States, institutional ethics committees (IECs) have become a standard vehicle for the education of health professionals about biomedical ethics, for the drafting and review of hospital policy, and for clinical ethics case consultation. In addition, there is increasing interest in a role for the IEC in organizational ethics. Recommendations are made about the membership and structure of an IEC, and guidelines are provided for those serving on an ethics committee. (1/01, reaffirmed 1/04, 1/09, 10/12)

INSTRUMENT-BASED PEDIATRIC VISION SCREENING POLICY STATEMENT
Section on Ophthalmology and Committee on Practice and Ambulatory Medicine (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)
ABSTRACT. A policy statement describing the use of automated vision screening technology (instrument-based vision screening) is presented. Screening for amblyogenic refractive error with instrument-based screening is not dependent on behavioral responses of children, as when visual acuity is measured. Instrument-based screening is quick, requires minimal cooperation of the child, and is especially useful in the preverbal, preliterate, or developmentally delayed child. Children younger than 4 years can benefit from instrument-based screening, and visual acuity testing can be used reliably in older children. Adoption of this new technology is highly dependent on third-party payment policies, which could present a significant barrier to adoption. (10/12)

INSURANCE COVERAGE OF MENTAL HEALTH AND SUBSTANCE ABUSE SERVICES FOR CHILDREN AND ADOLESCENTS: A CONSENSUS STATEMENT
Joint Statement (10/00)

INTENSIVE TRAINING AND SPORTS SPECIALIZATION IN YOUNG ATHLETES
Committee on Sports Medicine and Fitness
ABSTRACT. Children involved in sports should be encouraged to participate in a variety of different activities and develop a wide range of skills. Young athletes who specialize in just one sport may be denied the benefits of varied activity while facing additional physical, physiologic, and psychologic demands from intense training and competition.

This statement reviews the potential risks of high-intensity training and sports specialization in young athletes. Pediatricians who recognize these risks can have a key role in monitoring the health of these young athletes and helping reduce risks associated with high-level sports participation. (7/00, reaffirmed 11/04, 1/06, 5/09)

INTIMATE PARTNER VIOLENCE: THE ROLE OF THE PEDIATRICIAN (CLINICAL REPORT)
Jonathan D. Thackeray, MD; Roberta Hibbard, MD; M. Denise Dowd, MD, MPH; Committee on Child Abuse and Neglect; and Committee on Injury, Violence, and Poison Prevention
ABSTRACT. The American Academy of Pediatrics and its members recognize the importance of improving the physician's ability to recognize intimate partner violence (IPV) and understand its effects on child health and development and its role in the continuum of family violence. Pediatricians are in a unique position to identify abused caregivers in pediatric settings and to evaluate and treat children raised in homes in which IPV may occur. Children exposed to IPV are at increased risk of being abused and neglected and are more likely to develop adverse health, behavioral, psychological, and social disorders later in life. Identifying IPV, therefore, may be one of the most effective means of preventing child abuse and identifying caregivers and children who may be in need of treatment and/or therapy. Pediatricians should be aware of the profound effects of exposure to IPV on children. (4/10)

KNEE BRACE USE IN THE YOUNG ATHLETE (TECHNICAL REPORT)
Committee on Sports Medicine and Fitness
ABSTRACT. This statement is a revision of a previous statement on prophylactic knee bracing and provides information for pediatricians regarding the use of various types of knee braces, indications for the use of knee braces, and the background knowledge necessary to prescribe the use of knee braces for children. (8/01, reaffirmed 1/07, 4/10, 5/13)

LACTOSE INTOLERANCE IN INFANTS, CHILDREN, AND ADOLESCENTS (CLINICAL REPORT)
Melvin B. Heyman, MD, MPH, for Committee on Nutrition
ABSTRACT. The American Academy of Pediatrics Committee on Nutrition presents an updated review of lactose intolerance in infants, children, and adolescents. Differences between primary, secondary, congenital, and developmental lactase deficiency that may result in lactose intolerance are discussed. Children with suspected lactose intolerance can be assessed clinically by dietary lactose elimination or by tests including noninvasive hydrogen breath testing or invasive intestinal biopsy determination of lactase (and other disaccharidase) concentrations. Treatment consists of use of lactase-treated dairy products or oral lactase supplementation, limitation of lactose-containing foods, or dairy elimination. The American Academy of Pediatrics supports use of dairy foods as an important source of calcium for bone mineral health and of other nutrients that facilitate growth in children and adolescents. If dairy products are eliminated, other dietary sources of calcium or calcium supplements need to be provided. (9/06, reaffirmed 8/12)

"LATE-PRETERM" INFANTS: A POPULATION AT RISK (CLINICAL REPORT)

William A. Engle, MD; Kay M. Tomashek, MD; Carol Wallman, MSN; and Committee on Fetus and Newborn

ABSTRACT. Late-preterm infants, defined by birth at 34$^{6}/_{7}$ through 36$^{6}/_{7}$ weeks' gestation, are less physiologically and metabolically mature than term infants. Thus, they are at higher risk of morbidity and mortality than term infants. The purpose of this report is to define "late preterm," recommend a change in terminology from "near term" to "late preterm," present the characteristics of late-preterm infants that predispose them to a higher risk of morbidity and mortality than term infants, and propose guidelines for the evaluation and management of these infants after birth. (12/07, reaffirmed 5/10)

LAWN MOWER-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. Lawn mower-related injuries to children are relatively common and can result in severe injury or death. Many amputations during childhood are caused by power mowers. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)

LAWN MOWER-RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Committee on Injury and Poison Prevention

ABSTRACT. In the United States, approximately 9400 children younger than 18 years receive emergency treatment annually for lawn mower-related injuries. More than 7% of these children require hospitalization, and power mowers cause a large proportion of the amputations during childhood. Prevention of lawn mower-related injuries can be achieved by design changes of lawn mowers, guidelines for mower operation, and education of parents, child caregivers, and children. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)

LEARNING DISABILITIES, DYSLEXIA, AND VISION

Section on Ophthalmology and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities, including reading disabilities, are commonly diagnosed in children. Their etiologies are multifactorial, reflecting genetic influences and dysfunction of brain systems. Learning disabilities are complex problems that require complex solutions. Early recognition and referral to qualified educational professionals for evidence-based evaluations and treatments seem necessary to achieve the best possible outcome. Most experts believe that dyslexia is a language-based disorder. Vision problems can interfere with the process of learning; however, vision problems are not the cause of primary dyslexia or learning disabilities. Scientific evidence does not support the efficacy of eye exercises, behavioral vision therapy, or special tinted filters or lenses for improving the long-term educational performance in these complex pediatric neurocognitive conditions. Diagnostic and treatment approaches that lack scientific evidence of efficacy, including eye exercises, behavioral vision therapy, or special tinted filters or lenses, are not endorsed and should not be recommended. (7/09)

LEARNING DISABILITIES, DYSLEXIA, AND VISION (TECHNICAL REPORT)

Sheryl M. Handler, MD; Walter M. Fierson, MD; and Section on Ophthalmology and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities constitute a diverse group of disorders in which children who generally possess at least average intelligence have problems processing information or generating output. Their etiologies are multifactorial and reflect genetic influences and dysfunction of brain systems. Reading disability, or dyslexia, is the most common learning disability. It is a receptive language-based learning disability that is characterized by difficulties with decoding, fluent word recognition, rapid automatic naming, and/or reading-comprehension skills. These difficulties typically result from a deficit in the phonologic component of language that makes it difficult to use the alphabetic code to decode the written word. Early recognition and referral to qualified professionals for evidence-based evaluations and treatments are necessary to achieve the best possible outcome. Because dyslexia is a language-based disorder, treatment should be directed at this etiology. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension. Most programs include daily intensive individualized instruction that explicitly teaches phonemic awareness and the application of phonics. Vision problems can interfere with the process of reading, but children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions. Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems cause or increase the severity of learning disabilities. Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of scientifically unsupported vision-based diagnostic and treatment procedures. Scientific evidence does not support the claims that visual training, muscle exercises, ocular pursuit-and-tracking exercises, behavioral/perceptual vision therapy, "training" glasses, prisms, and colored lenses and filters are effective direct or indirect treatments for learning disabilities. There is no valid evidence that children who participate in vision therapy are more responsive to educational instruction than children who do not participate. (3/11)

LEGALIZATION OF MARIJUANA: POTENTIAL IMPACT ON YOUTH

Committee on Substance Abuse and Committee on Adolescence

ABSTRACT. As experts in the health care of children and adolescents, pediatricians may be called on to advise legislators concerning the potential impact of changes in the legal status of marijuana on adolescents. Parents, too, may look to pediatricians for advice as they consider whether

to support state-level initiatives that propose to legalize the use of marijuana for medical purposes or to decriminalize possession of small amounts of marijuana. This policy statement provides the position of the American Academy of Pediatrics on the issue of marijuana legalization, and the accompanying technical report (available online) reviews what is currently known about the relationship between adolescents' use of marijuana and its legal status to better understand how change might influence the degree of marijuana use by adolescents in the future. (6/04)

LEGALIZATION OF MARIJUANA: POTENTIAL IMPACT ON YOUTH (TECHNICAL REPORT)

Committee on Substance Abuse and Committee on Adolescence

ABSTRACT. This technical report provides historical perspectives and comparisons of various approaches to the legal status of marijuana to aid in forming public policy. Information on the impact that decriminalization and legalization of marijuana could have on adolescents, in addition to concerns surrounding medicinal use of marijuana, are also addressed in this report. Recommendations are included in the accompanying policy statement. (6/04)

LEVELS OF NEONATAL CARE

Committee on Fetus and Newborn

ABSTRACT. Provision of risk-appropriate care for newborn infants and mothers was first proposed in 1976. This updated policy statement provides a review of data supporting evidence for a tiered provision of care and reaffirms the need for uniform, nationally applicable definitions and consistent standards of service for public health to improve neonatal outcomes. Facilities that provide hospital care for newborn infants should be classified on the basis of functional capabilities, and these facilities should be organized within a regionalized system of perinatal care. (8/12)

THE LIFELONG EFFECTS OF EARLY CHILDHOOD ADVERSITY AND TOXIC STRESS (TECHNICAL REPORT)

Jack P. Shonkoff, MD; Andrew S. Garner, MD, PhD; Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in fields of inquiry as diverse as neuroscience, molecular biology, genomics, developmental psychology, epidemiology, sociology, and economics are catalyzing an important paradigm shift in our understanding of health and disease across the lifespan. This converging, multidisciplinary science of human development has profound implications for our ability to enhance the life prospects of children and to strengthen the social and economic fabric of society. Drawing on these multiple streams of investigation, this report presents an ecobiodevelopmental framework that illustrates how early experiences and environmental influences can leave a lasting signature on the genetic predispositions that affect emerging brain architecture and long-term health. The report also examines extensive evidence of the disruptive impacts of toxic stress, offering intriguing insights into causal mechanisms that link early adversity to later impairments in learning, behavior, and both physical and mental well-being. The implications of this framework for the practice of medicine, in general, and pediatrics, specifically, are potentially transformational. They suggest that many adult diseases should be viewed as developmental disorders that begin early in life and that persistent health disparities associated with poverty, discrimination, or maltreatment could be reduced by the alleviation of toxic stress in childhood. An ecobiodevelopmental framework also underscores the need for new thinking about the focus and boundaries of pediatric practice. It calls for pediatricians to serve as both front-line guardians of healthy child development and strategically positioned, community leaders to inform new science-based strategies that build strong foundations for educational achievement, economic productivity, responsible citizenship, and lifelong health. (12/11)

LONG-TERM FOLLOW-UP CARE FOR PEDIATRIC CANCER SURVIVORS (CLINICAL REPORT)

Section on Hematology/Oncology (joint with Children's Oncology Group)

ABSTRACT. Progress in therapy has made survival into adulthood a reality for most children, adolescents, and young adults diagnosed with cancer today. Notably, this growing population remains vulnerable to a variety of long-term therapy-related sequelae. Systematic ongoing follow-up of these patients, therefore, is important for providing for early detection of and intervention for potentially serious late-onset complications. In addition, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care to promote risk reduction for health problems that commonly present during adulthood. Both general and subspecialty pediatric health care providers are playing an increasingly important role in the ongoing care of childhood cancer survivors, beyond the routine preventive care, health supervision, and anticipatory guidance provided to all patients. This report is based on the guidelines that have been developed by the Children's Oncology Group to facilitate comprehensive long-term follow-up of childhood cancer survivors (www.survivorshipguidelines.org). (3/09, reaffirmed 4/13)

MALE ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH CARE (CLINICAL REPORT)

Arik V. Marcell, MD, MPH; Charles Wibbelsman, MD; Warren M. Seigel, MD; and Committee on Adolescence

ABSTRACT. Male adolescents' sexual and reproductive health needs often go unmet in the primary care setting. This report discusses specific issues related to male adolescents' sexual and reproductive health care in the context of primary care, including pubertal and sexual development, sexual behavior, consequences of sexual behavior, and methods of preventing sexually transmitted infections (including HIV) and pregnancy. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, and delivering appropriate vaccinations. Pediatricians should provide these services to male ado-

lescent patients in a confidential and culturally appropriate manner, promote healthy sexual relationships and responsibility, and involve parents in age-appropriate discussions about sexual health with their sons. (11/11)

MALE CIRCUMCISION (TECHNICAL REPORT)

Task Force on Circumcision

ABSTRACT. Male circumcision consists of the surgical removal of some, or all, of the foreskin (or prepuce) from the penis. It is one of the most common procedures in the world. In the United States, the procedure is commonly performed during the newborn period. In 2007, the American Academy of Pediatrics (AAP) convened a multidisciplinary workgroup of AAP members and other stakeholders to evaluate the evidence regarding male circumcision and update the AAP's 1999 recommendations in this area. The Task Force included AAP representatives from specialty areas as well as members of the AAP Board of Directors and liaisons representing the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, and the Centers for Disease Control and Prevention. The Task Force members identified selected topics relevant to male circumcision and conducted a critical review of peer-reviewed literature by using the American Heart Association's template for evidence evaluation.

Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks; furthermore, the benefits of newborn male circumcision justify access to this procedure for families who choose it. Specific benefits from male circumcision were identified for the prevention of urinary tract infections, acquisition of HIV, transmission of some sexually transmitted infections, and penile cancer. Male circumcision does not appear to adversely affect penile sexual function/sensitivity or sexual satisfaction. It is imperative that those providing circumcision are adequately trained and that both sterile techniques and effective pain management are used. Significant acute complications are rare. In general, untrained providers who perform circumcisions have more complications than well-trained providers who perform the procedure, regardless of whether the former are physicians, nurses, or traditional religious providers.

Parents are entitled to factually correct, nonbiased information about circumcision and should receive this information from clinicians before conception or early in pregnancy, which is when parents typically make circumcision decisions. Parents should determine what is in the best interest of their child. Physicians who counsel families about this decision should provide assistance by explaining the potential benefits and risks and ensuring that parents understand that circumcision is an elective procedure. The Task Force strongly recommends the creation, revision, and enhancement of educational materials to assist parents of male infants with the care of circumcised and uncircumcised penises. The Task Force also strongly recommends the development of educational materials for providers to enhance practitioners' competency in discussing circumcision's benefits and risks with parents.

The Task Force made the following recommendations:

- Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks, and the benefits of newborn male circumcision justify access to this procedure for those families who choose it.
- Parents are entitled to factually correct, nonbiased information about circumcision that should be provided before conception and early in pregnancy, when parents are most likely to be weighing the option of circumcision of a male child.
- Physicians counseling families about elective male circumcision should assist parents by explaining, in a nonbiased manner, the potential benefits and risks and by ensuring that they understand the elective nature of the procedure.
- Parents should weigh the health benefits and risks in light of their own religious, cultural, and personal preferences, as the medical benefits alone may not outweigh these other considerations for individual families.
- Parents of newborn boys should be instructed in the care of the penis, regardless of whether the newborn has been circumcised or not.
- Elective circumcision should be performed only if the infant's condition is stable and healthy.
- Male circumcision should be performed by trained and competent practitioners, by using sterile techniques and effective pain management.
- Analgesia is safe and effective in reducing the procedural pain associated with newborn circumcision; thus, adequate analgesia should be provided whenever newborn circumcision is performed.
  - — Nonpharmacologic techniques (eg, positioning, sucrose pacifiers) alone are insufficient to prevent procedural and postprocedural pain and are not recommended as the sole method of analgesia. They should be used only as analgesic adjuncts to improve infant comfort during circumcision.
  - — If used, topical creams may cause a higher incidence of skin irritation in low birth weight infants, compared with infants of normal weight; penile nerve block techniques should therefore be chosen for this group of newborns.
- Key professional organizations (AAP, the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, the American Society of Anesthesiologists, the American College of Nurse Midwives, and other midlevel clinicians such as nurse practitioners) should work collaboratively to:
  - — Develop standards of trainee proficiency in the performance of anesthetic and procedure techniques, including suturing;
  - — Teach the procedure and analgesic techniques during postgraduate training programs;
  - — Develop educational materials for clinicians to enhance their own competency in discussing the benefits and risks of circumcision with parents;
  - — Offer educational materials to assist parents of male infants with the care of both circumcised and uncircumcised penises.

- The preventive and public health benefits associated with newborn male circumcision warrant third-party reimbursement of the procedure.

The American College of Obstetricians and Gynecologists has endorsed this technical report. (8/12)

MALTREATMENT OF CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Roberta A. Hibbard, MD; Larry W. Desch, MD; Committee on Child Abuse and Neglect; and Council on Children With Disabilities

ABSTRACT. Widespread efforts are being made to increase awareness and provide education to pediatricians regarding risk factors of child abuse and neglect. The purpose of this clinical report is to ensure that children with disabilities are recognized as a population that is also at risk of maltreatment. Some conditions related to a disability can be confused with maltreatment. The need for early recognition and intervention of child abuse and neglect in this population, as well as the ways that a medical home can facilitate the prevention and early detection of child maltreatment, are the subject of this report. (5/07, reaffirmed 1/11)

MANAGEMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDERS (CLINICAL REPORT)

Scott M. Myers, MD; Chris Plauché Johnson, MD, MEd; and Council on Children With Disabilities

ABSTRACT. Pediatricians have an important role not only in early recognition and evaluation of autism spectrum disorders but also in chronic management of these disorders. The primary goals of treatment are to maximize the child's ultimate functional independence and quality of life by minimizing the core autism spectrum disorder features, facilitating development and learning, promoting socialization, reducing maladaptive behaviors, and educating and supporting families. To assist pediatricians in educating families and guiding them toward empirically supported interventions for their children, this report reviews the educational strategies and associated therapies that are the primary treatments for children with autism spectrum disorders. Optimization of health care is likely to have a positive effect on habilitative progress, functional outcome, and quality of life; therefore, important issues, such as management of associated medical problems, pharmacologic and nonpharmacologic intervention for challenging behaviors or coexisting mental health conditions, and use of complementary and alternative medical treatments, are also addressed. (11/07, reaffirmed 9/10)

MANAGEMENT OF FOOD ALLERGY IN THE SCHOOL SETTING (CLINICAL REPORT)

Scott H. Sicherer, MD; Todd Mahr, MD; and Section on Allergy and Immunology

ABSTRACT. Food allergy is estimated to affect approximately 1 in 25 school-aged children and is the most common trigger of anaphylaxis in this age group. School food-allergy management requires strategies to reduce the risk of ingestion of the allergen as well as procedures to recognize and treat allergic reactions and anaphylaxis. The role of the pediatrician or pediatric health care provider may include diagnosing and documenting a potentially life-threatening food allergy, prescribing self-injectable epinephrine, helping the child learn how to store and use the medication in a responsible manner, educating the parents of their responsibility to implement prevention strategies within and outside the home environment, and working with families, schools, and students in developing written plans to reduce the risk of anaphylaxis and to implement emergency treatment in the event of a reaction. This clinical report highlights the role of the pediatrician and pediatric health care provider in managing students with food allergies. (11/10)

MANAGEMENT OF NEONATES WITH SUSPECTED OR PROVEN EARLY-ONSET BACTERIAL SEPSIS (CLINICAL REPORT)

Richard A. Polin, MD, and Committee on Fetus and Newborn

ABSTRACT. With improved obstetrical management and evidence-based use of intrapartum antimicrobial therapy, early-onset neonatal sepsis is becoming less frequent. However, early-onset sepsis remains one of the most common causes of neonatal morbidity and mortality in the preterm population. The identification of neonates at risk for early-onset sepsis is frequently based on a constellation of perinatal risk factors that are neither sensitive nor specific. Furthermore, diagnostic tests for neonatal sepsis have a poor positive predictive accuracy. As a result, clinicians often treat well-appearing infants for extended periods of time, even when bacterial cultures are negative. The optimal treatment of infants with suspected early-onset sepsis is broad-spectrum antimicrobial agents (ampicillin and an aminoglycoside). Once a pathogen is identified, antimicrobial therapy should be narrowed (unless synergism is needed). Recent data suggest an association between prolonged empirical treatment of preterm infants (≥5 days) with broad-spectrum antibiotics and higher risks of late onset sepsis, necrotizing enterocolitis, and mortality. To reduce these risks, antimicrobial therapy should be discontinued at 48 hours in clinical situations in which the probability of sepsis is low. The purpose of this clinical report is to provide a practical and, when possible, evidence-based approach to the management of infants with suspected or proven early-onset sepsis. (4/12)

MANAGEMENT OF PEDIATRIC TRAUMA

Section on Orthopaedics, Committee on Pediatric Emergency Medicine, Section on Critical Care, Section on Surgery, and Section on Transport Medicine (joint with Pediatric Orthopaedic Society of North America)

ABSTRACT. Injury is the number 1 killer of children in the United States. In 2004, injury accounted for 59.5% of all deaths in children younger than 18 years. The financial burden to society of children who survive childhood injury with disability continues to be enormous. The entire process of managing childhood injury is complex and varies by region. Only the comprehensive cooperation of a broadly diverse group of people will have a significant effect on improving the care and outcome of injured children. (4/08, reaffirmed 4/13)

MANAGEMENT OF TYPE 2 DIABETES MELLITUS IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Shelley C. Springer, MD, MBA, MSc, JD; Janet Silverstein, MD; Kenneth Copeland, MD; Kelly R. Moore, MD; Greg E. Prazar, MD; Terry Raymer, MD, CDE; Richard N. Shiffman, MD; Vidhu V. Thaker, MD; Meaghan Anderson, MS, RD, LD, CDE; Stephen J. Spann, MD, MBA; and Susan K. Flinn, MA

ABSTRACT. *Objective.* Over the last 3 decades, the prevalence of childhood obesity has increased dramatically in North America, ushering in a variety of health problems, including type 2 diabetes mellitus (T2DM), which previously was not typically seen until much later in life. This technical report describes, in detail, the procedures undertaken to develop the recommendations given in the accompanying clinical practice guideline, "Management of Type 2 Diabetes Mellitus in Children and Adolescents," and provides in-depth information about the rationale for the recommendations and the studies used to make the clinical practice guideline's recommendations.

Methods. A primary literature search was conducted relating to the treatment of T2DM in children and adolescents, and a secondary literature search was conducted relating to the screening and treatment of T2DM's comorbidities in children and adolescents. Inclusion criteria were prospectively and unanimously agreed on by members of the committee. An article was eligible for inclusion if it addressed treatment (primary search) or 1 of 4 comorbidities (secondary search) of T2DM, was published in 1990 or later, was written in English, and included an abstract. Only primary research inquiries were considered; review articles were considered if they included primary data or opinion. The research population had to constitute children and/or adolescents with an existing diagnosis of T2DM; studies of adult patients were considered if at least 10% of the study population was younger than 35 years. All retrieved titles, abstracts, and articles were reviewed by the consulting epidemiologist.

Results. Thousands of articles were retrieved and considered in both searches on the basis of the aforementioned criteria. From those, in the primary search, 199 abstracts were identified for possible inclusion, 58 of which were retained for systematic review. Five of these studies were classified as grade A studies, 1 as grade B, 20 as grade C, and 32 as grade D. Articles regarding treatment of T2DM selected for inclusion were divided into 4 major subcategories on the basis of type of treatment being discussed: (1) medical treatments (32 studies); (2) nonmedical treatments (9 studies); (3) provider behaviors (8 studies); and (4) social issues (9 studies). From the secondary search, an additional 336 abstracts relating to comorbidities were identified for possible inclusion, of which 26 were retained for systematic review. These articles included the following: 1 systematic review of literature regarding comorbidities of T2DM in adolescents; 5 expert opinions presenting global recommendations not based on evidence; 5 cohort studies reporting natural history of disease and comorbidities; 3 with specific attention to comorbidity patterns in specific ethnic groups (case-control, cohort, and clinical report using adult literature); 3 reporting an association between microalbuminuria and retinopathy (2 case-control, 1 cohort); 3 reporting the prevalence of nephropathy (cohort); 1 reporting peripheral vascular disease (case series); 2 discussing retinopathy (1 case-control, 1 position statement); and 3 addressing hyperlipidemia (American Heart Association position statement on cardiovascular risks; American Diabetes Association consensus statement; case series). A breakdown of grade of recommendation shows no grade A studies, 10 grade B studies, 6 grade C studies, and 10 grade D studies. With regard to screening and treatment recommendations for comorbidities, data in children are scarce, and the available literature is conflicting. Therapeutic recommendations for hypertension, dyslipidemia, retinopathy, microalbuminuria, and depression were summarized from expert guideline documents and are presented in detail in the guideline. The references are provided, but the committee did not independently assess the supporting evidence. Screening tools are provided in the Supplemental Information. (1/13)

MARIJUANA: A CONTINUING CONCERN FOR PEDIATRICIANS

Committee on Substance Abuse

ABSTRACT. Marijuana, the common name for products derived from the plant *Cannabis sativa,* is the most common illicit drug used by children and adolescents in the United States. Despite growing concerns by the medical profession about the physical and psychological effects of its active ingredient, Æ-9-tetrahydrocannabinol, survey data continue to show that increasing numbers of young people are using the drug as they become less concerned about its dangers. (10/99, reaffirmed 4/03)

MATERNAL-FETAL INTERVENTION AND FETAL CARE CENTERS (CLINICAL REPORT)

Committee on Bioethics (joint with American College of Obstetricians and Gynecologists Committee on Ethics)

ABSTRACT. The past 2 decades have yielded profound advances in the fields of prenatal diagnosis and fetal intervention. Although fetal interventions are driven by a beneficence-based motivation to improve fetal and neonatal outcomes, advancement in fetal therapies raises ethical issues surrounding maternal autonomy and decision-making, concepts of innovation versus research, and organizational aspects within institutions in the development of fetal care centers. To safeguard the interests of both the pregnant woman and the fetus, the American College of Obstetricians and Gynecologists and the American Academy of Pediatrics make recommendations regarding informed consent, the role of research subject advocates and other independent advocates, the availability of support services, the multidisciplinary nature of fetal intervention teams, the oversight of centers, and the need to accumulate maternal and fetal outcome data. (7/11)

MATERNAL PHENYLKETONURIA

Committee on Genetics

ABSTRACT. Elevated maternal phenylalanine concentrations during pregnancy are teratogenic and may result in growth retardation, microcephaly, significant developmental delays, and birth defects in the offspring of

women with poorly controlled phenylketonuria during pregnancy. Women of childbearing age with all forms of phenylketonuria, including mild variants such as mild hyperphenylalaninemia, should receive counseling concerning their risks for adverse fetal effects, optimally before conceiving. The best outcomes occur when strict control of maternal phenylalanine concentration is achieved before conception and continued throughout pregnancy. Included are brief descriptions of novel treatments for phenylketonuria. (8/08, reaffirmed 1/13)

MEDIA EDUCATION
Committee on Communications and Media
ABSTRACT. The American Academy of Pediatrics recognizes that exposure to mass media (eg, television, movies, video and computer games, the Internet, music lyrics and videos, newspapers, magazines, books, advertising) presents health risks for children and adolescents but can provide benefits as well. Media education has the potential to reduce the harmful effects of media and accentuate the positive effects. By understanding and supporting media education, pediatricians can play an important role in reducing harmful effects of media on children and adolescents. (9/10)

MEDIA USE BY CHILDREN YOUNGER THAN 2 YEARS
Council on Communications and Media
ABSTRACT. In 1999, the American Academy of Pediatrics (AAP) issued a policy statement addressing media use in children. The purpose of that statement was to educate parents about the effects that media—both the amount and the content—may have on children. In one part of that statement, the AAP recommended that "pediatricians should urge parents to avoid television viewing for children under the age of two years." The wording of the policy specifically discouraged media use in this age group, although it is frequently misquoted by media outlets as no media exposure in this age group. The AAP believed that there were significantly more potential negative effects of media than positive ones for this age group and, thus, advised families to thoughtfully consider media use for infants. This policy statement reaffirms the 1999 statement with respect to media use in infants and children younger than 2 years and provides updated research findings to support it. This statement addresses (1) the lack of evidence supporting educational or developmental benefits for media use by children younger than 2 years, (2) the potential adverse health and developmental effects of media use by children younger than 2 years, and (3) adverse effects of parental media use (background media) on children younger than 2 years. (10/11)

MEDIA VIOLENCE
Council on Communications and Media
ABSTRACT. Exposure to violence in media, including television, movies, music, and video games, represents a significant risk to the health of children and adolescents. Extensive research evidence indicates that media violence can contribute to aggressive behavior, desensitization to violence, nightmares, and fear of being harmed. Pediatricians should assess their patients' level of media exposure and intervene on media-related health risks. Pediatricians and other child health care providers can advocate for a safer media environment for children by encouraging media literacy, more thoughtful and proactive use of media by children and their parents, more responsible portrayal of violence by media producers, and more useful and effective media ratings. Office counseling has been shown to be effective. (10/09)

MEDICAID POLICY STATEMENT
Committee on Child Health Financing
ABSTRACT. Medicaid insures 39% of the children in the United States. This revision of the 2005 Medicaid Policy Statement of the American Academy of Pediatrics reflects opportunities for changes in state Medicaid programs resulting from the 2010 Patient Protection and Affordable Care Act as upheld in 2012 by the Supreme Court. Policy recommendations focus on the areas of benefit coverage, financing and payment, eligibility, outreach and enrollment, managed care, and quality improvement. (4/13)
See full text on page 721.

MEDICAL CONCERNS IN THE FEMALE ATHLETE
Committee on Sports Medicine and Fitness
ABSTRACT. Female children and adolescents who participate regularly in sports may develop certain medical conditions, including disordered eating, menstrual dysfunction, and decreased bone mineral density. The pediatrician can play an important role in monitoring the health of young female athletes. This revised policy statement provides updated and expanded information for pediatricians on these health concerns as well as recommendations for evaluation, treatment, and ongoing assessments of female athletes. (9/00, reaffirmed 5/05, 5/08)

MEDICAL CONDITIONS AFFECTING SPORTS PARTICIPATION (CLINICAL REPORT)
Stephen G. Rice, MD, PhD, MPH, and Council on Sports Medicine and Fitness
ABSTRACT. Children and adolescents with medical conditions present special issues with respect to participation in athletic activities. The pediatrician can play an important role in determining whether a child with a health condition should participate in certain sports by assessing the child's health status, suggesting appropriate equipment or modifications of sports to decrease the risk of injury, and educating the athlete, parent(s) or guardian, and coach regarding the risks of injury as they relate to the child's condition. This report updates a previous policy statement and provides information for pediatricians on sports participation for children and adolescents with medical conditions. (4/08, reaffirmed 5/11)

MEDICAL EMERGENCIES OCCURRING AT SCHOOL
Council on School Health
ABSTRACT. Children and adults might experience medical emergency situations because of injuries, complications of chronic health conditions, or unexpected major illnesses that occur in schools. In February 2001, the American Academy of Pediatrics issued a policy statement titled "Guidelines for Emergency Medical Care in Schools" (available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;107/2/435). Since the

release of that statement, the spectrum of potential individual student emergencies has changed significantly. The increase in the number of children with special health care needs and chronic medical conditions attending schools and the challenges associated with ensuring that schools have access to on-site licensed health care professionals on an ongoing basis have added to increasing the risks of medical emergencies in schools. The goal of this statement is to increase pediatricians' awareness of schools' roles in preparing for individual student emergencies and to provide recommendations for primary care and school physicians on how to assist and support school personnel. (10/08, reaffirmed 9/11)

THE MEDICAL HOME

Medical Home Initiatives for Children With Special Needs Project Advisory Committee (7/02, reaffirmed 5/08)

MEDICAL STAFF APPOINTMENT AND DELINEATION OF PEDIATRIC PRIVILEGES IN HOSPITALS (CLINICAL REPORT)

Daniel A. Rauch, MD; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The review and verification of credentials and the granting of clinical privileges are required of every hospital to ensure that members of the medical staff are competent and qualified to provide specified levels of patient care. The credentialing process involves the following: (1) assessment of the professional and personal background of each practitioner seeking privileges; (2) assignment of privileges appropriate for the clinician's training and experience; (3) ongoing monitoring of the professional activities of each staff member; and (4) periodic reappointment to the medical staff on the basis of objectively measured performance. We examine the essential elements of a credentials review for initial and renewed medical staff appointments along with suggested criteria for the delineation of clinical privileges. Sample forms for the delineation of privileges can be found on the American Academy of Pediatrics Committee on Hospital Care Web site (http://www.aap.org/visit/cmte19.htm). Because of differences among individual hospitals, no 1 method for credentialing is universally applicable. The medical staff of each hospital must, therefore, establish its own process based on the general principles reviewed in this report. The issues of medical staff membership and credentialing have become very complex, and institutions and medical staffs are vulnerable to legal action. Consequently, it is advisable for hospitals and medical staffs to obtain expert legal advice when medical staff bylaws are constructed or revised. (3/12)

MENINGOCOCCAL CONJUGATE VACCINES POLICY UPDATE: BOOSTER DOSE RECOMMENDATIONS

Committee on Infectious Diseases

ABSTRACT. The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics approved updated recommendations for the use of quadravalent (serogroups A, C, W-135, and Y) meningococcal conjugate vaccines (Menactra [Sanofi Pasteur, Swiftwater, PA] and Menveo [Novartis, Basel, Switzerland]) in adolescents and in people at persistent high risk of meningococcal disease. The recommendations supplement previous Advisory Committee on Immunization Practices and American Academy of Pediatrics recommendations for meningococcal vaccinations. Data were reviewed pertaining to immunogenicity in high-risk groups, bactericidal antibody persistence after immunization, current epidemiology of meningococcal disease, meningococcal conjugate vaccine effectiveness, and cost-effectiveness of different strategies for vaccination of adolescents. This review prompted the following recommendations: (1) adolescents should be routinely immunized at 11 through 12 years of age and given a booster dose at 16 years of age; (2) adolescents who received their first dose at age 13 through 15 years should receive a booster at age 16 through 18 years or up to 5 years after their first dose; (3) adolescents who receive their first dose of meningococcal conjugate vaccine at or after 16 years of age do not need a booster dose; (4) a 2-dose primary series should be administered 2 months apart for those who are at increased risk of invasive meningococcal disease because of persistent complement component (eg, C5–C9, properdin, factor H, or factor D) deficiency (9 months through 54 years of age) or functional or anatomic asplenia (2–54 years of age) and for adolescents with HIV infection; and (5) a booster dose should be given 3 years after the primary series if the primary 2-dose series was given from 2 through 6 years of age and every 5 years for persons whose 2-dose primary series or booster dose was given at 7 years of age or older who are at risk of invasive meningococcal disease because of persistent component (eg, C5–C9, properdin, factor H, or factor D) deficiency or functional or anatomic asplenia. (11/11)

MENSTRUATION IN GIRLS AND ADOLESCENTS: USING THE MENSTRUAL CYCLE AS A VITAL SIGN (CLINICAL REPORT)

Committee on Adolescence (joint with American College of Obstetricians and Gynecologists Committee on Adolescent Health Care)

ABSTRACT. Young patients and their parents often are unsure about what represents normal menstrual patterns, and clinicians also may be unsure about normal ranges for menstrual cycle length and amount and duration of flow through adolescence. It is important to be able to educate young patients and their parents regarding what to expect of a first period and about the range for normal cycle length of subsequent menses. It is equally important for clinicians to have an understanding of bleeding patterns in girls and adolescents, the ability to differentiate between normal and abnormal menstruation, and the skill to know how to evaluate young patients' conditions appropriately. Using the menstrual cycle as an additional vital sign adds a powerful tool to the assessment of normal development and the exclusion of pathological conditions. (11/06)

MINORS AS LIVING SOLID-ORGAN DONORS (CLINICAL REPORT)

Lainie Friedman Ross, MD, PhD; J. Richard Thistlethwaite Jr, MD, PhD; and Committee on Bioethics

ABSTRACT. In the past half-century, solid-organ transplantation has become standard treatment for a variety of diseases in children and adults. The major limitation

for all transplantation is the availability of donors, and the gap between demand and supply continues to grow despite the increase in living donors. Although rare, children do serve as living donors, and these donations raise serious ethical issues. This clinical report includes a discussion of the ethical considerations regarding minors serving as living donors, using the traditional benefit/burden calculus from the perspectives of both the donor and the recipient. The report also includes an examination of the circumstances under which a minor may morally participate as a living donor, how to minimize risks, and what the informed-consent process should entail. The American Academy of Pediatrics holds that minors can morally serve as living organ donors but only in exceptional circumstances when specific criteria are fulfilled. (8/08, reaffirmed 5/11)

MODEL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY FOR CHILDREN

Committee on Child Health Financing

ABSTRACT. The term "medical necessity" is used by Medicare and Medicaid and in insurance contracts to refer to medical services that are generally recognized as appropriate for the diagnosis, prevention, or treatment of disease and injury. There is no consensus on how to define and apply the term and the accompanying rules and regulations, and as a result there has been substantial variation in medical-necessity definitions and interpretations. With this policy statement, the American Academy of Pediatrics hopes to encourage insurers to adopt more consistent medical-necessity definitions that take into account the needs of children. (7/05, reaffirmed 10/11)

MOLECULAR GENETIC TESTING IN PEDIATRIC PRACTICE: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Genetics

ABSTRACT. Although many types of diagnostic and carrier testing for genetic disorders have been available for decades, the use of molecular methods is a relatively recent phenomenon. Such testing has expanded the range of disorders that can be diagnosed and has enhanced the ability of clinicians to provide accurate prognostic information and institute appropriate health supervision measures. However, the proper application of these tests may be difficult because of their scientific complexity and the potential for negative, sometimes unexpected, consequences for many patients. The purposes of this subject review are to provide background information on molecular genetic tests, to describe specific testing modalities, and to discuss some of the benefits and risks specific to the pediatric population. It is likely that pediatricians will use these testing methods increasingly for their patients and will need to evaluate critically their diagnostic and prognostic implications. (12/00, reaffirmed 5/07)

MOTOR DELAYS: EARLY IDENTIFICATION AND EVALUATION (CLINICAL REPORT)

Garey H. Noritz, MD; Nancy A. Murphy, MD; and Neuromotor Screening Expert Panel

ABSTRACT. Pediatricians often encounter children with delays of motor development in their clinical practices. Earlier identification of motor delays allows for timely referral for developmental interventions as well as diagnostic evaluations and treatment planning. A multidisciplinary expert panel developed an algorithm for the surveillance and screening of children for motor delays within the medical home, offering guidance for the initial workup and referral of the child with possible delays in motor development. Highlights of this clinical report include suggestions for formal developmental screening at the 9-, 18-, 30-, and 48-month well-child visits; approaches to the neurologic examination, with emphasis on the assessment of muscle tone; and initial diagnostic approaches for medical home providers. Use of diagnostic tests to evaluate children with motor delays are described, including brain MRI for children with high muscle tone, and measuring serum creatine kinase concentration of those with decreased muscle tone. The importance of pursuing diagnostic tests while concurrently referring patients to early intervention programs is emphasized. (5/13)

See full text on page 733.

NEONATAL DRUG WITHDRAWAL (CLINICAL REPORT)

Mark L. Hudak, MD; Rosemarie C. Tan, MD, PhD; Committee on Drugs; and Committee on Fetus and Newborn

ABSTRACT. Maternal use of certain drugs during pregnancy can result in transient neonatal signs consistent with withdrawal or acute toxicity or cause sustained signs consistent with a lasting drug effect. In addition, hospitalized infants who are treated with opioids or benzodiazepines to provide analgesia or sedation may be at risk for manifesting signs of withdrawal. This statement updates information about the clinical presentation of infants exposed to intrauterine drugs and the therapeutic options for treatment of withdrawal and is expanded to include evidence-based approaches to the management of the hospitalized infant who requires weaning from analgesics or sedatives. (1/12)

THE NEW MORBIDITY REVISITED: A RENEWED COMMITMENT TO THE PSYCHOSOCIAL ASPECTS OF PEDIATRIC CARE

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. In 1993, the American Academy of Pediatrics adopted the policy statement "The Pediatrician and the 'New Morbidity.'" Since then, social difficulties, behavioral problems, and developmental difficulties have become a main part of the scope of pediatric practice, and recognition of the importance of these areas has increased. This statement reaffirms the Academy's commitment to prevention, early detection, and management of behavioral, developmental, and social problems as a focus in pediatric practice. (11/01)

NEWBORN SCREENING EXPANDS: RECOMMENDATIONS FOR PEDIATRICIANS AND MEDICAL HOMES—IMPLICATIONS FOR THE SYSTEM (CLINICAL REPORT)

Newborn Screening Authoring Committee

ABSTRACT. Advances in newborn screening technology, coupled with recent advances in the diagnosis and treatment of rare but serious congenital conditions that affect newborn infants, provide increased opportunities for positively affecting the lives of children and their families. These advantages also pose new challenges to primary care pediatricians, both educationally and in response to the management of affected infants. Primary care pediatricians require immediate access to clinical and diagnostic information and guidance and have a proactive role to play in supporting the performance of the newborn screening system. Primary care pediatricians must develop office policies and procedures to ensure that newborn screening is conducted and that results are transmitted to them in a timely fashion; they must also develop strategies to use should these systems fail. In addition, collaboration with local, state, and national partners is essential for promoting actions and policies that will optimize the function of the newborn screening systems and ensure that families receive the full benefit of them. (1/08)

NEWBORN SCREENING FACT SHEETS, INTRODUCTION TO THE (TECHNICAL REPORT)

Celia I. Kaye, MD, PhD, and Committee on Genetics

ABSTRACT. Newborn screening fact sheets were last revised in 1996 by the Committee on Genetics of the American Academy of Pediatrics. These fact sheets have been revised again because of advances in the field, including technologic innovations such as tandem mass spectrometry, as well as greater appreciation of ethical issues such as informed consent. The fact sheets provide information to assist pediatricians and other professionals who care for children in performing their essential role within the newborn screening public health system. The newborn screening system consists of 5 parts: (1) newborn testing; (2) follow-up of abnormal screening results to facilitate timely diagnostic testing and management; (3) diagnostic testing; (4) disease management, which requires coordination with the medical home and genetic counseling; and (5) continuous evaluation and improvement of the newborn screening system. The following disorders are reviewed in the newborn screening fact sheets (which are available at www.pediatrics.org/cgi/content/full/118/3/e934): biotinidase deficiency, congenital adrenal hyperplasia, congenital hearing loss, congenital hypothyroidism, cystic fibrosis, galactosemia, homocystinuria, maple syrup urine disease, medium-chain acyl-coenzyme A dehydrogenase deficiency, phenylketonuria, sickle cell disease and other hemoglobinopathies, and tyrosinemia. (9/06, reaffirmed 1/11)

NEWBORN SCREENING FACT SHEETS (TECHNICAL REPORT)

Celia I. Kaye, MD, PhD, and Committee on Genetics

ABSTRACT. Newborn screening fact sheets were last revised in 1996 by the American Academy of Pediatrics Committee on Genetics. This revision was prompted by advances in the field since 1996, including technologic innovations, as well as greater appreciation of ethical issues such as those surrounding informed consent. The following disorders are discussed in this revision of the newborn screening fact sheets: biotinidase deficiency, congenital adrenal hyperplasia, congenital hearing loss, congenital hypothyroidism, cystic fibrosis, galactosemia, homocystinuria, maple syrup urine disease, medium-chain acyl-coenzyme A dehydrogenase deficiency, phenylketonuria, sickle cell disease and other hemoglobinopathies, and tyrosinemia. A series of topics related to newborn screening is discussed in a companion publication to this electronic publication of the fact sheets (available at: www.pediatrics.org/cgi/content/full/118/3/1304). These topics are newborn screening as a public health system; factors contributing to the need for review of the newborn screening system; informed consent; tandem mass spectrometry; DNA analysis in newborn screening; status of newborn screening in the United States; and the effect of sample timing, preterm birth, diet, transfusion, and total parenteral nutrition on newborn screening results. (9/06, reaffirmed 1/11)

NONDISCRIMINATION IN PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. This policy statement is a revision of a 2001 statement and articulates the positions of the American Academy of Pediatrics on nondiscrimination in pediatric health care. It addresses both pediatricians who provide health care and the infants, children, adolescents, and young adults whom they serve. (10/07, reaffirmed 6/11)

NONINITIATION OR WITHDRAWAL OF INTENSIVE CARE FOR HIGH-RISK NEWBORNS

Committee on Fetus and Newborn

ABSTRACT. Advances in medical technology have led to dilemmas in initiation and withdrawal of intensive care of newborn infants with a very poor prognosis. Physicians and parents together must make difficult decisions guided by their understanding of the child's best interest. The foundation for these decisions consists of several key elements: (1) direct and open communication between the health care team and the parents of the child with regard to the medical status, prognosis, and treatment options; (2) inclusion of the parents as active participants in the decision process; (3) continuation of comfort care even when intensive care is not being provided; and (4) treatment decisions that are guided primarily by the best interest of the child. (2/07, reaffirmed 5/10)

NONTHERAPEUTIC USE OF ANTIMICROBIAL AGENTS IN ANIMAL AGRICULTURE: IMPLICATIONS FOR PEDIATRICS (TECHNICAL REPORT)

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT. Antimicrobial resistance is widespread. Overuse or misuse of antimicrobial agents in veterinary and human medicine is responsible for increasing the crisis of resistance to antimicrobial agents. The American Academy of Pediatrics, in conjunction with the US Public Health Service, has begun to address this problem by disseminating policies on the judicious use of antimicrobial

agents in humans. Between 40% and 80% of the antimicrobial agents used in the United States each year are used in food animals; many are identical or very similar to drugs used in humans. Most of this use involves the addition of low doses of antimicrobial agents to the feed of healthy animals over prolonged periods to promote growth and increase feed efficiency or at a range of doses to prevent disease. These nontherapeutic uses contribute to resistance and create health dangers for humans. This report will describe how antimicrobial agents are used in animal agriculture and review the mechanisms by which such uses contribute to resistance in human pathogens. Although therapeutic use of antimicrobial agents in agriculture clearly contributes to the development of resistance, this report will concentrate on nontherapeutic uses in healthy animals. (9/04, reaffirmed 10/08, 4/13)

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH

Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to health disparities in mental health with higher rates of depression and suicidal ideation, higher rates of substance abuse, and more sexually transmitted and HIV infections. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Referrals for mental health or substance abuse may be warranted. Sexually active LGBTQ youth should have sexually transmitted infection/HIV testing according to recommendations of the Sexually Transmitted Diseases Treatment Guidelines of the Centers for Disease Control and Prevention based on sexual behaviors. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13)

See full text on page 747.

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH (TECHNICAL REPORT)

David A. Levine, MD, and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004.This technical report reflects the rapidly expanding medical and psychosocial literature about sexual minority youth. Pediatricians should be aware that some youth in their care may have concerns or questions about their sexual orientation or that of siblings, friends, parents, relatives, or others and should provide factual, current, nonjudgmental information in a confidential manner. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to increased mental health issues for sexual minority youth. LGBTQ and MSM/WSW (men having sex with men and women having sex with women) adolescents, in comparison with heterosexual adolescents, have higher rates of depression and suicidal ideation, higher rates of substance abuse, and more risky sexual behaviors. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. This includes having supportive, engaging office staff members who ensure that there are no barriers to care. For transgender youth, pediatricians should provide the opportunity to acknowledge and affirm their feelings of gender dysphoria and desires to transition to the opposite gender. Referral of transgender youth to a qualified mental health professional is critical to assist with the dysphoria, to educate them, and to assess their readiness for transition. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13)

See full text on page 755.

OFFICE-BASED COUNSELING FOR UNINTENTIONAL INJURY PREVENTION (CLINICAL REPORT)

H. Garry Gardner, MD, and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Unintentional injuries are the leading cause of death for children older than 1 year. Pediatricians should include unintentional injury prevention as a major component of anticipatory guidance for infants, children, and adolescents. The content of injury-prevention counseling varies for infants, preschool-aged children, school-aged children, and adolescents. This report provides guidance on the content of unintentional injury-prevention counseling for each of those age groups. (1/07)

OPHTHALMOLOGIC EXAMINATIONS IN CHILDREN WITH JUVENILE RHEUMATOID ARTHRITIS (CLINICAL REPORT)

James Cassidy, MD; Jane Kivlin, MD; Carol Lindsley, MD; James Nocton, MD; Section on Rheumatology; and Section on Ophthalmology

ABSTRACT. Unlike the joints, ocular involvement with juvenile rheumatoid arthritis is most often asymptomatic; yet, the inflammation can cause serious morbidity with loss of vision. Scheduled slit-lamp examinations by an ophthalmologist at specific intervals can detect ocular disease early, and prompt treatment can prevent vision loss. (5/06)

ORAL AND DENTAL ASPECTS OF CHILD ABUSE AND NEGLECT (CLINICAL REPORT)

Nancy Kellogg, MD, and Committee on Child Abuse and Neglect (joint with American Academy of Pediatric Dentistry)

ABSTRACT. In all 50 states, physicians and dentists are required to report suspected cases of abuse and neglect to social service or law enforcement agencies. The purpose of this report is to review the oral and dental aspects of physical and sexual abuse and dental neglect and the role of physicians and dentists in evaluating such condi-

tions. This report addresses the evaluation of bite marks as well as perioral and intraoral injuries, infections, and diseases that may cause suspicion for child abuse or neglect. Physicians receive minimal training in oral health and dental injury and disease and, thus, may not detect dental aspects of abuse or neglect as readily as they do child abuse and neglect involving other areas of the body. Therefore, physicians and dentists are encouraged to collaborate to increase the prevention, detection, and treatment of these conditions. (12/05, reaffirmed 1/09)

ORAL HEALTH CARE FOR CHILDREN WITH DEVELOPMENTAL DISABILITIES (CLINICAL REPORT)

Kenneth W. Norwood Jr, MD; Rebecca L. Slayton, DDS, PhD; Council on Children With Disabilities; and Section on Oral Health

ABSTRACT. Children with developmental disabilities often have unmet complex health care needs as well as significant physical and cognitive limitations. Children with more severe conditions and from low-income families are particularly at risk with high dental needs and poor access to care. In addition, children with developmental disabilities are living longer, requiring continued oral health care. This clinical report describes the effect that poor oral health has on children with developmental disabilities as well as the importance of partnerships between the pediatric medical and dental homes. Basic knowledge of the oral health risk factors affecting children with developmental disabilities is provided. Pediatricians may use the report to guide their incorporation of oral health assessments and education into their well-child examinations for children with developmental disabilities. This report has medical, legal, educational, and operational implications for practicing pediatricians. (2/13)

See full text on page 775.

ORAL HEALTH RISK ASSESSMENT TIMING AND ESTABLISHMENT OF THE DENTAL HOME

Section on Pediatric Dentistry

ABSTRACT. Early childhood dental caries has been reported by the Centers for Disease Control and Prevention to be perhaps the most prevalent infectious disease of our nation's children. Early childhood dental caries occurs in all racial and socioeconomic groups; however, it tends to be more prevalent in low-income children, in whom it occurs in epidemic proportions. Dental caries results from an overgrowth of specific organisms that are a part of normally occurring human flora. Human dental flora is site specific, and an infant is not colonized until the eruption of the primary dentition at approximately 6 to 30 months of age. The most likely source of inoculation of an infant's dental flora is the mother or another intimate care provider, through shared utensils, etc. Decreasing the level of cariogenic organisms in the mother's dental flora at the time of colonization can significantly impact the child's predisposition to caries. To prevent caries in children, high-risk individuals must be identified at an early age (preferably high-risk mothers during prenatal care), and aggressive strategies should be adopted, including anticipatory guidance, behavior modifications (oral hygiene and feeding practices), and establishment of a dental home by 1 year of age for children deemed at risk. (5/03, reaffirmed 5/09)

ORGANIC FOODS: HEALTH AND ENVIRONMENTAL ADVANTAGES AND DISADVANTAGES (CLINICAL REPORT)

Joel Forman, MD; Janet Silverstein, MD; Committee on Nutrition; and Council on Environmental Health

ABSTRACT. The US market for organic foods has grown from $3.5 billion in 1996 to $28.6 billion in 2010, according to the Organic Trade Association. Organic products are now sold in specialty stores and conventional supermarkets. Organic products contain numerous marketing claims and terms, only some of which are standardized and regulated.

In terms of health advantages, organic diets have been convincingly demonstrated to expose consumers to fewer pesticides associated with human disease. Organic farming has been demonstrated to have less environmental impact than conventional approaches. However, current evidence does not support any meaningful nutritional benefits or deficits from eating organic compared with conventionally grown foods, and there are no well-powered human studies that directly demonstrate health benefits or disease protection as a result of consuming an organic diet. Studies also have not demonstrated any detrimental or disease-promoting effects from an organic diet. Although organic foods regularly command a significant price premium, well-designed farming studies demonstrate that costs can be competitive and yields comparable to those of conventional farming techniques. Pediatricians should incorporate this evidence when discussing the health and environmental impact of organic foods and organic farming while continuing to encourage all patients and their families to attain optimal nutrition and dietary variety consistent with the US Department of Agriculture's MyPlate recommendations.

This clinical report reviews the health and environmental issues related to organic food production and consumption. It defines the term "organic," reviews organic food-labeling standards, describes organic and conventional farming practices, and explores the cost and environmental implications of organic production techniques. It examines the evidence available on nutritional quality and production contaminants in conventionally produced and organic foods. Finally, this report provides guidance for pediatricians to assist them in advising their patients regarding organic and conventionally produced food choices. (10/12)

ORGANIZED SPORTS FOR CHILDREN AND PREADOLESCENTS

Committee on Sports Medicine and Fitness and Committee on School Health

ABSTRACT. Participation in organized sports provides an opportunity for young people to increase their physical activity and develop physical and social skills. However, when the demands and expectations of organized sports exceed the maturation and readiness of the participant, the positive aspects of participation can be negated. The nature of parental or adult involvement can also influence the degree to which participation in organized sports is

a positive experience for preadolescents. This updates a previous policy statement on athletics for preadolescents and incorporates guidelines for sports participation for preschool children. Recommendations are offered on how pediatricians can help determine a child's readiness to participate, how risks can be minimized, and how child-oriented goals can be maximized. (6/01, reaffirmed 1/05, 6/11)

OUT-OF-SCHOOL SUSPENSION AND EXPULSION

Council on School Health

ABSTRACT. The primary mission of any school system is to educate students. To achieve this goal, the school district must maintain a culture and environment where all students feel safe, nurtured, and valued and where order and civility are expected standards of behavior. Schools cannot allow unacceptable behavior to interfere with the school district's primary mission. To this end, school districts adopt codes of conduct for expected behaviors and policies to address unacceptable behavior. In developing these policies, school boards must weigh the severity of the offense and the consequences of the punishment and the balance between individual and institutional rights and responsibilities. Out-of-school suspension and expulsion are the most severe consequences that a school district can impose for unacceptable behavior. Traditionally, these consequences have been reserved for offenses deemed especially severe or dangerous and/or for recalcitrant offenders. However, the implications and consequences of out-of-school suspension and expulsion and "zero-tolerance" are of such severity that their application and appropriateness for a developing child require periodic review. The indications and effectiveness of exclusionary discipline policies that demand automatic or rigorous application are increasingly questionable. The impact of these policies on offenders, other children, school districts, and communities is broad. Periodic scrutiny of policies should be placed not only on the need for a better understanding of the educational, emotional, and social impact of out-of-school suspension and expulsion on the individual student but also on the greater societal costs of such rigid policies. Pediatricians should be prepared to assist students and families affected by out-of-school suspension and expulsion and should be willing to guide school districts in their communities to find more effective and appropriate alternatives to exclusionary discipline policies for the developing child. A discussion of preventive strategies and alternatives to out-of-school suspension and expulsion, as well as recommendations for the role of the physician in matters of out-of-school suspension and expulsion are included. School-wide positive behavior support/positive behavior intervention and support is discussed as an effective alternative. (2/13)

See full text on page 783.

OVERCROWDING CRISIS IN OUR NATION'S EMERGENCY DEPARTMENTS: IS OUR SAFETY NET UNRAVELING?

Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency departments (EDs) are a vital component in our health care safety net, available 24 hours a day, 7 days a week, for all who require care. There has been a steady increase in the volume and acuity of patient visits to EDs, now with well over 100 million Americans (30 million children) receiving emergency care annually. This rise in ED utilization has effectively saturated the capacity of EDs and emergency medical services in many communities. The resulting phenomenon, commonly referred to as ED overcrowding, now threatens access to emergency services for those who need them the most. As managers of the pediatric medical home and advocates for children and optimal pediatric health care, there is a very important role for pediatricians and the American Academy of Pediatrics in guiding health policy decision-makers toward effective solutions that promote the medical home and timely access to emergency care. (9/04, reaffirmed 5/07, 6/11)

OVERUSE INJURIES, OVERTRAINING, AND BURNOUT IN CHILD AND ADOLESCENT ATHLETES (CLINICAL REPORT)

Joel S. Brenner, MD, MPH, and Council on Sports Medicine and Fitness

ABSTRACT. Overuse is one of the most common etiologic factors that lead to injuries in the pediatric and adolescent athlete. As more children are becoming involved in organized and recreational athletics, the incidence of overuse injuries is increasing. Many children are participating in sports year-round and sometimes on multiple teams simultaneously. This overtraining can lead to burnout, which may have a detrimental effect on the child participating in sports as a lifelong healthy activity. One contributing factor to overtraining may be parental pressure to compete and succeed. The purpose of this clinical report is to assist pediatricians in identifying and counseling at-risk children and their families. This report supports the American Academy of Pediatrics policy statement on intensive training and sport specialization. (6/07, reaffirmed 3/11)

PALLIATIVE CARE FOR CHILDREN

Committee on Bioethics and Committee on Hospital Care

ABSTRACT. This statement presents an integrated model for providing palliative care for children living with a life-threatening or terminal condition. Advice on the development of a palliative care plan and on working with parents and children is also provided. Barriers to the provision of effective pediatric palliative care and potential solutions are identified. The American Academy of Pediatrics recommends the development and broad availability of pediatric palliative care services based on child-specific guidelines and standards. Such services will require widely distributed and effective palliative care education of pediatric health care professionals. The Academy offers guidance on responding to requests for hastening death, but does not support the practice of physician-assisted suicide or euthanasia for children. (8/00, reaffirmed 6/03, 10/06, 2/12)

PARENT-PROVIDER-COMMUNITY PARTNERSHIPS: OPTIMIZING OUTCOMES FOR CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Paul S. Carbone, MD; and Council on Children With Disabilities

ABSTRACT. Children with disabilities and their families have multifaceted medical, developmental, educational, and habilitative needs that are best addressed through strong partnerships among parents, providers, and communities. However, traditional health care systems are designed to address acute rather than chronic conditions. Children with disabilities require high-quality medical homes that provide care coordination and transitional care, and their families require social and financial supports. Integrated community systems of care that promote participation of all children are needed. The purpose of this clinical report is to explore the challenges of developing effective community-based systems of care and to offer suggestions to pediatricians and policy-makers regarding the development of partnerships among children with disabilities, their families, and health care and other providers to maximize health and well-being of these children and their families. (9/11)

PARENTAL LEAVE FOR RESIDENTS AND PEDIATRIC TRAINING PROGRAMS

Section on Medical Students, Residents, and Fellowship Trainees and Committee on Early Childhood

ABSTRACT. The American Academy of Pediatrics (AAP) is committed to the development of rational, equitable, and effective parental leave policies that are sensitive to the needs of pediatric residents, families, and developing infants and that enable parents to spend adequate and good-quality time with their young children. It is important for each residency program to have a policy for parental leave that is written, that is accessible to residents, and that clearly delineates program practices regarding parental leave. At a minimum, a parental leave policy for residents and fellows should conform legally with the Family Medical Leave Act as well as with respective state laws and should meet institutional requirements of the Accreditation Council for Graduate Medical Education for accredited programs. Policies should be well formulated and communicated in a culturally sensitive manner. The AAP advocates for extension of benefits consistent with the Family Medical Leave Act to all residents and interns beginning at the time that pediatric residency training begins. The AAP recommends that regardless of gender, residents who become parents should be guaranteed 6 to 8 weeks, at a minimum, of parental leave with pay after the infant's birth. In addition, in conformance with federal law, the resident should be allowed to extend the leave time when necessary by using paid vacation time or leave without pay. Coparenting, adopting, or fostering of a child should entitle the resident, regardless of gender, to the same amount of paid leave (6–8 weeks) as a person who takes maternity/paternity leave. Flexibility, creativity, and advanced planning are necessary to arrange schedules that optimize resident education and experience, cultivate equity in sharing workloads, and protect pregnant residents from overly strenuous work experiences at critical times of their pregnancies. (1/13)

PATIENT- AND FAMILY-CENTERED CARE OF CHILDREN IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Patricia J. O'Malley, MD; Kathleen Brown, MD; Steven E. Krug, MD; and Committee on Pediatric Emergency Medicine

ABSTRACT. Patient- and family-centered care is an innovative approach to the planning, delivery, and evaluation of health care that is grounded in a mutually beneficial partnership among patients, families, and health care professionals. Providing patient- and family-centered care to children in the emergency department setting presents many opportunities and challenges. This technical report draws on previously published policy statements and reports, reviews the current literature, and describes the present state of practice and research regarding patient- and family-centered care for children in the emergency department setting as well as some of the complexities of providing such care. This technical report has been endorsed by the Academic Pediatric Association (formerly the Ambulatory Pediatric Association), the American College of Osteopathic Emergency Physicians, the National Association of Emergency Medical Technicians, the Institute for Family-Centered Care, and the American College of Emergency Physicians. This report is also supported by the Emergency Nurses Association. (8/08)

PATIENT- AND FAMILY-CENTERED CARE AND THE PEDIATRICIAN'S ROLE

Committee on Hospital Care and Institute for Patient- and Family-Centered Care

ABSTRACT. Drawing on several decades of work with families, pediatricians, other health care professionals, and policy makers, the American Academy of Pediatrics provides a definition of patient- and family-centered care. In pediatrics, patient- and family-centered care is based on the understanding that the family is the child's primary source of strength and support. Further, this approach to care recognizes that the perspectives and information provided by families, children, and young adults are essential components of high-quality clinical decision-making, and that patients and family are integral partners with the health care team. This policy statement outlines the core principles of patient- and family-centered care, summarizes some of the recent literature linking patient- and family-centered care to improved health outcomes, and lists various other benefits to be expected when engaging in patient- and family-centered pediatric practice. The statement concludes with specific recommendations for how pediatricians can integrate patient- and family-centered care in hospitals, clinics, and community settings, and in broader systems of care, as well. (1/12)

PATIENT- AND FAMILY-CENTERED CARE AND THE ROLE OF THE EMERGENCY PHYSICIAN PROVIDING CARE TO A CHILD IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Patient- and family-centered care is an approach to health care that recognizes the role of the family in providing medical care; encourages collaboration between the patient, family, and health care professionals; and honors individual and family strengths, cultures, traditions, and expertise. Although there are many opportunities for providing patient- and family-centered care in the emergency department, there are also challenges to doing so. The American Academy of Pediatrics and the American College of Emergency Physicians support promoting patient dignity, comfort, and autonomy; recognizing the patient and family as key decision-makers in the patient's medical care; recognizing the patient's experience and perspective in a culturally sensitive manner; acknowledging the interdependence of child and parent as well as the pediatric patient's evolving independence; encouraging family-member presence; providing information to the family during interventions; encouraging collaboration with other health care professionals; acknowledging the importance of the patient's medical home; and encouraging institutional policies for patient- and family-centered care. (11/06, reaffirmed 6/09, 10/11)

PATIENT SAFETY IN THE PEDIATRIC EMERGENCY CARE SETTING

Committee on Pediatric Emergency Medicine

ABSTRACT. Patient safety is a priority for all health care professionals, including those who work in emergency care. Unique aspects of pediatric care may increase the risk of medical error and harm to patients, especially in the emergency care setting. Although errors can happen despite the best human efforts, given the right set of circumstances, health care professionals must work proactively to improve safety in the pediatric emergency care system. Specific recommendations to improve pediatric patient safety in the emergency department are provided in this policy statement. (12/07, reaffirmed 6/11)

PAYMENT FOR TELEPHONE CARE

Section on Telephone Care and Committee on Child Health Financing

ABSTRACT. Telephone care in pediatrics requires medical judgment, is associated with practice expense and medical liability risk, and can often substitute for more costly face-to-face care. Despite this, physicians are infrequently paid by patients or third-party payors for medical services provided by telephone. As the costs of maintaining a practice continue to increase, pediatricians are increasingly seeking payment for the time and work involved in telephone care. This statement reviews the role of telephone care in pediatric practice, the current state of payment for telephone care, and the practical issues associated with charging for telephone care services, a service traditionally provided gratis to patients and families. Specific recommendations are presented for appropriate documenting, reporting, and billing for telephone care services. (10/06)

PEDESTRIAN SAFETY

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Each year, approximately 900 pediatric pedestrians younger than 19 years are killed. In addition, 51000 children are injured as pedestrians, and 5300 of them are hospitalized because of their injuries. Parents should be warned that young children often do not have the cognitive, perceptual, and behavioral abilities to negotiate traffic independently. Parents should also be informed about the danger of vehicle back-over injuries to toddlers playing in driveways. Because posttraumatic stress syndrome commonly follows even minor pedestrian injury, pediatricians should screen and refer for this condition as necessary. The American Academy of Pediatrics supports community- and school-based strategies that minimize a child's exposure to traffic, especially to high-speed, high-volume traffic. Furthermore, the American Academy of Pediatrics supports governmental and industry action that would lead to improvements in vehicle design, driver manuals, driver education, and data collection for the purpose of reducing pediatric pedestrian injury. (7/09, reaffirmed 8/13)

PEDIATRIC AND ADOLESCENT MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM (TECHNICAL REPORT)

Margaret A. Dolan, MD; Joel A. Fein, MD, MPH; and Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency department (ED) health care professionals often care for patients with previously diagnosed psychiatric illnesses who are ill, injured, or having a behavioral crisis. In addition, ED personnel encounter children with psychiatric illnesses who may not present to the ED with overt mental health symptoms. Staff education and training regarding identification and management of pediatric mental health illness can help EDs overcome the perceived limitations of the setting that influence timely and comprehensive evaluation. In addition, ED physicians can inform and advocate for policy changes at local, state, and national levels that are needed to ensure comprehensive care of children with mental health illnesses. This report addresses the roles that the ED and ED health care professionals play in emergency mental health care of children and adolescents in the United States, which includes the stabilization and management of patients in mental health crisis, the discovery of mental illnesses and suicidal ideation in ED patients, and approaches to advocating for improved recognition and treatment of mental illnesses in children. The report also addresses special issues related to mental illness in the ED, such as minority populations, children with special health care needs, and children's mental health during and after disasters and trauma. (4/11)

PEDIATRIC ASPECTS OF INPATIENT HEALTH INFORMATION TECHNOLOGY SYSTEMS (TECHNICAL REPORT)

George R. Kim; Christoph U. Lehmann, MD; and Council on Clinical Information Technology

ABSTRACT. US adoption of health information technology as a path to improved quality of patient care (effectiveness, safety, timeliness, patient-centeredness,

efficiency, and equity) has been promoted by the medical community. Children and infants (especially those with special health care needs) are at higher risk than are adults for medical errors and their consequences (particularly in environments in which children are not the primary patient population). However, development and adoption of health information technology tools and practices that promote pediatric quality and patient safety are lagging. Two inpatient clinical processes—medication delivery and patient care transitions—are discussed in terms of health information technology applications that support them and functions that are important to pediatric quality and safety. Pediatricians and their partners (pediatric nurses, pharmacists, etc) must develop awareness of technical and adaptive issues in adopting these tools and collaborate with organizational leaders and developers as advocates for the best interests and safety of pediatric patients. Pediatric health information technology adoption cannot be considered in terms of applications (such as electronic health records or computerized physician order entry) alone but must be considered globally in terms of technical (health information technology applications), organizational (structures and workflows of care), and cultural (stakeholders) aspects of what is best. (12/08)

PEDIATRIC CARE RECOMMENDATIONS FOR FREESTANDING URGENT CARE FACILITIES

Committee on Pediatric Emergency Medicine

ABSTRACT. Freestanding urgent care centers are not emergency departments or medical homes, yet they are sometimes used as a source of pediatric care. The purpose of this policy statement is to provide updated and expanded recommendations for ensuring appropriate stabilization in pediatric emergency situations and timely and appropriate transfer to a hospital for definitive care when necessary. (7/05, reaffirmed 1/09, 6/11)

PEDIATRIC FELLOWSHIP TRAINING

Federation of Pediatric Organizations (7/04)

PEDIATRIC MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Emergency departments are vital in the management of pediatric patients with mental health emergencies. Pediatric mental health emergencies are an increasing part of emergency medical practice because emergency departments have become the safety net for a fragmented mental health infrastructure that is experiencing critical shortages in services in all sectors. Emergency departments must safely, humanely, and in a culturally and developmentally appropriate manner manage pediatric patients with undiagnosed and known mental illnesses, including those with mental retardation, autistic spectrum disorders, and attention-deficit/hyperactivity disorder and those experiencing a behavioral crisis. Emergency departments also manage patients with suicidal ideation, depression, escalating aggression, substance abuse, posttraumatic stress disorder, and maltreatment and those exposed to violence and unexpected deaths. Emergency departments must address not only the physical but also the mental health needs of patients during and after mass-casualty incidents and disasters. The American Academy of Pediatrics and the American College of Emergency Physicians support advocacy for increased mental health resources, including improved pediatric mental health tools for the emergency department, increased mental health insurance coverage, and adequate reimbursement at all levels; acknowledgment of the importance of the child's medical home; and promotion of education and research for mental health emergencies. (10/06, reaffirmed 6/09, 4/13)

PEDIATRIC OBSERVATION UNITS (CLINICAL REPORT)

Gregory P. Conners, MD, MPH, MBA; Sanford M. Melzer, MD, MBA; Committee on Hospital Care; and Committee on Pediatric Emergency Medicine

ABSTRACT. Pediatric observation units (OUs) are hospital areas used to provide medical evaluation and/or management for health-related conditions in children, typically for a well-defined, brief period. Pediatric OUs represent an emerging alternative site of care for selected groups of children who historically may have received their treatment in an ambulatory setting, emergency department, or hospital-based inpatient unit. This clinical report provides an overview of pediatric OUs, including the definitions and operating characteristics of different types of OUs, quality considerations and coding for observation services, and the effect of OUs on inpatient hospital utilization. (6/12)

PEDIATRIC ORGAN DONATION AND TRANSPLANTATION

Committee on Hospital Care, Section on Surgery, and Section on Critical Care

ABSTRACT. Pediatric organ donation and organ transplantation can have a significant life-extending benefit to the young recipients of these organs and a high emotional impact on donor and recipient families. Pediatricians, pediatric medical specialists, and pediatric transplant surgeons need to be better acquainted with evolving national strategies that involve organ procurement and organ transplantation to help acquaint families with the benefits and risks of organ donation and transplantation. Efforts of pediatric professionals are needed to shape public policies to provide a system in which procurement, distribution, and cost are fair and equitable to children and adults. Major issues of concern are availability of and access to donor organs; oversight and control of the process; pediatric medical and surgical consultation and continued care throughout the organ-donation and transplantation process; ethical, social, financial, and follow-up issues; insurance-coverage issues; and public awareness of the need for organ donors of all ages. (3/10)

PEDIATRIC PALLIATIVE CARE AND HOSPICE CARE COMMITMENTS, GUIDELINES, AND RECOMMENDATIONS

Section on Hospice and Palliative Medicine and Committee on Hospital Care

ABSTRACT. Pediatric palliative care and pediatric hospice care (PPC-PHC) are often essential aspects of medical care for patients who have life-threatening conditions or

need end-of-life care. PPC-PHC aims to relieve suffering, improve quality of life, facilitate informed decision-making, and assist in care coordination between clinicians and across sites of care. Core commitments of PPC-PHC include being patient centered and family engaged; respecting and partnering with patients and families; pursuing care that is high quality, readily accessible, and equitable; providing care across the age spectrum and life span, integrated into the continuum of care; ensuring that all clinicians can provide basic palliative care and consult PPC-PHC specialists in a timely manner; and improving care through research and quality improvement efforts. PPC-PHC guidelines and recommendations include ensuring that all large health care organizations serving children with life-threatening conditions have dedicated interdisciplinary PPC-PHC teams, which should develop collaborative relationships between hospital- and community-based teams; that PPC-PHC be provided as integrated multimodal care and practiced as a cornerstone of patient safety and quality for patients with life-threatening conditions; that PPC-PHC teams should facilitate clear, compassionate, and forthright discussions about medical issues and the goals of care and support families, siblings, and health care staff; that PPC-PHC be part of all pediatric education and training curricula, be an active area of research and quality improvement, and exemplify the highest ethical standards; and that PPC-PHC services be supported by financial and regulatory arrangements to ensure access to high-quality PPC-PHC by all patients with life-threatening and life-shortening diseases. (10/13)

See full text on page 799.

PEDIATRIC PRIMARY HEALTH CARE

Committee on Pediatric Workforce (11/93, reaffirmed 6/01 *AAP News,* 1/05, 10/07, 9/10)

PEDIATRIC SUDDEN CARDIAC ARREST

Section on Cardiology and Cardiac Surgery

ABSTRACT. Pediatric sudden cardiac arrest (SCA), which can cause sudden cardiac death if not treated within minutes, has a profound effect on everyone: children, parents, family members, communities, and health care providers. Preventing the tragedy of pediatric SCA, defined as the abrupt and unexpected loss of heart function, remains a concern to all. The goal of this statement is to increase the knowledge of pediatricians (including primary care providers and specialists) of the incidence of pediatric SCA, the spectrum of causes of pediatric SCA, disease-specific presentations, the role of patient and family screening, the rapidly evolving role of genetic testing, and finally, important aspects of secondary SCA prevention. This statement is not intended to address sudden infant death syndrome or sudden unexplained death syndrome, nor will specific treatment of individual cardiac conditions be discussed. This statement has been endorsed by the American College of Cardiology, the American Heart Association, and the Heart Rhythm Society. (3/12)

THE PEDIATRICIAN AND CHILDHOOD BEREAVEMENT

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Pediatricians should understand and evaluate children's reactions to the death of a person important to them by using age-appropriate and culturally sensitive guidance while being alert for normal and complicated grief responses. Pediatricians also should advise and assist families in responding to the child's needs. Sharing, family support, and communication have been associated with positive long-term bereavement adjustment. (2/00, reaffirmed 1/04, 3/13)

THE PEDIATRICIAN AND DISASTER PREPAREDNESS

Committee on Pediatric Emergency Medicine, Committee on Medical Liability, and Task Force on Terrorism

ABSTRACT. Recent natural disasters and events of terrorism and war have heightened society's recognition of the need for emergency preparedness. In addition to the unique pediatric issues involved in general emergency preparedness, several additional issues related to terrorism preparedness must be considered, including the unique vulnerabilities of children to various agents as well as the limited availability of age- and weight-appropriate antidotes and treatments. Although children may respond more rapidly to therapeutic intervention, they are at the same time more susceptible to various agents and conditions and more likely to deteriorate if not monitored carefully.

The challenge of dealing with the threat of terrorism, natural disasters, and public health emergencies in the United States is daunting not only for disaster planners but also for our medical system and health professionals of all types, including pediatricians. As part of the network of health responders, pediatricians need to be able to answer concerns of patients and families, recognize signs of possible exposure to a weapon of terror, understand first-line response to such attacks, and sufficiently participate in disaster planning to ensure that the unique needs of children are addressed satisfactorily in the overall process. Pediatricians play a central role in disaster and terrorism preparedness with families, children, and their communities. This applies not only to the general pediatrician but also to the pediatric medical subspecialist and pediatric surgical specialist. Families view pediatricians as their expert resource, and most of them expect the pediatrician to be knowledgeable in areas of concern. Providing expert guidance entails educating families in anticipation of events and responding to questions during and after actual events. It is essential that pediatricians educate themselves regarding these issues of emergency preparedness.

For pediatricians, some information is currently available on virtually all of these issues in recently produced printed materials, at special conferences, in broadcasts of various types, and on the Internet. However, selecting appropriate, accurate sources of information and determining how much information is sufficient remain difficult challenges. Similarly, guidance is needed with respect to developing relevant curricula for medical students and postdoctoral clinical trainees. (2/06, reaffirmed 6/09, 9/13)

PEDIATRICIAN-FAMILY-PATIENT RELATIONSHIPS: MANAGING THE BOUNDARIES

Committee on Bioethics

ABSTRACT. All professionals are concerned about maintaining the appropriate limits in their relationships with those they serve. Pediatricians should be aware that, under normal circumstances, caring for one's own children presents significant ethical issues. Pediatricians also must strive to maintain appropriate professional boundaries in their relationships with the family members of their patients. Pediatricians should avoid behavior that patients and parents might misunderstand as having sexual or inappropriate social meaning. Romantic and sexual involvement between physicians and patients is unacceptable. The acceptance of gifts or nonmonetary compensation for medical services has the potential to affect the professional relationship adversely. (11/09)

THE PEDIATRICIAN WORKFORCE: CURRENT STATUS AND FUTURE PROSPECTS (TECHNICAL REPORT)

David C. Goodman, MD, MS, and Committee on Pediatric Workforce

ABSTRACT. The effective and efficient delivery of children's health care depends on the pediatrician workforce. The number, composition, and distribution of pediatricians necessary to deliver this care have been the subject of long-standing policy and professional debate. This technical report reviews current characteristics and recent trends in the pediatric workforce and couples the workforce to a conceptual model of improvement in children's health and well-being. Important recent changes in the workforce include (1) the growth in the number of pediatricians in relation to the child population, (2) increased numbers of female pediatricians and their attainment of majority gender status in the specialty, (3) the persistence of a large number of international medical graduates entering training programs, (4) a lack of ethnic and racial diversity in pediatricians compared with children, and (5) the persistence of marked regional variation in pediatrician supply. Supply models projecting the pediatric workforce are reviewed and generally indicate that the number of pediatricians per child will increase by 50% over the next 20 years. The differing methods of assessing workforce requirements are presented and critiqued. The report finds that the pediatric workforce is undergoing fundamental changes that will have important effects on the professional lives of pediatricians and children's health care delivery. (7/05)

PEDIATRICIAN WORKFORCE POLICY STATEMENT

Committee on Pediatric Workforce

ABSTRACT. This policy statement reviews important trends and other factors that affect the pediatrician workforce and the provision of pediatric health care, including changes in the pediatric patient population, pediatrician workforce, and nature of pediatric practice. The effect of these changes on pediatricians and the demand for pediatric care are discussed. The American Academy of Pediatrics (AAP) concludes that there is currently a shortage of pediatric medical subspecialists in many fields, as well as a shortage of pediatric surgical specialists. In addition, the AAP believes that the current distribution of primary care pediatricians is inadequate to meet the needs of children living in rural and other underserved areas, and more primary care pediatricians will be needed in the future because of the increasing number of children who have significant chronic health problems, changes in physician work hours, and implementation of current health reform efforts that seek to improve access to comprehensive patient- and family-centered care for all children in a medical home. The AAP is committed to being an active participant in physician workforce policy development with both professional organizations and governmental bodies to ensure a pediatric perspective on health care workforce issues. The overall purpose of this statement is to summarize policy recommendations and serve as a resource for the AAP and other stakeholders as they address pediatrician workforce issues that ultimately influence the quality of pediatric health care provided to children in the United States. (7/13)

See full text on page 809.

THE PEDIATRICIAN'S ROLE IN CHILD MALTREATMENT PREVENTION (CLINICAL REPORT)

Emalee G. Flaherty, MD; John Stirling Jr, MD; and Committee on Child Abuse and Neglect

ABSTRACT. It is the pediatrician's role to promote the child's well-being and to help parents raise healthy, well-adjusted children. Pediatricians, therefore, can play an important role in the prevention of child maltreatment. Previous clinical reports and policy statements from the American Academy of Pediatrics have focused on improving the identification and management of child maltreatment. This clinical report outlines how the pediatrician can help to strengthen families and promote safe, stable, nurturing relationships with the aim of preventing maltreatment. After describing some of the triggers and factors that place children at risk for maltreatment, the report describes how pediatricians can identify family strengths, recognize risk factors, provide helpful guidance, and refer families to programs and other resources with the goal of strengthening families, preventing child maltreatment, and enhancing child development. (9/10)

THE PEDIATRICIAN'S ROLE IN COMMUNITY PEDIATRICS

Committee on Community Health Services

ABSTRACT. This policy statement reaffirms the pediatrician's role in community pediatrics. It offers pediatricians a definition of community pediatrics and provides a set of specific recommendations that underscore the critical nature of this important dimension of the profession. (4/05, reaffirmed 1/10)

THE PEDIATRICIAN'S ROLE IN DEVELOPMENT AND IMPLEMENTATION OF AN INDIVIDUAL EDUCATION PLAN (IEP) AND/OR AN INDIVIDUAL FAMILY SERVICE PLAN (IFSP)

Committee on Children With Disabilities

ABSTRACT. The Individual Education Plan and Individual Family Service Plan are legally mandated documents developed by a multidisciplinary team assessment that specifies goals and services for each child eligible for special educational services or early intervention services.

Pediatricians need to be knowledgeable of federal, state, and local requirements; establish linkages with early intervention, educational professionals, and parent support groups; and collaborate with the team working with individual children. (7/99, reaffirmed 11/02, 1/06)

THE PEDIATRICIAN'S ROLE IN FAMILY SUPPORT AND FAMILY SUPPORT PROGRAMS

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Children's social, emotional, and physical health; their developmental trajectory; and the neurocircuits that are being created and reinforced in their developing brains are all directly influenced by their relationships during early childhood. The stresses associated with contemporary American life can challenge families' abilities to promote successful developmental outcomes and emotional health for their children. Pediatricians are positioned to serve as partners with families and other community providers in supporting the well-being of children and their families. The structure and support of families involve forces that are often outside the agenda of the usual pediatric health supervision visits. Pediatricians must ensure that their medical home efforts promote a holistically healthy family environment for all children. This statement recommends opportunities for pediatricians to develop their expertise in assessing the strengths and stresses in families, in counseling families about strategies and resources, and in collaborating with others in their communities to support family relationships. (11/11)

THE PEDIATRICIAN'S ROLE IN THE PREVENTION OF MISSING CHILDREN (CLINICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. In 2002, the *Second National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children* report was released by the US Department of Justice, providing new data on a problem that our nation continues to face. This clinical report describes the categories of missing children, the prevalence of each, and prevention strategies that primary care pediatricians can share with parents to increase awareness and education about the safety of their children. (10/04)

THE PEDIATRICIAN'S ROLE IN SUPPORTING ADOPTIVE FAMILIES (CLINICAL REPORT)

Veronnie F. Jones, MD, PhD; Elaine E. Schulte, MD, MPH; Committee on Early Childhood; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. Each year, more children join families through adoption. Pediatricians have an important role in assisting adoptive families in the various challenges they may face with respect to adoption. The acceptance of the differences between families formed through birth and those formed through adoption is essential in promoting positive emotional growth within the family. It is important for pediatricians to be aware of the adoptive parents' need to be supported in their communication with their adopted children. (9/12)

PERSONAL WATERCRAFT USE BY CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention

ABSTRACT. The use of personal watercraft (PWC) has increased dramatically during the past decade as have the speed and mobility of the watercraft. A similar dramatic increase in PWC-related injury and death has occurred simultaneously. No one younger than 16 years should operate a PWC. The operator and all passengers must wear US Coast Guard-approved personal flotation devices. Other safety recommendations are suggested for parents and pediatricians. (2/00, reaffirmed 5/04, 1/07, 6/10)

PESTICIDE EXPOSURE IN CHILDREN

Council on Environmental Health

ABSTRACT. This statement presents the position of the American Academy of Pediatrics on pesticides. Pesticides are a collective term for chemicals intended to kill unwanted insects, plants, molds, and rodents. Children encounter pesticides daily and have unique susceptibilities to their potential toxicity. Acute poisoning risks are clear, and understanding of chronic health implications from both acute and chronic exposure are emerging. Epidemiologic evidence demonstrates associations between early life exposure to pesticides and pediatric cancers, decreased cognitive function, and behavioral problems. Related animal toxicology studies provide supportive biological plausibility for these findings. Recognizing and reducing problematic exposures will require attention to current inadequacies in medical training, public health tracking, and regulatory action on pesticides. Ongoing research describing toxicologic vulnerabilities and exposure factors across the life span are needed to inform regulatory needs and appropriate interventions. Policies that promote integrated pest management, comprehensive pesticide labeling, and marketing practices that incorporate child health considerations will enhance safe use. (11/12)

PESTICIDE EXPOSURE IN CHILDREN (TECHNICAL REPORT)

James R. Roberts, MD, MPH; Catherine J. Karr, MD, PhD; and Council on Environmental Health

ABSTRACT. Pesticides are a collective term for a wide array of chemicals intended to kill unwanted insects, plants, molds, and rodents. Food, water, and treatment in the home, yard, and school are all potential sources of children's exposure. Exposures to pesticides may be overt or subacute, and effects range from acute to chronic toxicity. In 2008, pesticides were the ninth most common substance reported to poison control centers, and approximately 45% of all reports of pesticide poisoning were for children. Organophosphate and carbamate poisoning are perhaps the most widely known acute poisoning syndromes, can be diagnosed by depressed red blood cell cholinesterase levels, and have available antidotal therapy. However, numerous other pesticides that may cause acute toxicity, such as pyrethroid and neonicotinoid insecticides, herbicides, fungicides, and rodenticides, also have specific toxic effects; recognition of these effects may help identify acute exposures. Evidence is increasingly

emerging about chronic health implications from both acute and chronic exposure. A growing body of epidemiological evidence demonstrates associations between parental use of pesticides, particularly insecticides, with acute lymphocytic leukemia and brain tumors. Prenatal, household, and occupational exposures (maternal and paternal) appear to be the largest risks. Prospective cohort studies link early-life exposure to organophosphates and organochlorine pesticides (primarily DDT) with adverse effects on neurodevelopment and behavior. Among the findings associated with increased pesticide levels are poorer mental development by using the Bayley index and increased scores on measures assessing pervasive developmental disorder, inattention, and attention-deficit/hyperactivity disorder. Related animal toxicology studies provide supportive biological plausibility for these findings. Additional data suggest that there may also be an association between parental pesticide use and adverse birth outcomes including physical birth defects, low birth weight, and fetal death, although the data are less robust than for cancer and neurodevelopmental effects. Children's exposures to pesticides should be limited as much as possible. (11/12)

PHOTOTHERAPY TO PREVENT SEVERE NEONATAL HYPERBILIRUBINEMIA IN THE NEWBORN INFANT 35 OR MORE WEEKS OF GESTATION (TECHNICAL REPORT)

Vinod K. Bhutani, MD, and Committee on Fetus and Newborn

ABSTRACT. *Objective.* To standardize the use of phototherapy consistent with the American Academy of Pediatrics clinical practice guideline for the management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation.

Methods. Relevant literature was reviewed. Phototherapy devices currently marketed in the United States that incorporate fluorescent, halogen, fiber-optic, or blue light-emitting diode light sources were assessed in the laboratory.

Results. The efficacy of phototherapy units varies widely because of differences in light source and configuration. The following characteristics of a device contribute to its effectiveness: (1) emission of light in the blue-to-green range that overlaps the in vivo plasma bilirubin absorption spectrum (~460–490 nm); (2) irradiance of at least 30 $\mu W \cdot cm^{-2} \cdot nm^{-1}$ (confirmed with an appropriate irradiance meter calibrated over the appropriate wavelength range); (3) illumination of maximal body surface; and (4) demonstration of a decrease in total bilirubin concentrations during the first 4 to 6 hours of exposure.

Recommendations. The intensity and spectral output of phototherapy devices is useful in predicting potential effectiveness in treating hyperbilirubinemia (group B recommendation). Clinical effectiveness should be evaluated before and monitored during use (group B recommendation). Blocking the light source or reducing exposed body surface should be avoided (group B recommendation). Standardization of irradiance meters, improvements in device design, and lower-upper limits of light intensity for phototherapy units merit further study. Comparing the in vivo performance of devices is not practical, in general, and alternative procedures need to be explored. (9/11)

PHYSICIAN REFUSAL TO PROVIDE INFORMATION OR TREATMENT ON THE BASIS OF CLAIMS OF CONSCIENCE

Committee on Bioethics

ABSTRACT. Health care professionals may have moral objections to particular medical interventions. They may refuse to provide or cooperate in the provision of these interventions. Such objections are referred to as conscientious objections. Although it may be difficult to characterize or validate claims of conscience, respecting the individual physician's moral integrity is important. Conflicts arise when claims of conscience impede a patient's access to medical information or care. A physician's conscientious objection to certain interventions or treatments may be constrained in some situations. Physicians have a duty to disclose to prospective patients treatments they refuse to perform. As part of informed consent, physicians also have a duty to inform their patients of all relevant and legally available treatment options, including options to which they object. They have a moral obligation to refer patients to other health care professionals who are willing to provide those services when failing to do so would cause harm to the patient, and they have a duty to treat patients in emergencies when referral would significantly increase the probability of mortality or serious morbidity. Conversely, the health care system should make reasonable accommodations for physicians with conscientious objections. (11/09)

PHYSICIANS' ROLES IN COORDINATING CARE OF HOSPITALIZED CHILDREN (CLINICAL REPORT)

Patricia S. Lye, MD; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The care of hospitalized children and adolescents has become increasingly complex and often involves multiple physicians beyond the traditional primary care pediatrician. Hospitalists, medical subspecialists, surgical specialists, and hospital attending physicians may all participate in the care of hospitalized children and youth. This report summarizes the responsibilities of the pediatrician and other involved physicians in ensuring that children receive coordinated and comprehensive medical care delivered within the context of their medical homes as inpatients, and that care is appropriately continued on an outpatient basis. (9/10)

PLANNED HOME BIRTH

Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics concurs with the recent statement of the American College of Obstetricians and Gynecologists affirming that hospitals and birthing centers are the safest settings for birth in the United States while respecting the right of women to make a medically informed decision about delivery. This statement is intended to help pediatricians provide supportive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize the standards of care for newborn infants born at home, which are consistent with standards for infants born in a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care that adheres to the standards

highlighted in this statement, more completely described in other publications from the American Academy of Pediatrics, including *Guidelines for Perinatal Care.* The goal of providing high-quality care to all newborn infants can best be achieved through continuing efforts by all participating health care providers and institutions to develop and sustain communications and understanding on the basis of professional interaction and mutual respect throughout the health care system. (4/13)

See full text on page 819.

POLIOVIRUS

Committee on Infectious Diseases

ABSTRACT. Despite marked progress in global polio eradication, the threat of polio importation into the United States remains; therefore, all children should be protected against the disease. The standard schedule for poliovirus immunization remains 4 doses of inactivated poliovirus vaccine at 2, 4, and 6 through 18 months and 4 through 6 years of age. The minimum interval between doses 1 and 2 and between doses 2 and 3 is 4 weeks, and the minimum interval between doses 3 and 4 is 6 months. The minimum age for dose 1 is 6 weeks. Minimal age and intervals should be used when there is imminent threat of exposure, such as travel to an area in which polio is endemic or epidemic. The final dose in the inactivated poliovirus vaccine series should be administered at 4 through 6 years of age, regardless of the previous number of doses administered before the fourth birthday, and at least 6 months since the last dose was received. (9/11)

POSTDISCHARGE FOLLOW-UP OF INFANTS WITH CONGENITAL DIAPHRAGMATIC HERNIA (CLINICAL REPORT)

Section on Surgery and Committee on Fetus and Newborn

ABSTRACT. Infants with congenital diaphragmatic hernia often require intensive treatment after birth, have prolonged hospitalizations, and have other congenital anomalies. After discharge from the hospital, they may have long-term sequelae such as respiratory insufficiency, gastroesophageal reflux, poor growth, neurodevelopmental delay, behavior problems, hearing loss, hernia recurrence, and orthopedic deformities. Structured follow-up for these patients facilitates early recognition and treatment of these complications. In this report, follow-up of infants with congenital diaphragmatic hernia is outlined. (3/08, reaffirmed 5/11)

POSTEXPOSURE PROPHYLAXIS IN CHILDREN AND ADOLESCENTS FOR NONOCCUPATIONAL EXPOSURE TO HUMAN IMMUNODEFICIENCY VIRUS (CLINICAL REPORT)

Committee on Pediatric AIDS

ABSTRACT. Exposure to human immunodeficiency virus (HIV) can occur in a number of situations unique to, or more common among, children and adolescents. Guidelines for postexposure prophylaxis (PEP) for occupational and nonoccupational (eg, sexual, needle-sharing) exposures to HIV have been published by the US Public Health Service, but they do not directly address nonoccupational HIV exposures unique to children (such as accidental exposure to human milk from a woman infected with HIV or a puncture wound from a discarded needle on a playground), and they do not provide antiretroviral drug information relevant to PEP in children.

This clinical report reviews issues of potential exposure of children and adolescents to HIV and gives recommendations for PEP in those situations. The risk of HIV transmission from nonoccupational, nonperinatal exposure is generally low. Transmission risk is modified by factors related to the source and extent of exposure. Determination of the HIV infection status of the exposure source may not be possible, and data on transmission risk by exposure type may not exist. Except in the setting of perinatal transmission, no studies have demonstrated the safety and efficacy of postexposure use of antiretroviral drugs for the prevention of HIV transmission in nonoccupational settings. Antiretroviral therapy used for PEP is associated with significant toxicity. The decision to initiate prophylaxis needs to be made in consultation with the patient, the family, and a clinician with experience in treatment of persons with HIV infection. If instituted, therapy should be started as soon as possible after an exposure—no later than 72 hours—and continued for 28 days. Many clinicians would use 3 drugs for PEP regimens, although 2 drugs may be considered in certain circumstances. Instruction for avoiding secondary transmission should be given. Careful follow-up is needed for psychologic support, encouragement of medication adherence, toxicity monitoring, and serial HIV antibody testing. (6/03, reaffirmed 1/07, 10/08)

POSTNATAL CORTICOSTEROIDS TO PREVENT OR TREAT BRONCHOPULMONARY DYSPLASIA

Kristi L. Watterberg, MD, and Committee on Fetus and Newborn

ABSTRACT. The purpose of this revised statement is to review current information on the use of postnatal glucocorticoids to prevent or treat bronchopulmonary dysplasia in the preterm infant and to make updated recommendations regarding their use. High-dose dexamethasone (0.5 mg/kg per day) does not seem to confer additional therapeutic benefit over lower doses and is not recommended. Evidence is insufficient to make a recommendation regarding other glucocorticoid doses and preparations. The clinician must use clinical judgment when attempting to balance the potential adverse effects of glucocorticoid treatment with those of bronchopulmonary dysplasia. (9/10)

POSTNATAL GLUCOSE HOMEOSTASIS IN LATE-PRETERM AND TERM INFANTS (CLINICAL REPORT)

David H. Adamkin, MD, and Committee on Fetus and Newborn

ABSTRACT. This report provides a practical guide and algorithm for the screening and subsequent management of neonatal hypoglycemia. Current evidence does not support a specific concentration of glucose that can discriminate normal from abnormal or can potentially result in acute or chronic irreversible neurologic damage. Early identification of the at-risk infant and institution of prophylactic measures to prevent neonatal hypoglycemia are recommended as a pragmatic approach despite the absence of a consistent definition of hypoglycemia in the literature. (3/11)

PRECERTIFICATION PROCESS
Committee on Hospital Care
ABSTRACT. Precertification is a process still used by health insurance companies to control health care costs. Although we believe precertification is unnecessary and not cost-effective, in those instances where precertification is still being utilized, we suggest that the following procedures be adopted. This statement suggests guidelines that should help achieve this goal while allowing optimal access to care for children. (8/00, reaffirmed 5/05, 11/08)

PREMEDICATION FOR NONEMERGENCY ENDOTRACHEAL INTUBATION IN THE NEONATE (CLINICAL REPORT)
Praveen Kumar, MD; Susan E. Denson, MD; Thomas J. Mancuso, MD; Committee on Fetus and Newborn; and Section on Anesthesiology and Pain Medicine
ABSTRACT. Endotracheal intubation is a common procedure in newborn care. The purpose of this clinical report is to review currently available evidence on use of premedication for intubation, identify gaps in knowledge, and provide guidance for making decisions about the use of premedication. (2/10, reaffirmed 8/13)

PRENATAL SUBSTANCE ABUSE: SHORT- AND LONG-TERM EFFECTS ON THE EXPOSED FETUS (TECHNICAL REPORT)
Marylou Behnke, MD; Vincent C. Smith, MD; Committee on Substance Abuse; and Committee on Fetus and Newborn
ABSTRACT. Prenatal substance abuse continues to be a significant problem in this country and poses important health risks for the developing fetus. The primary care pediatrician's role in addressing prenatal substance exposure includes prevention, identification of exposure, recognition of medical issues for the exposed newborn infant, protection of the infant, and follow-up of the exposed infant. This report will provide information for the most common drugs involved in prenatal exposure: nicotine, alcohol, marijuana, opiates, cocaine, and methamphetamine. (2/13)
See full text on page 827.

THE PRENATAL VISIT (CLINICAL REPORT)
George J. Cohen, MD, and Committee on Psychosocial Aspects of Child and Family Health
ABSTRACT. As advocates for children and their families, pediatricians can support and guide expectant parents in the prenatal period. Prenatal visits allow the pediatrician to gather basic information from expectant parents, offer them information and advice, and identify high-risk conditions that may require special care. In addition, a prenatal visit is the first step in establishing a relationship between the family and the pediatrician (the infant's medical home) and in helping the parents develop parenting skills and confidence. There are several possible formats for this first visit. The one used depends on the experience and preference of the parents, the style of the pediatrician's practice, and pragmatic issues of reimbursement. (9/09)

PREPARATION FOR EMERGENCIES IN THE OFFICES OF PEDIATRICIANS AND PEDIATRIC PRIMARY CARE PROVIDERS
Committee on Pediatric Emergency Medicine
ABSTRACT. High-quality pediatric emergency care can be provided only through the collaborative efforts of many health care professionals and child advocates working together throughout a continuum of care that extends from prevention and the medical home to prehospital care, to emergency department stabilization, to critical care and rehabilitation, and finally to a return to care in the medical home. At times, the office of the pediatric primary care provider will serve as the entry site into the emergency care system, which comprises out-of-hospital emergency medical services personnel, emergency department nurses and physicians, and other emergency and critical care providers. Recognizing the important role of pediatric primary care providers in the emergency care system for children and understanding the capabilities and limitations of that system are essential if pediatric primary care providers are to offer the best chance at intact survival for every child who is brought to the office with an emergency. Optimizing pediatric primary care provider office readiness for emergencies requires consideration of the unique aspects of each office practice, the types of patients and emergencies that might be seen, the resources on site, and the resources of the larger emergency care system of which the pediatric primary care provider's office is a part. Parent education regarding prevention, recognition, and response to emergencies, patient triage, early recognition and stabilization of pediatric emergencies in the office, and timely transfer to an appropriate facility for definitive care are important responsibilities of every pediatric primary care provider. In addition, pediatric primary care providers can collaborate with out-of-hospital and hospital-based providers and advocate for the best-quality emergency care for their patients. (7/07, reaffirmed 6/11)

PREPARING FOR PEDIATRIC EMERGENCIES: DRUGS TO CONSIDER (CLINICAL REPORT)
Mary A. Hegenbarth, MD, and Committee on Drugs
ABSTRACT. This clinical report provides current recommendations regarding the selection and use of drugs in preparation for pediatric emergencies. It is not intended to be a comprehensive list of all medications that may be used in all emergencies. When possible, dosage recommendations are consistent with those used in current emergency references such as the *Advanced Pediatric Life Support and Pediatric Advanced Life Support* textbooks and the recently revised American Heart Association resuscitation guidelines. (2/08, reaffirmed 10/11)

PRESCRIBING ASSISTIVE-TECHNOLOGY SYSTEMS: FOCUS ON CHILDREN WITH IMPAIRED COMMUNICATION (CLINICAL REPORT)
Larry W. Desch, MD; Deborah Gaebler-Spira, MD; and Council on Children With Disabilities
ABSTRACT. This clinical report defines common terms of use and provides information on current practice, research, and limitations of assistive technology that can be used in systems for communication. The assessment

process to determine the best devices for use with a particular child (ie, the best fit of a device) is also reviewed. The primary care pediatrician, as part of the medical home, plays an important role in the interdisciplinary effort to provide appropriate assistive technology and may be asked to make a referral for assessment or prescribe a particular device. This report provides resources to assist pediatricians in this role and reviews the interdisciplinary team functional evaluation using standardized assessments; the multiple funding opportunities available for obtaining devices and ways in which pediatricians can assist families with obtaining them; the training necessary to use these systems once the devices are procured; the follow-up evaluation to ensure that the systems are meeting their goals; and the leadership skills needed to advocate for this technology. The American Academy of Pediatrics acknowledges the need for key resources to be identified in the community and recognizes that these resources are a shared medical, educational, therapeutic, and family responsibility. Although this report primarily deals with assistive technology specific for communication impairments, many of the details in this report also can aid in the acquisition and use of other types of assistive technology. (6/08, reaffirmed 1/12)

PRESCRIBING THERAPY SERVICES FOR CHILDREN WITH MOTOR DISABILITIES (CLINICAL REPORT)

Committee on Children With Disabilities

ABSTRACT. Pediatricians often are called on to prescribe physical, occupational, and speech-language therapy services for children with motor disabilities. This report defines the context in which rehabilitation therapies should be prescribed, emphasizing the evaluation and enhancement of the child's function and abilities and participation in age-appropriate life roles. The report encourages pediatricians to work with teams including the parents, child, teachers, therapists, and other physicians to ensure that their patients receive appropriate therapy services. (6/04, reaffirmed 5/07, 5/11)

PRESERVATION OF FERTILITY IN PEDIATRIC AND ADOLESCENT PATIENTS WITH CANCER (TECHNICAL REPORT)

Mary E. Fallat, MD; John Hutter, MD; Committee on Bioethics; Section on Hematology/Oncology; and Section on Surgery

ABSTRACT. Many cancers that present in children and adolescents are curable with surgery, chemotherapy, and/or radiation therapy. Potential adverse consequences of treatment include sterility, infertility, or subfertility as a result of either gonad removal or damage to germ cells from adjuvant therapy. In recent years, treatment of solid tumors and hematologic malignancies has been modified in an attempt to reduce damage to the gonads. Simultaneously, advances in assisted reproductive techniques have led to new possibilities for the prevention and treatment of infertility. This technical report reviews the topic of fertility preservation in pediatric and adolescent patients with cancer, including ethical considerations. (5/08, reaffirmed 2/12)

PREVENTING AND TREATING HOMESICKNESS (CLINICAL REPORT)

Christopher A. Thurber, PhD; Edward Walton, MD; and Council on School Health

ABSTRACT. Homesickness is the distress and functional impairment caused by an actual or anticipated separation from home and attachment objects such as parents. It is characterized by acute longing and preoccupying thoughts of home. Almost all children, adolescents, and adults experience some degree of homesickness when they are apart from familiar people and environments. Pediatricians and other health care professionals are in a unique position to assist families in understanding the etiology, prevention, and treatment of homesickness. In the case of planned separations, such as summer camp, techniques are provided that may aid in prevention. In the case of unanticipated or traumatic separations, such as hospitalization, effective treatment strategies are available. (1/07, reaffirmed 5/12)

PREVENTION OF AGRICULTURAL INJURIES AMONG CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention and Committee on Community Health Services

ABSTRACT. Although the annual number of farm deaths to children and adolescents has decreased since publication of the 1988 American Academy of Pediatrics statement, "Rural Injuries," the rate of nonfatal farm injuries has increased. Approximately 100 unintentional injury deaths occur annually to children and adolescents on US farms, and an additional 22 000 injuries to children younger than 20 years occur on farms. Relatively few adolescents are employed on farms compared with other types of industry, yet the proportion of fatalities in agriculture is higher than that for any other type of adolescent employment. The high mortality and severe morbidity associated with farm injuries require continuing and improved injury-control strategies. This statement provides recommendations for pediatricians regarding patient and community education as well as public advocacy related to agricultural injury prevention in childhood and adolescence. (10/01, reaffirmed 1/07, 11/11)

PREVENTION OF CHOKING AMONG CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Choking is a leading cause of morbidity and mortality among children, especially those aged 3 years or younger. Food, coins, and toys are the primary causes of choking-related injury and death. Certain characteristics, including shape, size, and consistency, of certain toys and foods increase their potential to cause choking among children. Childhood choking hazards should be addressed through comprehensive and coordinated prevention activities. The US Consumer Product Safety Commission (CPSC) should increase efforts to ensure that toys that are sold in retail store bins, vending machines, or on the Internet have appropriate choking-hazard warnings; work with manufacturers to improve the effectiveness of recalls of products that pose a choking risk to children; and increase efforts to prevent the resale of these recalled products via online auction sites. Current gaps in choking-prevention standards for children's toys should

be reevaluated and addressed, as appropriate, via revisions to the standards established under the Child Safety Protection Act, the Consumer Product Safety Improvement Act, or regulation by the CPSC. Prevention of food-related choking among children in the United States has been inadequately addressed at the federal level. The US Food and Drug Administration should establish a systematic, institutionalized process for examining and addressing the hazards of food-related choking. This process should include the establishment of the necessary surveillance, hazard evaluation, enforcement, and public education activities to prevent food-related choking among children. While maintaining its highly cooperative arrangements with the CPSC and the US Department of Agriculture, the Food and Drug Administration should have the authority to address choking-related risks of all food products, including meat products that fall under the jurisdiction of the US Department of Agriculture. The existing National Electronic Injury Surveillance System–All Injury Program of the CPSC should be modified to conduct more-detailed surveillance of choking on food among children. Food manufacturers should design new foods and redesign existing foods to avoid shapes, sizes, textures, and other characteristics that increase choking risk to children, to the extent possible. Pediatricians, dentists, and other infant and child health care providers should provide choking-prevention counseling to parents as an integral part of anticipatory guidance activities. (2/10)

PREVENTION OF DROWNING

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Drowning is a leading cause of injury-related death in children. In 2006, fatal drowning claimed the lives of approximately 1100 US children younger than 20 years. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in the prevention of drowning. (5/10)

PREVENTION OF DROWNING (TECHNICAL REPORT)

Committee on Injury, Violence, and Poison Prevention and Jeffrey Weiss, MD

ABSTRACT. Drowning is a leading cause of injury-related death in children. In 2006, approximately 1100 US children younger than 20 years died from drowning. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in the prevention of drowning. (5/10)

PREVENTION AND MANAGEMENT OF PAIN IN THE NEONATE: AN UPDATE

Committee on Fetus and Newborn and Section on Surgery (joint with Canadian Paediatric Society)

ABSTRACT. The prevention of pain in neonates should be the goal of all caregivers, because repeated painful exposures have the potential for deleterious consequences. Neonates at greatest risk of neurodevelopmental impairment as a result of preterm birth (ie, the smallest and sickest) are also those most likely to be exposed to the greatest number of painful stimuli in the NICU. Although there are major gaps in our knowledge regarding the most effective way to prevent and relieve pain in neonates, proven and safe therapies are currently underused for routine minor yet painful procedures. Every health care facility caring for neonates should implement an effective pain-prevention program, which includes strategies for routinely assessing pain, minimizing the number of painful procedures performed, effectively using pharmacologic and nonpharmacologic therapies for the prevention of pain associated with routine minor procedures, and eliminating pain associated with surgery and other major procedures. (11/06, reaffirmed 5/10)

PREVENTION AND MANAGEMENT OF POSITIONAL SKULL DEFORMITIES IN INFANTS (CLINICAL REPORT)

James Laughlin, MD; Thomas G. Luerssen, MD; Mark S. Dias, MD; Committee on Practice and Ambulatory Medicine; and Section on Neurological Surgery

ABSTRACT. Positional skull deformities may be present at birth or may develop during the first few months of life. Since the early 1990s, US pediatricians have seen an increase in the number of children with cranial asymmetry, particularly unilateral flattening of the occiput, likely attributable to parents following the American Academy of Pediatrics "Back to Sleep" positioning recommendations aimed at decreasing the risk of sudden infant death syndrome. Positional skull deformities are generally benign, reversible head-shape anomalies that do not require surgical intervention, as opposed to craniosynostosis, which can result in neurologic damage and progressive craniofacial distortion. Although associated with some risk of positional skull deformity, healthy young infants should be placed down for sleep on their backs. The practice of putting infants to sleep on their backs has been associated with a drastic decrease in the incidence of sudden infant death syndrome. Pediatricians need to be able to properly differentiate infants with benign skull deformities from those with craniosynostosis, educate parents on methods of proactively decreasing the likelihood of the development of occipital flattening, initiate appropriate management, and make referrals when necessary. This report provides guidance for the prevention, diagnosis, and management of positional skull deformity in an otherwise normal infant without evidence of associated anomalies, syndromes, or spinal disease. (11/11)

PREVENTION OF PEDIATRIC OVERWEIGHT AND OBESITY

Committee on Nutrition

ABSTRACT. The dramatic increase in the prevalence of childhood overweight and its resultant comorbidities are associated with significant health and financial burdens, warranting strong and comprehensive prevention efforts. This statement proposes strategies for early identification of excessive weight gain by using body mass index, for dietary and physical activity interventions during health supervision encounters, and for advocacy and research. (8/03, reaffirmed 10/06)

PREVENTION OF ROTAVIRUS DISEASE: UPDATED GUIDELINES FOR USE OF ROTAVIRUS VACCINE

Committee on Infectious Diseases

ABSTRACT. This statement updates and replaces the 2007 American Academy of Pediatrics statement for prevention of rotavirus gastroenteritis. In February 2006, a live oral human-bovine reassortant rotavirus vaccine (RV5 [RotaTeq]) was licensed as a 3-dose series for use in infants in the United States. The American Academy of Pediatrics recommended routine use of RV5 in infants in the United States. In April 2008, a live, oral, human attenuated rotavirus vaccine (RV1 [Rotarix]) was licensed as a 2-dose series for use in infants in the United States. The American Academy of Pediatrics recommends routine immunization of infants in the United States with rotavirus vaccine. The American Academy of Pediatrics does not express a preference for either RV5 or RV1. RV5 is to be administered orally in a 3-dose series with doses administered at 2, 4, and 6 months of age; RV1 is to be administered orally in a 2-dose series with doses administered at 2 and 4 months of age. The first dose of rotavirus vaccine should be administered from 6 weeks through 14 weeks, 6 days of age. The minimum interval between doses of rotavirus vaccine is 4 weeks. All doses should be administered by 8 months, 0 days of age. Recommendations in this statement also address the maximum ages for doses, contraindications, precautions, and special situations for administration of rotavirus vaccine. (3/09)

PREVENTION OF SEXUAL HARASSMENT IN THE WORKPLACE AND EDUCATIONAL SETTINGS

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics is committed to working to ensure that workplaces and educational settings in which pediatricians spend time are free of sexual harassment. The purpose of this statement is to heighten awareness and sensitivity to this important issue, recognizing that institutions, clinics, and office-based practices may have existing policies. (10/06, reaffirmed 5/09, 1/12)

PREVENTION AND TREATMENT OF TYPE 2 DIABETES MELLITUS IN CHILDREN, WITH SPECIAL EMPHASIS ON AMERICAN INDIAN AND ALASKA NATIVE CHILDREN (CLINICAL REPORT)

Committee on Native American Child Health and Section on Endocrinology

ABSTRACT. The emergence of type 2 diabetes mellitus in the American Indian/Alaska Native pediatric population presents a new challenge for pediatricians and other health care professionals. This chronic disease requires preventive efforts, early diagnosis, and collaborative care of the patient and family within the context of a medical home. (10/03, reaffirmed 10/08)

THE PREVENTION OF UNINTENTIONAL INJURY AMONG AMERICAN INDIAN AND ALASKA NATIVE CHILDREN: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Native American Child Health and Committee on Injury and Poison Prevention

ABSTRACT. Among ethnic groups in the United States, American Indian and Alaska Native (AI/AN) children experience the highest rates of injury mortality and morbidity. Injury mortality rates for AI/AN children have decreased during the past quarter century, but remain almost double the rate for all children in the United States. The Indian Health Service (IHS), the federal agency with the primary responsibility for the health care of AI/AN people, has sponsored an internationally recognized injury prevention program designed to reduce the risk of injury death by addressing community-specific risk factors. Model programs developed by the IHS and tribal governments have led to successful outcomes in motor vehicle occupant safety, drowning prevention, and fire safety. Injury prevention programs in tribal communities require special attention to the sovereignty of tribal governments and the unique cultural aspects of health care and communication. Pediatricians working with AI/AN children on reservations or in urban environments are strongly urged to collaborate with tribes and the IHS to create community-based coalitions and develop programs to address highly preventable injury-related mortality and morbidity. Strong advocacy also is needed to promote childhood injury prevention as an important priority for federal agencies and tribes. (12/99, reaffirmed 12/02 COIVPP, 5/03 CONACH, 1/06, 1/09)

PREVENTION OF VARICELLA: UPDATE OF RECOMMENDATIONS FOR USE OF QUADRIVALENT AND MONOVALENT VARICELLA VACCINES IN CHILDREN

Committee on Infectious Diseases

ABSTRACT. Two varicella-containing vaccines are licensed for use in the United States: monovalent varicella vaccine (Varivax [Merck & Co, Inc, West Point, PA]) and quadrivalent measles-mumps-rubella-varicella vaccine (MMRV) (ProQuad [Merck & Co, Inc]). It is estimated from postlicensure data that after vaccination at 12 through 23 months of age, 7 to 9 febrile seizures occur per 10 000 children who receive the MMRV, and 3 to 4 febrile seizures occur per 10 000 children who receive the measles-mumps-rubella (MMR) and varicella vaccines administered concurrently but at separate sites. Thus, 1 additional febrile seizure is expected to occur per approximately 2300 to 2600 children 12 to 23 months old vaccinated with the MMRV, when compared with separate MMR and varicella vaccine administration. The period of risk for febrile seizures is from 5 through 12 days after receipt of the vaccine(s). No increased risk of febrile seizures is seen among patients 4 to 6 years of age receiving MMRV. Febrile seizures do not predispose to epilepsy or neurodevelopmental delays later in life and are not associated with long-term health impairment. The American Academy of Pediatrics recommends that either MMR and varicella vaccines separately or the MMRV be used for the first dose of measles, mumps, rubella, and varicella vac-

cines administered at 12 through 47 months of age. For the first dose of measles, mumps, rubella, and varicella vaccines administered at ages 48 months and older, and for dose 2 at any age (15 months to 12 years), use of MMRV generally is preferred over separate injections of MMR and varicella vaccines. (8/11)

PREVENTIVE ORAL HEALTH INTERVENTION FOR PEDIATRICIANS

Section on Pediatric Dentistry and Oral Health

ABSTRACT. This policy is a compilation of current concepts and scientific evidence required to understand and implement practice-based preventive oral health programs designed to improve oral health outcomes for all children and especially children at significant risk of dental decay. In addition, it reviews cariology and caries risk assessment and defines, through available evidence, appropriate recommendations for preventive oral health intervention by primary care pediatric practitioners. (12/08)

PRINCIPLES FOR THE DEVELOPMENT AND USE OF QUALITY MEASURES

Steering Committee on Quality Improvement and Management and Committee on Practice and Ambulatory Medicine

ABSTRACT. The American Academy of Pediatrics and its members are committed to improving the health care system to provide the highest-quality and safest health care for infants, children, adolescents, and young adults. This statement is intended as a guide for pediatricians and pediatric leadership on the appropriate uses of quality measures and the criteria on which they should be based. The statement summarizes the current national efforts on quality measurement and provides a set of principles for the development, use, and evaluation of quality measures for improving children's health and health care. The American Academy of Pediatrics recommends that these measures address important issues for children; be appropriate for children's health and health care, scientifically valid, and feasible; and focus on what can be improved. In addition, the American Academy of Pediatrics supports reasonable principles for the oversight and implementation of pay-for-performance programs. (2/08)

PRINCIPLES OF HEALTH CARE FINANCING

Committee on Child Health Financing

ABSTRACT. The American Academy of Pediatrics advocates that all children must have health insurance coverage that ensures them access to affordable and comprehensive quality care. Access to care depends on the design and implementation of payment systems that ensure the economic viability of the medical home; support and grow the professional pediatric workforce; promote the adoption and implementation of health information technology; enhance medical education, training, and research; and encourage and reward quality-improvement programs that advance and strengthen the medical home. Health insurance plans must be portable from state to state, with administrative procedures to eliminate breaks and gaps in coverage to ensure continuous coverage from year to year. Plans should ensure free choice of clinicians and foster coordination with public and private community-based programs for infants, children, and adolescents through the age of 26. The scope of services provided by all health plans must include preventive, acute and chronic illness, behavioral, inpatient, emergency, and home health care. These plans must be affordable and have cost-sharing policies that protect patients and families from financial strain and are without risk of loss of benefits because of plan design, current illness, or preexisting condition. (10/10, reaffirmed 4/13)

PRINCIPLES OF JUDICIOUS ANTIBIOTIC PRESCRIBING FOR UPPER RESPIRATORY TRACT INFECTIONS IN PEDIATRICS (CLINICAL REPORT)

Committee on Infectious Diseases

ABSTRACT. Most upper respiratory tract infections are caused by viruses and require no antibiotics. This clinical report focuses on antibiotic prescribing strategies for bacterial upper respiratory tract infections, including acute otitis media, acute bacterial sinusitis, and streptococcal pharyngitis. The principles for judicious antibiotic prescribing that are outlined focus on applying stringent diagnostic criteria, weighing the benefits and harms of antibiotic therapy, and understanding situations when antibiotics may not be indicated. The principles can be used to amplify messages from recent clinical guidelines for local guideline development and for patient communication; they are broadly applicable to antibiotic prescribing in general. (11/13)

PRINCIPLES OF PEDIATRIC PATIENT SAFETY: REDUCING HARM DUE TO MEDICAL CARE

Steering Committee on Quality Improvement and Management and Committee on Hospital Care

ABSTRACT. Pediatricians are rendering care in an environment that is increasingly complex, which results in multiple opportunities to cause unintended harm. National awareness of patient safety risks has grown in the 10 years since the Institute of Medicine published its report *To Err Is Human,* and patients and society as a whole continue to challenge health care providers to examine their practices and implement safety solutions. The depth and breadth of harm incurred by the practice of medicine is still being defined as reports continue to uncover a variety of avoidable errors, from those that involve specific high-risk medications to those that are more generalizable, such as patient misidentification. Pediatricians in all venues must have a working knowledge of patient-safety language, advocate for best practices that attend to risks that are unique to children, identify and support a culture of safety, and lead efforts to eliminate avoidable harm in any setting in which medical care is rendered to children. (5/11)

PROBIOTICS AND PREBIOTICS IN PEDIATRICS (CLINICAL REPORT)

Dan W. Thomas, MD; Frank R. Greer, MD; Committee on Nutrition; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. This clinical report reviews the currently known health benefits of probiotic and prebiotic products, including those added to commercially available infant formula and other food products for use in children. Probiotics are supplements or foods that contain viable microorganisms that cause alterations of the microflora of the host. Use of probiotics has been shown to be modestly effective in randomized clinical trials (RCTs) in (1) treating acute viral gastroenteritis in healthy children; and (2) preventing antibiotic-associated diarrhea in healthy children. There is some evidence that probiotics prevent necrotizing enterocolitis in very low birth weight infants (birth weight between 1000 and 1500 g), but more studies are needed. The results of RCTs in which probiotics were used to treat childhood *Helicobacter pylori* gastritis, irritable bowel syndrome, chronic ulcerative colitis, and infantile colic, as well as in preventing childhood atopy, although encouraging, are preliminary and require further confirmation. Probiotics have not been proven to be beneficial in treating or preventing human cancers or in treating children with Crohn disease. There are also safety concerns with the use of probiotics in infants and children who are immunocompromised, chronically debilitated, or seriously ill with indwelling medical devices.

Prebiotics are supplements or foods that contain a nondigestible food ingredient that selectively stimulates the favorable growth and/or activity of indigenous probiotic bacteria. Human milk contains substantial quantities of prebiotics. There is a paucity of RCTs examining prebiotics in children, although there may be some long-term benefit of prebiotics for the prevention of atopic eczema and common infections in healthy infants. Confirmatory well-designed clinical research studies are necessary. (11/10)

PROFESSIONAL LIABILITY INSURANCE AND MEDICOLEGAL EDUCATION FOR PEDIATRIC RESIDENTS AND FELLOWS

Committee on Medical Liability and Risk Management

ABSTRACT. The American Academy of Pediatrics believes that pediatric residents and fellows should be fully informed of the scope and limitations of their professional liability insurance coverage while in training. The academy states that residents and fellows should be educated by their training institutions on matters relating to medical liability and the importance of maintaining adequate and continuous professional liability insurance coverage throughout their careers in medicine. (8/11)

PROFESSIONALISM IN PEDIATRICS: STATEMENT OF PRINCIPLES

Committee on Bioethics

ABSTRACT. The purpose of this statement is to delineate the concept of professionalism within the context of pediatrics and to provide a brief statement of principles to guide the behavior and professional practice of pediatricians. (10/07, reaffirmed 5/11)

PROFESSIONALISM IN PEDIATRICS (TECHNICAL REPORT)

Mary E. Fallat, MD; Jacqueline Glover, PhD; and Committee on Bioethics

ABSTRACT. The purpose of this report is to provide a concrete overview of the ideal standards of behavior and professional practice to which pediatricians should aspire and by which students and residents can be evaluated. Recognizing that the ideal is not always achievable in the practical sense, this document details the key components of professionalism in pediatric practice with an emphasis on core professional values for which pediatricians should strive and that will serve as a moral compass needed to provide quality care for children and their families. (10/07, reaffirmed 5/11)

PROMOTING EDUCATION, MENTORSHIP, AND SUPPORT FOR PEDIATRIC RESEARCH

Committee on Pediatric Research

ABSTRACT. Pediatricians have an important role to play in the advancement of child health research and should be encouraged and supported to pursue research activities. Education and training in child health research should be part of every level of pediatric training. Continuing education and access to research advisors should be available to practitioners and academic faculty. Recommendations to promote additional research education and support at all levels of pediatric training, from premedical to continuing medical education, as well as suggestions for means to increase support and mentorship for research activities, are outlined in this statement. (6/01, reaffirmed 1/05, 5/08, 10/11)

PROMOTING THE PARTICIPATION OF CHILDREN WITH DISABILITIES IN SPORTS, RECREATION, AND PHYSICAL ACTIVITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Paul S. Carbone, MD; and Council on Children With Disabilities

ABSTRACT. The benefits of physical activity are universal for all children, including those with disabilities. The participation of children with disabilities in sports and recreational activities promotes inclusion, minimizes deconditioning, optimizes physical functioning, and enhances overall well-being. Despite these benefits, children with disabilities are more restricted in their participation, have lower levels of fitness, and have higher levels of obesity than their peers without disabilities. Pediatricians and parents may overestimate the risks or overlook the benefits of physical activity in children with disabilities. Well-informed decisions regarding each child's participation must consider overall health status, individual activity preferences, safety precautions, and availability of appropriate programs and equipment. Health supervision visits afford pediatricians, children with disabilities, and parents opportunities to collaboratively generate goal-directed activity "prescriptions." Child, family, financial, and societal barriers to participation need to be directly identified and addressed in the context of local, state, and federal laws. The goal is inclusion for all children with disabilities in appropriate activities. This clinical report discusses the importance of physical activity, recreation, and sports participation for children with disabilities

and offers practical suggestions to pediatric health care professionals for the promotion of participation. (5/08, reaffirmed 1/12)

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. To promote optimal health and well-being of all children, the American Academy of Pediatrics (AAP) supports access for all children to (1) civil marriage rights for their parents and (2) willing and capable foster and adoptive parents, regardless of the parents' sexual orientation. The AAP has always been an advocate for, and has developed policies to support, the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. In so doing, the AAP has supported families in all their diversity, because the family has always been the basic social unit in which children develop the supporting and nurturing relationships with adults that they need to thrive. Children may be born to, adopted by, or cared for temporarily by married couples, nonmarried couples, single parents, grandparents, or legal guardians, and any of these may be heterosexual, gay or lesbian, or of another orientation. Children need secure and enduring relationships with committed and nurturing adults to enhance their life experiences for optimal social-emotional and cognitive development. Scientific evidence affirms that children have similar developmental and emotional needs and receive similar parenting whether they are raised by parents of the same or different genders. If a child has 2 living and capable parents who choose to create a permanent bond by way of civil marriage, it is in the best interests of their child(ren) that legal and social institutions allow and support them to do so, irrespective of their sexual orientation. If 2 parents are not available to the child, adoption or foster parenting remain acceptable options to provide a loving home for a child and should be available without regard to the sexual orientation of the parent(s). (3/13)

See full text on page 857.

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN (TECHNICAL REPORT)

Ellen C. Perrin, MD, MA; Benjamin S. Siegel, MD; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Extensive data available from more than 30 years of research reveal that children raised by gay and lesbian parents have demonstrated resilience with regard to social, psychological, and sexual health despite economic and legal disparities and social stigma. Many studies have demonstrated that children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents. Lack of opportunity for same-gender couples to marry adds to families' stress, which affects the health and welfare of all household members. Because marriage strengthens families and, in so doing, benefits children's development, children should not be deprived of the opportunity for their parents to be married. Paths to parenthood that include assisted reproductive techniques, adoption, and foster parenting should focus on competency of the parents rather than their sexual orientation. (3/13)

See full text on page 863.

PROMOTION OF HEALTHY WEIGHT-CONTROL PRACTICES IN YOUNG ATHLETES

Committee on Sports Medicine and Fitness

ABSTRACT. Children and adolescents are often involved in sports in which weight loss or weight gain is perceived as an advantage. This policy statement describes unhealthy weight-control practices that may be harmful to the health and/or performance of athletes. Healthy methods of weight loss and weight gain are discussed, and physicians are given resources and recommendations that can be used to counsel athletes, parents, coaches, and school administrators in discouraging inappropriate weight-control behaviors and encouraging healthy methods of weight gain or loss, when needed. (12/05)

PROTECTING CHILDREN FROM SEXUAL ABUSE BY HEALTH CARE PROVIDERS

Committee on Child Abuse and Neglect

ABSTRACT. Sexual abuse or exploitation of children is never acceptable. Such behavior by health care providers is particularly concerning because of the trust that children and their families place on adults in the health care profession. The American Academy of Pediatrics strongly endorses the social and moral prohibition against sexual abuse or exploitation of children by health care providers. The academy opposes any such sexual abuse or exploitation by providers, particularly by the academy's members. Health care providers should be trained to recognize and abide by appropriate provider-patient boundaries. Medical institutions should screen staff members for a history of child abuse issues, train them to respect and maintain appropriate boundaries, and establish policies and procedures to receive and investigate concerns about patient abuse. Each person has a responsibility to ensure the safety of children in health care settings and to scrupulously follow appropriate legal and ethical reporting and investigation procedures. (6/11)

PROTECTIVE EYEWEAR FOR YOUNG ATHLETES

*Committee on Sports Medicine and Fitness (*joint with American Academy of Ophthalmology)

ABSTRACT. The American Academy of Pediatrics and American Academy of Ophthalmology strongly recommend protective eyewear for all participants in sports in which there is risk of eye injury. Protective eyewear should be mandatory for athletes who are functionally 1-eyed and for athletes whose ophthalmologists recommend eye protection after eye surgery or trauma. (3/04, reaffirmed 2/08, 6/11)

PROVIDING CARE FOR CHILDREN AND ADOLESCENTS FACING HOMELESSNESS AND HOUSING INSECURITY

Council on Community Pediatrics

ABSTRACT. Child health and housing security are closely intertwined, and children without homes are more likely to suffer from chronic disease, hunger, and malnutrition than are children with homes. Homeless children and

youth often have significant psychosocial development issues, and their education is frequently interrupted. Given the overall effects that homelessness can have on a child's health and potential, it is important for pediatricians to recognize the factors that lead to homelessness, understand the ways that homelessness and its causes can lead to poor health outcomes, and when possible, help children and families mitigate some of the effects of homelessness. Through practice change, partnership with community resources, awareness, and advocacy, pediatricians can help optimize the health and well-being of children affected by homelessness. (5/13)

See full text on page 875.

PROVIDING CARE FOR IMMIGRANT, MIGRANT, AND BORDER CHILDREN

Council on Community Pediatrics

ABSTRACT. This policy statement, which recognizes the large changes in immigrant status since publication of the 2005 statement "Providing Care for Immigrant, Homeless, and Migrant Children," focuses on strategies to support the health of immigrant children, infants, adolescents, and young adults. Homeless children will be addressed in a forthcoming separate statement ("Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity"). While recognizing the diversity across and within immigrant, migrant, and border populations, this statement provides a basic framework for serving and advocating for all immigrant children, with a particular focus on low-income and vulnerable populations. Recommendations include actions needed within and outside the health care system, including expansion of access to high-quality medical homes with culturally and linguistically effective care as well as education and literacy programs. The statement recognizes the unique and special role that pediatricians can play in the lives of immigrant children and families. Recommendations for policies that support immigrant child health are included. (5/13)

See full text on page 883.

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH CEREBRAL PALSY (CLINICAL REPORT)

Gregory S. Liptak, MD, MPH; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. All primary care providers will care for children with cerebral palsy in their practice. In addition to well-child and acute illness care, the role of the medical home in the management of these children includes diagnosis, planning for interventions, authorizing treatments, and follow-up. Optimizing health and well-being for children with cerebral palsy and their families entails family-centered care provided in the medical home; comanagement is the most common model. This report reviews the aspects of care specific to cerebral palsy that a medical home should provide beyond the routine health care needed by all children. (10/11)

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH SPINA BIFIDA (CLINICAL REPORT)

Robert Burke, MD, MPH; Gregory S. Liptak, MD, MPH; and Council on Children With Disabilities

ABSTRACT. The pediatric primary care provider in the medical home has a central and unique role in the care of children with spina bifida. The primary care provider addresses not only the typical issues of preventive and acute health care but also the needs specific to these children. Optimal care requires communication and comanagement with pediatric medical and developmental subspecialists, surgical specialists, therapists, and community providers. The medical home provider is essential in supporting the family and advocating for the child from the time of entry into the practice through adolescence, which includes transition and transfer to adult health care. This report reviews aspects of care specific to the infant with spina bifida (particularly myelomeningocele) that will facilitate optimal medical, functional, and developmental outcomes. (11/11)

PROVISION OF EDUCATIONALLY RELATED SERVICES FOR CHILDREN AND ADOLESCENTS WITH CHRONIC DISEASES AND DISABLING CONDITIONS

Council on Children With Disabilities

ABSTRACT. Children and adolescents with chronic diseases and disabling conditions often need educationally related services. As medical home providers, physicians and other health care professionals can assist children, adolescents, and their families with the complex federal, state, and local laws, regulations, and systems associated with these services. Expanded roles for physicians and other health care professionals in individualized family service plan, individualized education plan, and Section 504 plan development and implementation are recommended. Recent updates to the Individuals With Disabilities Education Act will also affect these services. Funding for these services by private and nonprivate sources also continue to affect the availability of these educationally related services.

The complex range of federal, state, and local laws, regulations, and systems for special education and related services for children and adolescents in public schools is beyond the scope of this statement. Readers are referred to the American Academy of Pediatrics policy statement "The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP)" for additional background materials. The focus of this statement is the role that health care professionals have in determining and managing educationally related services in the school setting.

This policy statement is a revision of a previous statement, "Provision of Educationally Related Services for Children and Adolescents With Chronic Diseases and Disabling Conditions," published in February 2000 by the Committee on Children With Disabilities (http://aappolicy.aappublications.org/cgi/content/full/pediatrics;105/2/448). (6/07)

PSYCHOLOGICAL MALTREATMENT (CLINICAL REPORT)

Roberta Hibbard, MD; Jane Barlow, Dphil; Harriet MacMillan, MD; Committee on Child Abuse and Neglect (joint with American Academy of Child and Adolescent Psychiatry Child Maltreatment and Violence Committee)

ABSTRACT. Psychological or emotional maltreatment of children may be the most challenging and prevalent form of child abuse and neglect. Caregiver behaviors include acts of omission (ignoring need for social interactions) or commission (spurning, terrorizing); may be verbal or nonverbal, active or passive, and with or without intent to harm; and negatively affect the child's cognitive, social, emotional, and/or physical development. Psychological maltreatment has been linked with disorders of attachment, developmental and educational problems, socialization problems, disruptive behavior, and later psychopathology. Although no evidence-based interventions that can prevent psychological maltreatment have been identified to date, it is possible that interventions shown to be effective in reducing overall types of child maltreatment, such as the Nurse Family Partnership, may have a role to play. Furthermore, prevention before occurrence will require both the use of universal interventions aimed at promoting the type of parenting that is now recognized to be necessary for optimal child development, alongside the use of targeted interventions directed at improving parental sensitivity to a child's cues during infancy and later parent-child interactions. Intervention should, first and foremost, focus on a thorough assessment and ensuring the child's safety. Potentially effective treatments include cognitive behavioral parenting programs and other psychotherapeutic interventions. The high prevalence of psychological abuse in advanced Western societies, along with the serious consequences, point to the importance of effective management. Pediatricians should be alert to the occurrence of psychological maltreatment and identify ways to support families who have risk indicators for, or evidence of, this problem. (7/12)

PSYCHOSOCIAL IMPLICATIONS OF DISASTER OR TERRORISM ON CHILDREN: A GUIDE FOR THE PEDIATRICIAN (CLINICAL REPORT)

Joseph F. Hagan Jr, MD; Committee on Psychosocial Aspects of Child and Family Health; and Task Force on Terrorism

ABSTRACT. During and after disasters, pediatricians can assist parents and community leaders not only by accommodating the unique needs of children but also by being cognizant of the psychological responses of children to reduce the possibility of long-term psychological morbidity. The effects of disaster on children are mediated by many factors including personal experience, parental reaction, developmental competency, gender, and the stage of disaster response. Pediatricians can be effective advocates for the child and family and at the community level and can affect national policy in support of families. In this report, specific children's responses are delineated, risk factors for adverse reactions are discussed, and advice is given for pediatricians to ameliorate the effects of disaster on children. (9/05)

PSYCHOSOCIAL RISKS OF CHRONIC HEALTH CONDITIONS IN CHILDHOOD AND ADOLESCENCE

Committee on Children With Disabilities and Committee on Psychosocial Aspects of Child and Family Health (12/93, reaffirmed 10/96)

QUALITY EARLY EDUCATION AND CHILD CARE FROM BIRTH TO KINDERGARTEN

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. High-quality early education and child care for young children improves their health and promotes their development and learning. Early education includes all of a child's experiences at home, in child care, and in other preschool settings. Pediatricians have a role in promoting access to quality early education and child care beginning at birth for all children. The American Academy of Pediatrics affords pediatricians the opportunity to promote the educational and socioemotional needs of young children with other advocacy groups. (1/05, reaffirmed 12/09)

RABIES-PREVENTION POLICY UPDATE: NEW REDUCED-DOSE SCHEDULE

Committee on Infectious Diseases

ABSTRACT. The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention recommends reducing the number of doses from 5 to 4 of human diploid cell vaccine or purified chick embryo cell vaccine required for postexposure prophylaxis to prevent rabies in humans. The vaccine doses should be given on day 0 (first day of prophylaxis) and days 3, 7, and 14 after the first dose. For persons with immune suppression, the 5-dose regimen should continue to be used. Recommendations for the use of human rabies immunoglobulin remain unchanged. The American Academy of Pediatrics endorses these recommendations. (3/11)

RACE/ETHNICITY, GENDER, SOCIOECONOMIC STATUS—RESEARCH EXPLORING THEIR EFFECTS ON CHILD HEALTH: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Pediatric Research

ABSTRACT. Data on research participants and populations frequently include race, ethnicity, and gender as categorical variables, with the assumption that these variables exert their effects through innate or genetically determined biologic mechanisms. There is a growing body of research that suggests, however, that these variables have strong social dimensions that influence health. Socioeconomic status, a complicated construct in its own right, interacts with and confounds analyses of race/ethnicity and gender. The Academy recommends that research studies include race/ethnicity, gender, and socioeconomic status as explanatory variables only when data relevant to the underlying social mechanisms have been collected and included in the analyses. (6/00, reaffirmed 10/05, 1/09)

RACIAL AND ETHNIC DISPARITIES IN THE HEALTH AND HEALTH CARE OF CHILDREN (TECHNICAL REPORT)

Glenn Flores, MD, and Committee on Pediatric Research

ABSTRACT. *Objective.* This technical report reviews and synthesizes the published literature on racial/ethnic disparities in children's health and health care.

Methods. A systematic review of the literature was conducted for articles published between 1950 and March 2007. Inclusion criteria were peer-reviewed, original research articles in English on racial/ethnic disparities in the health and health care of US children. Search terms used included "child," "disparities," and the Index Medicus terms for each racial/ethnic minority group.

Results. Of 781 articles initially reviewed, 111 met inclusion criteria and constituted the final database. Review of the literature revealed that racial/ethnic disparities in children's health and health care are quite extensive, pervasive, and persistent. Disparities were noted across the spectrum of health and health care, including in mortality rates, access to care and use of services, prevention and population health, health status, adolescent health, chronic diseases, special health care needs, quality of care, and organ transplantation. Mortality-rate disparities were noted for children in all 4 major US racial/ethnic minority groups, including substantially greater risks than white children of all-cause mortality; death from drowning, from acute lymphoblastic leukemia, and after congenital heart defect surgery; and an earlier median age at death for those with Down syndrome and congenital heart defects. Certain methodologic flaws were commonly observed among excluded studies, including failure to evaluate children separately from adults (22%), combining all nonwhite children into 1 group (9%), and failure to provide a white comparison group (8%). Among studies in the final database, 22% did not perform multivariable or stratified analyses to ensure that disparities persisted after adjustment for potential confounders.

Conclusions. Racial/ethnic disparities in children's healthand health care are extensive, pervasive, and persistent, and occur across the spectrum of health and health care. Methodologic flaws were identified in how such disparities are sometimes documented and analyzed. Optimal health and health care for all children will require recognition of disparities as pervasive problems, methodologically sound disparities studies, and rigorous evaluation of disparities interventions. (3/10, reaffirmed 5/13)

RADIATION DISASTERS AND CHILDREN

Committee on Environmental Health

ABSTRACT. The special medical needs of children make it essential that pediatricians be prepared for radiation disasters, including 1) the detonation of a nuclear weapon; 2) a nuclear power plant event that unleashes a radioactive cloud; and 3) the dispersal of radionuclides by conventional explosive or the crash of a transport vehicle. Any of these events could occur unintentionally or as an act of terrorism. Nuclear facilities (eg, power plants, fuel processing centers, and food irradiation facilities) are often located in highly populated areas, and as they age, the risk of mechanical failure increases. The short- and long-term consequences of a radiation disaster are significantly greater in children for several reasons. First, children have a disproportionately higher minute ventilation, leading to greater internal exposure to radioactive gases. Children have a significantly greater risk of developing cancer even when they are exposed to radiation in utero. Finally, children and the parents of young children are more likely than are adults to develop enduring psychologic injury after a radiation disaster. The pediatrician has a critical role in planning for radiation disasters. For example, potassium iodide is of proven value for thyroid protection but must be given before or soon after exposure to radioiodines, requiring its placement in homes, schools, and child care centers. Pediatricians should work with public health authorities to ensure that children receive full consideration in local planning for a radiation disaster. (6/03, reaffirmed 1/07)

RADIATION RISK TO CHILDREN FROM COMPUTED TOMOGRAPHY (CLINICAL REPORT)

Alan S. Brody, MD; Donald P. Frush, MD; Walter Huda, PhD; Robert L. Brent, MD, PhD; and Section on Radiology

ABSTRACT. Imaging studies that use ionizing radiation are an essential tool for the evaluation of many disorders of childhood. Ionizing radiation is used in radiography, fluoroscopy, angiography, and computed tomography scanning. Computed tomography is of particular interest because of its relatively high radiation dose and wide use. Consensus statements on radiation risk suggest that it is reasonable to act on the assumption that low-level radiation may have a small risk of causing cancer. The medical community should seek ways to decrease radiation exposure by using radiation doses as low as reasonably achievable and by performing these studies only when necessary. There is wide agreement that the benefits of an indicated computed tomography scan far outweigh the risks. Pediatric health care professionals' roles in the use of computed tomography on children include deciding when a computed tomography scan is necessary and discussing the risk with patients and families. Radiologists should be a source of consultation when forming imaging strategies and should create specific protocols with scanning techniques optimized for pediatric patients. Families and patients should be encouraged to ask questions about the risks and benefits of computed tomography scanning. The information in this report is provided to aid in decision-making and discussions with the health care team, patients, and families. (9/07)

RECOGNITION AND MANAGEMENT OF IATROGENICALLY INDUCED OPIOID DEPENDENCE AND WITHDRAWAL IN CHILDREN (CLINICAL REPORT)

Jeffrey Galinkin, MD, FAAP; Jeffrey Lee Koh, MD, FAAP; Committee on Drugs; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Opioids are often prescribed to children for pain relief related to procedures, acute injuries, and chronic conditions. Round-the-clock dosing of opioids can produce opioid dependence within 5 days. According to a 2001 consensus paper from the American Academy of Pain Medicine, American Pain Society, and American Society of Addiction Medicine, dependence is defined as "a state of adaptation that is manifested by a drug class

specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist." Although the experience of many children undergoing iatrogenically induced withdrawal may be mild or goes unreported, there is currently no guidance for recognition or management of withdrawal for this population. Guidance on this subject is available only for adults and primarily for adults with substance use disorders. The guideline will summarize existing literature and provide readers with information currently not available in any single source specific for this vulnerable pediatric population. (12/13)

See full text on page 893.

RECOGNIZING AND RESPONDING TO MEDICAL NEGLECT (CLINICAL REPORT)

Carole Jenny, MD, MBA, and Committee on Child Abuse and Neglect

ABSTRACT. A caregiver may fail to recognize or respond to a child's medical needs for a variety of reasons. An effective response by a health care professional to medical neglect requires a comprehensive assessment of the child's needs, the parents' resources, the parents' efforts to provide for the needs of the child, and options for ensuring optimal health for the child. Such an assessment requires clear, 2-way communication between the family and the health care professional. Physicians should consider the least intrusive options for managing cases of medical neglect that ensure the health and safety of the child. (12/07, reaffirmed 1/11)

RECOMMENDATION FOR MANDATORY INFLUENZA IMMUNIZATION OF ALL HEALTH CARE PERSONNEL

Henry H. Bernstein, DO; Jeffrey R. Starke, MD; and Committee on Infectious Diseases

ABSTRACT. The purpose of this statement is to recommend implementation of a mandatory influenza immunization policy for all health care personnel. Immunization of health care personnel is a critically important step to substantially reduce health care–associated influenza infections. Despite the efforts of many organizations to improve influenza immunization rates with the use of voluntary campaigns, influenza coverage among health care personnel remains unacceptably low. Mandatory influenza immunization for all health care personnel is ethically justified, necessary, and long overdue to ensure patient safety. (9/10)

RECOMMENDATIONS FOR ADMINISTERING HEPATITIS A VACCINE TO CONTACTS OF INTERNATIONAL ADOPTEES

Committee on Infectious Diseases

ABSTRACT. The Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention and the American Academy of Pediatrics (AAP) recommend routine administration of hepatitis A vaccine for household members and close contacts, including baby-sitters, when children are adopted from countries with high or intermediate rates of hepatitis A infection. This policy expands previous AAP recommendations to immunize travelers to countries who are seeking to adopt a child in countries with high or medium hepatitis A endemicity. All previously nonimmune unvaccinated people who anticipate close exposure to international adoptees during the 60 days after their arrival should receive hepatitis A immunization, ideally 2 or more weeks before the arrival of the adopted child. (9/11)

RECOMMENDATIONS FOR PREVENTION AND CONTROL OF INFLUENZA IN CHILDREN, 2013–2014

Committee on Infectious Diseases

ABSTRACT. The purpose of this statement is to update recommendations for routine use of seasonal influenza vaccine and antiviral medications for the prevention and treatment of influenza in children. Highlights for the upcoming 2013–2014 season include (1) this year's trivalent influenza vaccine contains an A/California/7/2009 (H1N1) pdm09-like virus (same as 2012–2013); an A/Texas/50/2012 (H3N2) virus (antigenically like the 2012–2013 strain); and a B/Massachusetts/2/2012-like virus (a B/Yamagata lineage like 2012–2013 but a different virus); (2) new quadrivalent influenza vaccines with an additional B virus (B/Brisbane/60/2008-like virus [B/Victoria lineage]) have been licensed by the US Food and Drug Administration; (3) annual universal influenza immunization is indicated with either a trivalent or quadrivalent vaccine (no preference); and (4) the dosing algorithm for administration of influenza vaccine to children 6 months through 8 years of age is unchanged from 2012–2013. As always, pediatricians, nurses, and all health care personnel should promote influenza vaccine use and infection control measures. In addition, pediatricians should promptly identify influenza infections to enable rapid antiviral treatment, when indicated, to reduce morbidity and mortality. (9/13)

See full text on page 899.

RECOMMENDATIONS FOR THE PREVENTION OF PERINATAL GROUP B STREPTOCOCCAL (GBS) DISEASE

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. The Centers for Disease Control and Prevention (CDC) guidelines for the prevention of perinatal group B streptococcal (GBS) disease were initially published in 1996. The American Academy of Pediatrics (AAP) also published a policy statement on this topic in 1997. In 2002, the CDC published revised guidelines that recommended universal antenatal GBS screening; the AAP endorsed these guidelines and published recommendations based on them in the 2003 *Red Book.* Since then, the incidence of early-onset GBS disease in neonates has decreased by an estimated 80%. However, in 2010, GBS disease remained the leading cause of early-onset neonatal sepsis. The CDC issued revised guidelines in 2010 based on evaluation of data generated after 2002. These revised and comprehensive guidelines, which have been endorsed by the AAP, reaffirm the major prevention strategy—universal antenatal GBS screening and intrapartum antibiotic prophylaxis for culture-positive and high-risk women—and include new recommendations for laboratory methods for identification of GBS colonization during pregnancy, algorithms for screening and intrapartum prophylaxis for women with preterm labor and premature

rupture of membranes, updated prophylaxis recommendations for women with a penicillin allergy, and a revised algorithm for the care of newborn infants. The purpose of this policy statement is to review and discuss the differences between the 2002 and 2010 CDC guidelines that are most relevant for the practice of pediatrics. (8/11)

RECOMMENDATIONS FOR THE PREVENTION OF *STREPTOCOCCUS PNEUMONIAE* INFECTIONS IN INFANTS AND CHILDREN: USE OF 13-VALENT PNEUMOCOCCAL CONJUGATE VACCINE (PCV13) AND PNEUMOCOCCAL POLYSACCHARIDE VACCINE (PPSV23)

Committee on Infectious Diseases

ABSTRACT. Routine use of the 7-valent pneumococcal conjugate vaccine (PCV7), available since 2000, has resulted in a dramatic reduction in the incidence of invasive pneumococcal disease (IPD) attributable to serotypes of Streptococcus pneumoniae contained in the vaccine. However, IPD caused by nonvaccine pneumococcal serotypes has increased, and nonvaccine serotypes are now responsible for the majority of the remaining cases of IPD occurring in children. A 13-valent pneumococcal conjugate vaccine has been licensed by the US Food and Drug Administration, which, in addition to the 7 serotypes included in the original PCV7, contains the 6 pneumococcal serotypes responsible for 63% of IPD cases now occurring in children younger than 5 years. Because of the expanded coverage provided by PCV13, it will replace PCV7. This statement provides recommendations for (1) the transition from PCV7 to PCV13; (2) the routine use of PCV13 for healthy children and children with an underlying medical condition that increases the risk of IPD; (3) a supplemental dose of PCV13 for (a) healthy children 14 through 59 months of age who have completed the PCV7 series and (b) children 14 through 71 months of age with an underlying medical condition that increases the risk of IPD who have completed the PCV7 series; (4) "catch-up" immunization for children behind schedule; and (5) PCV13 for certain children at high risk from 6 through 18 years of age. In addition, recommendations for the use of pneumococcal polysaccharide vaccine for children at high risk of IPD are also updated. (5/10)

RECOMMENDATIONS FOR PREVENTIVE PEDIATRIC HEALTH CARE

Committee on Practice and Ambulatory Medicine and Bright Futures Steering Committee

ABSTRACT. Each child and family is unique; therefore, these Recommendations for Preventive Pediatric Health Care are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in satisfactory fashion. Additional visits may become necessary if circumstances suggest variations from normal.

Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits.

These guidelines represent a consensus by the American Academy of Pediatrics (AAP) and Bright Futures. The AAP continues to emphasize the great importance of continuity of care in comprehensive health supervision and the need to avoid fragmentation of care. (12/07, reaffirmed 1/11)

RECOMMENDED CHILDHOOD AND ADOLESCENT IMMUNIZATION SCHEDULE—UNITED STATES, 2014

Committee on Infectious Diseases (1/14)

See full text on page 917.

RED REFLEX EXAMINATION IN NEONATES, INFANTS, AND CHILDREN

*Section on Ophthalmology (*joint with American Association for Pediatric Ophthalmology and Strabismus, American Academy of Ophthalmology, and American Association of Certified Orthoptists)

ABSTRACT. Red reflex testing is an essential component of the neonatal, infant, and child physical examination. This statement, which is a revision of the previous policy statement published in 2002, describes the rationale for testing, the technique used to perform this examination, and the indications for referral to an ophthalmologist experienced in the examination of children. (12/08)

REDUCING THE NUMBER OF DEATHS AND INJURIES FROM RESIDENTIAL FIRES

Committee on Injury and Poison Prevention

ABSTRACT. Smoke inhalation, severe burns, and death from residential fires are devastating events, most of which are preventable. In 1998, approximately 381 500 residential structure fires resulted in 3250 non-firefighter deaths, 17 175 injuries, and approximately $4.4 billion in property loss. This statement reviews important prevention messages and intervention strategies related to residential fires. It also includes recommendations for pediatricians regarding office anticipatory guidance, work in the community, and support of regulation and legislation that could result in a decrease in the number of fire-related injuries and deaths to children. (6/00)

REDUCING THE RISK OF HIV INFECTION ASSOCIATED WITH ILLICIT DRUG USE

Committee on Pediatric AIDS

ABSTRACT. Substance abuse, specifically the use of illicit drugs that are administered intravenously, continues to play a role in the transmission of human immunodeficiency virus type 1 (HIV-1) among adolescents and young adults (youth). Risks of HIV-1 infection may result from direct exposure to contaminated blood through sharing of injection drug equipment and from unsafe sexual practices (while under the influence of drugs and/or in exchange for drugs). Reducing the risk of HIV-1 infection that is associated with illicit drug use requires prevention education and prompt engagement in treatment. Providing patients with education, instruction on decontamination of used injection drug equipment, improved access to sterile syringes and needles, and postexposure prophylaxis may decrease their risk of acquiring HIV-1 infection. Pediatricians should assess risk behaviors as part of every health care encounter, including queries about tobacco, alcohol, and marijuana use. The risks and benefits of postexposure prophylaxis with antiretroviral drugs should be considered for youth with a single recent (within 72 hours) high-risk exposure to HIV-1 through

sharing needles/syringes with an HIV-1–infected individual or having unprotected intercourse with an individual who engages in injection drug use. Such prophylaxis must be accompanied by risk-reduction counseling, appropriate referrals for treatment, and evaluation for pregnancy and associated sexually transmitted infections. There is an urgent need for more substance-abuse prevention and treatment programs, legislation that facilitates unencumbered access to sterile syringes, and expedient availability of reproductive health care services for sexually active youth, including voluntary HIV-1 counseling and testing. (2/06, reaffirmed 5/09, 5/12)

REIMBURSEMENT FOR FOODS FOR SPECIAL DIETARY USE

Committee on Nutrition

ABSTRACT. Foods for special dietary use are recommended by physicians for chronic diseases or conditions of childhood, including inherited metabolic diseases. Although many states have created legislation requiring reimbursement for foods for special dietary use, legislation is now needed to mandate consistent coverage and reimbursement for foods for special dietary use and related support services with accepted medical benefit for children with designated medical conditions. (5/03, reaffirmed 1/06)

RELIEF OF PAIN AND ANXIETY IN PEDIATRIC PATIENTS IN EMERGENCY MEDICAL SYSTEMS (CLINICAL REPORT)

Joel A. Fein, MD, MPH; William T. Zempsky, MD, MPH; Joseph P. Cravero, MD; Committee on Pediatric Emergency Medicine; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Control of pain and stress for children is a vital component of emergency medical care. Timely administration of analgesia affects the entire emergency medical experience and can have a lasting effect on a child's and family's reaction to current and future medical care. A systematic approach to pain management and anxiolysis, including staff education and protocol development, can provide comfort to children in the emergency setting and improve staff and family satisfaction. (10/12)

RELIGIOUS OBJECTIONS TO MEDICAL CARE

Committee on Bioethics

ABSTRACT. Parents sometimes deny their children the benefits of medical care because of religious beliefs. In some jurisdictions, exemptions to child abuse and neglect laws restrict government action to protect children or seek legal redress when the alleged abuse or neglect has occurred in the name of religion. The American Academy of Pediatrics (AAP) believes that all children deserve effective medical treatment that is likely to prevent substantial harm or suffering or death. In addition, the AAP advocates that all legal interventions apply equally whenever children are endangered or harmed, without exemptions based on parental religious beliefs. To these ends, the AAP calls for the repeal of religious exemption laws and supports additional efforts to educate the public about the medical needs of children. (2/97, reaffirmed 10/00, 6/03, 10/06, 5/09)

RESPIRATORY SUPPORT IN PRETERM INFANTS AT BIRTH

Committee on Fetus and Newborn

ABSTRACT. Current practice guidelines recommend administration of surfactant at or soon after birth in preterm infants with respiratory distress syndrome. However, recent multicenter randomized controlled trials indicate that early use of continuous positive airway pressure with subsequent selective surfactant administration in extremely preterm infants results in lower rates of bronchopulmonary dysplasia/death when compared with treatment with prophylactic or early surfactant therapy. Continuous positive airway pressure started at or soon after birth with subsequent selective surfactant administration may be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants. (12/13)

See full text on page 927.

RESPONDING TO PARENTAL REFUSALS OF IMMUNIZATION OF CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH, and Committee on Bioethics

ABSTRACT. The American Academy of Pediatrics strongly endorses universal immunization. However, for childhood immunization programs to be successful, parents must comply with immunization recommendations. The problem of parental refusal of immunization for children is an important one for pediatricians. The goal of this report is to assist pediatricians in understanding the reasons parents may have for refusing to immunize their children, review the limited circumstances under which parental refusals should be referred to child protective services agencies or public health authorities, and provide practical guidance to assist the pediatrician faced with a parent who is reluctant to allow immunization of his or her child. (5/05, reaffirmed 1/09, 11/12)

RESTRAINT USE ON AIRCRAFT

Committee on Injury and Poison Prevention

ABSTRACT. Occupant protection policies for children younger than 2 years on aircraft are inconsistent with all other national policies on safe transportation. Children younger than 2 years are not required to be restrained or secured on aircraft during takeoff, landing, and conditions of turbulence. They are permitted to be held on the lap of an adult. Preventable injuries and deaths have occurred in children younger than 2 years who were unrestrained in aircraft during survivable crashes and conditions of turbulence. The American Academy of Pediatrics recommends a mandatory federal requirement for restraint use for children on aircraft. The Academy further recommends that parents ensure that a seat is available for all children during aircraft transport and follow current recommendations for restraint use for all children. Physicians play a significant role in counseling families, advocating for public policy mandates, and encouraging technologic research that will improve protection of children in aircraft. (11/01, reaffirmed 5/05, 10/08)

RETURNING TO LEARNING FOLLOWING A CONCUSSION (CLINICAL REPORT)

Mark E. Halstead, MD, FAAP; Karen McAvoy, PsyD; Cynthia D. Devore, MD, FAAP; Rebecca Carl, MD, FAAP; Michael Lee, MD, FAAP; Kelsey Logan, MD, FAAP; Council on Sports Medicine and Fitness; and Council on School Health

ABSTRACT. Following a concussion, it is common for children and adolescents to experience difficulties in the school setting. Cognitive difficulties, such as learning new tasks or remembering previously learned material, may pose challenges in the classroom. The school environment may also increase symptoms with exposure to bright lights and screens or noisy cafeterias and hallways. Unfortunately, because most children and adolescents look physically normal after a concussion, school officials often fail to recognize the need for academic or environmental adjustments. Appropriate guidance and recommendations from the pediatrician may ease the transition back to the school environment and facilitate the recovery of the child or adolescent. This report serves to provide a better understanding of possible factors that may contribute to difficulties in a school environment after a concussion and serves as a framework for the medical home, the educational home, and the family home to guide the student to a successful and safe return to learning. (10/13)

See full text on page 933.

RITUAL GENITAL CUTTING OF FEMALE MINORS

Board of Directors (6/10)

THE ROLE OF HOME-VISITATION PROGRAMS IN IMPROVING HEALTH OUTCOMES FOR CHILDREN AND FAMILIES

Council on Child and Adolescent Health

ABSTRACT. Traditional pediatric care is often based on the assumption that parents have the basic knowledge and resources to provide a nurturing, safe environment and to provide for the emotional, physical, developmental, and health care needs of their infants and young children. Unfortunately, many families have insufficient knowledge of parenting skills and an inadequate support system of friends, extended family, or professionals to help with these vital tasks. Home-visitation programs offer an effective mechanism to ensure ongoing parental education, social support, and linkage with public and private community services. This statement reviews the history and current research on home-visitation programs and provides recommendations about the pediatrician's role in supporting and using home visitation. (3/98, reaffirmed 5/01)

ROLE OF THE MEDICAL HOME IN FAMILY-CENTERED EARLY INTERVENTION SERVICES

Council on Children With Disabilities

ABSTRACT. There is growing evidence that early intervention services have a positive influence on the developmental outcome of children with established disabilities as well as those who are considered to be "at risk" of disabilities. Various federal and state laws now mandate the establishment of community-based, coordinated, multidisciplinary, family-centered programs that are accessible to children and families. The medical home, in close collaboration with the family and the early intervention team, can play a critical role in ensuring that at-risk children receive appropriate clinical and developmental early intervention services. The purpose of this statement is to assist the pediatric health care professional in assuming a proactive role with the interdisciplinary team that provides early intervention services. (11/07)

THE ROLE OF THE PEDIATRICIAN IN RURAL EMERGENCY MEDICAL SERVICES FOR CHILDREN

Committee on Pediatric Emergency Medicine

ABSTRACT. In rural America, pediatricians can play a key role in the development, implementation, and ongoing supervision of emergency medical services for children (EMSC). Pediatricians may represent the only source of pediatric expertise for a large region and are a vital resource for rural physicians (eg, general and family practice, emergency medicine) and other rural health care professionals (physician assistants, nurse practitioners, and emergency medical technicians), providing education about management and prevention of pediatric illness and injury; appropriate equipment for the acutely ill or injured child; and acute, chronic, and rehabilitative care. In addition to providing clinical expertise, the pediatrician may be involved in quality assurance, clinical protocol development, and advocacy, and may serve as a liaison between emergency medical services and other entities working with children (eg, school nurses, child care centers, athletic programs, and programs for children with special health care needs). (10/12)

ROLE OF THE PEDIATRICIAN IN YOUTH VIOLENCE PREVENTION

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Youth violence continues to be a serious threat to the health of children and adolescents in the United States. It is crucial that pediatricians clearly define their role and develop the appropriate skills to address this threat effectively. From a clinical perspective, pediatricians should become familiar with *Connected Kids: Safe, Strong, Secure,* the American Academy of Pediatrics' primary care violence prevention protocol. Using this material, practices can incorporate preventive education, screening for risk, and linkages to community-based counseling and treatment resources. As advocates, pediatricians may bring newly developed information regarding key risk factors such as exposure to firearms, teen dating violence, and bullying to the attention of local and national policy makers. This policy statement refines the developing role of pediatricians in youth violence prevention and emphasizes the importance of this issue in the strategic agenda of the American Academy of Pediatrics. (6/09)

ROLE OF PEDIATRICIANS IN ADVOCATING LIFE SUPPORT TRAINING COURSES FOR PARENTS AND THE PUBLIC

Committee on Pediatric Emergency Medicine

ABSTRACT. Available literature suggests a need for both initial cardiopulmonary resuscitation basic life support training and refresher courses for parents and the public as well as health care professionals. The promotion of basic life support training courses that establish a pediat-

ric chain of survival spanning from prevention of cardiac arrest and trauma to rehabilitative and follow-up care for victims of cardiopulmonary arrest is advocated in this policy statement and is the focus of an accompanying technical report. Immediate bystander cardiopulmonary resuscitation for victims of cardiac arrest improves survival for out-of-hospital cardiac arrest. Pediatricians will improve the chance of survival of children and adults who experience cardiac arrest by advocating for cardiopulmonary resuscitation training and participating in basic life support training courses as participants and instructors. (12/04, reaffirmed 5/07, 8/10, 8/13)

ROLE OF PEDIATRICIANS IN ADVOCATING LIFE SUPPORT TRAINING COURSES FOR PARENTS AND THE PUBLIC (TECHNICAL REPORT)

Lee A. Pyles, MD; Jane Knapp, MD; and Committee on Pediatric Emergency Medicine

ABSTRACT. Available literature suggests a need for both initial cardiopulmonary resuscitation training and refresher courses. The establishment of a pediatric chain of survival for victims of cardiopulmonary arrest is the focus of this technical report and is advocated in the accompanying policy statement. Immediate bystander cardiopulmonary resuscitation for victims of cardiac arrest improves survival for out-of-hospital cardiac arrest. Pediatricians will improve the chance of survival of children and adults who experience cardiac arrest by advocating for basic life support training and participating in basic life support courses as participants and teachers. (12/04, reaffirmed 5/07, 8/10)

THE ROLE OF PRESCHOOL HOME-VISITING PROGRAMS IN IMPROVING CHILDREN'S DEVELOPMENTAL AND HEALTH OUTCOMES

Council on Community Pediatrics

ABSTRACT. Child health and developmental outcomes depend to a large extent on the capabilities of families to provide a nurturing, safe environment for their infants and young children. Unfortunately, many families have insufficient knowledge about parenting skills and an inadequate support system of friends, extended family, or professionals to help with or advise them regarding child rearing. Home-visiting programs offer a mechanism for ensuring that at-risk families have social support, linkage with public and private community services, and ongoing health, developmental, and safety education. When these services are part of a system of high-quality well-child care linked or integrated with the pediatric medical home, they have the potential to mitigate health and developmental outcome disparities. This statement reviews the history of home visiting in the United States and reaffirms the support of the American Academy of Pediatrics for home-based parenting education and support. (1/09)

ROLE OF PULSE OXIMETRY IN EXAMINING NEWBORNS FOR CONGENITAL HEART DISEASE: A SCIENTIFIC STATEMENT FROM THE AHA AND AAP

William T. Mahle, MD; Jane W. Newburger, MD, MPH; G. Paul Matherne, MD; Frank C. Smith, MD; Tracey R. Hoke, MD; Robert Koppel, MD; Samuel S. Gidding, MD; Robert H. Beekman, III, MD; Scott D. Grosse, PhD; on behalf of American Heart Association Congenital Heart Defects Committee of the Council on Cardiovascular Disease in the Young, Council on Cardiovascular Nursing, and Interdisciplinary Council on Quality of Care and Outcomes Research; and American Academy of Pediatrics Section on Cardiology and Cardiac Surgery and Committee on Fetus and Newborn

ABSTRACT. *Background.* The purpose of this statement is to address the state of evidence on the routine use of pulse oximetry in newborns to detect critical congenital heart disease (CCHD).

Methods and Results. A writing group appointed by the American Heart Association and the American Academy of Pediatrics reviewed the available literature addressing current detection methods for CCHD, burden of missed and/or delayed diagnosis of CCHD, rationale of oximetry screening, and clinical studies of oximetry in otherwise asymptomatic newborns. MEDLINE database searches from 1966 to 2008 were done for English-language papers using the following search terms: congenital heart disease, pulse oximetry, physical examination, murmur, echocardiography, fetal echocardiography, and newborn screening. The reference lists of identified papers were also searched. Published abstracts from major pediatric scientific meetings in 2006 to 2008 were also reviewed. The American Heart Association classification of recommendations and levels of evidence for practice guidelines were used. In an analysis of pooled studies of oximetry assessment performed after 24 hours of life, the estimated sensitivity for detecting CCHD was 69.6%, and the positive predictive value was 47.0%; however, sensitivity varied dramatically among studies from 0% to 100%. False-positive screens that required further evaluation occurred in only 0.035% of infants screened after 24 hours.

Conclusions. Currently, CCHD is not detected in some newborns until after their hospital discharge, which results in significant morbidity and occasional mortality. Furthermore, routine pulse oximetry performed on asymptomatic newborns after 24 hours of life, but before hospital discharge, may detect CCHD. Routine pulse oximetry performed after 24 hours in hospitals that have on-site pediatric cardiovascular services incurs very low cost and risk of harm. Future studies in larger populations and across a broad range of newborn delivery systems are needed to determine whether this practice should become standard of care in the routine assessment of the neonate. (8/09)

ROLE OF THE SCHOOL NURSE IN PROVIDING SCHOOL HEALTH SERVICES

Council on School Health

ABSTRACT. The school nurse has a crucial role in the seamless provision of comprehensive health services to children and youth. Increasing numbers of students enter schools with chronic health conditions that require management during the school day. This policy statement describes for pediatricians the role of the school nurse in serving as a team member in providing preventive services, early identification of problems, interventions, and referrals to foster health and educational success. To optimally care for children, preparation, ongoing education, and appropriate staffing levels of school nurses are important factors for success. Recommendations are

offered to facilitate the working relationship between the school nurse and the child's medical home. This statement has been endorsed by the National Association of School Nurses. (5/08)

ROLE OF THE SCHOOL PHYSICIAN
Council on School Health
ABSTRACT. The American Academy of Pediatrics recognizes the important role physicians play in promoting the optimal biopsychosocial well-being of children in the school setting. Although the concept of a school physician has existed for more than a century, uniformity among states and school districts regarding physicians in schools and the laws governing it are lacking. By understanding the roles and contributions physicians can make to schools, pediatricians can support and promote school physicians in their communities and improve health and safety for children. (12/12)

THE ROLE OF SCHOOLS IN COMBATING ILLICIT SUBSTANCE ABUSE
Council on School Health and Committee on Substance Abuse
ABSTRACT. Disturbingly high levels of illicit drug use remain a problem among American teenagers. As the physical, social, and psychological "home away from home" for most youth, schools naturally assume a primary role in substance abuse education, prevention, and early identification. However, the use of random drug testing on students as a component of drug prevention programs requires additional, more rigorous scientific evaluation. Widespread implementation should await the result of ongoing studies to address the effectiveness of testing and evaluate possible inadvertent harm. If drug testing on students is conducted, it should never be implemented in isolation. A comprehensive assessment and therapeutic management program for the student who tests positive should be in place before any testing is performed. Schools have the opportunity to work with parents, health care professionals, and community officials to use programs with proven effectiveness, to identify students who show behavioral risks for drug-related problems, and to make referrals to a student's medical home. When use of an illicit substance is detected, schools can foster relationships with established health care experts to assist them. A student undergoing individualized intervention for using illicit substances merits privacy. This requires that awareness of the student's situation be limited to parents, the student's physician, and only those designated school health officials with a need to know. For the purposes of this statement, alcohol, tobacco, and inhalants are not addressed. (12/07)

SAFE TRANSPORTATION OF NEWBORNS AT HOSPITAL DISCHARGE
Committee on Injury and Poison Prevention
ABSTRACT. All hospitals should set policies that require the discharge of every newborn in a car safety seat that is appropriate for the infant's maturity and medical condition. Discharge policies for newborns should include a parent education component, regular review of educational materials, and periodic in-service education for responsible staff. Appropriate child restraint systems should become a benefit of coverage by Medicaid, managed care organizations, and other third-party insurers. (10/99, reaffirmed 1/03, 1/06, 10/08)

SAFE TRANSPORTATION OF PRETERM AND LOW BIRTH WEIGHT INFANTS AT HOSPITAL DISCHARGE (CLINICAL REPORT)
Marilyn J. Bull, MD; William A. Engle, MD; Committee on Injury, Violence, and Poison Prevention; and Committee on Fetus and Newborn
ABSTRACT. Safe transportation of preterm and low birth weight infants requires special considerations. Both physiologic immaturity and low birth weight must be taken into account to properly position such infants. This clinical report provides guidelines for pediatricians and other caregivers who counsel parents of preterm and low birth weight infants about car safety seats. (4/09, reaffirmed 8/13)

SAFETY IN YOUTH ICE HOCKEY: THE EFFECTS OF BODY CHECKING
Committee on Sports Medicine and Fitness
ABSTRACT. Ice hockey is a sport enjoyed by many young people. The occurrence of injury can offset what may otherwise be a positive experience. A high proportion of injuries in hockey appear to result from intentional body contact or the practice of checking. The American Academy of Pediatrics recommends limiting checking in hockey players 15 years of age and younger as a means to reduce injuries. Strategies such as the fair play concept can also help decrease injuries that result from penalties or unnecessary contact. (3/00, reaffirmed 1/06, 5/09)

SCHOOL BUS TRANSPORTATION OF CHILDREN WITH SPECIAL HEALTH CARE NEEDS
Committee on Injury and Poison Prevention (8/01, reaffirmed 1/05, 2/08)

SCHOOL HEALTH ASSESSMENTS
Committee on School Health
ABSTRACT. Comprehensive health assessments often are performed in school-based clinics or public health clinics by health professionals other than pediatricians. Pediatricians or other physicians skilled in child health care should participate in such evaluations. This statement provides guidance on the scope of in-school health assessments and the roles of the pediatrician, school nurse, school, and community. (4/00, reaffirmed 6/03, 5/06, 10/11)

SCHOOL HEALTH CENTERS AND OTHER INTEGRATED SCHOOL HEALTH SERVICES
Committee on School Health
ABSTRACT. This statement offers guidelines on the integration of expanded school health services, including school-based and school-linked health centers, into community-based health care systems. Expanded school health services should be integrated so that they enhance accessibility, provide high-quality health care, link children to a medical home, are financially sustainable, and address both long- and short-term needs of children and adolescents. (1/01)

SCHOOL READINESS (TECHNICAL REPORT)

Pamela C. High, MD; Committee on Early Childhood, Adoption, and Dependent Care; and Council on School Health

ABSTRACT. School readiness includes the readiness of the individual child, the school's readiness for children, and the ability of the family and community to support optimal early child development. It is the responsibility of schools to be ready for all children at all levels of readiness. Children's readiness for kindergarten should become an outcome measure for community-based programs, rather than an exclusion criterion at the beginning of the formal educational experience. Our new knowledge of early brain and child development has revealed that modifiable factors in a child's early experience can greatly affect that child's learning trajectory. Many US children enter kindergarten with limitations in their social, emotional, cognitive, and physical development that might have been significantly diminished or eliminated through early identification of and attention to child and family needs. Pediatricians have a role in promoting school readiness for all children, beginning at birth, through their practices and advocacy. The American Academy of Pediatrics affords pediatricians many opportunities to promote the physical, social-emotional, and educational health of young children, with other advocacy groups. This technical report supports American Academy of Pediatrics policy statements "Quality Early Education and Child Care From Birth to Kindergarten" and "The Inappropriate Use of School 'Readiness' Tests." (4/08, reaffirmed 9/13)

SCHOOL TRANSPORTATION SAFETY

Committee on Injury, Violence, and Poison Prevention and Council on School Health

ABSTRACT. This policy statement replaces the previous version published in 1996. It provides new information, studies, regulations, and recommendations related to the safe transportation of children to and from school and school-related activities. Pediatricians can play an important role at the patient/family, community, state, and national levels as child advocates and consultants to schools and early education programs about transportation safety. (7/07, reaffirmed 10/11)

SCHOOL-BASED HEALTH CENTERS AND PEDIATRIC PRACTICE

Council on School Health

ABSTRACT. School-based health centers (SBHCs) have become an important method of health care delivery for the youth of our nation. Although they only represent 1 aspect of a coordinated school health program approach, SBHCs have provided access to health care services for youth confronted with age, financial, cultural, and geographic barriers. A fundamental principle of SBHCs is to create an environment of service coordination and collaboration that addresses the health needs and well-being of youth with health disparities or poor access to health care services. Some pediatricians have concerns that these centers are in conflict with the primary care provider's medical home. This policy provides an overview of SBHCs and some of their documented benefits, addresses the issue of potential conflict with the medical home, and provides recommendations that support the integration and coordination of SBHCs and the pediatric medical home practice. (1/12)

SCHOOL-BASED MENTAL HEALTH SERVICES

Committee on School Health

ABSTRACT. More than 20% of children and adolescents have mental health problems. Health care professionals for children and adolescents must educate key stakeholders about the extent of these problems and work together with them to increase access to mental health resources. School-based programs offer the promise of improving access to diagnosis of and treatment for the mental health problems of children and adolescents. Pediatric health care professionals, educators, and mental health specialists should work in collaboration to develop and implement effective school-based mental health services. (6/04, reaffirmed 5/09)

SCOPE OF HEALTH CARE BENEFITS FOR CHILDREN FROM BIRTH THROUGH AGE 26

Committee on Child Health Financing

ABSTRACT. The optimal health of all children is best achieved with access to appropriate and comprehensive health care benefits. This policy statement outlines and defines the recommended set of health insurance benefits for children through age 26. The American Academy of Pediatrics developed a set of recommendations concerning preventive care services for children, adolescents, and young adults. These recommendations are compiled in the publication *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* third edition. The Bright Futures recommendations were referenced as a standard for access and design of age-appropriate health insurance benefits for infants, children, adolescents, and young adults in the Patient Protection and Affordable Care Act of 2010 (Pub L No. 114–148). (11/11)

SCOPE OF PRACTICE ISSUES IN THE DELIVERY OF PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics (AAP) believes that optimal pediatric health care depends on a team-based approach with supervision by a physician leader, preferably a pediatrician. The pediatrician, here defined to include not only pediatric generalists but all pediatric medical subspecialists, all surgical specialists, and internal medicine/pediatric physicians, is uniquely qualified to manage, coordinate, and supervise the entire spectrum of pediatric care, from diagnosis through all stages of treatment, in all practice settings. The AAP recognizes the valuable contributions of nonphysician clinicians, including nurse practitioners and physician assistants, in delivering optimal pediatric care. However, the expansion of the scope of practice of nonphysician pediatric clinicians raises critical public policy and child health advocacy concerns. Pediatricians should serve as advocates for optimal pediatric care in state legislatures, public policy forums, and the media and should pursue opportunities to resolve scope of practice conflicts outside state legislatures. The AAP affirms the importance

of appropriate documentation and standards in pediatric education, training, skills, clinical competencies, examination, regulation, and patient care to ensure safety and quality health care for all infants, children, adolescents, and young adults. (5/13)

See full text on page 945.

SCREENING EXAMINATION OF PREMATURE INFANTS FOR RETINOPATHY OF PREMATURITY

Section on Ophthalmology (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. This statement revises a previous statement on screening of preterm infants for retinopathy of prematurity (ROP) that was published in 2006. ROP is a pathologic process that occurs only in immature retinal tissue and can progress to a tractional retinal detachment, which can result in functional or complete blindness. Use of peripheral retinal ablative therapy by using laser photocoagulation for nearly 2 decades has resulted in a high probability of markedly decreasing the incidence of this poor visual outcome, but the sequential nature of ROP creates a requirement that at-risk preterm infants be examined at proper times and intervals to detect the changes of ROP before they become permanently destructive. This statement presents the attributes on which an effective program for detecting and treating ROP could be based, including the timing of initial examination and subsequent reexamination intervals. (12/12)

SCREENING FOR RETINOPATHY IN THE PEDIATRIC PATIENT WITH TYPE 1 DIABETES MELLITUS (CLINICAL REPORT)

Gregg T. Lueder, MD; Janet Silverstein, MD; Section on Ophthalmology; and Section on Endocrinology (joint with American Association for Pediatric Ophthalmology and Strabismus)

ABSTRACT. Diabetic retinopathy (DR) is the leading cause of blindness in young adults in the United States. Early identification and treatment of DR can decrease the risk of vision loss in affected patients. This clinical report reviews the risk factors for the development of DR and screening guidance for pediatric patients with type 1 diabetes mellitus. (7/05, reaffirmed 1/09)

SECONDHAND AND PRENATAL TOBACCO SMOKE EXPOSURE (TECHNICAL REPORT)

Dana Best, MD, MPH; Committee on Environmental Health; Committee on Native American Child Health; and Committee on Adolescence

ABSTRACT. Secondhand tobacco smoke (SHS) exposure of children and their families causes significant morbidity and mortality. In their personal and professional roles, pediatricians have many opportunities to advocate for elimination of SHS exposure of children, to counsel tobacco users to quit, and to counsel children never to start. This report discusses the harms of tobacco use and SHS exposure, the extent and costs of tobacco use and SHS exposure, and the evidence that supports counseling and other clinical interventions in the cycle of tobacco use. Recommendations for future research, policy, and clinical practice change are discussed. To improve understanding and provide support for these activities, the harms of SHS exposure are discussed, effective ways to eliminate or reduce SHS exposure are presented, and policies that support a smoke-free environment are outlined. (10/09)

SELECTING APPROPRIATE TOYS FOR YOUNG CHILDREN: THE PEDIATRICIAN'S ROLE (CLINICAL REPORT)

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Play is essential for learning in children. Toys are the tools of play. Which play materials are provided and how they are used are equally important. Adults caring for children can be reminded that toys facilitate but do not substitute for the most important aspect of nurture—warm, loving, dependable relationships. Toys should be safe, affordable, and developmentally appropriate. Children do not need expensive toys. Toys should be appealing to engage the child over a period of time. Information and resources are provided in this report so pediatricians can give parents advice about selecting toys. (4/03, reaffirmed 10/06, 5/11)

SELF-INJECTABLE EPINEPHRINE FOR FIRST-AID MANAGEMENT OF ANAPHYLAXIS (CLINICAL REPORT)

Scott H. Sicherer, MD; F. Estelle R. Simons, MD; and Section on Allergy and Immunology

ABSTRACT. Anaphylaxis is a severe, potentially fatal systemic allergic reaction that is rapid in onset and may cause death. Epinephrine is the primary medical therapy, and it must be administered promptly. This clinical report focuses on practical issues concerning the administration of self-injectable epinephrine for first-aid treatment of anaphylaxis in the community. The recommended epinephrine dose for anaphylaxis in children, based primarily on anecdotal evidence, is 0.01 mg/kg, up to 0.30 mg. Intramuscular injection of epinephrine into the lateral thigh (vastus lateralis) is the preferred route for therapy in first-aid treatment. Epinephrine autoinjectors are currently available in only 2 fixed doses: 0.15 and 0.30 mg. On the basis of current, albeit limited, data, it seems reasonable to recommend autoinjectors with 0.15 mg of epinephrine for otherwise healthy young children who weigh 10 to 25 kg (22–55 lb) and autoinjectors with 0.30 mg of epinephrine for those who weigh approximately 25 kg (55 lb) or more; however, specific clinical circumstances must be considered in these decisions. This report also describes several quandaries in regard to management, including the selection of dose, indications for prescribing an autoinjector, and decisions regarding when to inject epinephrine. Effective care for individuals at risk of anaphylaxis requires a comprehensive management approach involving families, allergic children, schools, camps, and other youth organizations. Risk reduction entails confirmation of the trigger, discussion of avoidance of the relevant allergen, a written individualized emergency anaphylaxis action plan, and education of supervising adults with regard to recognition and treatment of anaphylaxis. (3/07)

SENSORY INTEGRATION THERAPIES FOR CHILDREN WITH DEVELOPMENTAL AND BEHAVIORAL DISORDERS

Section on Complementary and Integrative Medicine and Council on Children With Disabilities

ABSTRACT. Sensory-based therapies are increasingly used by occupational therapists and sometimes by other types of therapists in treatment of children with developmental and behavioral disorders. Sensory-based therapies involve activities that are believed to organize the sensory system by providing vestibular, proprioceptive, auditory, and tactile inputs. Brushes, swings, balls, and other specially designed therapeutic or recreational equipment are used to provide these inputs. However, it is unclear whether children who present with sensory-based problems have an actual "disorder" of the sensory pathways of the brain or whether these deficits are characteristics associated with other developmental and behavioral disorders. Because there is no universally accepted framework for diagnosis, sensory processing disorder generally should not be diagnosed. Other developmental and behavioral disorders must always be considered, and a thorough evaluation should be completed. Difficulty tolerating or processing sensory information is a characteristic that may be seen in many developmental behavioral disorders, including autism spectrum disorders, attention-deficit/hyperactivity disorder, developmental coordination disorders, and childhood anxiety disorders.

Occupational therapy with the use of sensory-based therapies may be acceptable as one of the components of a comprehensive treatment plan. However, parents should be informed that the amount of research regarding the effectiveness of sensory integration therapy is limited and inconclusive. Important roles for pediatricians and other clinicians may include discussing these limitations with parents, talking with families about a trial period of sensory integration therapy, and teaching families how to evaluate the effectiveness of a therapy. (5/12)

SEXUAL ORIENTATION AND ADOLESCENTS (CLINICAL REPORT)

Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its first statement on homosexuality and adolescents in 1983, with a revision in 1993. This report reflects the growing understanding of youth of differing sexual orientations. Young people are recognizing their sexual orientation earlier than in the past, making this a topic of importance to pediatricians. Pediatricians should be aware that some youths in their care may have concerns about their sexual orientation or that of siblings, friends, parents, relatives, or others. Health care professionals should provide factual, current, nonjudgmental information in a confidential manner. All youths, including those who know or wonder whether they are not heterosexual, may seek information from physicians about sexual orientation, sexually transmitted diseases, substance abuse, or various psychosocial difficulties. The pediatrician should be attentive to various potential psychosocial difficulties, offer counseling or refer for counseling when necessary and ensure that every sexually active youth receives a thorough medical history, physical examination, immunizations, appropriate laboratory tests, and counseling about sexually transmitted diseases (including human immunodeficiency virus infection) and appropriate treatment if necessary.

Not all pediatricians may feel able to provide the type of care described in this report. Any pediatrician who is unable to care for and counsel nonheterosexual youth should refer these patients to an appropriate colleague. (6/04)

SEXUALITY OF CHILDREN AND ADOLESCENTS WITH DEVELOPMENTAL DISABILITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Ellen Roy Elias, MD; for Council on Children With Disabilities

ABSTRACT. Children and adolescents with developmental disabilities, like all children, are sexual persons. However, attention to their complex medical and functional issues often consumes time that might otherwise be invested in addressing the anatomic, physiologic, emotional, and social aspects of their developing sexuality. This report discusses issues of puberty, contraception, psychosexual development, sexual abuse, and sexuality education specific to children and adolescents with disabilities and their families. Pediatricians, in the context of the medical home, are encouraged to discuss issues of sexuality on a regular basis, ensure the privacy of each child and adolescent, promote self-care and social independence among persons with disabilities, advocate for appropriate sexuality education, and provide ongoing education for children and adolescents with developmental disabilities and their families. (7/06, reaffirmed 12/09, 7/13)

SEXUALITY, CONTRACEPTION, AND THE MEDIA

Victor C. Strasburger, MD, and Council on Communications and Media

ABSTRACT. From a health viewpoint, early sexual activity among US adolescents is a potential problem because of the risk of pregnancy and sexually transmitted infections. New evidence points to the media adolescents use frequently (television, music, movies, magazines, and the Internet) as important factors in the initiation of sexual intercourse. There is a major disconnect between what mainstream media portray—casual sex and sexuality with no consequences—and what children and teenagers need—straightforward information about human sexuality and the need for contraception when having sex. Television, film, music, and the Internet are all becoming increasingly sexually explicit, yet information on abstinence, sexual responsibility, and birth control remains rare. It is unwise to promote "abstinence-only" sex education when it has been shown to be ineffective and when the media have become such an important source of information about "nonabstinence." Recommendations are presented to help pediatricians address this important issue. (8/10)

SEXUALITY EDUCATION FOR CHILDREN AND ADOLESCENTS

Committee on Psychosocial Aspects of Child and Family Health and Committee on Adolescence

ABSTRACT. Children and adolescents need accurate and comprehensive education about sexuality to practice healthy sexual behavior as adults. Early, exploitative, or risky sexual activity may lead to health and social problems, such as unintended pregnancy and sexually transmitted diseases, including human immunodeficiency virus infection and acquired immunodeficiency syndrome. This statement reviews the role of the pediatrician in providing sexuality education to children, adolescents, and their families. Pediatricians should integrate sexuality education into the confidential and longitudinal relationship they develop with children, adolescents, and families to complement the education children obtain at school and at home. Pediatricians must be aware of their own attitudes, beliefs, and values so their effectiveness in discussing sexuality in the clinical setting is not limited. (8/01, reaffirmed 10/04)

SHOPPING CART–RELATED INJURIES TO CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Shopping cart–related injuries to children are common and can result in severe injury or even death. Most injuries result from falls from carts or cart tip-overs, and injuries to the head and neck represent three fourths of cases. The current US standard for shopping carts should be revised to include clear and effective performance criteria to prevent falls from carts and cart tipovers. Pediatricians have an important role as educators, researchers, and advocates to promote the prevention of these injuries. (8/06, reaffirmed 4/09, 8/13)

SHOPPING CART–RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Gary A. Smith, MD, DrPH, for Committee on Injury, Violence, and Poison Prevention

ABSTRACT. An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries. Approximately 4% of shopping cart–related injuries to children younger than 15 years require admission to the hospital. Injuries to the head and neck represent three fourths of all injuries. Fractures account for 45% of all hospitalizations. Deaths have occurred from falls from shopping carts and cart tip-overs. Falls are the most common mechanism of injury and account for more than half of injuries associated with shopping carts. Cart tip-overs are the second most common mechanism, responsible for up to one fourth of injuries and almost 40% of shopping cart–related injuries among children younger than 2 years. Public-awareness initiatives, education programs, and parental supervision, although important, are not enough to prevent these injuries effectively. European Standard EN 1929-1:1998 and joint Australian/New Zealand Standard AS/NZS 3847.1:1999 specify requirements for the construction, performance, testing, and safety of shopping carts and have been implemented as national standards in 21 countries. A US performance standard for shopping carts (ASTM [American Society for Testing and Materials] F2372-04) was established in July 2004; however, it does not adequately address falls and cart tip-overs, which are the leading mechanisms of shopping cart–related injuries to children. The current US standard for shopping carts should be revised to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs. This is imperative to decrease the number and severity of shopping cart–related injuries to children. Recommendations from the American Academy of Pediatrics regarding prevention of shopping cart–related injuries are included in the accompanying policy statement. (8/06, reaffirmed 4/09, 8/13)

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EXPANSION OF RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT

Task Force on Sudden Infant Death Syndrome

ABSTRACT. Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death that occur during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from focusing only on SIDS to focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths, including SIDS. The recommendations described in this policy statement include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunizations, consideration of using a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in the accompanying "Technical Report—SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment." (10/11)

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EXPANSION OF RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT (TECHNICAL REPORT)

Task Force on Sudden Infant Death Syndrome

ABSTRACT. Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death occurring during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last

statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from being only SIDS-focused to focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths including SIDS. The recommendations described in this report include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunization, consideration of a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in this technical report. The recommendations are published in the accompanying "Policy Statement—Sudden Infant Death Syndrome and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment." (10/11)

SKATEBOARD AND SCOOTER INJURIES

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Skateboard-related injuries account for an estimated 50 000 emergency department visits and 1500 hospitalizations among children and adolescents in the United States each year. Nonpowered scooter-related injuries accounted for an estimated 9400 emergency department visits between January and August 2000, and 90% of these patients were children younger than 15 years. Many such injuries can be avoided if children and youth do not ride in traffic, if proper protective gear is worn, and if, in the absence of close adult supervision, skateboards and scooters are not used by children younger than 10 and 8 years, respectively. (3/02, reaffirmed 5/05, 10/08)

SNOWMOBILING HAZARDS

Committee on Injury and Poison Prevention

ABSTRACT. Snowmobiles continue to pose a significant risk to children younger than 15 years and adolescents and young adults 15 through 24 years of age. Head injuries remain the leading cause of mortality and serious morbidity, arising largely from snowmobilers colliding, falling, or overturning during operation. Children also were injured while being towed in a variety of conveyances by snowmobiles. No uniform code of state laws governs the use of snowmobiles by children and youth. Because evidence is lacking to support the effectiveness of operator safety certification and because many children and adolescents do not have the required strength and skills to operate a snowmobile safely, the recreational operation of snowmobiles by persons younger than 16 years is not recommended. Snowmobiles should not be used to tow persons on a tube, tire, sled, or saucer. Furthermore, a graduated licensing program is advised for snowmobilers 16 years and older. Both active and passive snowmobile injury prevention strategies are suggested, as well as recommendations for manufacturers to make safer equipment for snowmobilers of all ages. (11/00, reaffirmed 5/04, 1/07, 6/10)

SOFT DRINKS IN SCHOOLS

Committee on School Health

ABSTRACT. This statement is intended to inform pediatricians and other health care professionals, parents, superintendents, and school board members about nutritional concerns regarding soft drink consumption in schools. Potential health problems associated with high intake of sweetened drinks are 1) overweight or obesity attributable to additional calories in the diet; 2) displacement of milk consumption, resulting in calcium deficiency with an attendant risk of osteoporosis and fractures; and 3) dental caries and potential enamel erosion. Contracts with school districts for exclusive soft drink rights encourage consumption directly and indirectly. School officials and parents need to become well informed about the health implications of vended drinks in school before making a decision about student access to them. A clearly defined, district-wide policy that restricts the sale of soft drinks will safeguard against health problems as a result of overconsumption. (1/04, reaffirmed 1/09)

SPECIAL REQUIREMENTS OF ELECTRONIC HEALTH RECORD SYSTEMS IN PEDIATRICS (CLINICAL REPORT)

S. Andrew Spooner, MD, MS, and Council on Clinical Information Technology

ABSTRACT. Some functions of an electronic health record system are much more important in providing pediatric care than in adult care. Pediatricians commonly complain about the absence of these "pediatric functions" when they are not available in electronic health record systems. To stimulate electronic health record system vendors to recognize and incorporate pediatric functionality into pediatric electronic health record systems, this clinical report reviews the major functions of importance to child health care providers. Also reviewed are important but less critical functions, any of which might be of major importance in a particular clinical context. The major areas described here are immunization management, growth tracking, medication dosing, data norms, and privacy in special pediatric populations. The American Academy of Pediatrics believes that if the functions described in this document are supported in all electronic health record systems, these systems will be more useful for patients of all ages. (3/07, reaffirmed 5/12)

SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS

Committee on Environmental Health

ABSTRACT. Molds are eukaryotic (possessing a true nucleus) nonphotosynthetic organisms that flourish both indoors and outdoors. For humans, the link between mold exposure and asthma exacerbations, allergic rhinitis, infections, and toxicities from ingestion of mycotoxin-contaminated foods are well known. However, the cause-and-effect relationship between inhalational exposure to mold and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) requires additional investigation. Pediatricians play an important role in the education of families about mold, its adverse health effects, exposure prevention, and remediation procedures. (12/06, reaffirmed 1/11)

SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS (TECHNICAL REPORT)

Lynnette J. Mazur, MD, MPH; Janice Kim, MD, PhD, MPH; and Committee on Environmental Health

ABSTRACT. Molds are multicellular fungi that are ubiquitous in outdoor and indoor environments. For humans, they are both beneficial (for the production of antimicrobial agents, chemotherapeutic agents, and vitamins) and detrimental. Exposure to mold can occur through inhalation, ingestion, and touching moldy surfaces. Adverse health effects may occur through allergic, infectious, irritant, or toxic processes. The cause-and-effect relationship between mold exposure and allergic and infectious illnesses is well known. Exposures to toxins via the gastrointestinal tract also are well described. However, the cause-and-effect relationship between inhalational exposure to mold toxins and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) is controversial and requires additional investigation. In this report we examine evidence of fungal-related illnesses and the unique aspects of mold exposure to children. Mold-remediation procedures are also discussed. (12/06, reaffirmed 1/11)

SPORT-RELATED CONCUSSION IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Mark E. Halstead, MD; Kevin D. Walter, MD; and Council on Sports Medicine and Fitness

ABSTRACT. Sport-related concussion is a "hot topic" in the media and in medicine. It is a common injury that is likely underreported by pediatric and adolescent athletes. Football has the highest incidence of concussion, but girls have higher concussion rates than boys do in similar sports. A clear understanding of the definition, signs, and symptoms of concussion is necessary to recognize it and rule out more severe intracranial injury. Concussion can cause symptoms that interfere with school, social and family relationships, and participation in sports. Recognition and education are paramount, because although proper equipment, sport technique, and adherence to rules of the sport may decrease the incidence or severity of concussions, nothing has been shown to prevent them. Appropriate management is essential for reducing the risk of long-term symptoms and complications. Cognitive and physical rest is the mainstay of management after diagnosis, and neuropsychological testing is a helpful tool in the management of concussion. Return to sport should be accomplished by using a progressive exercise program while evaluating for any return of signs or symptoms. This report serves as a basis for understanding the diagnosis and management of concussion in children and adolescent athletes. (8/10)

SPORTS DRINKS AND ENERGY DRINKS FOR CHILDREN AND ADOLESCENTS: ARE THEY APPROPRIATE? (CLINICAL REPORT)

Committee on Nutrition and Council on Sports Medicine and Fitness

ABSTRACT. Sports and energy drinks are being marketed to children and adolescents for a wide variety of inappropriate uses. Sports drinks and energy drinks are significantly different products, and the terms should not be used interchangeably. The primary objectives of this clinical report are to define the ingredients of sports and energy drinks, categorize the similarities and differences between the products, and discuss misuses and abuses. Secondary objectives are to encourage screening during annual physical examinations for sports and energy drink use, to understand the reasons why youth consumption is widespread, and to improve education aimed at decreasing or eliminating the inappropriate use of these beverages by children and adolescents. Rigorous review and analysis of the literature reveal that caffeine and other stimulant substances contained in energy drinks have no place in the diet of children and adolescents. Furthermore, frequent or excessive intake of caloric sports drinks can substantially increase the risk for overweight or obesity in children and adolescents. Discussion regarding the appropriate use of sports drinks in the youth athlete who participates regularly in endurance or high-intensity sports and vigorous physical activity is beyond the scope of this report. (5/11)

STANDARD TERMINOLOGY FOR FETAL, INFANT, AND PERINATAL DEATHS (CLINICAL REPORT)

CAPT Wanda Denise Barfield, MD, MPH, and Committee on Fetus and Newborn

ABSTRACT. Accurately defining and reporting perinatal deaths (ie, fetal and infant deaths) is a critical first step in understanding the magnitude and causes of these important events. In addition to obstetric health care providers, neonatologists and pediatricians should know the current US definitions and reporting requirements for live births, fetal deaths, and infant deaths. Correct identification of these vital events will improve our local, state, and national data so that these deaths can be better addressed and reduced. (6/11)

STANDARDS FOR HEALTH INFORMATION TECHNOLOGY TO ENSURE ADOLESCENT PRIVACY

Committee on Adolescence and Council on Clinical Information Technology

ABSTRACT. Privacy and security of health information is a basic expectation of patients. Despite the existence of federal and state laws safeguarding the privacy of health information, health information systems currently lack the capability to allow for protection of this information for minors. This policy statement reviews the challenges to privacy for adolescents posed by commercial health information technology systems and recommends basic principles for ideal electronic health record systems. This policy statement has been endorsed by the Society for Adolescent Health and Medicine. (10/12)

STATE CHILDREN'S HEALTH INSURANCE PROGRAM ACHIEVEMENTS, CHALLENGES, AND POLICY RECOMMENDATIONS

Committee on Child Health Financing

ABSTRACT. This policy statement reviews the impressive progress of the State Children's Health Insurance Program since its enactment in 1997 and identifies outstanding challenges and state and federal policy recommendations. The American Academy of Pediatrics urges Congress to reauthorize SCHIP to strengthen its historic gains. The following set of recommended strategies for reauthorization

pertain to funding, eligibility and enrollment, coverage, cost sharing, payment and provider-network capacity, and quality performance. (6/07)

STRATEGIES FOR PREVENTION OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (CLINICAL REPORT)

Richard A. Polin, MD; Susan Denson, MD; Michael T. Brady, MD; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU result in increased morbidity and mortality, prolonged lengths of stay, and increased medical costs. Neonates are at high risk of acquiring health care–associated infections because of impaired host-defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of their skin, use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotic agents. This clinical report reviews management and prevention of health care–associated infections in newborn infants. (3/12)

STRENGTH TRAINING BY CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness

ABSTRACT. Pediatricians are often asked to give advice on the safety and efficacy of strength-training programs for children and adolescents. This statement, which is a revision of a previous American Academy of Pediatrics policy statement, defines relevant terminology and provides current information on risks and benefits of strength training for children and adolescents. (4/08, reaffirmed 6/11)

SUBSTANCE USE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT FOR PEDIATRICIANS

Committee on Substance Abuse

ABSTRACT. As a component of comprehensive pediatric care, adolescents should receive appropriate guidance regarding substance use during routine clinical care. This statement addresses practitioner challenges posed by the spectrum of pediatric substance use and presents an algorithm-based approach to augment the pediatrician's confidence and abilities related to substance use screening, brief intervention, and referral to treatment in the primary care setting. Adolescents with addictions should be managed collaboratively (or comanaged) with child and adolescent mental health or addiction specialists. This statement reviews recommended referral guidelines that are based on established patient-treatment–matching criteria and the risk level for substance abuse. (10/11)

SUICIDE AND SUICIDE ATTEMPTS IN ADOLESCENTS (CLINICAL REPORT)

Benjamin N. Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Suicide is the third-leading cause of death for adolescents 15 to 19 years old. Pediatricians can take steps to help reduce the incidence of adolescent suicide by screening for depression and suicidal ideation and behavior. This report updates the previous statement of the American Academy of Pediatrics and is intended to assist the pediatrician in the identification and management of the adolescent at risk of suicide. The extent to which pediatricians provide appropriate care for suicidal adolescents depends on their knowledge, skill, comfort with the topic, and ready access to appropriate community resources. All teenagers with suicidal thoughts or behaviors should know that their pleas for assistance are heard and that pediatricians are willing to serve as advocates to help resolve the crisis. (9/07)

SUPPLEMENTAL SECURITY INCOME (SSI) FOR CHILDREN AND YOUTH WITH DISABILITIES

Council on Children With Disabilities

ABSTRACT. The Supplemental Security Income (SSI) program remains an important source of financial support for low-income families of children with special health care needs and disabling conditions. In most states, SSI eligibility also qualifies children for the state Medicaid program, providing access to health care services. The Social Security Administration (SSA), which administers the SSI program, considers a child disabled under SSI if there is a medically determinable physical or mental impairment or combination of impairments that results in marked and severe functional limitations. The impairment(s) must be expected to result in death or have lasted or be expected to last for a continuous period of at least 12 months. The income and assets of families of children with disabilities are also considered when determining financial eligibility. When an individual with a disability becomes an adult at 18 years of age, the SSA considers only the individual's income and assets. The SSA considers an adult to be disabled if there is a medically determinable impairment (or combination of impairments) that prevents substantial gainful activity for at least 12 continuous months. SSI benefits are important for youth with chronic conditions who are transitioning to adulthood. The purpose of this statement is to provide updated information about the SSI medical and financial eligibility criteria and the disability-determination process. This statement also discusses how pediatricians can help children and youth when they apply for SSI benefits. (11/09)

SUPPORTING THE FAMILY AFTER THE DEATH OF A CHILD (CLINICAL REPORT)

Esther Wender, MD, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. The death of a child can have a devastating effect on the family. The pediatrician has an important role to play in supporting the parents and any siblings still in his or her practice after such a death. Pediatricians may be poorly prepared to provide this support. Also, because of the pain of confronting the grief of family members, they may be reluctant to become involved. This statement gives guidelines to help the pediatrician provide such support. It describes the grief reactions that can be expected in family members after the death of a child. Ways of supporting family members are suggested, and other helpful resources in the community are described. The goal of this guidance is to prevent outcomes that may impair the health and development of affected parents and children. (11/12)

SUPPORTING THE HEALTH CARE TRANSITION FROM ADOLESCENCE TO ADULTHOOD IN THE MEDICAL HOME (CLINICAL REPORT)

American Academy of Pediatrics, American Academy of Family Physicians, and American College of Physicians Transitions Clinical Report Authoring Group

ABSTRACT. Optimal health care is achieved when each person, at every age, receives medically and developmentally appropriate care. The goal of a planned health care transition is to maximize lifelong functioning and well-being for all youth, including those who have special health care needs and those who do not. This process includes ensuring that high-quality, developmentally appropriate health care services are available in an uninterrupted manner as the person moves from adolescence to adulthood. A well-timed transition from child- to adult-oriented health care is specific to each person and ideally occurs between the ages of 18 and 21 years. Coordination of patient, family, and provider responsibilities enables youth to optimize their ability to assume adult roles and activities. This clinical report represents expert opinion and consensus on the practice-based implementation of transition for all youth beginning in early adolescence. It provides a structure for training and continuing education to further understanding of the nature of adolescent transition and how best to support it. Primary care physicians, nurse practitioners, and physician assistants, as well as medical subspecialists, are encouraged to adopt these materials and make this process specific to their settings and populations. (7/11)

SURFACTANT REPLACEMENT THERAPY FOR PRETERM AND TERM NEONATES WITH RESPIRATORY DISTRESS (CLINICAL REPORT)

Richard A. Polin, MD, FAAP; Waldemar A. Carlo, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Respiratory failure secondary to surfactant deficiency is a major cause of morbidity and mortality in preterm infants. Surfactant therapy substantially reduces mortality and respiratory morbidity for this population. Secondary surfactant deficiency also contributes to acute respiratory morbidity in late-preterm and term neonates with meconium aspiration syndrome, pneumonia/sepsis, and perhaps pulmonary hemorrhage; surfactant replacement may be beneficial for these infants. This statement summarizes the evidence regarding indications, administration, formulations, and outcomes for surfactant-replacement therapy. The clinical strategy of intubation, surfactant administration, and extubation to continuous positive airway pressure and the effect of continuous positive airway pressure on outcomes and surfactant use in preterm infants are also reviewed. (12/13)

See full text on page 953.

SURVEILLANCE OF PEDIATRIC HIV INFECTION

Committee on Pediatric AIDS

ABSTRACT. Pediatric human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS) surveillance should expand to include perinatal HIV exposure and HIV infection as well as AIDS to delineate completely the extent and impact of HIV infection on children and families, accurately assess the resources necessary to provide services to this population, evaluate the efficacy of public health recommendations, and determine any potential long-term consequences of interventions to prevent perinatal transmission to children ultimately determined to be uninfected as well as for those who become infected. Ensuring the confidentiality of information collected in the process of surveillance is critical. In addition, expansion of surveillance must not compromise the established, ongoing surveillance system for pediatric AIDS. An expanded pediatric HIV surveillance program provides an important counterpart to existing American Academy of Pediatrics and American College of Obstetricians and Gynecologists recommendations for HIV counseling and testing in the prenatal setting. (2/98, reaffirmed 2/02, 1/06, 1/11)

SWIMMING PROGRAMS FOR INFANTS AND TODDLERS

Committee on Sports Medicine and Fitness and Committee on Injury and Poison Prevention

ABSTRACT. Infant and toddler aquatic programs provide an opportunity to introduce young children to the joy and risks of being in or around water. Generally, children are not developmentally ready for swimming lessons until after their fourth birthday. Aquatic programs for infants and toddlers have not been shown to decrease the risk of drowning, and parents should not feel secure that their child is safe in water or safe from drowning after participating in such programs. Young children should receive constant, close supervision by an adult while in and around water. (4/00, reaffirmed 5/04)

THE TEEN DRIVER

Committee on Injury, Violence, and Poison Prevention and Committee on Adolescence

ABSTRACT. Motor vehicle–related injuries to adolescents continue to be of paramount importance to society. Since the original policy statement on the teenaged driver was published in 1996, there have been substantial changes in many state laws and much new research on this topic. There is a need to provide pediatricians with up-to-date information and materials to facilitate appropriate counseling and anticipatory guidance. This statement describes why teenagers are at greater risk of motor vehicle–related injuries, suggests topics suitable for office-based counseling, describes innovative programs, and proposes preventive interventions for pediatricians, parents, legislators, educators, and other child advocates. (12/06, reaffirmed 6/10)

TESTING FOR DRUGS OF ABUSE IN CHILDREN AND ADOLESCENTS

Committee on Substance Abuse

ABSTRACT. The American Academy of Pediatrics (AAP) recognizes the abuse of psychoactive drugs as one of the greatest problems facing children and adolescents and condemns all such use. Diagnostic testing for drugs of abuse is frequently an integral part of the pediatrician's evaluation and management of those suspected of such use. "Voluntary screening" is the term applied to many mass non–suspicion-based screening programs, yet such programs may not be truly voluntary as there are often negative consequences for those who choose not to take

part. Participation in such programs should not be a prerequisite to participation in school activities. Involuntary testing is not appropriate in adolescents with decisional capacity—even with parental consent—and should be performed only if there are strong medical or legal reasons to do so. The AAP reaffirms its position that the appropriate response to the suspicion of drug abuse in a young person is the referral to a qualified health care professional for comprehensive evaluation. (8/96, reaffirmed 5/99, 5/06)

TESTING FOR DRUGS OF ABUSE IN CHILDREN AND ADOLESCENTS: ADDENDUM—TESTING IN SCHOOLS AND AT HOME

Committee on Substance Abuse and Council on School Health

ABSTRACT. The American Academy of Pediatrics continues to believe that adolescents should not be drug tested without their knowledge and consent. Recent US Supreme Court decisions and market forces have resulted in recommendations for drug testing of adolescents at school and products for parents to use to test adolescents at home. The American Academy of Pediatrics has strong reservations about testing adolescents at school or at home and believes that more research is needed on both safety and efficacy before school-based testing programs are implemented. The American Academy of Pediatrics also believes that more adolescent-specific substance abuse treatment resources are needed to ensure that testing leads to early rehabilitation rather than to punitive measures only. (3/07)

TOBACCO, ALCOHOL, AND OTHER DRUGS: THE ROLE OF THE PEDIATRICIAN IN PREVENTION, IDENTIFICATION, AND MANAGEMENT OF SUBSTANCE ABUSE (CLINICAL REPORT)

John W. Kulig, MD, MPH, and Committee on Substance Abuse

ABSTRACT. Substance abuse remains a major public health concern, and pediatricians are uniquely positioned to assist their patients and families with its prevention, detection, and treatment. The American Academy of Pediatrics has highlighted the importance of such issues in a variety of ways, including its guidelines for preventive services. The harmful consequences of tobacco, alcohol, and other drug use are a concern of medical professionals who care for infants, children, adolescents, and young adults. Thus, pediatricians should include discussion of substance abuse as a part of routine health care, starting with the prenatal visit, and as part of ongoing anticipatory guidance. Knowledge of the nature and extent of the consequences of tobacco, alcohol, and other drug use as well as the physical, psychological, and social consequences is essential for pediatricians. Pediatricians should incorporate substance-abuse prevention into daily practice, acquire the skills necessary to identify young people at risk of substance abuse, and provide or facilitate assessment, intervention, and treatment as necessary. (3/05, reaffirmed 3/13)

TOBACCO AS A SUBSTANCE OF ABUSE (TECHNICAL REPORT)

Tammy H. Sims, MD, MS, and Committee on Substance Abuse

ABSTRACT. Tobacco use is the leading preventable cause of morbidity and death in the United States. Because 80% to 90% of adult smokers began during adolescence, and two thirds became regular, daily smokers before they reached 19 years of age, tobacco use may be viewed as a pediatric disease. Every year in the United States, approximately 1.4 million children younger than 18 years start smoking, and many of them will die prematurely from a smoking-related disease. Moreover, there is recent evidence that adolescents report symptoms of tobacco dependence early in the smoking process, even before becoming daily smokers. The prevalence of tobacco use is higher among teenagers and young adults than among older adult populations. The critical role of pediatricians in helping to reduce tobacco use and addiction and secondhand tobacco-smoke exposure in the pediatric population includes education and prevention, screening and detection, and treatment and referral. (10/09)

TOBACCO USE: A PEDIATRIC DISEASE

Committee on Environmental Health, Committee on Substance Abuse, Committee on Adolescence, and Committee on Native American Child Health

ABSTRACT. Tobacco use and secondhand tobacco-smoke (SHS) exposure are major national and international health concerns. Pediatricians and other clinicians who care for children are uniquely positioned to assist patients and families with tobacco-use prevention and treatment. Understanding the nature and extent of tobacco use and SHS exposure is an essential first step toward the goal of eliminating tobacco use and its consequences in the pediatric population. The next steps include counseling patients and family members to avoid SHS exposures or cease tobacco use; advocacy for policies that protect children from SHS exposure; and elimination of tobacco use in the media, public places, and homes. Three overarching principles of this policy can be identified: (1) there is no safe way to use tobacco; (2) there is no safe level or duration of exposure to SHS; and (3) the financial and political power of individuals, organizations, and government should be used to support tobacco control. Pediatricians are advised not to smoke or use tobacco; to make their homes, cars, and workplaces tobacco free; to consider tobacco control when making personal and professional decisions; to support and advocate for comprehensive tobacco control; and to advise parents and patients not to start using tobacco or to quit if they are already using tobacco. Prohibiting both tobacco advertising and the use of tobacco products in the media is recommended. Recommendations for eliminating SHS exposure and reducing tobacco use include attaining universal (1) smoke-free home, car, school, work, and play environments, both inside and outside, (2) treatment of tobacco use and dependence through employer, insurance, state, and federal supports, (3) implementation

and enforcement of evidence-based tobacco-control measures in local, state, national, and international jurisdictions, and (4) financial and systems support for training in and research of effective ways to prevent and treat tobacco use and SHS exposure. Pediatricians, their staff and colleagues, and the American Academy of Pediatrics have key responsibilities in tobacco control to promote the health of children, adolescents, and young adults. (10/09)

TOWARD TRANSPARENT CLINICAL POLICIES

Steering Committee on Quality Improvement and Management

ABSTRACT. Clinical policies of professional societies such as the American Academy of Pediatrics are valued highly, not only by clinicians who provide direct health care to children but also by many others who rely on the professional expertise of these organizations, including parents, employers, insurers, and legislators. The utility of a policy depends, in large part, on the degree to which its purpose and basis are clear to policy users, an attribute known as the policy's transparency. This statement describes the critical importance and special value of transparency in clinical policies, guidelines, and recommendations; helps identify obstacles to achieving transparency; and suggests several approaches to overcome these obstacles. (3/08)

TRAMPOLINE SAFETY IN CHILDHOOD AND ADOLESCENCE

Council on Sports Medicine and Fitness

ABSTRACT. Despite previous recommendations from the American Academy of Pediatrics discouraging home use of trampolines, recreational use of trampolines in the home setting continues to be a popular activity among children and adolescents. This policy statement is an update to previous statements, reflecting the current literature on prevalence, patterns, and mechanisms of trampoline-related injuries. Most trampoline injuries occur with multiple simultaneous users on the mat. Cervical spine injuries often occur with falls off the trampoline or with attempts at somersaults or flips. Studies on the efficacy of trampoline safety measures are reviewed, and although there is a paucity of data, current implementation of safety measures have not appeared to mitigate risk substantially. Therefore, the home use of trampolines is strongly discouraged. The role of trampoline as a competitive sport and in structured training settings is reviewed, and recommendations for enhancing safety in these environments are made. (9/12)

THE TRANSFER OF DRUGS AND THERAPEUTICS INTO HUMAN BREAST MILK: AN UPDATE ON SELECTED TOPICS (CLINICAL REPORT)

Hari Cheryl Sachs, MD, FAAP, and Committee on Drugs

ABSTRACT. Many mothers are inappropriately advised to discontinue breastfeeding or avoid taking essential medications because of fears of adverse effects on their infants. This cautious approach may be unnecessary in many cases, because only a small proportion of medications are contraindicated in breastfeeding mothers or associated with adverse effects on their infants. Information to inform physicians about the extent of excretion for a particular drug into human milk is needed but may not be available. Previous statements on this topic from the American Academy of Pediatrics provided physicians with data concerning the known excretion of specific medications into breast milk. More current and comprehensive information is now available on the Internet, as well as an application for mobile devices, at LactMed (http://toxnet.nlm.nih.gov). Therefore, with the exception of radioactive compounds requiring temporary cessation of breastfeeding, the reader will be referred to LactMed to obtain the most current data on an individual medication. This report discusses several topics of interest surrounding lactation, such as the use of psychotropic therapies, drugs to treat substance abuse, narcotics, galactagogues, and herbal products, as well as immunization of breastfeeding women. A discussion regarding the global implications of maternal medications and lactation in the developing world is beyond the scope of this report. The World Health Organization offers several programs and resources that address the importance of breastfeeding (see http://www.who.int/topics/breastfeeding/en/). (8/13)

See full text on page 963.

TRANSITIONING HIV-INFECTED YOUTH INTO ADULT HEALTH CARE

Committee on Pediatric AIDS

ABSTRACT. With advances in antiretroviral therapy, most HIV-infected children survive into adulthood. Optimal health care for these youth includes a formal plan for the transition of care from primary and/or subspecialty pediatric/adolescent/family medicine health care providers (medical home) to adult health care provider(s). Successful transition involves the early engagement and participation of the youth and his or her family with the pediatric medical home and adult health care teams in developing a formal plan. Referring providers should have a written policy for the transfer of HIV-infected youth to adult care, which will guide in the development of an individualized plan for each youth. The plan should be introduced to the youth in early adolescence and modified as the youth approaches transition. Assessment of developmental milestones is important to define the readiness of the youth in assuming responsibility for his or her own care before initiating the transfer. Communication among all providers is essential and should include both personal contact and a written medical summary. Progress toward the transition should be tracked and, once completed, should be documented and assessed. (6/13)

See full text on page 979.

TRANSPORTING CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Committee on Injury and Poison Prevention

ABSTRACT. Children with special health care needs should have access to proper resources for safe transportation. This statement reviews important considerations for transporting children with special health care needs and provides current guidelines for the protection of children with specific health care needs, including those with a tracheostomy, a spica cast, challenging behaviors, or muscle tone abnormalities as well as those transported in wheelchairs. (10/99, reaffirmed 1/03, 1/06, 3/13)

THE TREATMENT OF NEUROLOGICALLY IMPAIRED CHILDREN USING PATTERNING

Committee on Children With Disabilities

ABSTRACT. This statement reviews patterning as a treatment for children with neurologic impairments. This treatment is based on an outmoded and oversimplified theory of brain development. Current information does not support the claims of proponents that this treatment is efficacious, and its use continues to be unwarranted. (11/99, reaffirmed 11/02, 1/06, 8/10)

ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS

Council on Environmental Health and Section on Dermatology

ABSTRACT. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Public awareness of the risk is not optimal, overall compliance with sun protection is inconsistent, and melanoma rates continue to rise. The risk of skin cancer increases when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Yet, people continue to sunburn, and teenagers and adults alike remain frequent visitors to tanning parlors. Pediatricians should provide advice about UVR exposure during health-supervision visits and at other relevant times. Advice includes avoiding sunburning, wearing clothing and hats, timing activities (when possible) before or after periods of peak sun exposure, wearing protective sunglasses, and applying and reapplying sunscreen. Advice should be framed in the context of promoting outdoor physical activity. Adolescents should be strongly discouraged from visiting tanning parlors. Sun exposure and vitamin D status are intertwined. Cutaneous vitamin D production requires sunlight exposure, and many factors, such as skin pigmentation, season, and time of day, complicate efficiency of cutaneous vitamin D production that results from sun exposure. Adequate vitamin D is needed for bone health. Accumulating information suggests a beneficial influence of vitamin D on many health conditions. Although vitamin D is available through the diet, supplements, and incidental sun exposure, many children have low vitamin D concentrations. Ensuring vitamin D adequacy while promoting sun-protection strategies will require renewed attention to children's use of dietary and supplemental vitamin D. (2/11)

ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Sophie J. Balk, MD; Council on Environmental Health; and Section on Dermatology

ABSTRACT. Sunlight sustains life on earth. Sunlight is essential for vitamin D synthesis in the skin. The sun's ultraviolet rays can be hazardous, however, because excessive exposure causes skin cancer and other adverse health effects. Skin cancer is a major public health problem; more than 2 million new cases are diagnosed in the United States each year. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Exposure to UVR from sunlight and artificial sources early in life elevates the risk of developing skin cancer. Approximately 25% of sun exposure occurs before 18 years of age. The risk of skin cancer is increased when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Public awareness of the risk is not optimal, compliance with sun protection is inconsistent, and skin-cancer rates continue to rise in all age groups including the younger population. People continue to sunburn, and teenagers and adults are frequent visitors to tanning parlors. Sun exposure and vitamin D status are intertwined. Adequate vitamin D is needed for bone health in children and adults. In addition, there is accumulating information suggesting a beneficial influence of vitamin D on various health conditions. Cutaneous vitamin D production requires sunlight, and many factors complicate the efficiency of vitamin D production that results from sunlight exposure. Ensuring vitamin D adequacy while promoting sun-protection strategies, therefore, requires renewed attention to evaluating the adequacy of dietary and supplemental vitamin D. Daily intake of 400 IU of vitamin D will prevent vitamin D deficiency rickets in infants. The vitamin D supplementation amounts necessary to support optimal health in older children and adolescents are less clear. This report updates information on the relationship of sun exposure to skin cancer and other adverse health effects, the relationship of exposure to artificial sources of UVR and skin cancer, sun-protection methods, vitamin D, community skin-cancer–prevention efforts, and the pediatrician's role in preventing skin cancer. In addition to pediatricians' efforts, a sustained public health effort is needed to change attitudes and behaviors regarding UVR exposure. (3/11)

UNDERINSURANCE OF ADOLESCENTS: RECOMMENDATIONS FOR IMPROVED COVERAGE OF PREVENTIVE, REPRODUCTIVE, AND BEHAVIORAL HEALTH CARE SERVICES

Committee on Adolescence and Committee on Child Health Financing

ABSTRACT. The purpose of this policy statement is to address the serious underinsurance (ie, insurance that exists but is inadequate) problems affecting insured adolescents' access to needed preventive, reproductive, and behavioral health care. In addition, the statement addresses provider payment problems that disproportionately affect clinicians who care for adolescents.

Among adolescents with insurance, particularly private health insurance, coverage of needed services is often inadequate. Benefits are typically limited in scope and amount; certain diagnoses are often excluded; and cost-sharing requirements are often too high. As a result, underinsurance represents a substantial problem among adolescents and adversely affects their health and well-being.

In addition to underinsurance problems, payment problems in the form of inadequate payment, uncompensated care for confidential reproductive services, and the failure of insurers to recognize and pay for certain billing and diagnostic codes are widespread among both private and public insurers. Payment problems negatively affect clinicians' ability to offer needed services to adolescents, especially publicly insured adolescents. (12/08)

UNDERSTANDING THE BEHAVIORAL AND EMOTIONAL CONSEQUENCES OF CHILD ABUSE (CLINICAL REPORT)

John Stirling Jr, MD; Committee on Child Abuse and Neglect; and Section on Adoption and Foster Care (joint with Lisa Amaya-Jackson, MD, MPH; American Academy of Child and Adolescent Psychiatry; and National Center for Child Traumatic Stress)

ABSTRACT. Children who have suffered early abuse or neglect may later present with significant behavior problems including emotional instability, depression, and a tendency to be aggressive or violent with others. Troublesome behaviors may persist long after the abusive or neglectful environment has changed or the child has been in foster care placement. Neurobiological research has shown that early abuse results in an altered physiological response to stressful stimuli, a response that deleteriously affects the child's subsequent socialization. Pediatricians can assist caregivers by helping them recognize the abused or neglected child's altered responses, formulate more effective coping strategies, and mobilize available community resources. (9/08)

UPDATE OF NEWBORN SCREENING AND THERAPY FOR CONGENITAL HYPOTHYROIDISM (CLINICAL REPORT)

Susan R. Rose, MD; Section on Endocrinology; and Committee on Genetics (joint with American Thyroid Association; Rosalind S. Brown, MD; and Lawson Wilkins Pediatric Endocrine Society)

ABSTRACT. Unrecognized congenital hypothyroidism leads to mental retardation. Newborn screening and thyroid therapy started within 2 weeks of age can normalize cognitive development. The primary thyroid-stimulating hormone screening has become standard in many parts of the world. However, newborn thyroid screening is not yet universal in some countries. Initial dosage of 10 to 15 μg/kg levothyroxine is recommended. The goals of thyroid hormone therapy should be to maintain frequent evaluations of total thyroxine or free thyroxine in the upper half of the reference range during the first 3 years of life and to normalize the serum thyroid-stimulating hormone concentration to ensure optimal thyroid hormone dosage and compliance.

Improvements in screening and therapy have led to improved developmental outcomes in adults with congenital hypothyroidism who are now in their 20s and 30s. Thyroid hormone regimens used today are more aggressive in targeting early correction of thyroid-stimulating hormone than were those used 20 or even 10 years ago. Thus, newborn infants with congenital hypothyroidism today may have an even better intellectual and neurologic prognosis. Efforts are ongoing to establish the optimal therapy that leads to maximum potential for normal development for infants with congenital hypothyroidism.

Remaining controversy centers on infants whose abnormality in neonatal thyroid function is transient or mild and on optimal care of very low birth weight or preterm infants. Of note, thyroid-stimulating hormone is not elevated in central hypothyroidism. An algorithm is proposed for diagnosis and management.

Physicians must not relinquish their clinical judgment and experience in the face of normal newborn thyroid test results. Hypothyroidism can be acquired after the newborn screening. When clinical symptoms and signs suggest hypothyroidism, regardless of newborn screening results, serum free thyroxine and thyroid-stimulating hormone determinations should be performed. (6/06, reaffirmed 12/11)

USE OF CHAPERONES DURING THE PHYSICAL EXAMINATION OF THE PEDIATRIC PATIENT

Committee on Practice and Ambulatory Medicine

ABSTRACT. Physicians should always communicate the scope and nature of the physical examination to be performed to the pediatric patient and his or her parent. This statement addresses the use of chaperones and issues of patient comfort, confidentiality, and privacy. The use of a chaperone should be a shared decision between the patient and physician. In some states, the use of a chaperone is mandated by state regulations. (4/11)

USE OF CODEINE- AND DEXTROMETHORPHAN-CONTAINING COUGH REMEDIES IN CHILDREN

Committee on Drugs

ABSTRACT. Numerous prescription and nonprescription medications are currently available for suppression of cough, a common symptom in children. Because adverse effects and overdosage associated with the administration of cough and cold preparations in children have been reported, education of patients and parents about the lack of proven antitussive effects and the potential risks of these products is needed. (6/97, reaffirmed 5/00, 6/03, 10/06)

THE USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE IN PEDIATRICS (CLINICAL REPORT)

Kathi J. Kemper, MD, MPH; Sunita Vohra, MD; Richard Walls, MD, PhD; Task Force on Complementary and Alternative Medicine; and Provisional Section on Complementary, Holistic, and Integrative Medicine

ABSTRACT. The American Academy of Pediatrics is dedicated to optimizing the well-being of children and advancing family-centered health care. Related to these goals, the American Academy of Pediatrics recognizes the increasing use of complementary and alternative medicine in children and, as a result, the need to provide information and support for pediatricians. From 2000 to 2002, the American Academy of Pediatrics convened and charged the Task Force on Complementary and Alternative Medicine to address issues related to the use of complementary and alternative medicine in children and to develop resources to educate physicians, patients, and families. One of these resources is this report describing complementary and alternative medicine services, current levels of utilization and financial expenditures, and associated legal and ethical considerations. The subject of complementary and alternative medicine is large and diverse, and consequently, an in-depth discussion of each method of complementary and alternative medicine is beyond the scope of this report. Instead, this report will define terms; describe epidemiology; outline common types of complementary and alternative medicine therapies; review medicolegal, ethical, and research implications; review education and training for complementary

and alternative medicine providers; provide resources for learning more about complementary and alternative medicine; and suggest communication strategies to use when discussing complementary and alternative medicine with patients and families. (12/08, reaffirmed 10/12, 1/13)

USE OF INHALED NITRIC OXIDE
Committee on Fetus and Newborn
ABSTRACT. Approval of inhaled nitric oxide by the US Food and Drug Administration for hypoxic respiratory failure of the term and near-term newborn provides an important new therapy for this serious condition. This statement addresses the conditions under which inhaled nitric oxide should be administered to the neonate with hypoxic respiratory failure. (8/00, reaffirmed 4/03, 12/09)

USE OF INHALED NITRIC OXIDE IN PRETERM INFANTS (CLINICAL REPORT)
Praveen Kumar, MD, FAAP, and Committee on Fetus and Newborn
ABSTRACT. Nitric oxide, an important signaling molecule with multiple regulatory effects throughout the body, is an important tool for the treatment of full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure. Several randomized controlled trials have evaluated its role in the management of preterm infants ≤34 weeks' gestational age with varying results. The purpose of this clinical report is to summarize the existing evidence for the use of inhaled nitric oxide in preterm infants and provide guidance regarding its use in this population. (12/13)
See full text on page 987.

THE USE AND MISUSE OF FRUIT JUICE IN PEDIATRICS
Committee on Nutrition
ABSTRACT. Historically, fruit juice was recommended by pediatricians as a source of vitamin C and an extra source of water for healthy infants and young children as their diets expanded to include solid foods with higher renal solute. Fruit juice is marketed as a healthy, natural source of vitamins and, in some instances, calcium. Because juice tastes good, children readily accept it. Although juice consumption has some benefits, it also has potential detrimental effects. Pediatricians need to be knowledgeable about juice to inform parents and patients on its appropriate uses. (5/01, reaffirmed 10/06, 8/13)

USE OF PERFORMANCE-ENHANCING SUBSTANCES
Committee on Sports Medicine and Fitness
ABSTRACT. Performance-enhancing substances include dietary supplements, prescription medications, and illicit drugs. Virtually no data are available on the efficacy and safety in children and adolescents of widely used performance-enhancing substances. This statement is intended to provide a generalized but functional definition of performance-enhancing substances. The American Academy of Pediatrics strongly condemns the use of performance-enhancing substances and vigorously endorses efforts to eliminate their use among children and adolescents. (4/05, reaffirmed 5/08)

USE OF SOY PROTEIN-BASED FORMULAS IN INFANT FEEDING (CLINICAL REPORT)
Jatinder Bhatia, MD; Frank Greer, MD; and Committee on Nutrition
ABSTRACT. Soy protein-based formulas have been available for almost 100 years. Since the first use of soy formula as a milk substitute for an infant unable to tolerate a cow milk protein-based formula, the formulation has changed to the current soy protein isolate. Despite very limited indications for its use, soy protein-based formulas in the United States may account for nearly 25% of the formula market. This report reviews the limited indications and contraindications of soy formulas. It will also review the potential harmful effects of soy protein-based formulas and the phytoestrogens contained in these formulas. (5/08)

THE USE OF SYSTEMIC AND TOPICAL FLUOROQUINOLONES (CLINICAL REPORT)
John S. Bradley, MD; Mary Anne Jackson, MD; and Committee on Infectious Diseases
ABSTRACT. Appropriate prescribing practices for fluoroquinolones are essential as evolving resistance patterns are considered, additional treatment indications are identified, and the toxicity profile of fluoroquinolones in children becomes better defined. Earlier recommendations for systemic therapy remain; expanded uses of fluoroquinolones for the treatment of certain infections are outlined in this report. Although fluoroquinolones are reasonably safe in children, clinicians should be aware of the specific adverse reactions. Use of fluoroquinolones in children should continue to be limited to treatment of infections for which no safe and effective alternative exists. (9/11)

USES OF DRUGS NOT DESCRIBED IN THE PACKAGE INSERT (OFF-LABEL USES)
Committee on Drugs
ABSTRACT. New regulatory initiatives have been designed to ensure that new drugs and biologicals include adequate pediatric labeling for the claimed indications at the time of, or soon after, approval. However, because such labeling may not immediately be available, off-label use (or use that is not included in the approved label) of therapeutic agents is likely to remain common in the practice of pediatrics. This policy statement was written to address questions practitioners have regarding off-label use. The purpose of off-label use is to benefit the individual patient. Practitioners may use their professional judgment to determine these uses. Practitioners should understand that the Food and Drug Administration does not regulate off-label use. (7/02, reaffirmed 10/05)

USING PERSONAL HEALTH RECORDS TO IMPROVE THE QUALITY OF HEALTH CARE FOR CHILDREN
Council on Clinical Information Technology
ABSTRACT. A personal health record (PHR) is a repository of information from multiple contributors (eg, patient, family, guardians, physicians, and other health care professionals) regarding the health of an individual. The development of electronic PHRs presents new opportunities and challenges to the practice of pediatrics. This policy statement provides recommendations for actions

that pediatricians can take to support the development and use of PHRs for children.

Pediatric health care professionals must become actively involved in developing and adopting PHRs and PHR systems. The American Academy of Pediatrics supports development of:

- educational programs for families and clinicians on effective and efficient use of PHRs;
- incentives to facilitate PHR use and maintenance; and
- child- and adolescent-friendly standards for PHR content, portability, security, and privacy.

Properly designed PHR systems for pediatric care can empower patients. PHRs can improve access to health information, improve coordination of preventive health and health maintenance activities, and support emergency and disaster management activities. PHRs provide support for the medical home for all children, including those with special health care needs and those in foster care. PHRs can also provide information to serve as the basis for pediatric quality improvement efforts.

For PHRs to be adopted sufficiently to realize these benefits, we must determine how best to support their development and adoption. Privacy and security issues, especially with regard to children and adolescents, must be addressed. (6/09)

VENTRICULAR FIBRILLATION AND THE USE OF AUTOMATED EXTERNAL DEFIBRILLATORS ON CHILDREN

Committee on Pediatric Emergency Medicine and Section on Cardiology and Cardiac Surgery

ABSTRACT. The use of automated external defibrillators (AEDs) has been advocated in recent years as one part of the chain of survival to improve outcomes for adult cardiac arrest victims. When AEDs first entered the market, they had not been tested for pediatric usage and rhythm interpretation. In addition, the presumption was that children do not experience ventricular fibrillation, so they would not benefit from the use of AEDs. Recent literature has shown that children do experience ventricular fibrillation, which has a better outcome than do other cardiac arrest rhythms. At the same time, the arrhythmia software on AEDs has become more extensive and validated for children, and attenuation devices have become available to downregulate the energy delivered by AEDs to allow their use on children. Pediatricians are now being asked whether AED programs should be implemented, and where they are being implemented, pediatricians are being asked to provide guidance on the use of them on children. As AED programs expand, pediatricians must advocate on behalf of children so that their needs are accounted for. For pediatricians to be able to provide guidance and ensure that children are included in AED programs, it is important for pediatricians to know how AEDs work, be up-to-date on the literature regarding pediatric fibrillation and energy delivery, and understand the role of AEDs as life-saving interventions for children. (11/07, reaffirmed 6/11)

WHEN IS LACK OF SUPERVISION NEGLECT? (CLINICAL REPORT)

Kent P. Hymel, MD, and Committee on Child Abuse and Neglect

ABSTRACT. Occasionally, pediatricians become aware of children who are inadequately supervised. More frequently, pediatricians treat children for traumatic injuries or ingestions that they suspect could have been prevented with better supervision. This clinical report contains guidance for pediatricians considering a referral to a child protective services agency on the basis of suspicion of supervisory neglect. (9/06)

WIC PROGRAM

Provisional Section on Breastfeeding

ABSTRACT. This policy statement highlights the important collaboration between pediatricians and local Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) programs to ensure that infants and children receive high-quality, cost-effective health care and nutrition services. Specific recommendations are provided for pediatricians and WIC personnel to help children and their families receive optimum services through a medical home. (11/01)

YEAR 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY HEARING DETECTION AND INTERVENTION PROGRAMS

Joint Committee on Infant Hearing

ABSTRACT. The Joint Committee on Infant Hearing (JCIH) endorses early detection of and intervention for infants with hearing loss. The goal of early hearing detection and intervention (EHDI) is to maximize linguistic competence and literacy development for children who are deaf or hard of hearing. Without appropriate opportunities to learn language, these children will fall behind their hearing peers in communication, cognition, reading, and social-emotional development. Such delays may result in lower educational and employment levels in adulthood. To maximize the outcome for infants who are deaf or hard of hearing, the hearing of all infants should be screened at no later than 1 month of age. Those who do not pass screening should have a comprehensive audiological evaluation at no later than 3 months of age. Infants with confirmed hearing loss should receive appropriate intervention at no later than 6 months of age from health care and education professionals with expertise in hearing loss and deafness in infants and young children. Regardless of previous hearing-screening outcomes, all infants with or without risk factors should receive ongoing surveillance of communicative development beginning at 2 months of age during well-child visits in the medical home. EHDI systems should guarantee seamless transitions for infants and their families through this process. (10/07)

SECTION 6

Endorsed Policies

The American Academy of Pediatrics endorses and accepts as its policy the following documents from other organizations.

AMERICAN ACADEMY OF PEDIATRICS

Endorsed Policies

APPROPRIATE MEDICAL CARE FOR THE SECONDARY SCHOOL-AGE ATHLETE COMMUNICATION
National Athletic Trainers' Association (2004)

BEST PRACTICE FOR INFANT SURGERY: A POSITION STATEMENT FROM THE AMERICAN PEDIATRIC SURGICAL ASSOCIATION
American Pediatric Surgical Association (9/08)

CARDIOVASCULAR RISK REDUCTION IN HIGH-RISK PEDIATRIC POPULATIONS
American Heart Association
ABSTRACT. Although for most children the process of atherosclerosis is subclinical, dramatically accelerated atherosclerosis occurs in some pediatric disease states, with clinical coronary events occurring in childhood and very early adult life. As with most scientific statements about children and the future risk for cardiovascular disease, there are no randomized trials documenting the effects of risk reduction on hard clinical outcomes. A growing body of literature, however, identifies the importance of premature cardiovascular disease in the course of certain pediatric diagnoses and addresses the response to risk factor reduction. For this scientific statement, a panel of experts reviewed what is known about very premature cardiovascular disease in 8 high-risk pediatric diagnoses and, from the science base, developed practical recommendations for management of cardiovascular risk. (*Circulation.* 2006;114:000-000.) (12/06)

A COMPREHENSIVE IMMUNIZATION STRATEGY TO ELIMINATE TRANSMISSION OF HEPATITIS B VIRUS INFECTION IN THE UNITED STATES
Advisory Committee on Immunization Practices and Centers for Disease Control and Prevention
SUMMARY. This report is the first of a two-part statement from the Advisory Committee on Immunization Practices (ACIP) that updates the strategy to eliminate hepatitis B virus (HBV) transmission in the United States. The report provides updated recommendations to improve prevention of perinatal and early childhood HBV transmission, including implementation of universal infant vaccination beginning at birth, and to increase vaccine coverage among previously unvaccinated children and adolescents. Strategies to enhance implementation of the recommendations include 1) establishing standing orders for administration of hepatitis B vaccination beginning at birth; 2) instituting delivery hospital policies and procedures and case management programs to improve identification of and administration of immunoprophylaxis to infants born to mothers who are hepatitis B surface antigen (HBsAg) positive and to mothers with unknown HBsAg status at the time of delivery; and 3) implementing vaccination record reviews for all children aged 11–12 years and children and adolescents aged <19 years who were born in countries with intermediate and high levels of HBV endemicity, adopting hepatitis B vaccine requirements for school entry, and integrating hepatitis B vaccination services into settings that serve adolescents. The second part of the ACIP statement, which will include updated recommendations and strategies to increase hepatitis B vaccination of adults, will be published separately. (7/06)

CONSENSUS STATEMENT: DEFINITIONS FOR CONSISTENT EMERGENCY DEPARTMENT METRICS
American Academy of Emergency Medicine, American Association of Critical Care Nurses, American College of Emergency Physicians, Association of periOperative Registered Nurses, Emergency Department Practice Management Association, Emergency Nurses Association, and National Association of EMS Physicians (2/10)

CONSENSUS STATEMENT ON MANAGEMENT OF INTERSEX DISORDERS
International Consensus Conference on Intersex (Lawson Wilkins Pediatric Endocrine Society and European Society for Paediatric Endocrinology)
INTRODUCTION. The birth of an intersex child prompts a long-term management strategy that involves myriad professionals working with the family. There has been progress in diagnosis, surgical techniques, understanding psychosocial issues, and recognizing and accepting the place of patient advocacy. The Lawson Wilkins Pediatric Endocrine Society and the European Society for Paediatric Endocrinology considered it timely to review the management of intersex disorders from a broad perspective, review data on longer-term outcome, and formulate proposals for future studies. The methodology comprised establishing a number of working groups, the membership of which was drawn from 50 international experts in the field. The groups prepared previous written responses to a defined set of questions resulting from evidence-based review of the literature. At a subsequent gathering of participants, a framework for a consensus document was agreed. This article constitutes its final form. (8/06)

DEFINING PEDIATRIC MALNUTRITION: A PARADIGM SHIFT TOWARD ETIOLOGY-RELATED DEFINITIONS
American Society for Parenteral and Enteral Nutrition
ABSTRACT. Lack of a uniform definition is responsible for underrecognition of the prevalence of malnutrition and its impact on outcomes in children. A pediatric malnutrition definitions workgroup reviewed existing pediatric age group English-language literature from 1955 to 2011, for relevant references related to 5 domains of the definition of *malnutrition* that were a *priori* identified: anthropometric parameters, growth, chronicity of malnutrition, etiology and pathogenesis, and developmental/functional outcomes. Based on available evidence and an iterative process to arrive at multidisciplinary consensus in the group, these domains were included in the overall construct of a new definition. Pediatric malnutrition

(undernutrition) is defined as an imbalance between nutrient requirements and intake that results in cumulative deficits of energy, protein, or micronutrients that may negatively affect growth, development, and other relevant outcomes. A summary of the literature is presented and a new classification scheme is proposed that incorporates chronicity, etiology, mechanisms of nutrient imbalance, severity of malnutrition, and its impact on outcomes. Based on its etiology, malnutrition is either *illness related* (secondary to 1 or more diseases/injury) or *non–illness related,* (caused by environmental/behavioral factors), or both. Future research must focus on the relationship between inflammation and illness-related malnutrition. We anticipate that the definition of malnutrition will continue to evolve with improved understanding of the processes that lead to and complicate the treatment of this condition. A uniform definition should permit future research to focus on the impact of pediatric malnutrition on functional outcomes and help solidify the scientific basis for evidence-based nutrition practices. EVIDENCE REPORT: GENETIC AND METABOLIC TESTING ON CHILDREN WITH GLOBAL DEVELOPMENTAL DELAY
American Academy of Neurology and Child Neurology Society
ABSTRACT. *Objective.* To systematically review the evidence concerning the diagnostic yield of genetic and metabolic evaluation of children with global developmental delay or intellectual disability (GDD/ID).

Methods. Relevant literature was reviewed, abstracted, and classified according to the 4-tiered American Academy of Neurology classification of evidence scheme.

Results and Conclusions. In patients with GDD/ID, microarray testing is diagnostic on average in 7.8% (Class III), G-banded karyotyping is abnormal in at least 4% (Class II and III), and subtelomeric fluorescence in situ hybridization is positive in 3.5% (Class I, II, and III). Testing for X-linked ID genes has a yield of up to 42% in males with an appropriate family history (Class III). *FMR1* testing shows full expansion in at least 2% of patients with mild to moderate GDD/ID (Class II and III), and *MeCP2* testing is diagnostic in 1.5% of females with moderate to severe GDD/ID (Class III). Tests for metabolic disorders have a yield of up to 5%, and tests for congenital disorders of glycosylation and cerebral creatine disorders have yields of up to 2.8% (Class III). Several genetic and metabolic screening tests have been shown to have a better than 1% diagnostic yield in selected populations of children with GDD/ID. These values should be among the many factors considered in planning the laboratory evaluation of such children. (9/11)

EVIDENCE-BASED GUIDELINE UPDATE: MEDICAL TREATMENT OF INFANTILE SPASMS
American Academy of Neurology and Child Neurology Society
ABSTRACT. *Objective.* To update the 2004 American Academy of Neurology/Child Neurology Society practice parameter on treatment of infantile spasms in children.

Methods. MEDLINE and EMBASE were searched from 2002 to 2011 and searches of reference lists of retrieved articles were performed. Sixty-eight articles were selected for detailed review; 26 were included in the analysis. Recommendations were based on a 4-tiered classification scheme combining pre-2002 evidence and more recent evidence.

Results. There is insufficient evidence to determine whether other forms of corticosteroids are as effective as adrenocorticotropic hormone (ACTH) for short-term treatment of infantile spasms. However, low-dose ACTH is probably as effective as high-dose ACTH. ACTH is more effective than vigabatrin (VGB) for short-term treatment of children with infantile spasms (excluding those with tuberous sclerosis complex). There is insufficient evidence to show that other agents and combination therapy are effective for short-term treatment of infantile spasms. Short lag time to treatment leads to better long-term developmental outcome. Successful short-term treatment of cryptogenic infantile spasms with ACTH or prednisolone leads to better long-term developmental outcome than treatment with VGB.

Recommendations. Low-dose ACTH should be considered for treatment of infantile spasms. ACTH or VGB may be useful for short-term treatment of infantile spasms, with ACTH considered preferentially over VGB. Hormonal therapy (ACTH or prednisolone) may be considered for use in preference to VGB in infants with cryptogenic infantile spasms, to possibly improve developmental outcome. A shorter lag time to treatment of infantile spasms with either hormonal therapy or VGB possibly improves long-term developmental outcomes. (6/12)

Society for Adolescent Medicine (10/04)

EXPEDITED PARTNER THERAPY FOR ADOLESCENTS DIAGNOSED WITH CHLAMYDIA OR GONORRHEA: A POSITION PAPER OF THE SOCIETY FOR ADOLESCENT MEDICINE

Society for Adolescent Medicine

ABSTRACT. Chlamydia and gonorrhea, the most frequently reported sexually transmitted infections (STIs), present substantial public health challenges among adolescents. Although these infections are easily treated with antibiotics, many adolescents are reinfected within 3–6 months, usually because their partners remain untreated. The standard approaches to notifying and treating a partner of an STI-infected patient are patient referral, whereby the patient notifies his/her partners to seek care, and provider referral, whereby the provider or public health disease intervention specialist notifies the partner and directs him/her toward treatment. These methods rely on the accuracy of the disclosed partner information as well as other limitations, such as compliance and staffing resources. Another approach to partner notification is expedited partner therapy (EPT), treating sex partners without requiring a prior clinical evaluation. In randomized trials, EPT has reduced the rates of persistent or recurrent gonorrhea and chlamydia infection; however, its routine use is limited by concerns related to liability, cost, compliance, and missed opportunities for prevention counseling. The Society for Adolescent Medicine (SAM) recommends that providers who care for adolescents should do the following: use EPT as an option for STI care among chlamydia- or gonorrhea-infected heterosexual males and females who are unlikely or unable to otherwise receive treatment; through SAM and AAP chapters, collaborate with policy makers to remove EPT legal barriers and facilitate reimbursement; and collaborate with health departments for implementation assistance. (9/09)

EXPERT PANEL ON INTEGRATED GUIDELINES FOR CARDIOVASCULAR HEALTH AND RISK REDUCTION IN CHILDREN AND ADOLESCENTS: SUMMARY REPORT

National Heart, Lung and Blood Institute

INTRODUCTION (EXCERPT). Atherosclerotic cardiovascular disease (CVD) remains the leading cause of death in North Americans, but manifest disease in childhood and adolescence is rare. By contrast, risk factors and risk behaviors that accelerate the development of atherosclerosis begin in childhood, and there is increasing evidence that risk reduction delays progression toward clinical disease. In response, the former director of the National Heart, Lung, and Blood Institute (NHLBI), Dr Elizabeth Nabel, initiated development of cardiovascular health guidelines for pediatric care providers based on a formal evidence review of the science with an integrated format addressing all the major cardiovascular risk factors simultaneously. An expert panel was appointed to develop the guidelines in the fall of 2006. (3/12)

GENERAL RECOMMENDATIONS ON IMMUNIZATION: RECOMMENDATIONS OF THE ADVISORY COMMITTEE ON IMMUNIZATION PRACTICES (ACIP)

Advisory Committee on Immunization Practices

SUMMARY. This report is a revision of General Recommendations on Immunization and updates the 2002 statement by the Advisory Committee on Immunization Practices (ACIP) (CDC. General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices and the American Academy of Family Physicians. MMWR 2002;51[No. RR-2]). This report is intended to serve as a general reference on vaccines and immunization. The principal changes include 1) expansion of the discussion of vaccination spacing and timing; 2) an increased emphasis on the importance of injection technique/age/body mass in determining appropriate needle length; 3) expansion of the discussion of storage and handling of vaccines, with a table defining the appropriate storage temperature range for inactivated and live vaccines; 4) expansion of the discussion of altered immunocompetence, including new recommendations about use of live-attenuated vaccines with therapeutic monoclonal antibodies; and 5) minor changes to the recommendations about vaccination during pregnancy and vaccination of internationally adopted children, in accordance with new ACIP vaccine-specific recommendations for use of inactivated influenza vaccine and hepatitis B vaccine. The most recent ACIP recommendations for each specific vaccine should be consulted for comprehensive discussion. This report, ACIP recommendations for each vaccine, and other information about vaccination can be accessed at CDC's National Center for Immunization and Respiratory Diseases (proposed) (formerly known as the National Immunization Program) website at http//:www.cdc.gov/nip. (12/06)

GENETIC BASIS FOR CONGENITAL HEART DEFECTS: CURRENT KNOWLEDGE

American Heart Association

ABSTRACT. The intent of this review is to provide the clinician with a summary of what is currently known about the contribution of genetics to the origin of congenital heart disease. Techniques are discussed to evaluate children with heart disease for genetic alterations. Many of these techniques are now available on a clinical basis. Information on the genetic and clinical evaluation of children with cardiac disease is presented, and several tables have been constructed to aid the clinician in the assessment of children with different types of heart disease. Genetic algorithms for cardiac defects have been constructed and are available in an appendix. It is anticipated that this summary will update a wide range of medical personnel, including pediatric cardiologists and pediatricians, adult cardiologists, internists, obstetricians, nurses, and thoracic surgeons, about the genetic aspects of congenital heart disease and will encourage an interdisciplinary approach to the child and adult with congenital heart disease. IMPORTANCE AND IMPLEMENTATION OF TRAINING IN CARDIOPULMONARY RESUSCITATION AND AUTOMATED EXTERNAL DEFIBRILLATION IN SCHOOLS
American Heart Association Emergency Cardiovascular Care Committee, Council on Cardiopulmonary, Critical Care, Perioperative and Resuscitation, Council on Cardiovascular Diseases in the Young, Council on Cardiovascular Nursing, Council on Clinical Cardiology, and Advocacy Coordinating Committee

ABSTRACT. In 2003, the International Liaison Committee on Resuscitation published a consensus document on education in resuscitation that strongly recommended that "…instruction in CPR [cardiopulmonary resuscitation] be incorporated as a standard part of the school curriculum."[1] The next year the American Heart Association (AHA) recommended that schools "…establish a goal to train every teacher in CPR and first aid and train all students in CPR" as part of their preparation for a response to medical emergencies on campus.[2]

Since that time, there has been an increased interest in legislation that would mandate that school curricula include training in CPR or CPR and automated external defibrillation. Laws or curriculum content standards in 36 states (as of the 2009–2010 school year) now encourage the inclusion of CPR training programs in school curricula. The language in those laws and standards varies greatly, ranging from a suggestion that students "recognize" the steps of CPR to a requirement for certification in CPR. Not surprisingly, then, implementation is not uniform among states, even those whose laws or standards encourage CPR training in schools in the strongest language. This statement recommends that training in CPR and familiarization with automated external defibrillators (AEDs) should be required elements of secondary school curricula and provides the rationale for implementation of CPR training, as well as guidance in overcoming barriers to implementation. LIGHTNING SAFETY FOR ATHLETICS AND RECREATION
National Athletic Trainers' Association

Abstract. *Objective.* To educate athletic trainers and others about the dangers of lightning, provide lightning-safety guidelines, define safe structures and locations, and advocate prehospital care for lightning-strike victims.
Background. Lightning may be the most frequently encountered severe-storm hazard endangering physically active people each year. Millions of lightning flashes strike the ground annually in the United States, causing nearly 100 deaths and 400 injuries. Three quarters of all lightning casualties occur between May and September, and nearly four fifths occur between 10:00 AM and 7:00 PM, which coincides with the hours for most athletic or recreational activities. Additionally, lightning casualties from sports and recreational activities have risen alarmingly in recent decades.
Recommendations. The National Athletic Trainers' Association recommends a proactive approach to lightning safety, including the implementation of a lightning-safety policy that identifies safe locations for shelter from the lightning hazard. Further components of this policy are monitoring local weather forecasts, designating a weather watcher, and establishing a chain of command. Additionally, a flash-to-bang count of 30 seconds or more should be used as a minimal determinant of when to suspend activities. Waiting 30 minutes or longer after the last flash of lightning or sound of thunder is recommended before athletic or recreational activities are resumed. Lightning safety strategies include avoiding shelter under trees, avoiding open fields and spaces, and suspending the use of land-line telephones during thunderstorms. Also outlined in this document are the prehospital care guidelines for triaging and treating lightning-strike victims. It is important to evaluate victims quickly for apnea, asystole, hypothermia, shock, fractures, and burns. Cardiopulmonary resuscitation is effective in resuscitating pulseless victims of lightning strike. Maintenance of cardiopulmonary resuscitation and first-aid certification should be required of all persons involved in sports and recreational activities. (12/00)

NONINHERITED RISK FACTORS AND CONGENITAL CARDIOVASCULAR DEFECTS: CURRENT KNOWLEDGE
American Heart Association
ABSTRACT. Prevention of congenital cardiovascular defects has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Over the past decade, there have been major breakthroughs in the understanding of inherited causes of congenital heart disease, including the identification of specific genetic abnormalities for some types of malformations. Although relatively less information has been available on noninherited modifiable factors that may have an adverse effect on the fetal heart, there is a growing body of epidemiological literature on this topic. This statement summarizes the currently available literature on potential fetal exposures that might alter risk for cardiovascular defects. Information is summarized for periconceptional multivitamin or folic acid intake, which may reduce the risk of cardiac disease in the fetus, and for additional types of potential exposures that may increase the risk, including maternal illnesses, maternal therapeutic and nontherapeutic drug exposures, environmental exposures, and paternal exposures. Information is highlighted regarding definitive risk factors such as maternal rubella; phenylketonuria; pregestational diabetes; exposure to thalidomide, vitamin A cogeners, or retinoids; and indomethacin tocolysis. Caveats regarding interpretation of possible exposure-outcome relationships from case-control studies are given because this type of study has provided most of the available information. Guidelines for prospective parents that could reduce the likelihood that their child will have a major cardiac malformation are given. Issues related to pregnancy monitoring are discussed. Knowledge gaps and future sources of new information on risk factors are described. (*Circulation.* 2007;115:2995-3014.) (6/07)

PEDIATRIC CARE IN THE EMERGENCY DEPARTMENT
Society for Academic Emergency Medicine
ABSTRACT. Physicians who have successfully completed an accredited Emergency Medicine residency and are certified in emergency medicine by the American Board of Emergency Medicine (ABEM) or the American Osteopathic Board of Emergency Medicine (AOBEM) ABEM/AOBEM or those who are certified in pediatric emergency medicine by ABEM or the American Board of Pediatrics (ABP) possess the knowledge and skills required to provide quality emergency medical care to children of all ages for a wide variety of illnesses, injuries or poisonings. To provide quality care, the emergency physician must have all necessary and age-appropriate medical equipment readily available. The emergency physician must also have access via consultation, admission, or transfer, to appropriate specialty and sub-specialty physicians, to who will provide any needed patient care after emergency department treatment. Physically separated care areas for children are not mandatory in order to provide high-quality care to patients of all ages. Although physically separate care areas for children are ideal, they are not mandatory to provide high-quality care. (11/03)

PREVENTION AND CONTROL OF MENINGOCOCCAL DISEASE: RECOMMENDATIONS OF THE ADVISORY COMMITTEE ON IMMUNIZATION PRACTICES (ACIP)
Centers for Disease Control and Prevention
SUMMARY. Meningococcal disease describes the spectrum of infections caused by Neisseria meningiditis, including meningitdis, bacteremia, and bacteremic pneumonia. Two quadrivalent meningococcal polysaccharide-protein conjugate vaccines that provide protection against meningococcal serogroups A, C, W, and Y (MenACWY-D [Menactra, manufactured by Sanofi Pasteur, Inc., Swiftwater, Pennsylvania] and MenACWY-CRM [Menveo, manufactured by Novartis Vaccines, Cambridge, Massachusetts]) are licensed in the United States for use among persons aged 2 through 55 years. MenACWY-D also is licensed for use among infants and toddlers aged 9 through 23 months. Quadrivalent meningococcal polysaccharide vaccine (MPSV4 [Menommune, manufactured by sanofi pasteur, Inc., Swiftwater, Pennsylvania]) is the only vaccine licensed for use among persons aged ≥56 years. A bivalent meningococcal polysaccharide protein conjugate vaccine that provides protection against meningococcal serogroups C and Y along with Haemophilus influenzae type b (Hib) (Hib-MenCY-TT [MenHibrix, manufactured by GlaxoSmithKline Biologicals, Rixensart, Belgium]) is licensed for use in children aged 6 weeks through 18 months.

This report compiles and summarizes all recommendations from CDC's Advisory Committee on Immunization

Practices (ACIP) regarding prevention and control of meningococcal disease in the United States, specifically the changes in the recommendations published since 2005 (CDC. Prevention and control of meningococcal disease: recommendations of the Advisory Committee on Immunization Practices [ACIP]. MMWR 2005;54 Adobe PDF file [No. RR-7]). As a comprehensive summary of previously published recommendations, this report does not contain any new recommendations; it is intended for use by clinicians as a resource. ACIP recommends routine vaccination with a quadrivalent meningococcal conjugate vaccine (MenACWY) for adolescents aged 11 or 12 years, with a booster dose at age 16 years. ACIP also recommends routine vaccination for persons at increased risk for meningococcal disease (i.e., persons who have persistent complement component deficiencies, persons who have anatomic or functional asplenia, microbiologists who routinely are exposed to isolates of N. meningitidis, military recruits, and persons who travel to or reside in areas in which meningococcal disease is hyperendemic or epidemic). Guidelines for antimicrobial chemoprophylaxis and for evaluation and management of suspected outbreaks of meningococcal disease also are provided. (3/13)

PREVENTION OF RHEUMATIC FEVER AND DIAGNOSIS AND TREATMENT OF ACUTE STREPTOCOCCAL PHARYNGITIS

American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee of the Council on Cardiovascular Disease in the Young, Interdisciplinary Council on Functional Genomics and Translational Biology, and Interdisciplinary Council on Quality of Care and Outcomes Research

ABSTRACT. Primary prevention of acute rheumatic fever is accomplished by proper identification and adequate antibiotic treatment of group A â-hemolytic streptococcal (GAS) tonsillopharyngitis. Diagnosis of GAS pharyngitis is best accomplished by combining clinical judgment with diagnostic test results, the criterion standard of which is the throat culture. Penicillin (either oral penicillin V or injectable benzathine penicillin) is the treatment of choice, because it is cost-effective, has a narrow spectrum of activity, and has long-standing proven efficacy, and GAS resistant to penicillin have not been documented. For penicillin-allergic individuals, acceptable alternatives include a narrow-spectrum oral cephalosporin, oral clindamycin, or various oral macrolides or azalides. The individual who has had an attack of rheumatic fever is at very high risk of developing recurrences after subsequent GAS pharyngitis and needs continuous antimicrobial prophylaxis to prevent such recurrences (secondary prevention). The recommended duration of prophylaxis depends on the number of previous attacks, the time elapsed since the last attack, the risk of exposure to GAS infections, the age of the patient, and the presence or absence of cardiac involvement. Penicillin is again the agent of choice for secondary prophylaxis, but sulfadiazine or a macrolide or azalide are acceptable alternatives in penicillin-allergic individuals. This report updates the 1995 statement by the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee. It includes new recommendations for the diagnosis and treatment of GAS pharyngitis, as well as for the secondary prevention of rheumatic fever, and classifies the strength of the recommendations and level of evidence supporting them. World Health Organization's Strategic Advisory Group of Experts (SAGE) on Immunization (5/12)

REPORT OF THE NATIONAL CONSENSUS CONFERENCE ON FAMILY PRESENCE DURING PEDIATRIC CARDIOPULMONARY RESUSCITATION AND PROCEDURES

Ambulatory Pediatric Association

INTRODUCTION. The National Consensus Conference on Family Presence during Pediatric Cardiopulmonary Resuscitation and Procedures was held in Washington, DC, on September 7–8, 2003. The concept, funding, planning and organization for the conference were the Ambulatory Pediatric Association (APA) Presidential Project of James Seidel, M.D., Ph.D. Dr. Seidel was in the final stages of preparation for chairing the conference when he died on July 25, 2003. In Dr. Seidel's absence, the conference was chaired by Deborah Parkman Henderson R.N., PhD, his co-investigator, and Jane F. Knapp, M.D, a colleague.

The National Consensus Conference on Family Presence during Pediatric Procedures and Cardiopulmonary Resuscitation was funded by a grant to the APA from the Maternal Child Health Bureau (MCHB) Partnership for Children. This meeting brought together a panel of over 20 appointed representatives from a multidisciplinary, diverse group of national organizations interested in the emergency care of children. The conference was part of a multiphase process designed with the goal of publishing consensus guidelines useful for defining policy regarding family presence (FP) during pediatric procedures and CPR in the Emergency Department (ED). It is also possible that the consensus panel recommendations could be applied to other settings.

Panel members completed a review of the literature prior to attending the conference. This review, along with results of a pre-conference questionnaire, formed the basis of the discussion during the conference. During the two day conference the participants completed the outline of the guidelines presented here. We believe these recommendations are a powerful testimony to Dr. Seidel's vision for promoting FP through multidisciplinary consensus building. Beyond that vision, however, we hope that the guidelines will make a difference in improving the quality of children's health care. (9/03)

SCREENING FOR IDIOPATHIC SCOLIOSIS IN ADOLESCENTS
Pediatric Orthopaedic Society of North America, American Academy of Orthopaedic Surgeons, and Scoliosis Research Society
EXECUTIVE SUMMARY. Many states mandate school screening to identify children at risk for scoliosis, though recent studies have cast some controversy on the effectiveness of routine scoliosis screening. Previous studies have both supported and discouraged routine screening.

Prevention of severe scoliosis is a major commitment of physicians caring for children with spinal deformities. For this reason, the American Academy of Orthopaedic Surgeons (AAOS), the Scoliosis Research Society (SRS), the Pediatric Orthopaedic Society of North America (POSNA), and the American Academy of Pediatrics (AAP) convened a task force to examine issues related to scoliosis screening and to put forth the present information statement. The societies acknowledge the important role of a systematic review of the literature as well as the role of consensus expert opinion in the common situation where the available evidence does not yet exist to speak definitely for, or against, an evaluation or intervention.

Costs involved with scoliosis screening are relatively low on a societal level and may justify the possibility of preventing surgery in adolescents with scoliosis. Adolescents without significant spinal deformity who are referred to a specialist for evaluation often do not require radiographs. For those who do need radiographic evaluation, it is important to know that the radiation exposure using current-day radiographic techniques, including digital radiography, is significantly smaller than in the past.

Opponents to scoliosis screening have focused on concerns about a low predictive value of screening and the cost-effectiveness of referral. There have also been concerns about the possibility of unnecessary treatment, including brace use, and the effect of exposure to radiation when radiographs are obtained.

With regard to early treatment in those adolescents detected with moderate scoliosis, the available data neither definitively support nor refute the efficacy of bracing. To most effectively answer this, a well-organized level I study is needed. Such a study, a five-year multicenter randomized controlled trial of bracing sponsored by the National Institutes of Health/National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIH/NIAMS), is currently under way.

In 1996, the United States Preventive Services Task Force (USPSTF) concluded that there was insufficient evidence to make a recommendation for, or against, screening. However, in 2004, the USPSTF changed their position and recommended against the routine screening of asymptomatic adolescents for idiopathic scoliosis. The AAOS, SRS, POSNA, and AAP have concerns that this change in position by the USPSTF came in the absence of any significant change in the available literature, in the absence of any change in position statements by the AAOS, SRS, POSNA, and AAP, and in the absence of any significant input from specialists who commonly care for children with scoliosis.

As the primary care providers for adolescents with idiopathic scoliosis, the AAOS, SRS, POSNA, and AAP do not support any recommendation against scoliosis screening, given the available literature. (1/08)

SELECTED ISSUES FOR THE ADOLESCENT ATHLETE AND THE TEAM PHYSICIAN: A CONSENSUS STATEMENT
American Academy of Family Physicians, American Academy of Orthopaedic Surgeons, American College of Sports Medicine, American Medical Society for Sports Medicine, American Orthopaedic Society for Sports Medicine, and American Osteopathic Academy of Sports Medicine
GOAL. The goal of this document is to help the team physician improve the care of the adolescent athlete by understanding the medical, musculoskeletal and psychological factors common in this age group. To accomplish this goal, the team physician should have knowledge of and be involved with:

- Musculoskeletal injuries of the adolescent athlete, specifically those to the shoulder, knee, elbow and spine
- Medical conditions of the adolescent athlete, especially those pertaining to infectious diseases, concussion, and nutrition and supplementation
- Psychological issues related to sports specialization and overtraining. (11/08)

SKIING AND SNOWBOARDING INJURY PREVENTION
Canadian Paediatric Society
ABSTRACT. Skiing and snowboarding are popular recreational and competitive sport activities for children and youth. Injuries associated with both activities are frequent and can be serious. There is new evidence documenting the benefit of wearing helmets while skiing and snowboarding, as well as data refuting suggestions that helmet use may increase the risk of neck injury. There is also evidence to support using wrist guards while snowboarding. There is poor uptake of effective preventive measures such as protective equipment use and related policy. Physicians should have the information required to counsel children, youth and families regarding safer snow sport participation, including helmet use, wearing wrist guards for snowboarding, training and supervision, the importance of proper equipment fitting and binding adjustment, sun safety and avoiding substance use while on the slopes. (1/12)

SUPPLEMENT TO THE JCIH 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY INTERVENTION AFTER CONFIRMATION THAT A CHILD IS DEAF OR HARD OF HEARING
Joint Committee on Infant Hearing
PREFACE. This document is a supplement to the recommendations in the year 2007 position statement of the Joint Committee on Infant Hearing (JCIH) and provides comprehensive guidelines for early hearing detection and intervention (EHDI) programs on establishing strong early intervention (EI) systems with appropriate expertise to meet the needs of children who are deaf or hard of hearing (D/HH).

EI services represent the purpose and goal of the entire EHDI process. Screening and confirmation that a child is D/HH are largely meaningless without appropriate, individualized, targeted and high-quality intervention. For the infant or young child who is D/HH to reach his or her full potential, carefully designed individualized intervention must be implemented promptly, utilizing service providers with optimal knowledge and skill levels and providing services on the basis of research, best practices, and proven models.

The delivery of EI services is complex and requires individualization to meet the identified needs of the child and family. Because of the diverse needs of the population of children who are D/HH and their families, well-controlled intervention studies are challenging. At this time, few comparative effectiveness studies have been conducted. Randomized controlled trials are particularly difficult for ethical reasons, making it challenging to establish causal links between interventions and outcomes. EI systems must partner with colleagues in research to document what works for children and families and to strengthen the evidence base supporting practices.

Despite limitations and gaps in the evidence, the literature does contain research studies in which all children who were D/HH had access to the same well-defined EI service. These studies indicate that positive outcomes are possible, and they provide guidance about key program components that appear to promote these outcomes. This EI services document, drafted by teams of professionals with extensive expertise in EI programs for children who are D/HH and their families, relied on literature searches, existing systematic reviews, and recent professional consensus statements in developing this set of guidelines.

Terminology presented a challenge throughout document development. The committee noted that many of the frequently occurring terms necessary within the supplement may not reflect the most contemporary understanding and/or could convey inaccurate meaning. Rather than add to the lack of clarity or consensus and to avoid introducing new terminology to stakeholders, the committee opted to use currently recognized terms consistently herein and will monitor the emergence and/or development of new descriptors before the next JCIH consensus statement.

For purposes of this supplement:

- Language refers to all spoken and signed languages.
- Early intervention (EI), according to part C of the Individuals with Disabilities Education Improvement Act (IDEA) of 2004, is the process of providing services, education, and support to young children who are deemed to have an established condition, those who are evaluated and deemed to have a diagnosed physical or mental condition (with a high probability of resulting in a developmental delay), those who have an existing delay, or those who are at risk of developing a delay or special need that may affect their development or impede their education.
- Communication is used in lieu of terms such as communication options, methods, opportunities, approaches, etc.
- Deaf or hard of hearing (D/HH) is intended to be inclusive of all children with congenital and acquired hearing loss, unilateral and bilateral hearing loss, all degrees of hearing loss from minimal to profound, and all types of hearing loss (sensorineural, auditory neuropathy spectrum disorder, permanent conductive, and mixed).
- Core knowledge and skills is used to describe the expertise needed to provide appropriate EI that will optimize the development and well-being of infants/children and their families. Core knowledge and skills will differ according to the roles of individuals within the EI system (eg, service coordinator or EI provider).

This supplement to JCIH 2007 focuses on the practices of EI providers outside of the primary medical care and specialty medical care realms, rather than including the full spectrum of necessary medical, audiologic, and educational interventions. For more information about the recommendations for medical follow-up, primary care surveillance for related medical conditions, and specialty medical care and monitoring, the reader is encouraged to reference the year 2007 position statement of the JCIH as well as any subsequent revision. When an infant is confirmed to be D/HH, the importance of ongoing medical and audiologic management and surveillance both in the medical home and with the hearing health professionals, the otolaryngologist and the audiologist, cannot be overstated. A comprehensive discussion of those services is beyond the scope of this document. (3/13)

TARGETED TUBERCULIN TESTING AND TREATMENT OF LATENT TUBERCULOSIS INFECTION

American Thoracic Society and Centers for Disease Control and Prevention (4/00) *(The AAP endorses and accepts as its policy the sections of this statement as they relate to infants and children.)*

TIMING OF UMBILICAL CORD CLAMPING AFTER BIRTH

American College of Obstetricians and Gynecologists Committee on Obstetric Practice (12/12)

TYPE 2 DIABETES IN CHILDREN AND ADOLESCENTS

American Diabetes Association (3/00)

UPDATE ON JAPANESE ENCEPHALITIS VACCINE FOR CHILDREN—UNITED STATES, MAY 2011

Centers for Disease Control and Prevention

Inactivated mouse brain-derived Japanese encephalitis (JE) vaccine (JE-MB [manufactured as JE-Vax]), the only JE vaccine that is licensed for use in children in the United States, is no longer available. This notice provides updated information regarding options for obtaining JE vaccine for U.S. children. (8/11)

WEIGHING PEDIATRIC PATIENTS IN KILOGRAMS

Emergency Nurses Association (3/12)

Appendix 1

Policies by Committee

AMERICAN ACADEMY OF PEDIATRICS

Policies by Committee

BLACK BOX WORKING GROUP

Cardiovascular Monitoring and Stimulant Drugs for Attention-Deficit/Hyperactivity Disorder (joint with Section on Cardiology and Cardiac Surgery), 8/08

BOARD OF DIRECTORS

Ritual Genital Cutting of Female Minors, 6/10

BRIGHT FUTURES STEERING COMMITTEE

Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening (joint with Council on Children With Disabilities, Section on Developmental and Behavioral Pediatrics, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee), 7/06, reaffirmed 12/09

Recommendations for Preventive Pediatric Health Care (joint with Committee on Practice and Ambulatory Medicine), 12/07, reaffirmed 1/11

CHILD AND ADOLESCENT HEALTH ACTION GROUP (FORMERLY COUNCIL ON CHILD AND ADOLESCENT HEALTH)

Age Limits of Pediatrics, 5/88, reaffirmed 9/92, 1/97, 3/02, 1/06, 10/11

The Role of Home-Visitation Programs in Improving Health Outcomes for Children and Families, 3/98, reaffirmed 5/01

COMMITTEE ON ADOLESCENCE

Achieving Quality Health Services for Adolescents, 6/08, reaffirmed 3/13

Adolescent Pregnancy: Current Trends and Issues (Clinical Report), 7/05

Adolescents and Human Immunodeficiency Virus Infection: The Role of the Pediatrician in Prevention and Intervention (joint with Committee on Pediatric AIDS), 1/01, reaffirmed 10/03, 1/05

The Adolescent's Right to Confidential Care When Considering Abortion, 5/96, reaffirmed 5/99, 11/02

Care of Adolescent Parents and Their Children (Clinical Report) (joint with Committee on Early Childhood), 11/12

Care of the Adolescent Sexual Assault Victim (Clinical Report), 8/08

Collaborative Role of the Pediatrician in the Diagnosis and Management of Bipolar Disorder in Adolescents (Clinical Report), 11/12

Condom Use by Adolescents, 10/13

Confidentiality in Adolescent Health Care, 4/89, reaffirmed 1/93, 11/97, 5/00, 5/04

Contraception and Adolescents, 11/07

Counseling the Adolescent About Pregnancy Options, 5/98, reaffirmed 1/01, 1/06

Emergency Contraception, 11/12

Excessive Sleepiness in Adolescents and Young Adults: Causes, Consequences, and Treatment Strategies (Technical Report) (joint with Working Group on Sleepiness in Adolescents/Young Adults), 6/05

Gynecologic Examination for Adolescents in the Pediatric Office Setting (Clinical Report), 8/10, reaffirmed 5/13

Health Care for Youth in the Juvenile Justice System, 11/11

Identification and Management of Eating Disorders in Children and Adolescents (Clinical Report), 11/10

Legalization of Marijuana: Potential Impact on Youth (joint with Committee on Substance Abuse), 6/04

Legalization of Marijuana: Potential Impact on Youth (Technical Report) (joint with Committee on Substance Abuse), 6/04

Male Adolescent Sexual and Reproductive Health Care (Clinical Report), 11/11

Menstruation in Girls and Adolescents: Using the Menstrual Cycle as a Vital Sign (Clinical Report) (joint with American College of Obstetricians and Gynecologists), 11/06

Office-Based Care for Lesbian, Gay, Bisexual, Transgender, and Questioning Youth, 6/13

Office-Based Care for Lesbian, Gay, Bisexual, Transgender, and Questioning Youth (Technical Report), 6/13

Secondhand and Prenatal Tobacco Smoke Exposure (Technical Report) (joint with Committee on Environmental Health and Committee on Native American Child Health), 10/09

Sexual Orientation and Adolescents (Clinical Report), 6/04

Sexuality Education for Children and Adolescents (joint with Committee on Psychosocial Aspects of Child and Family Health), 8/01, reaffirmed 10/04

Standards for Health Information Technology to Ensure Adolescent Privacy (joint with Council on Clinical Information Technology), 10/12

Suicide and Suicide Attempts in Adolescents (Clinical Report), 9/07

The Teen Driver (joint with Committee on Injury, Violence, and Poison Prevention), 12/06, reaffirmed 6/10

Tobacco Use: A Pediatric Disease (joint with Committee on Environmental Health, Committee on Substance Abuse, and Committee on Native American Child Health), 10/09

Underinsurance of Adolescents: Recommendations for Improved Coverage of Preventive, Reproductive, and Behavioral Health Care Services (joint with Committee on Child Health Financing), 12/08

COMMITTEE ON BIOETHICS

Children as Hematopoietic Stem Cell Donors, 1/10

Communicating With Children and Families: From Everyday Interactions to Skill in Conveying Distressing Information (Technical Report), 5/08, reaffirmed 5/11

Conflicts Between Religious or Spiritual Beliefs and Pediatric Care: Informed Refusal, Exemptions, and Public Funding, 10/13

Consent for Emergency Medical Services for Children and Adolescents (joint with Committee on Pediatric Emergency Medicine), 7/11

Do-Not-Resuscitate Orders for Pediatric Patients Who Require Anesthesia and Surgery (Clinical Report) (joint with Section on Surgery and Section on Anesthesia and Pain Medicine), 12/04, reaffirmed 1/09, 10/12

Ethical Controversies in Organ Donation After Circulatory Death, 4/13

Ethical Issues With Genetic Testing in Pediatrics, 6/01, reaffirmed 1/05, 1/09

Ethical and Policy Issues in Genetic Testing and Screening of Children (joint with Committee on Genetics and American College of Medical Genetics and Genomics), 2/13

Ethics and the Care of Critically Ill Infants and Children, 7/96, reaffirmed 10/99, 6/03

Forgoing Life-Sustaining Medical Treatment in Abused Children (joint with Committee on Child Abuse and Neglect), 11/00, reaffirmed 6/03, 10/06, 4/09

Forgoing Medically Provided Nutrition and Hydration in Children (Clinical Report), 7/09

Guidelines on Forgoing Life-Sustaining Medical Treatment, 3/94, reaffirmed 11/97, 10/00, 1/04, 1/09, 10/12

Honoring Do-Not-Attempt-Resuscitation Requests in Schools (joint with Council on School Health), 4/10, reaffirmed 7/13

Human Embryonic Stem Cell (hESC) and Human Embryo Research (joint with Committee on Pediatric Research), 10/12

Informed Consent, Parental Permission, and Assent in Pediatric Practice, 2/95, reaffirmed 11/98, 11/02, 10/06, 5/11

Institutional Ethics Committees, 1/01, reaffirmed 1/04, 1/09, 10/12

Maternal-Fetal Intervention and Fetal Care Centers (Clinical Report) (joint with American College of Obstetricians and Gynecologists), 7/11

Minors as Living Solid-Organ Donors (Clinical Report), 8/08, reaffirmed 5/11

Palliative Care for Children (joint with Committee on Hospital Care), 8/00, reaffirmed 6/03, 10/06, 2/12

Pediatrician-Family-Patient Relationships: Managing the Boundaries, 11/09

Physician Refusal to Provide Information or Treatment on the Basis of Claims of Conscience, 11/09

Preservation of Fertility in Pediatric and Adolescent Patients With Cancer (Technical Report) (joint with Section on Hematology/Oncology and Section on Surgery), 5/08, reaffirmed 2/12

Professionalism in Pediatrics: Statement of Principles, 10/07, reaffirmed 5/11

Professionalism in Pediatrics (Technical Report), 10/07, reaffirmed 5/11

Religious Objections to Medical Care, 2/97, reaffirmed 10/00, 6/03, 10/06, 5/09

Responding to Parental Refusals of Immunization of Children (Clinical Report), 5/05, reaffirmed 1/09

COMMITTEE ON CHILD ABUSE AND NEGLECT

Abusive Head Trauma in Infants and Children, 4/09, reaffirmed 3/13

Caregiver-Fabricated Illness in a Child: A Manifestation of Child Maltreatment (Clinical Report), 8/13

Child Abuse, Confidentiality, and the Health Insurance Portability and Accountability Act, 12/09

Child Fatality Review (joint with Committee on Injury, Violence, and Poison Prevention and Council on Community Pediatrics), 8/10

Distinguishing Sudden Infant Death Syndrome From Child Abuse Fatalities (Clinical Report) (joint with National Association of Medical Examiners), 7/06, reaffirmed 4/09, 3/13

Evaluating Infants and Young Children With Multiple Fractures (Clinical Report), 9/06

Evaluating for Suspected Child Abuse: Conditions That Predispose to Bleeding (Technical Report) (joint with Section on Hematology/Oncology), 3/13

Evaluation for Bleeding Disorders in Suspected Child Abuse (Clinical Report) (joint with Section on Hematology/Oncology), 3/13

The Evaluation of Children in the Primary Care Setting When Sexual Abuse Is Suspected (Clinical Report), 7/13

The Evaluation of Sexual Behaviors in Children (Clinical Report), 8/09, reaffirmed 3/13

Evaluation of Suspected Child Physical Abuse (Clinical Report), 6/07, reaffirmed 5/12

The Eye Examination in the Evaluation of Child Abuse (Clinical Report) (joint with Section on Ophthalmology), 7/10

Failure to Thrive as a Manifestation of Child Neglect (Clinical Report) (joint with Committee on Nutrition), 11/05, reaffirmed 1/09

Forgoing Life-Sustaining Medical Treatment in Abused Children (joint with Committee on Bioethics), 11/00, reaffirmed 6/03, 10/06, 4/09

Intimate Partner Violence: The Role of the Pediatrician (Clinical Report) (joint with Committee on Injury, Violence, and Poison Prevention), 4/10

Maltreatment of Children With Disabilities (Clinical Report) (joint with Council on Children With Disabilities), 5/07, reaffirmed 1/11

Oral and Dental Aspects of Child Abuse and Neglect (Clinical Report) (joint with American Academy of Pediatric Dentistry), 12/05, reaffirmed 1/09

The Pediatrician's Role in Child Maltreatment Prevention (Clinical Report), 9/10

Protecting Children From Sexual Abuse by Health Care Providers, 6/11

Psychological Maltreatment (Clinical Report) (joint with American Academy of Child and Adolescent Psychiatry), 7/12

Recognizing and Responding to Medical Neglect (Clinical Report), 12/07, reaffirmed 1/11

Understanding the Behavioral and Emotional Consequences of Child Abuse (Clinical Report) (joint with Section on Adoption and Foster Care, American Academy of Child and Adolescent Psychiatry, and National Center for Child Traumatic Stress), 9/08

When Is Lack of Supervision Neglect? (Clinical Report), 9/06

COMMITTEE ON CHILD HEALTH FINANCING

Essential Contractual Language for Medical Necessity in Children, 7/13

Financing of Pediatric Home Health Care (joint with Section on Home Care), 8/06

Guiding Principles for Managed Care Arrangements for the Health Care of Newborns, Infants, Children, Adolescents, and Young Adults, 10/13

High-Deductible Health Plans and the New Risks of Consumer-Driven Health Insurance Products, 3/07

Implementation Principles and Strategies for the State Children's Health Insurance Program, 5/01

Improving Substance Abuse Prevention, Assessment, and Treatment Financing for Children and Adolescents (joint with Committee on Substance Abuse), 10/01

Medicaid Policy Statement, 4/13

Model Contractual Language for Medical Necessity for Children, 7/05, reaffirmed 10/11

Payment for Telephone Care (joint with Section on Telephone Care), 10/06

Principles of Health Care Financing, 10/10, reaffirmed 4/13

Scope of Health Care Benefits for Children From Birth Through Age 26, 11/11

State Children's Health Insurance Program Achievements, Challenges, and Policy Recommendations, 6/07

Underinsurance of Adolescents: Recommendations for Improved Coverage of Preventive, Reproductive, and Behavioral Health Care Services (joint with Committee on Adolescence), 12/08

COMMITTEE ON CODING AND NOMENCLATURE

Application of the Resource-Based Relative Value Scale System to Pediatrics, 12/08

COMMITTEE ON DRUGS

Fever and Antipyretic Use in Children (Clinical Report) (joint with Section on Clinical Pharmacology and Therapeutics), 2/11

Generic Prescribing, Generic Substitution, and Therapeutic Substitution, 5/87, reaffirmed 6/93, 5/96, 6/99, 5/01, 5/05, 10/08, 10/12

Guidelines for the Ethical Conduct of Studies to Evaluate Drugs in Pediatric Populations (Clinical Report) (joint with Committee on Pediatric Research), 3/10

Neonatal Drug Withdrawal (Clinical Report) (joint with Committee on Fetus and Newborn), 1/12

Preparing for Pediatric Emergencies: Drugs to Consider (Clinical Report), 2/08, reaffirmed 10/11

Recognition and Management of Iatrogenically Induced Opioid Dependence and Withdrawal in Children (Clinical Report) (joint with Section on Anesthesiology and Pain Medicine), 12/13

The Transfer of Drugs and Therapeutics Into Human Breast Milk: An Update on Selected Topics (Clinical Report), 8/13

Use of Codeine- and Dextromethorphan-Containing Cough Remedies in Children, 6/97, reaffirmed 5/00, 6/03, 10/06

Uses of Drugs Not Described in the Package Insert (Off-Label Uses), 7/02, reaffirmed 10/05

COMMITTEE ON FETUS AND NEWBORN

Advanced Practice in Neonatal Nursing, 5/09

Age Terminology During the Perinatal Period, 11/04, reaffirmed 10/07, 11/08, 1/09

Antenatal Counseling Regarding Resuscitation at an Extremely Low Gestational Age (Clinical Report), 6/09

The Apgar Score (joint with American College of Obstetricians and Gynecologists), 4/06, reaffirmed 1/09

Assessment and Management of Inguinal Hernia in Infants (Clinical Report) (joint with Section on Surgery), 9/12

Controversies Concerning Vitamin K and the Newborn, 7/03, reaffirmed 5/06, 5/09

Epidemiology and Diagnosis of Health Care–Associated Infections in the NICU (Technical Report) (joint with Committee on Infectious Diseases), 3/12

Guidance on Management of Asymptomatic Neonates Born to Women With Active Genital Herpes Lesions (Clinical Report) (joint with Committee on Infectious Diseases), 1/13

Hospital Discharge of the High-Risk Neonate, 11/08, reaffirmed 5/11

Hospital Stay for Healthy Term Newborns, 1/10

Human Immunodeficiency Virus Screening (joint with Committee on Pediatric AIDS and American College of Obstetricians and Gynecologists), 7/99, reaffirmed 6/02, 5/05, 10/08, 5/12

"Late-Preterm" Infants: A Population at Risk (Clinical Report), 12/07, reaffirmed 5/10

Levels of Neonatal Care, 8/12

Management of Neonates With Suspected or Proven Early-Onset Bacterial Sepsis (Clinical Report), 4/12

Neonatal Drug Withdrawal (Clinical Report) (joint with Committee on Drugs), 1/12

Noninitiation or Withdrawal of Intensive Care for High-Risk Newborns, 2/07, reaffirmed 5/10

Phototherapy to Prevent Severe Neonatal Hyperbilirubinemia in the Neonate Infant 35 or More Weeks of Gestation (Technical Report), 9/11

Planned Home Birth, 4/13

Postdischarge Follow-up of Infants With Congenital Diaphragmatic Hernia (Clinical Report) (joint with Section on Surgery), 3/08, reaffirmed 5/11

Postnatal Corticosteroids to Prevent or Treat Bronchopulmonary Dysplasia, 9/10

Postnatal Glucose Homeostasis in Late-Preterm and Term Infants (Clinical Report), 3/11

Premedication for Nonemergency Endotracheal Intubation in the Neonate (Clinical Report) (joint with Section on Anesthesiology and Pain Medicine), 2/10, reaffirmed 8/13

Prenatal Substance Abuse: Short- and Long-term Effects on the Exposed Fetus (Technical Report) (joint with Committee on Substance Abuse), 2/13

Prevention and Management of Pain in the Neonate: An Update (joint with Section on Surgery and Canadian Paediatric Society), 11/06, reaffirmed 5/10

Recommendations for the Prevention of Perinatal Group B Streptococcal (GBS) Disease (joint with Committee on Infectious Diseases), 8/11

Respiratory Support in Preterm Infants at Birth, 12/13

Role of Pulse Oximetry in Examining Newborns for Congenital Heart Disease: A Scientific Statement from the AHA and AAP (joint with Section on Cardiology and Cardiac Surgery and American Heart Association Congenital Heart Defects Committee of the Council on Cardiovascular Disease in the Young, Council on Cardiovascular Nursing, and Interdisciplinary Council on Quality of Care and Outcomes Research), 8/09

Safe Transportation of Preterm and Low Birth Weight Infants at Hospital Discharge (Clinical Report) (joint with Committee on Injury, Violence, and Poison Prevention), 4/09, reaffirmed 8/13

Standard Terminology for Fetal, Infant, and Perinatal Deaths (Clinical Report), 6/11

Strategies for Prevention of Health Care–Associated Infections in the NICU (Clinical Report) (joint with Committee on Infectious Diseases), 3/12

Surfactant Replacement Therapy for Preterm and Term Neonates With Respiratory Distress (Clinical Report), 12/13

Use of Inhaled Nitric Oxide, 8/00, reaffirmed 4/03, 12/09

Use of Inhaled Nitric Oxide in Preterm Infants (Clinical Report), 12/13

COMMITTEE ON GENETICS

Clinical Genetic Evaluation of the Child With Mental Retardation or Developmental Delays (Clinical Report), 6/06, reaffirmed 5/12

Congenital Adrenal Hyperplasia (Technical Report) (joint with Section on Endocrinology), 12/00, reaffirmed 10/04

Ethical and Policy Issues in Genetic Testing and Screening of Children (joint with Committee on Bioethics and American College of Medical Genetics and Genomics), 2/13

Folic Acid for the Prevention of Neural Tube Defects, 8/99, reaffirmed 11/02, 1/07, 5/12

Health Care Supervision for Children With Williams Syndrome, 5/01, reaffirmed 5/05, 1/09

Health Supervision for Children With Achondroplasia (Clinical Report), 9/05, reaffirmed 5/12

Health Supervision for Children With Down Syndrome (Clinical Report), 7/11

Health Supervision for Children With Fragile X Syndrome (Clinical Report), 4/11

Health Supervision for Children With Marfan Syndrome (Clinical Report), 9/13

Health Supervision for Children With Neurofibromatosis (Clinical Report), 3/08

Health Supervision for Children With Prader-Willi Syndrome (Clinical Report), 12/10

Health Supervision for Children With Sickle Cell Disease (joint with Section on Hematology/Oncology), 3/02, reaffirmed 1/06, 1/11

Maternal Phenylketonuria, 8/08, reaffirmed 1/13

Molecular Genetic Testing in Pediatric Practice: A Subject Review (Clinical Report), 12/00, reaffirmed 5/07

Newborn Screening Fact Sheets, Introduction to the (Technical Report), 9/06, reaffirmed 1/11

Newborn Screening Fact Sheets (Technical Report), 9/06, reaffirmed 1/11

Update of Newborn Screening and Therapy for Congenital Hypothyroidism (Clinical Report) (joint with Section on Endocrinology, American Thyroid Association, and Lawson Wilkins Pediatric Endocrine Society), 6/06, reaffirmed 12/11

COMMITTEE ON HOSPITAL CARE

Admission and Discharge Guidelines for the Pediatric Patient Requiring Intermediate Care (Clinical Report) (joint with Section on Critical Care and Society of Critical Care Medicine), 5/04, reaffirmed 2/08, 1/13

Child Life Services (joint with Child Life Council), 10/06, reaffirmed 2/12

Facilities and Equipment for the Care of Pediatric Patients in a Community Hospital (Clinical Report), 5/03, reaffirmed 5/07, 8/13

Guidelines for Developing Admission and Discharge Policies for the Pediatric Intensive Care Unit (Clinical Report) (joint with Section on Critical Care and Society of Critical Care Medicine), 4/99, reaffirmed 5/05, 2/08, 1/13

Medical Staff Appointment and Delineation of Pediatric Privileges in Hospitals (Clinical Report) (joint with Section on Hospital Medicine), 3/12

Palliative Care for Children (joint with Committee on Bioethics), 8/00, reaffirmed 6/03, 10/06, 2/12

Patient- and Family-Centered Care and the Pediatrician's Role (joint with Institute for Patient- and Family-Centered Care), 1/12

Pediatric Observation Units (Clinical Report) (joint with Committee on Pediatric Emergency Medicine), 6/12

Pediatric Organ Donation and Transplantation (joint with Section on Surgery and Section on Critical Care), 3/10

Pediatric Palliative Care and Hospice Care Commitments, Guidelines, and Recommendations (joint with Section on Hospice and Palliative Medicine), 10/13

Physicians' Roles in Coordinating Care of Hospitalized Children (Clinical Report) (joint with Section on Hospital Medicine), 9/10

Precertification Process, 8/00, reaffirmed 5/05, 11/08

Principles of Pediatric Patient Safety: Reducing Harm Due to Medical Care (joint with Steering Committee on Quality Improvement and Management), 5/11

COMMITTEE ON INFECTIOUS DISEASES

Additional Recommendations for Use of Tetanus Toxoid, Reduced Content Diphtheria Toxoid, and Acellular Pertussis Vaccine (Tdap), 9/11

Antiviral Therapy and Prophylaxis for Influenza in Children (Clinical Report), 4/07, reaffirmed 7/10

Chemical-Biological Terrorism and Its Impact on Children (joint with Committee on Environmental Health), 9/06, reaffirmed 1/11

Clostridium difficile Infection in Infants and Children, 12/12

Cochlear Implants in Children: Surgical Site Infections and Prevention and Treatment of Acute Otitis Media and Meningitis (joint with Section on Otolaryngology–Head and Neck Surgery), 7/10

Consumption of Raw or Unpasteurized Milk and Milk Products by Pregnant Women and Children (joint with Committee on Nutrition), 12/13

Drinking Water From Private Wells and Risks to Children (joint with Committee on Environmental Health), 5/09, reaffirmed 1/13

Drinking Water From Private Wells and Risks to Children (Technical Report) (joint with Committee on Environmental Health), 5/09, reaffirmed 1/13

Epidemiology and Diagnosis of Health Care–Associated Infections in the NICU (Technical Report) (joint with Committee on Fetus and Newborn), 3/12

Exposure to Nontraditional Pets at Home and to Animals in Public Settings: Risks to Children (Clinical Report), 10/08, reaffirmed 12/11

Guidance on Management of Asymptomatic Neonates Born to Women With Active Genital Herpes Lesions (Clinical Report) (joint with Committee on Fetus and Newborn), 1/13

Head Lice (Clinical Report) (joint with Council on School Health), 7/10

HPV Vaccine Recommendations, 2/12

Immunizing Parents and Other Close Family Contacts in the Pediatric Office Setting (Technical Report) (joint with Committee on Practice and Ambulatory Medicine), 12/11

Infection Prevention and Control in Pediatric Ambulatory Settings, 9/07, reaffirmed 8/10

Meningococcal Conjugate Vaccines Policy Update: Booster Dose Recommendations, 11/11

Nontherapeutic Use of Antimicrobial Agents in Animal Agriculture: Implications for Pediatrics (Technical Report) (joint with Committee on Environmental Health), 9/04, reaffirmed 10/08, 4/13

Poliovirus, 9/11

Prevention of Rotavirus Disease: Updated Guidelines for Use of Rotavirus Vaccine, 3/09

Prevention of Varicella: Update of Recommendations for Use of Quadrivalent and Monovalent Varicella Vaccines in Children, 8/11

Principles of Judicious Antibiotic Prescribing for Upper Respiratory Tract Infections in Pediatrics (Clinical Report), 11/13

Rabies-Prevention Policy Update: New Reduced-Dose Schedule, 3/11

Recommendation for Mandatory Influenza Immunization of All Health Care Personnel, 9/10

Recommendations for Administering Hepatitis A Vaccine to Contacts of International Adoptees, 9/11

Recommendations for Prevention and Control of Influenza in Children, 2013–2014, 9/13

Recommendations for the Prevention of Perinatal Group B Streptococcal (GBS) Disease (joint with Committee on Fetus and Newborn), 8/11

Recommendations for the Prevention of *Streptococcus pneumoniae* Infections in Infants and Children: Use of 13-Valent Pneumococcal Conjugate Vaccine (PCV13) and Pneumococcal Polysaccharide Vaccine (PPSV23), 5/10

Recommended Childhood and Adolescent Immunization Schedule—United States, 2014, 1/14

Strategies for Prevention of Health Care–Associated Infections in the NICU (Clinical Report) (joint with Committee on Fetus and Newborn), 3/12

The Use of Systemic and Topical Fluoroquinolones (Clinical Report), 9/11

COMMITTEE ON MEDICAL LIABILITY AND RISK MANAGEMENT

Consent by Proxy for Nonurgent Pediatric Care (Clinical Report), 10/10

Dealing With the Parent Whose Judgment Is Impaired by Alcohol or Drugs: Legal and Ethical Considerations (Clinical Report), 9/04, reaffirmed 9/10

Expert Witness Participation in Civil and Criminal Proceedings, 6/09

The Pediatrician and Disaster Preparedness (joint with Committee on Pediatric Emergency Medicine and Task Force on Terrorism), 2/06, reaffirmed 6/09, 9/13

Professional Liability Insurance and Medicolegal Education for Pediatric Residents and Fellows, 8/11

COMMITTEE ON NATIVE AMERICAN CHILD HEALTH

Early Childhood Caries in Indigenous Communities (joint with Canadian Paediatric Society), 5/11

Ethical Considerations in Research With Socially Identifiable Populations (joint with Committee on Community Health Services), 1/04, reaffirmed 10/07, 1/13

Health Equity and Children's Rights (joint with Council on Community Pediatrics), 3/10, reaffirmed 10/13

Inhalant Abuse (Clinical Report) (joint with Committee on Substance Abuse), 5/07

Prevention and Treatment of Type 2 Diabetes Mellitus in Children, With Special Emphasis on American Indian and Alaska Native Children (Clinical Report) (joint with Section on Endocrinology), 10/03, reaffirmed 10/08

The Prevention of Unintentional Injury Among American Indian and Alaska Native Children: A Subject Review (Clinical Report) (joint with Committee on Injury and Poison Prevention), 12/99, reaffirmed 5/03, 1/06, 1/09

Secondhand and Prenatal Tobacco Smoke Exposure (Technical Report) (joint with Committee on Environmental Health and Committee on Adolescence), 10/09

Tobacco Use: A Pediatric Disease (joint with Committee on Environmental Health, Committee on Substance Abuse, and Committee on Adolescence), 10/09

COMMITTEE ON NUTRITION

Calcium and Vitamin D Requirements of Enterally Fed Preterm Infants (Clinical Report), 4/13

Consumption of Raw or Unpasteurized Milk and Milk Products by Pregnant Women and Children (joint with Committee on Infectious Diseases), 12/13

Diagnosis and Prevention of Iron Deficiency and Iron-Deficiency Anemia in Infants and Young Children (0–3 Years of Age) (Clinical Report), 10/10

Effects of Early Nutritional Interventions on the Development of Atopic Disease in Infants and Children: The Role of Maternal Dietary Restriction, Breastfeeding, Timing of Introduction of Complementary Foods, and Hydrolyzed Formulas (Clinical Report) (joint with Section on Allergy and Immunology), 1/08

Failure to Thrive as a Manifestation of Child Neglect (Clinical Report) (joint with Committee on Child Abuse and Neglect), 11/05, reaffirmed 1/09

Infant Methemoglobinemia: The Role of Dietary Nitrate in Food and Water (Clinical Report) (joint with Committee on Environmental Health), 9/05, reaffirmed 4/09

Lactose Intolerance in Infants, Children, and Adolescents (Clinical Report), 9/06, reaffirmed 8/12

Organic Foods: Health and Environmental Advantages and Disadvantages (Clinical Report) (joint with Council on Environmental Health), 10/12

Prevention of Pediatric Overweight and Obesity, 8/03, reaffirmed 10/06

Probiotics and Prebiotics in Pediatrics (Clinical Report) (joint with Section on Gastroenterology, Hepatology, and Nutrition), 11/10

Reimbursement for Foods for Special Dietary Use, 5/03, reaffirmed 1/06

Sports Drinks and Energy Drinks for Children and Adolescents: Are They Appropriate? (Clinical Report) (joint with Council on Sports Medicine and Fitness), 5/11

The Use and Misuse of Fruit Juice in Pediatrics, 5/01, reaffirmed 10/06, 8/13

Use of Soy Protein-Based Formulas in Infant Feeding (Clinical Report), 5/08

COMMITTEE ON PEDIATRIC AIDS

Adolescents and HIV Infection: The Pediatrician's Role in Promoting Routine Testing, 10/11

Adolescents and Human Immunodeficiency Virus Infection: The Role of the Pediatrician in Prevention and Intervention (joint with Committee on Adolescence), 1/01, reaffirmed 10/03, 1/05

Diagnosis of HIV-1 Infection in Children Younger Than 18 Months in the United States (Technical Report), 12/07, reaffirmed 4/10

Disclosure of Illness Status to Children and Adolescents With HIV Infection, 1/99, reaffirmed 2/02, 5/05, 1/09, 1/12

Education of Children With Human Immunodeficiency Virus Infection, 6/00, reaffirmed 3/03, 10/06, 4/10, 3/13

Evaluation and Management of the Infant Exposed to HIV-1 in the United States (Clinical Report), 12/08

HIV Testing and Prophylaxis to Prevent Mother-to-Child Transmission in the United States, 11/08, reaffirmed 6/11

Human Immunodeficiency Virus Screening (joint with Committee on Fetus and Newborn and American College of Obstetricians and Gynecologists), 7/99, reaffirmed 6/02, 5/05, 10/08, 5/12

Human Milk, Breastfeeding, and Transmission of Human Immunodeficiency Virus in the United States, 11/95, reaffirmed 11/99, 11/03, 2/08

Human Milk, Breastfeeding, and Transmission of Human Immunodeficiency Virus Type 1 in the United States (Technical Report), 11/03, reaffirmed 1/07

Identification and Care of HIV-Exposed and HIV-Infected Infants, Children, and Adolescents in Foster Care, 7/00, reaffirmed 3/03, 2/08, 6/11

Increasing Antiretroviral Drug Access for Children With HIV Infection (joint with Section on International Child Health), 4/07, reaffirmed 4/10

Infant Feeding and Transmission of Human Immunodeficiency Virus in the United States, 1/13

Postexposure Prophylaxis in Children and Adolescents for Nonoccupational Exposure to Human Immunodeficiency Virus (Clinical Report), 6/03, reaffirmed 1/07, 10/08

Reducing the Risk of HIV Infection Associated With Illicit Drug Use, 2/06, reaffirmed 5/09, 5/12

Surveillance of Pediatric HIV Infection, 2/98, reaffirmed 2/02, 1/06, 1/11

Transitioning HIV-Infected Youth Into Adult Health Care, 6/13

COMMITTEE ON PEDIATRIC EMERGENCY MEDICINE

Access to Optimal Emergency Care for Children, 1/07, reaffirmed 8/10

Consent for Emergency Medical Services for Children and Adolescents (joint with Committee on Bioethics), 7/11

Death of a Child in the Emergency Department (Technical Report), 5/05, reaffirmed 8/13

Death of a Child in the Emergency Department: Joint Statement of the American Academy of Pediatrics and the American College of Emergency Physicians (joint with American College of Emergency Physicians), 10/02, reaffirmed 1/06, 1/09, 8/13

Dispensing Medications at the Hospital Upon Discharge From an Emergency Department (Technical Report), 1/12

Emergency Information Forms and Emergency Preparedness for Children With Special Health Care Needs (joint with Council on Clinical Information Technology and American College of Emergency Physicians Pediatric Emergency Medicine Committee), 3/10

Guidelines for Care of Children in the Emergency Department (joint with American College of Emergency Physicians and Emergency Nurses Association), 9/09, reaffirmed 4/13

Management of Pediatric Trauma (joint with Section on Orthopaedics, Section on Critical Care, Section on Surgery, Section on Transport Medicine, and Pediatric Orthopaedic Society of North America), 4/08, reaffirmed 4/13

Overcrowding Crisis in Our Nation's Emergency Departments: Is Our Safety Net Unraveling?, 9/04, reaffirmed 5/07, 6/11

Patient- and Family-Centered Care of Children in the Emergency Department (Technical Report), 8/08

Patient- and Family-Centered Care and the Role of the Emergency Physician Providing Care to a Child in the Emergency Department (joint with American College of Emergency Physicians), 11/06, reaffirmed 6/09, 10/11

Patient Safety in the Pediatric Emergency Care Setting, 12/07, reaffirmed 6/11

Pediatric and Adolescent Mental Health Emergencies in the Emergency Medical Services System (Technical Report), 4/11

Pediatric Care Recommendations for Freestanding Urgent Care Facilities, 7/05, reaffirmed 1/09, 6/11

Pediatric Mental Health Emergencies in the Emergency Medical Services System (joint with American College of Emergency Physicians), 10/06, reaffirmed 6/09, 4/13

Pediatric Observation Units (Clinical Report) (joint with Committee on Hospital Care), 6/12

The Pediatrician and Disaster Preparedness (joint with Committee on Medical Liability and Task Force on Terrorism), 2/06, reaffirmed 6/09, 9/13

Preparation for Emergencies in the Offices of Pediatricians and Pediatric Primary Care Providers, 7/07, reaffirmed 6/11

Relief of Pain and Anxiety in Pediatric Patients in Emergency Medical Systems (Clinical Report) (joint with Section on Anesthesiology and Pain Medicine), 10/12

The Role of the Pediatrician in Rural Emergency Medical Services for Children, 10/12

Role of Pediatricians in Advocating Life Support Training Courses for Parents and the Public, 12/04, reaffirmed 5/07, 8/10, 8/13

Role of Pediatricians in Advocating Life Support Training Courses for Parents and the Public (Technical Report), 12/04, reaffirmed 5/07, 8/10

Ventricular Fibrillation and the Use of Automated External Defibrillators on Children (joint with Section on Cardiology and Cardiac Surgery), 11/07, reaffirmed 6/11

COMMITTEE ON PEDIATRIC RESEARCH

Guidelines for the Ethical Conduct of Studies to Evaluate Drugs in Pediatric Populations (Clinical Report) (joint with Committee on Drugs), 3/10

Human Embryonic Stem Cell (hESC) and Human Embryo Research (joint with Committee on Bioethics), 10/12

Promoting Education, Mentorship, and Support for Pediatric Research, 6/01, reaffirmed 1/05, 5/08, 10/11

Race/Ethnicity, Gender, Socioeconomic Status—Research Exploring Their Effects on Child Health: A Subject Review (Clinical Report), 6/00, reaffirmed 10/05, 1/09

Racial and Ethnic Disparities in the Health and Health Care of Children (Technical Report), 3/10, reaffirmed 5/13

COMMITTEE ON PEDIATRIC WORKFORCE

Enhancing Pediatric Workforce Diversity and Providing Culturally Effective Pediatric Care: Implications for Practice, Education, and Policy Making, 9/13

Financing Graduate Medical Education to Meet the Needs of Children and the Future Pediatrician Workforce, 4/08, reaffirmed 1/12

Nondiscrimination in Pediatric Health Care, 10/07, reaffirmed 6/11

Pediatric Primary Health Care, 11/93, reaffirmed 6/01, 1/05, 10/07, 9/10

The Pediatrician Workforce: Current Status and Future Prospects (Technical Report), 7/05

Pediatrician Workforce Policy Statement, 7/13

Prevention of Sexual Harassment in the Workplace and Educational Settings, 10/06, reaffirmed 5/09, 1/12

Scope of Practice Issues in the Delivery of Pediatric Health Care, 5/13

COMMITTEE ON PRACTICE AND AMBULATORY MEDICINE

Eye Examination in Infants, Children, and Young Adults by Pediatricians (joint with Section on Ophthalmology, American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology), 4/03, reaffirmed 5/07

Hearing Assessment in Infants and Children: Recommendations Beyond Neonatal Screening (Clinical Report) (joint with Section on Otolaryngology–Head and Neck Surgery), 9/09

Immunization Information Systems, 9/06, reaffirmed 10/11

Immunizing Parents and Other Close Family Contacts in the Pediatric Office Setting (Technical Report) (joint with Committee on Infectious Diseases), 12/11

Increasing Immunization Coverage (joint with Council on Community Pediatrics), 5/10

Instrument-Based Pediatric Vision Screening Policy Statement (joint with Section on Ophthalmology, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 10/12

Prevention and Management of Positional Skull Deformities in Infants (Clinical Report) (joint with Section on Neurological Surgery), 11/11

Principles for the Development and Use of Quality Measures (joint with Steering Committee on Quality Improvement and Management), 2/08

Recommendations for Preventive Pediatric Health Care (joint with Bright Futures Steering Committee), 12/07, reaffirmed 1/11

Use of Chaperones During the Physical Examination of the Pediatric Patient, 4/11

COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH

The Child in Court: A Subject Review (Clinical Report), 11/99, reaffirmed 11/02

Coparent or Second-Parent Adoption by Same-Sex Parents, 2/02, reaffirmed 5/09

Coparent or Second-Parent Adoption by Same-Sex Parents (Technical Report), 2/02, reaffirmed 5/09

Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health (joint with Committee on Early Childhood, Adoption, and Dependent Care and Section on Developmental and Behavioral Pediatrics), 12/11

Fathers and Pediatricians: Enhancing Men's Roles in the Care and Development of Their Children (Clinical Report), 5/04, reaffirmed 8/13

The Future of Pediatrics: Mental Health Competencies for Pediatric Primary Care (joint with Task Force on Mental Health), 6/09, reaffirmed 8/13

Guidance for Effective Discipline, 4/98, reaffirmed 3/01, 1/05, 5/12

Health and Mental Health Needs of Children in US Military Families (Clinical Report) (joint with Section on Uniformed Services), 5/13

Helping Children and Families Deal With Divorce and Separation (Clinical Report), 11/02, reaffirmed 1/06

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bonds (Clinical Report) (joint with Committee on Communications), 1/07

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bond: Focus on Children in Poverty (Clinical Report) (joint with Council on Communications and Media), 12/11

Incorporating Recognition and Management of Perinatal and Postpartum Depression Into Pediatric Practice (Clinical Report), 10/10

The Lifelong Effects of Early Childhood Adversity and Toxic Stress (Technical Report) (joint with Committee on Early Childhood, Adoption, and Dependent Care and Section on Developmental and Behavioral Pediatrics), 12/11

The New Morbidity Revisited: A Renewed Commitment to the Psychosocial Aspects of Pediatric Care, 11/01

The Pediatrician and Childhood Bereavement, 2/00, reaffirmed 1/04, 3/13

The Pediatrician's Role in the Prevention of Missing Children (Clinical Report), 10/04

The Prenatal Visit (Clinical Report), 9/09

Promoting the Well-Being of Children Whose Parents Are Gay or Lesbian, 3/13

Promoting the Well-Being of Children Whose Parents Are Gay or Lesbian (Technical Report), 3/13

Psychosocial Implications of Disaster or Terrorism on Children: A Guide for the Pediatrician (Clinical Report) (joint with Task Force on Terrorism), 9/05

Psychosocial Risks of Chronic Health Conditions in Childhood and Adolescence (joint with Committee on Children With Disabilities), 12/93, reaffirmed 10/96

Sexuality Education for Children and Adolescents (joint with Committee on Adolescence), 8/01, reaffirmed 10/04

Supporting the Family After the Death of a Child (Clinical Report), 11/12

COMMITTEE ON SUBSTANCE ABUSE

Alcohol Use by Youth and Adolescents: A Pediatric Concern, 4/10

Improving Substance Abuse Prevention, Assessment, and Treatment Financing for Children and Adolescents (joint with Committee on Child Health Financing), 10/01

Indications for Management and Referral of Patients Involved in Substance Abuse, 7/00

Inhalant Abuse (Clinical Report) (joint with Committee on Native American Child Health), 5/07

Legalization of Marijuana: Potential Impact on Youth (joint with Committee on Adolescence), 6/04

Legalization of Marijuana: Potential Impact on Youth (Technical Report) (joint with Committee on Adolescence), 6/04

Marijuana: A Continuing Concern for Pediatricians, 10/99, reaffirmed 4/03

Prenatal Substance Abuse: Short- and Long-term Effects on the Exposed Fetus (Technical Report) (joint with Committee on Fetus and Newborn), 2/13

The Role of Schools in Combating Illicit Substance Abuse (joint with Council on School Health), 12/07

Substance Use Screening, Brief Intervention, and Referral to Treatment for Pediatricians, 10/11

Testing for Drugs of Abuse in Children and Adolescents, 8/96, reaffirmed 5/99, 5/06

Testing for Drugs of Abuse in Children and Adolescents: Addendum—Testing in Schools and at Home (joint with Council on School Health), 3/07

Tobacco, Alcohol, and Other Drugs: The Role of the Pediatrician in Prevention, Identification, and Management of Substance Abuse (Clinical Report), 3/05, reaffirmed 3/13

Tobacco as a Substance of Abuse (Technical Report), 10/09

Tobacco Use: A Pediatric Disease (joint with Committee on Environmental Health, Committee on Adolescence, and Committee on Native American Child Health), 10/09

COUNCIL ON CHILDREN WITH DISABILITIES (FORMERLY COMMITTEE ON CHILDREN WITH DISABILITIES AND SECTION ON CHILDREN WITH DISABILITIES)

Auditory Integration Training and Facilitated Communication for Autism, 8/98, reaffirmed 5/02, 1/06, 12/09

Care Coordination in the Medical Home: Integrating Health and Related Systems of Care for Children With Special Health Care Needs, 11/05

Counseling Families Who Choose Complementary and Alternative Medicine for Their Child With Chronic Illness or Disability, 3/01, reaffirmed 1/05, 5/10

Early Intervention, IDEA Part C Services, and the Medical Home: Collaboration for Best Practice and Best Outcomes (Clinical Report), 9/13

Guidelines for Home Care of Infants, Children, and Adolescents With Chronic Disease, 7/95, reaffirmed 4/00, 1/06

Home Care of Children and Youth With Complex Health Care Needs and Technology Dependencies (Clinical Report), 4/12

Identification and Evaluation of Children With Autism Spectrum Disorders (Clinical Report), 11/07, reaffirmed 9/10

Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening (joint with Section on Developmental and Behavioral Pediatrics, Bright Futures Steering Committee, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee), 7/06, reaffirmed 12/09

Learning Disabilities, Dyslexia, and Vision (joint with Section on Ophthalmology, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 7/09

Learning Disabilities, Dyslexia, and Vision (Technical Report) (joint with Section on Ophthalmology, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 3/11

Maltreatment of Children With Disabilities (Clinical Report) (joint with Committee on Child Abuse and Neglect), 5/07, reaffirmed 1/11

Management of Children With Autism Spectrum Disorders (Clinical Report), 11/07, reaffirmed 9/10

Oral Health Care for Children With Developmental Disabilities (Clinical Report) (joint with Section on Oral Health), 2/13

Parent-Provider-Community Partnerships: Optimizing Outcomes for Children With Disabilities (Clinical Report), 9/11

The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP), 7/99, reaffirmed 11/02, 1/06

Prescribing Assistive-Technology Systems: Focus on Children With Impaired Communication (Clinical Report), 6/08, reaffirmed 1/12

Prescribing Therapy Services for Children With Motor Disabilities (Clinical Report), 6/04, reaffirmed 5/07, 5/11

Promoting the Participation of Children With Disabilities in Sports, Recreation, and Physical Activities (Clinical Report), 5/08, reaffirmed 1/12

Providing a Primary Care Medical Home for Children and Youth With Cerebral Palsy (Clinical Report), 10/11

Providing a Primary Care Medical Home for Children and Youth With Spina Bifida (Clinical Report), 11/11

Provision of Educationally Related Services for Children and Adolescents With Chronic Diseases and Disabling Conditions, 6/07

Psychosocial Risks of Chronic Health Conditions in Childhood and Adolescence (joint with Committee on Psychosocial Aspects of Child and Family Health), 12/93, reaffirmed 10/96

Role of the Medical Home in Family-Centered Early Intervention Services, 11/07

Sensory Integration Therapies for Children With Developmental and Behavioral Disorders (joint with Section on Complementary and Integrative Medicine), 5/12

Sexuality of Children and Adolescents With Developmental Disabilities (Clinical Report), 7/06, reaffirmed 12/09, 7/13

Supplemental Security Income (SSI) for Children and Youth With Disabilities, 11/09

The Treatment of Neurologically Impaired Children Using Patterning, 11/99, reaffirmed 11/02, 1/06, 8/10

COUNCIL ON CLINICAL INFORMATION TECHNOLOGY (FORMERLY STEERING COMMITTEE ON CLINICAL INFORMATION TECHNOLOGY, SECTION ON COMPUTERS AND OTHER TECHNOLOGIES, AND TASK FORCE ON MEDICAL INFORMATICS)

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management, 3/13

Electronic Prescribing in Pediatrics: Toward Safer and More Effective Medication Management (Technical Report), 3/13

Electronic Prescribing Systems in Pediatrics: The Rationale and Functionality Requirements, 6/07

Electronic Prescribing Systems in Pediatrics: The Rationale and Functionality Requirements (Technical Report), 6/07

E-mail Communication Between Pediatricians and Their Patients (Clinical Report), 7/04, reaffirmed 2/08

Emergency Information Forms and Emergency Preparedness for Children With Special Health Care Needs (joint with Committee on Pediatric Emergency Medicine and American College of Emergency Physicians Pediatric Emergency Medicine Committee), 3/10

Health Information Technology and the Medical Home, 4/11

Pediatric Aspects of Inpatient Health Information Technology Systems (Technical Report), 12/08

Special Requirements of Electronic Health Record Systems in Pediatrics (Clinical Report), 3/07, reaffirmed 5/12

Standards for Health Information Technology to Ensure Adolescent Privacy (joint with Committee on Adolescence), 10/12

Using Personal Health Records to Improve the Quality of Health Care for Children, 6/09

COUNCIL ON COMMUNICATIONS AND MEDIA (FORMERLY COMMITTEE ON COMMUNICATIONS AND COMMITTEE ON PUBLIC EDUCATION)

Children, Adolescents, and Advertising, 12/06, reaffirmed 3/10

Children, Adolescents, and the Media, 10/13

Children, Adolescents, Obesity, and the Media, 7/11

Children, Adolescents, Substance Abuse, and the Media, 9/10

Children, Adolescents, and Television, 2/01

Impact of Music, Music Lyrics, and Music Videos on Children and Youth, 10/09

The Impact of Social Media on Children, Adolescents, and Families (Clinical Report), 3/11

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bonds (Clinical Report) (joint with Committee on Psychosocial Aspects of Child and Family Health), 1/07

The Importance of Play in Promoting Healthy Child Development and Maintaining Strong Parent-Child Bond: Focus on Children in Poverty (Clinical Report) (joint with Committee on Psychosocial Aspects of Child and Family Health), 12/11

Media Education, 9/10

Media Use by Children Younger Than 2 Years, 10/11

Media Violence, 10/09

Sexuality, Contraception, and the Media, 8/10

COUNCIL ON COMMUNITY PEDIATRICS (FORMERLY COMMITTEE ON COMMUNITY HEALTH SERVICES)

Child Fatality Review (joint with Committee on Child Abuse and Neglect and Committee on Injury, Violence, and Poison Prevention), 8/10

Community Pediatrics: Navigating the Intersection of Medicine, Public Health, and Social Determinants of Children's Health, 2/13

Ethical Considerations in Research With Socially Identifiable Populations (joint with Committee on Native American Child Health), 1/04, reaffirmed 10/07, 1/13

Health Equity and Children's Rights (joint with Committee on Native American Child Health), 3/10, reaffirmed 10/13

Increasing Immunization Coverage (joint with Committee on Practice and Ambulatory Medicine), 5/10

The Pediatrician's Role in Community Pediatrics, 4/05, reaffirmed 1/10

Prevention of Agricultural Injuries Among Children and Adolescents (joint with Committee on Injury and Poison Prevention), 10/01, reaffirmed 1/07, 11/11

Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity, 5/13

Providing Care for Immigrant, Migrant, and Border Children, 5/13

The Role of Preschool Home-Visiting Programs in Improving Children's Developmental and Health Outcomes, 1/09

COUNCIL ON EARLY CHILDHOOD (FORMERLY COMMITTEE ON EARLY CHILDHOOD, ADOPTION, AND DEPENDENT CARE AND COMMITTEE ON EARLY CHILDHOOD)

Care of Adolescent Parents and Their Children (Clinical Report) (joint with Committee on Adolescence), 11/12

Comprehensive Health Evaluation of the Newly Adopted Child (Clinical Report), 12/11

Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health (joint with Committee on Psychosocial Aspects of Child and Family Health and Section on Developmental and Behavioral Pediatrics), 12/11

Families and Adoption: The Pediatrician's Role in Supporting Communication (Clinical Report), 12/03

Health Care of Youth Aging Out of Foster Care (joint with Council on Foster Care, Adoption, and Kinship Care), 11/12

The Inappropriate Use of School "Readiness" Tests (joint with Committee on School Health), 3/95, reaffirmed 4/98, 1/04, 4/10

The Lifelong Effects of Early Childhood Adversity and Toxic Stress (Technical Report) (joint with Committee on Psychosocial Aspects of Child and Family Health and Section on Developmental and Behavioral Pediatrics), 12/11

Parental Leave for Residents and Pediatric Training Programs (joint with Section on Medical Students, Residents, and Fellowship Trainees), 1/13

The Pediatrician's Role in Family Support and Family Support Programs, 11/11

The Pediatrician's Role in Supporting Adoptive Families (Clinical Report) (joint with Council on Foster Care, Adoption, and Kinship Care), 9/12

Quality Early Education and Child Care From Birth to Kindergarten, 1/05, reaffirmed 12/09

School Readiness (Technical Report) (joint with Council on School Health), 4/08, reaffirmed 9/13

Selecting Appropriate Toys for Young Children: The Pediatrician's Role (Clinical Report), 4/03, reaffirmed 10/06, 5/11

COUNCIL ON ENVIRONMENTAL HEALTH (FORMERLY COMMITTEE ON ENVIRONMENTAL HEALTH)

Ambient Air Pollution: Health Hazards to Children, 12/04, reaffirmed 4/09

The Built Environment: Designing Communities to Promote Physical Activity in Children, 5/09, reaffirmed 1/13

Chemical-Biological Terrorism and Its Impact on Children (joint with Committee on Infectious Diseases), 9/06, reaffirmed 1/11

Chemical-Management Policy: Prioritizing Children's Health, 4/11

Drinking Water From Private Wells and Risks to Children (joint with Committee on Infectious Diseases), 5/09, reaffirmed 1/13

Drinking Water From Private Wells and Risks to Children (Technical Report) (joint with Committee on Infectious Diseases), 5/09, reaffirmed 1/13

Global Climate Change and Children's Health, 11/07, reaffirmed 5/12

Global Climate Change and Children's Health (Technical Report), 11/07, reaffirmed 5/12

Infant Methemoglobinemia: The Role of Dietary Nitrate in Food and Water (Clinical Report) (joint with Committee on Nutrition), 9/05, reaffirmed 4/09

Nontherapeutic Use of Antimicrobial Agents in Animal Agriculture: Implications for Pediatrics (Technical Report) (joint with Committee on Infectious Diseases), 9/04, reaffirmed 10/08, 4/13

Organic Foods: Health and Environmental Advantages and Disadvantages (Clinical Report) (joint with Committee on Nutrition), 10/12

Pesticide Exposure in Children, 11/12

Pesticide Exposure in Children (Technical Report), 11/12

Radiation Disasters and Children, 6/03, reaffirmed 1/07

Secondhand and Prenatal Tobacco Smoke Exposure (Technical Report) (joint with Committee on Native American Child Health and Committee on Adolescence), 10/09

Spectrum of Noninfectious Health Effects From Molds, 12/06, reaffirmed 1/11

Spectrum of Noninfectious Health Effects From Molds (Technical Report), 12/06, reaffirmed 1/11

Tobacco Use: A Pediatric Disease (joint with Committee on Substance Abuse, Committee on Adolescence, and Committee on Native American Child Health), 10/09

Ultraviolet Radiation: A Hazard to Children and Adolescents (joint with Section on Dermatology), 2/11

Ultraviolet Radiation: A Hazard to Children and Adolescents (Technical Report) (joint with Section on Dermatology), 3/11

COUNCIL ON FOSTER CARE, ADOPTION, AND KINSHIP CARE (FORMALLY SECTION ON ADOPTION AND FOSTER CARE, TASK FORCE ON FOSTER CARE, AND COMMITTEE ON EARLY CHILDHOOD, ADOPTION, AND DEPENDENT CARE)

Families and Adoption: The Pediatrician's Role in Supporting Communication (Clinical Report), 12/03

Health Care of Youth Aging Out of Foster Care (joint with Committee on Early Childhood), 11/12

The Inappropriate Use of School "Readiness" Tests (joint with Committee on School Health), 3/95, reaffirmed 4/98, 1/04, 4/10

The Pediatrician's Role in Family Support and Family Support Programs, 11/11

The Pediatrician's Role in Supporting Adoptive Families (Clinical Report) (joint with Committee on Early Childhood), 9/12

Quality Early Education and Child Care From Birth to Kindergarten, 1/05, reaffirmed 12/09

School Readiness (Technical Report) (joint with Council on School Health), 4/08, reaffirmed 9/13

Selecting Appropriate Toys for Young Children: The Pediatrician's Role (Clinical Report), 4/03, reaffirmed 10/06, 5/11

Understanding the Behavioral and Emotional Consequences of Child Abuse (Clinical Report) (joint with Committee on Child Abuse and Neglect, American Academy of Child and Adolescent Psychiatry, and National Center for Child Traumatic Stress), 9/08

COUNCIL ON INJURY, VIOLENCE, AND POISON PREVENTION (FORMALLY COMMITTEE ON INJURY, VIOLENCE, AND POISON PREVENTION)

All-Terrain Vehicle Injury Prevention: Two-, Three-, and Four-Wheeled Unlicensed Motor Vehicles, 6/00, reaffirmed 5/04, 1/07

Bicycle Helmets, 10/01, reaffirmed 1/05, 2/08, 11/11

Child Fatality Review (joint with Committee on Child Abuse and Neglect and Council on Community Pediatrics), 8/10

Child Passenger Safety, 3/11

Child Passenger Safety (Technical Report), 3/11

Children in Pickup Trucks, 10/00, reaffirmed 5/04, 1/07

Falls From Heights: Windows, Roofs, and Balconies, 5/01, reaffirmed 10/04, 5/07, 6/10

Firearm-Related Injuries Affecting the Pediatric Population, 10/12

Fireworks-Related Injuries to Children, 7/01, reaffirmed 1/05, 2/08, 10/11

The Hospital Record of the Injured Child and the Need for External Cause-of-Injury Codes, 2/99, reaffirmed 5/02, 5/05, 10/08

Injuries Associated With Infant Walkers, 9/01, reaffirmed 1/05, 2/08, 10/11

Injury Risk of Nonpowder Guns (Technical Report), 11/04, reaffirmed 2/08, 10/11

In-line Skating Injuries in Children and Adolescents (joint with Committee on Sports Medicine and Fitness), 4/98, reaffirmed 1/02, 1/06, 1/09, 11/11

Intimate Partner Violence: The Role of the Pediatrician (Clinical Report) (joint with Committee on Child Abuse and Neglect), 4/10

Lawn Mower-Related Injuries to Children, 6/01, reaffirmed 10/04, 5/07, 6/10

Lawn Mower-Related Injuries to Children (Technical Report), 6/01, reaffirmed 10/04, 5/07, 6/10

Office-Based Counseling for Unintentional Injury Prevention (Clinical Report), 1/07

Pedestrian Safety, 7/09, reaffirmed 8/13

Personal Watercraft Use by Children and Adolescents, 2/00, reaffirmed 5/04, 1/07, 6/10

Prevention of Agricultural Injuries Among Children and Adolescents (joint with Committee on Community Health Services), 10/01, reaffirmed 1/07, 11/11

Prevention of Choking Among Children, 2/10

Prevention of Drowning, 5/10

Prevention of Drowning (Technical Report), 5/10

The Prevention of Unintentional Injury Among American Indian and Alaska Native Children: A Subject Review (Clinical Report) (joint with Committee on Native American Child Health), 12/99, reaffirmed 12/02, 1/06, 1/09

Reducing the Number of Deaths and Injuries From Residential Fires, 6/00

Restraint Use on Aircraft, 11/01, reaffirmed 5/05, 10/08

Role of the Pediatrician in Youth Violence Prevention, 6/09

Safe Transportation of Newborns at Hospital Discharge, 10/99, reaffirmed 1/03, 1/06, 10/08

Safe Transportation of Preterm and Low Birth Weight Infants at Hospital Discharge (Clinical Report) (joint with Committee on Fetus and Newborn), 4/09, reaffirmed 8/13

School Bus Transportation of Children With Special Health Care Needs, 8/01, reaffirmed 1/05, 2/08

School Transportation Safety (joint with Council on School Health), 7/07, reaffirmed 10/11

Shopping Cart–Related Injuries to Children, 8/06, reaffirmed 4/09, 8/13

Shopping Cart–Related Injuries to Children (Technical Report), 8/06, reaffirmed 4/09, 8/13

Skateboard and Scooter Injuries, 3/02, reaffirmed 5/05, 10/08

Snowmobiling Hazards, 11/00, reaffirmed 5/04, 1/07, 6/10

Swimming Programs for Infants and Toddlers (joint with Committee on Sports Medicine and Fitness), 4/00, reaffirmed 5/04

The Teen Driver (joint with Committee on Adolescence), 12/06, reaffirmed 6/10

Transporting Children With Special Health Care Needs, 10/99, reaffirmed 1/03, 1/06, 3/13

COUNCIL ON SCHOOL HEALTH (FORMERLY COMMITTEE ON SCHOOL HEALTH AND SECTION ON SCHOOL HEALTH)

Active Healthy Living: Prevention of Childhood Obesity Through Increased Physical Activity (joint with Council on Sports Medicine and Fitness), 5/06, reaffirmed 5/09, 8/12

Climatic Heat Stress and Exercising Children and Adolescents (joint with Council on Sports Medicine and Fitness), 8/11

Corporal Punishment in Schools, 8/00, reaffirmed 6/03, 5/06, 2/12

Creating Healthy Camp Experiences, 3/11

The Crucial Role of Recess in School, 12/12

Disaster Planning for Schools, 10/08, reaffirmed 9/11

Guidance for the Administration of Medication in School, 9/09, reaffirmed 2/13

Head Lice (Clinical Report) (joint with Committee on Infectious Diseases), 7/10

Home, Hospital, and Other Non–School-based Instruction for Children and Adolescents Who Are Medically Unable to Attend School, 11/00, reaffirmed 6/03, 5/06

Honoring Do-Not-Attempt-Resuscitation Requests in Schools (joint with Committee on Bioethics), 4/10, reaffirmed 7/13

The Inappropriate Use of School "Readiness" Tests (joint with Committee on Early Childhood, Adoption, and Dependent Care), 3/95, reaffirmed 4/98, 1/04, 4/10

Medical Emergencies Occurring at School, 10/08, reaffirmed 9/11

Organized Sports for Children and Preadolescents (joint with Committee on Sports Medicine and Fitness), 6/01, reaffirmed 1/05, 6/11

Out-of-School Suspension and Expulsion, 2/13

Preventing and Treating Homesickness (Clinical Report), 1/07, reaffirmed 5/12

Returning to Learning Following a Concussion (Clinical Report) (joint with Council on Sports Medicine and Fitness), 10/13

Role of the School Nurse in Providing School Health Services, 5/08

Role of the School Physician, 12/12

The Role of Schools in Combating Illicit Substance Abuse (joint with Committee on Substance Abuse), 12/07

School-Based Health Centers and Pediatric Practice, 1/12

School Health Assessments, 4/00, reaffirmed 6/03, 5/06, 10/11

School Health Centers and Other Integrated School Health Services, 1/01

School Readiness (Technical Report) (joint with Committee on Early Childhood, Adoption, and Dependent Care), 4/08, reaffirmed 9/13

School Transportation Safety (joint with Committee on Injury, Violence, and Poison Prevention), 7/07, reaffirmed 10/11

School-Based Mental Health Services, 6/04, reaffirmed 5/09

Soft Drinks in Schools, 1/04, reaffirmed 1/09

Testing for Drugs of Abuse in Children and Adolescents: Addendum—Testing in Schools and at Home (joint with Committee on Substance Abuse), 3/07

COUNCIL ON SPORTS MEDICINE AND FITNESS (FORMERLY COMMITTEE ON SPORTS MEDICINE AND FITNESS AND SECTION ON SPORTS MEDICINE AND FITNESS)

Active Healthy Living: Prevention of Childhood Obesity Through Increased Physical Activity (joint with Council on School Health), 5/06, reaffirmed 5/09, 8/12

Athletic Participation by Children and Adolescents Who Have Systemic Hypertension, 5/10, reaffirmed 5/13

Baseball and Softball, 2/12

Boxing Participation by Children and Adolescents (joint with Canadian Paediatric Society), 8/11

Cheerleading Injuries: Epidemiology and Recommendations for Prevention, 10/12

Climatic Heat Stress and Exercising Children and Adolescents (joint with Council on School Health), 8/11

Human Immunodeficiency Virus and Other Blood-borne Viral Pathogens in the Athletic Setting, 12/99, reaffirmed 1/05, 1/09, 11/11

Injuries in Youth Soccer (Clinical Report), 1/10, reaffirmed 5/13

In-line Skating Injuries in Children and Adolescents (joint with Committee on Injury and Poison Prevention), 4/98, reaffirmed 1/02, 1/06, 1/09, 11/11

Intensive Training and Sports Specialization in Young Athletes, 7/00, reaffirmed 11/04, 1/06, 5/09

Knee Brace Use in the Young Athlete (Technical Report), 8/01, reaffirmed 1/07, 4/10, 5/13

Medical Concerns in the Female Athlete, 9/00, reaffirmed 5/05, 5/08

Medical Conditions Affecting Sports Participation (Clinical Report), 4/08, reaffirmed 5/11

Organized Sports for Children and Preadolescents (joint with Committee on School Health), 6/01, reaffirmed 1/05, 6/11

Overuse Injuries, Overtraining, and Burnout in Child and Adolescent Athletes (Clinical Report), 6/07, reaffirmed 3/11

Promotion of Healthy Weight-Control Practices in Young Athletes, 12/05

Protective Eyewear for Young Athletes (joint with American Academy of Ophthalmology), 3/04, reaffirmed 2/08, 6/11

Returning to Learning Following a Concussion (Clinical Report) (joint with Council on School Health), 10/13

Safety in Youth Ice Hockey: The Effects of Body Checking, 3/00, reaffirmed 1/06, 5/09

Sport-Related Concussion in Children and Adolescents (Clinical Report), 8/10

Sports Drinks and Energy Drinks for Children and Adolescents: Are They Appropriate? (Clinical Report) (joint with Committee on Nutrition), 5/11

Strength Training by Children and Adolescents, 4/08, reaffirmed 6/11

Swimming Programs for Infants and Toddlers (joint with Committee on Injury and Poison Prevention), 4/00, reaffirmed 5/04

Trampoline Safety in Childhood and Adolescence, 9/12

Use of Performance-Enhancing Substances, 4/05, reaffirmed 5/08

JOINT COMMITTEE ON INFANT HEARING

Supplement to the JCIH 2007 Position Statement: Principles and Guidelines for Early Intervention After Confirmation That a Child Is Deaf or Hard of Hearing, 3/13

Year 2007 Position Statement: Principles and Guidelines for Early Hearing Detection and Intervention Programs, 10/07

MEDICAL HOME INITIATIVES FOR CHILDREN WITH SPECIAL NEEDS PROJECT ADVISORY COMMITTEE

Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening (joint with Council on Children With Disabilities, Section on Developmental and Behavioral Pediatrics, and Bright Futures Steering Committee), 7/06, reaffirmed 12/09

The Medical Home, 7/02, reaffirmed 5/08

NEUROMOTOR SCREENING EXPERT PANEL

Motor Delays: Early Identification and Evaluation (Clinical Report), 5/13

NEWBORN SCREENING AUTHORING COMMITTEE

Newborn Screening Expands: Recommendations for Pediatricians and Medical Homes—Implications for the System (Clinical Report), 1/08

RETAIL-BASED CLINIC POLICY WORK GROUP

AAP Principles Concerning Retail-Based Clinics, 12/06, reaffirmed 1/11

SECTION ON ALLERGY AND IMMUNOLOGY

Allergy Testing in Childhood: Using Allergen-Specific IgE Tests (Clinical Report), 12/11

Effects of Early Nutritional Interventions on the Development of Atopic Disease in Infants and Children: The Role of Maternal Dietary Restriction, Breastfeeding, Timing of Introduction of Complementary Foods, and Hydrolyzed Formulas (Clinical Report) (joint with Committee on Nutrition), 1/08

Management of Food Allergy in the School Setting (Clinical Report), 11/10

Self-injectable Epinephrine for First-Aid Management of Anaphylaxis (Clinical Report), 3/07

SECTION ON ANESTHESIOLOGY AND PAIN MEDICINE

Premedication for Nonemergency Endotracheal Intubation in the Neonate (Clinical Report) (joint with Committee on Fetus and Newborn), 2/10, reaffirmed 8/13

Recognition and Management of Iatrogenically Induced Opioid Dependence and Withdrawal in Children (Clinical Report) (joint with Committee on Drugs), 12/13

Relief of Pain and Anxiety in Pediatric Patients in Emergency Medical Systems (Clinical Report) (joint with Committee on Pediatric Emergency Medicine), 10/12

SECTION ON BREASTFEEDING

Breastfeeding and the Use of Human Milk, 2/12

WIC Program, 11/01

SECTION ON CARDIOLOGY AND CARDIAC SURGERY

ACCF/AHA/AAP Recommendations for Training in Pediatric Cardiology (joint with American College of Cardiology Foundation and American Heart Association), 12/05, reaffirmed 1/09

Cardiovascular Health Supervision for Individuals Affected by Duchenne or Becker Muscular Dystrophy (Clinical Report), 12/05, reaffirmed 1/09

Cardiovascular Monitoring and Stimulant Drugs for Attention-Deficit/Hyperactivity Disorder (joint with Black Box Working Group), 8/08

Echocardiography in Infants and Children, 6/97, reaffirmed 3/03, 3/07

Endorsement of Health and Human Services Recommendation for Pulse Oximetry Screening for Critical Congenital Heart Disease, 12/11

Guidelines for Pediatric Cardiovascular Centers, 3/02, reaffirmed 10/07

Pediatric Sudden Cardiac Arrest, 3/12

Role of Pulse Oximetry in Examining Newborns for Congenital Heart Disease: A Scientific Statement from the AHA and AAP (joint with Committee on Fetus and Newborn and American Heart Association Congenital Heart Defects Committee of the Council on Cardiovascular Disease in the Young, Council on Cardiovascular Nursing, and Interdisciplinary Council on Quality of Care and Outcomes Research), 8/09

Ventricular Fibrillation and the Use of Automated External Defibrillators on Children (joint with Committee on Pediatric Emergency Medicine), 11/07, reaffirmed 6/11

SECTION ON CLINICAL PHARMACOLOGY AND THERAPEUTICS

Fever and Antipyretic Use in Children (Clinical Report) (joint with Committee on Drugs), 2/11

SECTION ON COMPLEMENTARY AND INTEGRATIVE MEDICINE (FORMERLY PROVISIONAL SECTION ON COMPLEMENTARY, HOLISTIC, AND INTEGRATIVE MEDICINE)

Sensory Integration Therapies for Children With Developmental and Behavioral Disorders (joint with Council on Children With Disabilities), 5/12

The Use of Complementary and Alternative Medicine in Pediatrics (Clinical Report) (joint with Task Force on Complementary and Alternative Medicine), 12/08, reaffirmed 10/12, 1/13

SECTION ON CRITICAL CARE

Admission and Discharge Guidelines for the Pediatric Patient Requiring Intermediate Care (Clinical Report) (joint with Committee on Hospital Care and Society of Critical Care Medicine), 5/04, reaffirmed 2/08, 1/13

Guidelines for the Determination of Brain Death in Infants and Children: An Update of the 1987 Task Force Recommendations (Clinical Report) (joint with Section on Neurology, Society of Critical Care Medicine, and Child Neurology Society), 8/11

Guidelines for Developing Admission and Discharge Policies for the Pediatric Intensive Care Unit (joint with Committee on Hospital Care and Society of Critical Care Medicine), 4/99, reaffirmed 5/05, 2/08, 1/13

Management of Pediatric Trauma (joint with Section on Orthopaedics, Committee on Pediatric Emergency Medicine, Section on Surgery, Section on Transport Medicine, and Pediatric Orthopaedic Society of North America), 4/08, reaffirmed 4/13

Pediatric Organ Donation and Transplantation (joint with Committee on Hospital Care and Section on Surgery), 3/10

SECTION ON DERMATOLOGY

Ultraviolet Radiation: A Hazard to Children and Adolescents (joint with Council on Environmental Health), 2/11

Ultraviolet Radiation: A Hazard to Children and Adolescents (Technical Report) (joint with Council on Environmental Health), 3/11

SECTION ON DEVELOPMENTAL AND BEHAVIORAL PEDIATRICS

Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health (joint with Committee on Psychosocial Aspects of Child and Family Health and Committee on Early Childhood, Adoption, and Dependent Care), 12/11

Identifying Infants and Young Children With Developmental Disorders in the Medical Home: An Algorithm for Developmental Surveillance and Screening (joint with Council on Children With Disabilities, Bright Futures Steering Committee, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee), 7/06, reaffirmed 12/09

The Lifelong Effects of Early Childhood Adversity and Toxic Stress (Technical Report) (joint with Committee on Psychosocial Aspects of Child and Family Health and Committee on Early Childhood, Adoption, and Dependent Care), 12/11

SECTION ON ENDOCRINOLOGY

Bone Densitometry in Children and Adolescents (Clinical Report), 12/10

Congenital Adrenal Hyperplasia (Technical Report) (joint with Committee on Genetics), 12/00, reaffirmed 10/04

Prevention and Treatment of Type 2 Diabetes Mellitus in Children, With Special Emphasis on American Indian and Alaska Native Children (Clinical Report) (joint with Committee on Native American Child Health), 10/03, reaffirmed 10/08

Screening for Retinopathy in the Pediatric Patient With Type 1 Diabetes Mellitus (Clinical Report) (joint with Section on Ophthalmology and American Association for Pediatric Ophthalmology and Strabismus), 7/05, reaffirmed 1/09

Update of Newborn Screening and Therapy for Congenital Hypothyroidism (Clinical Report) (joint with Committee on Genetics, American Thyroid Association, and Lawson Wilkins Pediatric Endocrine Society), 6/06, reaffirmed 12/11

SECTION ON GASTROENTEROLOGY, HEPATOLOGY, AND NUTRITION

Gastroesophageal Reflux: Management Guidance for the Pediatrician (Clinical Report), 4/13

Probiotics and Prebiotics in Pediatrics (Clinical Report) (joint with Committee on Nutrition), 11/10

SECTION ON HEMATOLOGY/ONCOLOGY

Evaluating for Suspected Child Abuse: Conditions That Predispose to Bleeding (Technical Report) (joint with Committee on Child Abuse and Neglect), 3/13

Evaluation for Bleeding Disorders in Suspected Child Abuse (Clinical Report) (joint with Committee on Child Abuse and Neglect), 3/13

Guidelines for Pediatric Cancer Centers, 6/04, reaffirmed 10/08

Health Supervision for Children With Sickle Cell Disease (joint with Committee on Genetics), 3/02, reaffirmed 1/06, 1/11

Long-term Follow-up Care for Pediatric Cancer Survivors (Clinical Report) (joint with Children's Oncology Group), 3/09, reaffirmed 4/13

Preservation of Fertility in Pediatric and Adolescent Patients With Cancer (Technical Report) (joint with Committee on Bioethics and Section on Surgery), 5/08, reaffirmed 2/12

SECTION ON HOME CARE

Financing of Pediatric Home Health Care (joint with Committee on Child Health Financing), 8/06

SECTION ON HOSPICE AND PALLIATIVE MEDICINE

Pediatric Palliative Care and Hospice Care Commitments, Guidelines, and Recommendations (joint with Committee on Hospital Care), 10/13

SECTION ON HOSPITAL MEDICINE

Guiding Principles for Pediatric Hospital Medicine Programs, 9/13

Medical Staff Appointment and Delineation of Pediatric Privileges in Hospitals (Clinical Report) (joint with Committee on Hospital Care), 3/12

Physicians' Roles in Coordinating Care of Hospitalized Children (Clinical Report) (joint with Committee on Hospital Care), 9/10

SECTION ON INTERNATIONAL CHILD HEALTH

Increasing Antiretroviral Drug Access for Children With HIV Infection (joint with Committee on Pediatric AIDS), 4/07, reaffirmed 4/10

SECTION ON MEDICAL STUDENTS, RESIDENTS, AND FELLOWSHIP TRAINEES

Parental Leave for Residents and Pediatric Training Programs (joint with Committee on Early Childhood), 1/13

SECTION ON NEUROLOGICAL SURGERY

Prevention and Management of Positional Skull Deformities in Infants (Clinical Report) (joint with Committee on Practice and Ambulatory Medicine), 11/11

SECTION ON NEUROLOGY

Guidelines for the Determination of Brain Death in Infants and Children: An Update of the 1987 Task Force Recommendations (Clinical Report) (joint with Section on Critical Care, Society of Critical Care Medicine, and Child Neurology Society), 8/11

SECTION ON OPHTHALMOLOGY

The Eye Examination in the Evaluation of Child Abuse (Clinical Report) (joint with Committee on Child Abuse and Neglect), 7/10

Eye Examination in Infants, Children, and Young Adults by Pediatricians (joint with Committee on Practice and Ambulatory Medicine, American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology), 4/03, reaffirmed 5/07

Instrument-Based Pediatric Vision Screening Policy Statement (joint with Committee on Practice and Ambulatory Medicine, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 10/12

Learning Disabilities, Dyslexia, and Vision (joint with Council on Children With Disabilities, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 7/09

Learning Disabilities, Dyslexia, and Vision (Technical Report) (joint with Council on Children With Disabilities, American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 3/11

Ophthalmologic Examinations in Children With Juvenile Rheumatoid Arthritis (Clinical Report) (joint with Section on Rheumatology), 5/06

Red Reflex Examination in Neonates, Infants, and Children (joint with American Association for Pediatric Ophthalmology and Strabismus, American Academy of Ophthalmology, and American Association of Certified Orthoptists), 12/08

Screening Examination of Premature Infants for Retinopathy of Prematurity (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists), 12/12

Screening for Retinopathy in the Pediatric Patient With Type 1 Diabetes Mellitus (Clinical Report) (joint with Section on Endocrinology and American Association for Pediatric Ophthalmology and Strabismus), 7/05, reaffirmed 1/09

SECTION ON ORAL HEALTH (FORMERLY SECTION ON PEDIATRIC DENTISTRY AND SECTION ON PEDIATRIC DENTISTRY AND ORAL HEALTH)

Oral Health Care for Children With Developmental Disabilities (Clinical Report) (joint with Council on Children With Disabilities), 2/13

Oral Health Risk Assessment Timing and Establishment of the Dental Home, 5/03, reaffirmed 5/09

Preventive Oral Health Intervention for Pediatricians, 12/08

SECTION ON ORTHOPAEDICS

Management of Pediatric Trauma (joint with Committee on Pediatric Emergency Medicine, Section on Critical Care, Section on Surgery, Section on Transport Medicine, and Pediatric Orthopaedic Society of North America), 4/08, reaffirmed 4/13

SECTION ON OTOLARYNGOLOGY—HEAD & NECK SURGERY

Cochlear Implants in Children: Surgical Site Infections and Prevention and Treatment of Acute Otitis Media and Meningitis (joint with Committee on Infectious Diseases), 7/10

Follow-up Management of Children With Tympanostomy Tubes, 2/02

Hearing Assessment in Infants and Children: Recommendations Beyond Neonatal Screening (Clinical Report) (joint with Committee on Practice and Ambulatory Medicine), 9/09

SECTION ON RADIOLOGY

Diagnostic Imaging of Child Abuse, 4/09

Radiation Risk to Children From Computed Tomography (Clinical Report), 9/07

SECTION ON RHEUMATOLOGY

Ophthalmologic Examinations in Children With Juvenile Rheumatoid Arthritis (Clinical Report) (joint with Section on Ophthalmology), 5/06

SECTION ON SURGERY

Assessment and Management of Inguinal Hernia in Infants (Clinical Report) (joint with Committee on Fetus and Newborn), 9/12

Do-Not-Resuscitate Orders for Pediatric Patients Who Require Anesthesia and Surgery (Clinical Report) (joint with Section on Anesthesia and Pain Medicine and Committee on Bioethics), 12/04, reaffirmed 1/09, 10/12

Management of Pediatric Trauma (joint with Section on Orthopaedics, Committee on Pediatric Emergency Medicine, Section on Critical Care, Section on Transport Medicine, and Pediatric Orthopaedic Society of North America), 4/08, reaffirmed 4/13

Pediatric Organ Donation and Transplantation (joint with Committee on Hospital Care and Section on Critical Care), 3/10

Postdischarge Follow-up of Infants With Congenital Diaphragmatic Hernia (Clinical Report) (joint with Committee on Fetus and Newborn), 3/08, reaffirmed 5/11

Preservation of Fertility in Pediatric and Adolescent Patients With Cancer (Technical Report) (joint with Committee on Bioethics and Section on Hematology/Oncology), 5/08, reaffirmed 2/12

Prevention and Management of Pain in the Neonate: An Update (joint with Committee on Fetus and Newborn and Canadian Paediatric Society), 11/06, reaffirmed 5/10

SECTION ON TELEHEALTH CARE (FORMERLY SECTION ON TELEPHONE CARE)

Payment for Telephone Care (joint with Committee on Child Health Financing), 10/06

SECTION ON TRANSPORT MEDICINE

Management of Pediatric Trauma (joint with Section on Orthopaedics, Committee on Pediatric Emergency Medicine, Section on Critical Care, Section on Surgery, and Pediatric Orthopaedic Society of North America), 4/08, reaffirmed 4/13

SECTION ON UNIFORMED SERVICES

Health and Mental Health Needs of Children in US Military Families (Clinical Report) (join with Committee on Psychosocial Aspects of Child and Family Health), 5/13

STEERING COMMITTEE ON QUALITY IMPROVEMENT AND MANAGEMENT

ADHD: Clinical Practice Guideline for the Diagnosis, Evaluation, and Treatment of Attention-Deficit/Hyperactivity Disorder in Children and Adolescents (Clinical Practice Guideline) (joint with Subcommittee on Attention-Deficit/Hyperactivity Disorder), 10/11

Classifying Recommendations for Clinical Practice Guidelines, 9/04

Developmental Dysplasia of the Hip Practice Guideline (Technical Report), 4/00

Diagnosis and Management of Acute Otitis Media (Clinical Practice Guideline) (joint with American Academy of Family Physicians), 5/04

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (Clinical Practice Guideline) (joint with Subcommittee on Obstructive Sleep Apnea Syndrome), 8/12

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (Technical Report) (joint with Subcommittee on Obstructive Sleep Apnea Syndrome), 8/12

Early Detection of Developmental Dysplasia of the Hip (Clinical Practice Guideline), 4/00

An Evidence-Based Review of Important Issues Concerning Neonatal Hyperbilirubinemia (Technical Report), 7/04

Febrile Seizures: Clinical Practice Guideline for the Long-term Management of the Child With Simple Febrile Seizures (Clinical Practice Guideline) (joint with Subcommittee on Febrile Seizures), 6/08

Management of Hyperbilirubinemia in the Newborn Infant 35 or More Weeks of Gestation (Clinical Practice Guideline), 7/04

Management of Sinusitis (Clinical Practice Guideline), 9/01

Otitis Media With Effusion (Clinical Practice Guideline), 5/04

Principles for the Development and Use of Quality Measures (joint with Committee on Practice and Ambulatory Medicine), 2/08

Principles of Pediatric Patient Safety: Reducing Harm Due to Medical Care (joint with Committee on Hospital Care), 5/11

Toward Transparent Clinical Policies, 3/08

Urinary Tract Infection: Clinical Practice Guideline for the Diagnosis and Management of the Initial UTI in Febrile Infants and Children 2 to 24 Months (Clinical Practice Guideline) (joint with Subcommittee on Urinary Tract Infection), 8/11

SUBCOMMITTEE ON ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

ADHD: Clinical Practice Guideline for the Diagnosis, Evaluation, and Treatment of Attention-Deficit/Hyperactivity Disorder in Children and Adolescents (Clinical Practice Guideline) (joint with Steering Committee on Quality Improvement and Management), 10/11

SUBCOMMITTEE ON CHRONIC ABDOMINAL PAIN

Chronic Abdominal Pain in Children (Clinical Report) (joint with North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition), 3/05

Chronic Abdominal Pain in Children (Technical Report) (joint with North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition), 3/05

SUBCOMMITTEE ON DIAGNOSIS AND MANAGEMENT OF BRONCHIOLITIS

Diagnosis and Management of Bronchiolitis (Clinical Practice Guideline), 10/06

SUBCOMMITTEE ON FEBRILE SEIZURES

Febrile Seizures: Clinical Practice Guideline for the Long-term Management of the Child With Simple Febrile Seizures (Clinical Practice Guideline) (joint with Steering Committee on Quality Improvement and Management), 6/08

Febrile Seizures: Guideline for the Neurodiagnostic Evaluation of the Child With a Simple Febrile Seizure (Clinical Practice Guideline), 2/11

SUBCOMMITTEE ON OBSTRUCTIVE SLEEP APNEA SYNDROME

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (Clinical Practice Guideline) (joint with Steering Committee on Quality Improvement and Management), 8/12

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome (Technical Report) (joint with Steering Committee on Quality Improvement and Management), 8/12

SUBCOMMITTEE ON URINARY TRACT INFECTION

Diagnosis and Management of an Initial UTI in Febrile Infants and Young Children (Technical Report), 8/11

Urinary Tract Infection: Clinical Practice Guideline for the Diagnosis and Management of the Initial UTI in Febrile Infants and Children 2 to 24 Months (Clinical Practice Guideline) (joint with Steering Committee on Quality Improvement and Management), 8/11

SURGICAL ADVISORY PANEL

Guidelines for Referral to Pediatric Surgical Specialists, 7/02, reaffirmed 1/07

TASK FORCE ON CIRCUMCISION

Circumcision Policy Statement, 8/12

Male Circumcision (Technical Report), 8/12

TASK FORCE ON COMPLEMENTARY AND ALTERNATIVE MEDICINE

The Use of Complementary and Alternative Medicine in Pediatrics (Clinical Report) (joint with Provisional Section on Complementary, Holistic, and Integrative Medicine), 12/08, reaffirmed 10/12, 1/13

TASK FORCE ON GRADUATE MEDICAL EDUCATION REFORM

Graduate Medical Education and Pediatric Workforce Issues and Principles, 6/94

TASK FORCE ON MENTAL HEALTH

The Future of Pediatrics: Mental Health Competencies for Pediatric Primary Care (joint with Committee on Psychosocial Aspects of Child and Family Health), 6/09, reaffirmed 8/13

TASK FORCE ON SUDDEN INFANT DEATH SYNDROME

The Changing Concept of Sudden Infant Death Syndrome: Diagnostic Coding Shifts, Controversies Regarding the Sleeping Environment, and New Variables to Consider in Reducing Risk, 11/05, reaffirmed 5/08

SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment, 10/11

SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment (Technical Report), 10/11

TASK FORCE ON TERRORISM

The Pediatrician and Disaster Preparedness (joint with Committee on Pediatric Emergency Medicine and Committee on Medical Liability), 2/06, reaffirmed 6/09, 9/13

Psychosocial Implications of Disaster or Terrorism on Children: A Guide for the Pediatrician (Clinical Report) (joint with Committee on Psychosocial Aspects of Child and Family Health), 9/05

WORK GROUP ON SEDATION

Guidelines for Monitoring and Management of Pediatric Patients During and After Sedation for Diagnostic and Therapeutic Procedures: An Update (Clinical Report) (joint with American Academy of Pediatric Dentistry), 12/06, reaffirmed 3/11

WORKING GROUP ON SLEEPINESS IN ADOLESCENTS/ YOUNG ADULTS

Excessive Sleepiness in Adolescents and Young Adults: Causes, Consequences, and Treatment Strategies (Technical Report) (joint with Committee on Adolescence), 6/05

JOINT STATEMENTS

Joint Statement of the American Academy of Pediatrics and the American Academy of Child and Adolescent Psychiatry

Psychological Maltreatment (Clinical Report), 7/12

Joint Statement of the American Academy of Pediatrics, the American Academy of Child and Adolescent Psychiatry, and the National Center for Child Traumatic Stress

Understanding the Behavioral and Emotional Consequences of Child Abuse (Clinical Report), 9/08

Joint Statement of the American Academy of Pediatrics and the American Academy of Family Physicians

Diagnosis and Management of Acute Otitis Media (Clinical Practice Guideline), 5/04

Joint Statement of the American Academy of Pediatrics, the American Academy of Family Physicians, and the American College of Physicians

Supporting the Health Care Transition From Adolescence to Adulthood in the Medical Home (Clinical Report), 7/11

Joint Statement of the American Academy of Pediatrics, the American Academy of Family Physicians, and the American College of Physicians-American Society of Internal Medicine

A Consensus Statement on Health Care Transitions for Young Adults With Special Health Care Needs, 12/02

Joint Statement of the American Academy of Pediatrics and the American Academy of Ophthalmology

Protective Eyewear for Young Athletes, 3/04, reaffirmed 2/08, 6/11

Joint Statement of the American Academy of Pediatrics, the American Academy of Ophthalmology, the American Association for Pediatric Ophthalmology and Strabismus, and the American Association of Certified Orthoptists

Instrument-Based Pediatric Vision Screening Policy Statement, 10/12

Screening Examination of Premature Infants for Retinopathy of Prematurity, 12/12

Joint Statement of the American Academy of Pediatrics and the American Academy of Pediatric Dentistry

Guidelines for Monitoring and Management of Pediatric Patients During and After Sedation for Diagnostic and Therapeutic Procedures: An Update (Clinical Report), 12/06, reaffirmed 3/11

Oral and Dental Aspects of Child Abuse and Neglect (Clinical Report), 12/05, reaffirmed 1/09

Joint Statement of the American Academy of Pediatrics, the American Association of Certified Orthoptists, the American Association for Pediatric Ophthalmology and Strabismus, and the American Academy of Ophthalmology

Eye Examination in Infants, Children, and Young Adults by Pediatricians, 4/03, reaffirmed 5/07

Learning Disabilities, Dyslexia, and Vision, 7/09

Learning Disabilities, Dyslexia, and Vision (Technical Report), 3/11

Red Reflex Examination in Neonates, Infants, and Children, 12/08

Joint Statement of the American Academy of Pediatrics and the American Association for Pediatric Ophthalmology and Strabismus

Screening for Retinopathy in the Pediatric Patient With Type 1 Diabetes Mellitus (Clinical Report), 7/05, reaffirmed 1/09

Joint Statement of the American Academy of Pediatrics, the American College of Cardiology Foundation, and the American Heart Association

ACCF/AHA/AAP Recommendations for Training in Pediatric Cardiology, 12/05, reaffirmed 1/09

Joint Statement of the American Academy of Pediatrics and the American College of Emergency Physicians

Death of a Child in the Emergency Department: Joint Statement of the American Academy of Pediatrics and the American College of Emergency Physicians, 10/02, reaffirmed 1/06, 1/09, 8/13

Emergency Information Forms and Emergency Preparedness for Children With Special Health Care Needs, 3/10

Patient- and Family-Centered Care and the Role of the Emergency Physician Providing Care to a Child in the Emergency Department, 11/06, reaffirmed 6/09, 10/11

Pediatric Mental Health Emergencies in the Emergency Medical Services System, 10/06, reaffirmed 6/09, 4/13

Joint Statement of the American Academy of Pediatrics, the American College of Emergency Physicians, and the Emergency Nurses Association

Guidelines for Care of Children in the Emergency Department, 9/09, reaffirmed 4/13

Joint Statement of the American Academy of Pediatrics and the American College of Medical Genetics and Genomics

Ethical and Policy Issues in Genetic Testing and Screening of Children, 2/13

Joint Statement of the American Academy of Pediatrics and the American College of Obstetricians and Gynecologists

The Apgar Score, 4/06, reaffirmed 1/09

Human Immunodeficiency Virus Screening, 7/99, reaffirmed 6/02, 5/05, 10/08, 5/12

Maternal-Fetal Intervention and Fetal Care Centers (Clinical Report), 7/11

Menstruation in Girls and Adolescents: Using the Menstrual Cycle as a Vital Sign (Clinical Report), 11/06

Joint Statement of the American Academy of Pediatrics, the American College of Surgeons Committee on Trauma, the American College of Emergency Physicians, the National Association of EMS Physicians, and the Pediatric Equipment Guidelines Committee—Emergency Medical Services for Children (EMSC) Partnership for Children Stakeholder Group

Equipment for Ambulances, 6/09

Joint Statement of the American Academy of Pediatrics and the American Heart Association

Role of Pulse Oximetry in Examining Newborns for Congenital Heart Disease: A Scientific Statement from the AHA and AAP, 8/09

Joint Statement of the American Academy of Pediatrics, the American Thyroid Association, and the Lawson Wilkins Pediatric Endocrine Society

Update of Newborn Screening and Therapy for Congenital Hypothyroidism (Clinical Report), 6/06, reaffirmed 12/11

Joint Statement of the American Academy of Pediatrics and the Canadian Paediatric Society

Boxing Participation by Children and Adolescents, 8/11

Early Childhood Caries in Indigenous Communities, 5/11

Prevention and Management of Pain in the Neonate: An Update, 11/06, reaffirmed 5/10

Joint Statement of the American Academy of Pediatrics and the Child Life Council

Child Life Services, 10/06, reaffirmed 2/12

Joint Statement of the American Academy of Pediatrics and the Children's Oncology Group

Long-term Follow-up Care for Pediatric Cancer Survivors (Clinical Report), 3/09, reaffirmed 4/13

Joint Statement of the American Academy of Pediatrics and the Institute for Patient- and Family-Centered Care

Patient- and Family-Centered Care and the Pediatrician's Role, 1/12

Joint Statement of the American Academy of Pediatrics and the National Association of Medical Examiners

Distinguishing Sudden Infant Death Syndrome From Child Abuse Fatalities (Clinical Report), 7/06, reaffirmed 4/09, 3/13

Joint Statement of the American Academy of Pediatrics and the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition

Chronic Abdominal Pain in Children (Clinical Report), 3/05

Chronic Abdominal Pain in Children (Technical Report), 3/05

Joint Statement of the American Academy of Pediatrics and Others

Insurance Coverage of Mental Health and Substance Abuse Services for Children and Adolescents: A Consensus Statement, 10/00

Joint Statement of the American Academy of Pediatrics and the Pediatric Orthopaedic Society of North America

Management of Pediatric Trauma, 4/08, reaffirmed 4/13

Joint Statement of the American Academy of Pediatrics and the Society of Critical Care Medicine

Admission and Discharge Guidelines for the Pediatric Patient Requiring Intermediate Care (Clinical Report), 5/04, reaffirmed 2/08, 1/13

Guidelines for Developing Admission and Discharge Policies for the Pediatric Intensive Care Unit (Clinical Report), 4/99, reaffirmed 5/05, 2/08, 1/13

Joint Statement of the American Academy of Pediatrics, the Society of Critical Care Medicine, and the Child Neurology Society
Guidelines for the Determination of Brain Death in Infants and Children: An Update of the 1987 Task Force Recommendations (Clinical Report), 8/11

Joint Statement of the Federation of Pediatric Organizations
Pediatric Fellowship Training, 7/04

ENDORSED CLINICAL PRACTICE GUIDELINES AND POLICIES
(*The AAP endorses and accepts as its policy the following clinical practice guidelines and policies that have been published by other organizations.)*

Advisory Committee on Immunization Practices
General Recommendations on Immunization: Recommendations of the Advisory Committee on Immunization Practices (ACIP), 12/06

Advisory Committee on Immunization Practices and Centers for Disease Control and Prevention
A Comprehensive Immunization Strategy to Eliminate Transmission of Hepatitis B Virus Infection in the United States, 7/06

Ambulatory Pediatric Association
Report of the National Consensus Conference on Family Presence during Pediatric Cardiopulmonary Resuscitation and Procedures, 9/03

American Academy of Child and Adolescent Psychiatry and Child Welfare League of America
Foster Care Mental Health Values, 2002
Mental Health and Substance Use Screening and Assessment of Children in Foster Care, 2003

American Academy of Emergency Medicine, American Association of Critical Care Nurses, American College of Emergency Physicians, Association of periOperative Registered Nurses, Emergency Department Practice Management Association, Emergencies Nurses Association, and National Association of EMS Physicians
Consensus Statement: Definitions for Consistent Emergency Department Metrics (2/10)

American Academy of Family Physicians, American Academy of Orthopaedic Surgeons, American College of Sports Medicine, American Medical Society for Sports Medicine, American Orthopaedic Society for Sports Medicine, and American Osteopathic Academy of Sports Medicine
Selected Issues for the Adolescent Athlete and the Team Physician: A Consensus Statement, 11/08

American Academy of Neurology and Child Neurology Society
Evidence Report: Genetic and Metabolic Testing on Children With Global Developmental Delay, 9/11
Evidence-Based Guidelines Update: Medical Treatment of Infantile Spasms, 6/12

American College of Emergency Physicians
Clinical Policy: Evidence-Based Approach to Pharmacologic Agents Used in Pediatric Sedation and Analgesia in the Emergency Department (Clinical Practice Guideline), 10/04

American College of Obstetricians and Gynecologists
Timing of Umbilical Cord Clamping After Birth, 12/12

American College of Rheumatology
Guidelines for Referral of Children and Adolescents to Pediatric Rheumatologists, 6/02, reaffirmed 5/07

American Diabetes Association
Diabetes Care for Emerging Adults: Recommendations for Transition From Pediatric to Adult Diabetes Care Systems, 11/11
Safe at School Campaign Statement of Principles, endorsed 2/06
Type 2 Diabetes in Children and Adolescents, 3/00

American Heart Association
Cardiovascular Risk Reduction in High-Risk Pediatric Populations, 12/06
Diagnosis, Treatment, and Long-Term Management of Kawasaki Disease: A Statement for Health Professionals (Clinical Report), 12/04
Dietary Recommendations for Children and Adolescents: A Guide for Practitioners, 9/05
Genetic Basis for Congenital Heart Defects: Current Knowledge, 6/07
Importance and Implementation of Training in Cardiopulmonary Resuscitation and Automated External Defibrillation in Schools, 2/11
Long-term Cardiovascular Toxicity in Children, Adolescents, and Young Adults Who Receive Cancer Therapy: Pathophysiology, Course, Monitoring, Management, Prevention, and Research Directions: A Scientific Statement From the American Heart Association, 9/13
Neurodevelopmental Outcomes in Children With Congenital Heart Disease: Evaluation and Management: A Scientific Statement From the American Heart Association, 7/12
Noninherited Risk Factors and Congenital Cardiovascular Defects: Current Knowledge, 6/07
Prevention of Infective Endocarditis: Guidelines From the American Heart Association (Clinical Practice Guideline), 5/07
Prevention of Rheumatic Fever and Diagnosis and Treatment of Acute Streptococcal Pharyngitis, 2/09
Response to Cardiac Arrest and Selected Life-Threatening Medical Emergencies: The Medical Emergency Response Plan for Schools. A Statement for Healthcare Providers, Policymakers, School Administrators, and Community Leaders, 1/04

American Medical Association
Gifts to Physicians From Industry, 8/01

American Pediatric Surgical Association
Best Practice for Infant Surgery: A Position Statement From the American Pediatric Surgical Association, 9/08

American Society for Parenteral and Enteral Nutrition
Defining Pediatric Malnutrition: A Paradigm Shift Toward Etiology-Related Definitions, 3/13

American Thoracic Society and Centers for Disease Control and Prevention

APPENDIX 2

PPI: AAP Partnership for Policy Implementation

BACKGROUND

The American Academy of Pediatrics (AAP) develops policies that promote the attainment of optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. These documents are valued highly not only by clinicians who provide direct health care to children, but by members of other organizations that share similar goals, and also by parents, payers, and legislators. Unfortunately, AAP policy documents vary widely in terms of how they are written, and some find these documents difficult to implement. Pediatricians who have expertise in medical informatics found AAP policy documents particularly challenging when they tried to convert policy recommendations into items that could be easily programmed into an electronic system. In June 2005, with initial funding support from the federal Maternal and Child Health Bureau, the AAP launched the Partnership for Policy Implementation (PPI), a pilot program to create changes in the development of policy statements, clinical reports, technical reports, and clinical practice guidelines—specifically, how they are written. Unofficially, collaboration began that resulted in this project to demonstrate the feasibility of integrating health information technology (HIT) functionalities into AAP policy. The PPI is currently funded by the AAP Child Health Informatics Center (CHIC).

VISION

The vision of the PPI is for all AAP policy statements, clinical reports, technical reports, and clinical practice guidelines to have medically sound content, a transparent evidence base, and clearly stated, actionable recommendations that can be implemented in practice and incorporated into electronic systems to support the delivery of high-quality care for children and youth and their families.

MISSION

The mission of the PPI is to facilitate implementation of AAP recommendations at the point of care by ensuring that AAP documents are written in a practical, action-oriented fashion with unambiguous recommendations.

WHAT IS THE PPI?

It is a network of pediatric informaticians who work with AAP authors and guideline subcommittees throughout the writing process.

Contributions of the PPI to the AAP writing process include disambiguation and specification; development of clear definitions; clearly defined logic; implementation techniques; action-oriented recommendations, including clinical algorithms; transparency of evidence basis for recommendations; and health information technology (HIT) standard development.

WHAT HAS THE PPI ACCOMPLISHED?

Since its inception, over 20 statements have been published using the PPI process covering child health topics as diverse as identifying developmental disorders through surveillance and screening (*Pediatrics.* 2006;118:405–420); diagnosis and management of bronchiolitis (*Pediatrics.* 2006;118:1774–1793); prevention of influenza (*Pediatrics.* 2007;119:846–851 and subsequent annual updates); identification, evaluation, and management of autism (*Pediatrics.* 2007;120:1162–1182 and *Pediatrics.* 2007;120:1183–1215); recommendations for and implications of newborn screening (*Pediatrics.* 2008;121:192–217); hearing assessment (*Pediatrics.* 2009; 124:1252–1263); enhancing pediatric mental health care (*Pediatrics.* 2010;125:S109–S125); and the diagnosis and management of childhood obstructive sleep apnea syndrome (Pediatrics. 2012; 130: e714–-e755).

One example of how a statement developed using the PPI process has gained broader acceptance is the influenza statement published in April 2007. The Centers for Disease Control and Prevention chose to adopt components of the PPI statement (specifically, the clinical algorithm) within its own statement on the same topic. In addition, the Childhood Influenza Immunization Coalition posted an interactive version of the influenza algorithm on its Web site (www.preventchildhoodinfluenza.org/resource/algorithm.swf).

WHAT IS THE PPI DOING NOW?

In addition to creating practical, action-oriented documents that pediatricians can use, the PPI is also working to make it easier for these documents to be incorporated into electronic systems. To date, the PPI has focused its involvement on the statement development process. The involvement of the PPI during the writing process helps to produce a clear, more concise document. As these standards of care become well documented, the PPI can begin to focus on building or mapping pediatric vocabulary; once solidified, this vocabulary can be built into electronic health record (EHR) systems. The standards of care can also be matched to the various logical and functional HIT standards that already exist today. Through this work, the PPI hopes to improve AAP policy documents by providing specific guidance to pediatricians at the point of care, to help ensure that EHRs are designed to assist pediatricians in providing optimal care for children.

For more information about the PPI, please visit the Web site (http://www2.aap.org/informatics/PPI.html) or contact Lisa Krams (lkrams@aap.org or 847/434-7663).

"A must-have tool for the busy pediatrician. I use PCO every day."
—Ramon Fonseca, MD

pediatric care online™

Clinical Answers and Patient Education Solutions at the Point of Care

www.pediatriccareonline.org

One convenient resource, integrating a full range of authoritative AAP clinical content

Pediatric Care Online™ (PCO) is a practical resource to help busy practitioners provide optimal patient care. It incorporates a wealth of point-of-care references, tools, patient education, and more—online and mobile. Tap into content written by hundreds of leading experts with a focus on **pediatrics**!

HERE'S WHAT'S INCLUDED.

Comprehensive Reference Library

- Point-of-Care Quick Reference
- *AAP Textbook of Pediatric Care*
- *Red Book®*
- Bright Futures Guidelines and Pocket Guide
- Performing Preventive Services: A Bright Futures Handbook
- Pediatric Drug Lookup
- Antimicrobial Therapy Guide
- Visual Library
- Webinars
- Pediatric Care Updates
- AAP Policy

Time-saving Clinical Tools

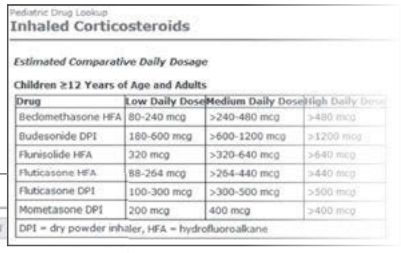
- Interactive Periodicity Schedule
- Signs & Symptoms Search
- Algorithms
- Patient Handouts
- Forms & Tools
- Clinical Calculators
- MEDLINE Search

Pediatric Care Online™ helps you...

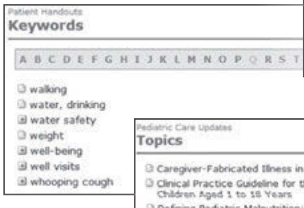
▶ **Conduct effective well-child visits:** Click on a specific visit in PCO's Interactive Periodicity Schedule to view recommended history, physical exam, immunizations, and screening assessments. Link to Bright Futures for additional information as needed: the *Guidelines, Pocket Guide,* and *Performing Preventive Services* manual are all included in PCO.

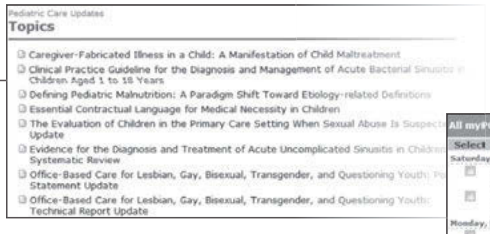
◀ **Evaluate acute complaints:** Search or browse to access diagnosis, treatment, and management information from key problem-solvers including the Point-of-Care Quick Reference, the *AAP Textbook of Pediatric Care, Red Book®,* and more.

▶ **Determine best treatment:** Find the forms, tools, and calculators you need; consult AAP Policy and the Pediatric Drug Lookup.



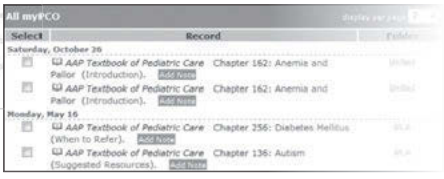
▶ **Provide reliable patient education:** Access more than 450 patient education tools from the AAP and other trusted sources—on what to expect, what to watch for, specific conditions, and more.





▶ **Stay current:** PCO is continually updated and regularly enhanced.

▼ **Customize your resource:** Save favorite search results and content to myPCO.



Plus—earn CME: *Pediatric Care Online*™ is an approved source that may be searched through the AAP PediaLink Internet Point of Care Search CME Activity, to claim *AMA PRA Category 1 Credits*™.

American Academy of Pediatrics

Pediatric Clinical Practice Guidelines & Policies

A Compendium of Evidence-based Research for Pediatric Practice
14th Edition

Text and CD-ROM all in one!

Clinical practice guidelines have long provided physicians with an evidence-based decision-making tool for managing common pediatric conditions. Policies issued and endorsed by the American Academy of Pediatrics (AAP) represent the AAP position on child health care issues.

More than 30 clinical practice guidelines and more than 400 policy statements, clinical reports, and technical reports have been combined into this fourteenth edition of *Pediatric Clinical Practice Guidelines & Policies* book and CD-ROM, giving you even easier access to the important clinical and policy information you need.

Manual includes

- Complete AAP clinical practice guidelines
- Complete 2013 AAP policy statements and clinical and technical reports
- Appendices on policies by committee, the AAP Partnership for Policy Implementation, and AAP acronyms
- Quick Reference Tools including coding tips, patient education handouts, and more
- Six-section organization for ease of use

CD-ROM includes

- Complete AAP clinical practice guidelines
- Complete text of all AAP policies through December 2013
- Full search capabilities
- AAP-endorsed policy statements from other medical groups

Clinical practice guidelines included in this edition cover the following pediatric conditions:

- Attention-deficit/hyperactivity disorder
- Autism
- Bronchiolitis
- Cerebral palsy
- Community-acquired pneumonia
- Congenital adrenal hyperplasia
- Depression
- Diabetes—*New!*
- Dialysis
- Dysplasia of the hip
- Endocarditis
- Febrile seizures
- Fluoride
- Food allergy
- Gastroenteritis
- Gastroesophageal reflux
- Group B streptococcal disease
- *Helicobacter pylori* infection
- Hematopoietic stem cell transplant
- Human immunodeficiency virus—*New!*
- Hyperbilirubinemia
- Influenza
- Intravascular catheter-related infections
- Jaundice
- Methicillin-resistant *Staphylococcus aureus*
- Migraine headache
- Nonfebrile seizures
- Otitis media—*New!*
- Radiology
- Sedation and analgesia
- Sinusitis—*New!*
- Sleep apnea
- Status epilepticus
- Tobacco use and dependence
- Urinary tract infection
- Vesicoureteral reflux

Organization of *Pediatric Clinical Practice Guidelines & Policies*, 14th Edition

Section 1:	Clinical Practice Guidelines From the American Academy of Pediatrics
Section 2:	Endorsed Clinical Practice Guidelines
Section 3:	Affirmation of Value Clinical Practice Guidelines
Section 4:	2013 Policies From the American Academy of Pediatrics
Section 5:	Current Policies From the American Academy of Pediatrics
Section 6:	Endorsed Policies
Appendix 1:	Policies by Committee
Appendix 2:	PPI: AAP Partnership for Policy Implementation
Appendix 3:	American Academy of Pediatrics Acronyms

Pediatric Clinical Practice Guidelines & Policies, 14th Edition, is the perfect practical reference book for primary care physicians, nurses, and allied health professionals, as well as an excellent resource for academic researchers, school and community health professionals, and anyone else involved in the care of infants, children, adolescents, and young adults.

For other pediatric resources, visit the American Academy of Pediatrics Online Bookstore at **www.aap.org/bookstore.**

CLINICAL REPORT

Assessment and Management of Inguinal Hernia in Infants

abstract

FREE

Inguinal hernia repair in infants is a routine surgical procedure. However, numerous issues, including timing of the repair, the need to explore the contralateral groin, use of laparoscopy, and anesthetic approach, remain unsettled. Given the lack of compelling data, consideration should be given to large, prospective, randomized controlled trials to determine best practices for the management of inguinal hernias in infants. *Pediatrics* 2012;130:768–773

Kasper S. Wang, MD, and the COMMITTEE ON FETUS AND NEWBORN AND SECTION ON SURGERY

KEY WORDS

inguinal hernia, infants, surgery, anesthesia, laparoscopy

ABBREVIATION

PPV—patent processus vaginalis

INTRODUCTION

Inguinal hernia is a common condition requiring surgical repair in the pediatric age group. The incidence of inguinal hernias is approximately 3% to 5% in term infants and 13% in infants born at less than 33 weeks of gestational age.[1] Inguinal hernias in both term and preterm infants are commonly repaired shortly after diagnosis to avoid incarceration of the hernia. Given the lack of definitive data, optimal timing for repair of inguinal hernias in infants remains debatable. This report reviews the embryology and natural history of inguinal hernias as well as published data regarding the timing and approach to inguinal hernia repair in infants.

EMBRYOLOGY AND NATURAL HISTORY OF THE PATENT PROCESSUS VAGINALIS

Complete understanding of the issues related to surgical repair of an inguinal hernia requires an understanding of the embryology of descent of the testes and the formation of the processus vaginalis.

Testicular descent involves 2 phases: intra-abdominal and extra-abdominal.[2] During the intra-abdominal phase, the testis, which derives from the bipotential gonad originating at the urogenital ridge, is attached to the diaphragm by the craniosuspensory ligament. In the male fetus, regression of the craniosuspensory ligament results in transabdominal migration of the testis between 8 and 15 weeks postconception. Simultaneously, there is thickening of the gubernaculum, which attaches the testis to the scrotum through the external and internal rings of the inguinal canal. As the male fetus grows and the abdomen elongates, the testis is essentially anchored by the thickened gubernaculum.[3] In the female fetus, the craniosuspensory ligament is maintained; hence, the ovary retains its dorsal (retrocoelomic or retroperitoneal)

intra-abdominal location. In addition, the gubernaculum does not thicken but persists as the ovarian round ligament.

The second phase occurs between 25 and 35 weeks of gestation.[4] The testis descends from its retroperitoneal, intra-abdominal location through the inguinal canal, drawing with it an extension of the peritoneal lining, which defines the processus vaginalis. Normally, the processus vaginalis obliterates and involutes, leaving no communication between the intra-abdominal peritoneal cavity and the extra-abdominal inguinal canal and scrotum. This enveloping involuted layer is the tunica vaginalis. Both human in vitro tissue culture and rodent model studies implicate genitofemoral nerve innervation as critical for regulation of gubernacular length as well as obliteration of the processus vaginalis.[5–7] Incomplete involution results in a patent processus vaginalis (PPV), through which fluid can travel and accumulate extra-abdominally as a hydrocele. If the communication is large, intra-abdominal structures such as bowel may herniate, resulting in an indirect inguinal hernia. The relation of the processus vaginalis with testicular descent is thought to explain why more than 90% of pediatric inguinal hernias are diagnosed in boys.[1] Involution of the left processus vaginalis precedes that of right, which is consistent with the observation that 60% of indirect inguinal hernias occur on the right side.[8]

The prevalence of PPV is highest during infancy and declines with age. Congenital hydroceles, which are essentially clinically apparent PPV, usually resolve spontaneously within 18 to 24 months.[9,10] The reported prevalence of PPV is as high as 80% in term male infants.[11] However, this prevalence is generally extrapolated from findings at time of exploration of the contralateral internal ring during time of inguinal hernia repair. Thus, most reported rates of bilateral PPV are derived from observations in patients with symptomatic unilateral inguinal hernias and likely overestimate the true prevalence of PPV in the general population. Rowe et al reported a 64% rate of contralateral PPV identified at the time of inguinal hernia repair in infants younger than 2 months. Reported rates of contralateral PPV decrease to between 33% and 50% in children younger than 1 year of age and are as low as 15% by 5 years of age.[12–16] Not all cases of PPV result in inguinal hernias. The estimated childhood risk of developing an inguinal hernia if there is a PPV is between 25% and 50%.[17,18] Even though the true prevalence of a PPV in the general pediatric population is likely lower than contralateral PPV reported at the time of hernia repair, it is clearly greatest at birth and declines with increasing age.

RATIONALE AND TIMING FOR ELECTIVE INGUINAL HERNIA REPAIR IN INFANTS

All inguinal hernias in infants are repaired to avoid the risk of incarceration of bowel and gonadal infarction and atrophy.[19–22] However, these risks must be balanced against the risk of potential operative and anesthetic complications. Unfortunately, data regarding these risks are not definitive.

Many investigators have sought to define the risk of inguinal hernia incarceration in young children. However, the physical features of hernia, such as the size of the abdominal wall defect, the amount of the herniating intestine, and the ease with which it can be reduced, do not consistently predict the risk of incarceration. Attempts have been made to correlate the age at diagnosis, the duration between diagnosis and hernia repair, and infants' gestational age with risk of inguinal hernia incarceration. Notably, in an analysis of a Canadian administrative database containing more than 1000 children with inguinal hernia, Zamakshary et al showed that children younger than 1 year had a twofold greater risk of inguinal hernia incarceration when repair was performed $\geq$14 days after diagnosis compared with children who had repair performed between 1 and 2 years of age.[23] Vaos et al reported a retrospective analysis of preterm infants undergoing inguinal hernia repair at 1 of 2 institutions.[24] They noted that infants undergoing repair later than 1 week after diagnosis were at significantly greater risk of inguinal hernia incarceration, postoperative hernia recurrence, and testicular atrophy, compared with infants undergoing earlier repair. Lautz et al analyzed the risk of inguinal hernia incarceration in approximately 49 000 preterm infants using the 2003 and 2006 Kids' Inpatient Databases.[25] They determined that the overall rate of inguinal hernia incarceration was approximately 16% and that the risk was greatest in infants in whom surgery was delayed beyond 40 weeks' corrected gestational age (21%) compared with those repaired between 36 and 39 weeks (9%) corrected age or less than 36 weeks corrected gestational age (11%). Furthermore, 28% of former preterm infants undergoing repair during a subsequent hospitalization were noted to have inguinal hernia incarceration, suggesting an even greater risk with further delay. Although fraught with limitations inherent to administrative databases, the conclusions of this study are compelling.

Conversely, other data indicate that delay in inguinal hernia repair is associated with low rates of inguinal hernia incarceration. Lee et al reported a 4.6% rate of hernia incarceration in 172 former preterm infants within a single Kaiser system hospital. Of the 127 infants who were discharged from

the hospital with known inguinal hernias and scheduled for a planned elective outpatient repair, there were no episodes of inguinal hernia incarceration while awaiting repair.[26] Uemura et al reported comparable inguinal hernia incarceration rates in 19 preterm infants (birth weight range 492–2401 g) who underwent repair at more than 2 weeks after diagnosis, compared with 21 preterm infants who underwent more urgent repair.[27] Although these studies suggest that inguinal hernia repair can be delayed, the data are not as compelling as those suggesting repair on a more urgent basis.

Inguinal hernia repair is associated with operative complications, including hernia recurrence, vas deferens injury, and testicular atrophy, the rates of which vary from 1% to 8%.[28–31] Long-term complications include chronic pain and infertility in adulthood.[32] In a single-institution, retrospective analysis, Moss et al observed low recurrence and complication rates up to 5 years after surgical repair in infants younger than 2 months of age.[33] Conversely, a retrospective analysis by Baird et al revealed a higher rate of complications in infants who were 43 weeks' corrected gestational age or younger, compared with those who underwent repair at an older age.[34] They speculated that the greater friability of the hernia sac in former preterm infants predisposes to repair failure.

Early repair of inguinal hernias in preterm infants must be further balanced against the risk of postoperative apnea after general anesthesia. Historically, the rate of postoperative apnea in preterm infants has been reported to be as high as 49%.[35,36] The risk of postoperative apnea is associated with perioperative anemia and a history of preoperative apnea as well as associated comorbidities.[35,37] Vaos et al noted that preterm infants undergoing inguinal hernia repair within 1 week of diagnosis experienced a significantly greater rate of apnea compared with those undergoing repair later.[24] Melone et al reported on a cohort of 127 former preterm infants (mean gestational age, 32.7 weeks) who underwent outpatient inguinal hernia repair at a mean corrected gestational age of 45.3 weeks. The authors identified only 2 infants who experienced episodes of apnea: 1 in the operating room, the other postdischarge. They concluded that because the apnea rate is so low, elective outpatient inguinal hernia repair is a feasible option for preterm infants. Lee et al reported no episodes of apnea in a cohort of preterm infants (30.7 weeks' gestation at birth) undergoing outpatient elective hernia repair.[26] However, the authors noted that 13 of 45 former preterm infants who underwent elective inguinal hernia repair before discharge from the NICU remained intubated for longer than 2 days postoperatively.

Younger corrected gestational age is associated with a greater risk of apnea.[38] Allen et al noted a nearly 9% rate of postoperative apnea in their cohort of 57 preterm infants undergoing inguinal hernia repair.[39] In a subset analysis, infants who experienced apnea episodes tended to be younger (41 weeks' corrected gestational age compared with 47 weeks' corrected gestational age); had significantly higher perioperative risk, as measured by American Society of Anesthesia scores (2.6 compared with 1.8); and were more likely to have received intraoperative narcotic and muscle relaxation compared with infants who were not apneic. A recent meta-analysis concluded that former preterm infants undergoing general anesthesia who are less than 46 weeks' corrected gestational age should be observed for at least 12 hours postoperatively and that those who are between 46 and 60 weeks' corrected gestational age should receive more individualized care on the basis of the presence or absence of associated comorbidities.[40]

To reduce the incidence of postoperative apnea, spinal, rather than general, anesthesia has been used for inguinal hernia repair in preterm infants.[41–43] Although some studies have been encouraging, none have been adequately powered. Indeed, Craven et al published a Cochrane Collaboration analysis in which only 108 patients from 4 small randomized or quasi-randomized studies comparing spinal and general anesthesia were identified.[44] The authors concluded that there was no evidence that spinal anesthesia was associated with a reduction in postoperative apnea, bradycardia, or oxygen desaturation. Furthermore, the authors concluded that a large, randomized controlled trial was necessary to determine whether spinal anesthesia reduces postoperative cardiorespiratory complications; to date, no such study has been reported.

Over the past decade, studies performed in rodents and nonhuman primates have shown a dose-dependent association of neuronal apoptosis with general anesthetic agents, including ketamine, propofol, and isoflurane.[45–47] Importantly, there is emerging evidence that the use of general anesthesia in infancy may be associated with long-term neurocognitive and developmental problems, specifically after multiple exposures to general anesthesia before 3 years of age.[48] DiMaggio et al, using a New York State Medicaid database, showed that children younger than 3 years who were given general anesthesia for inguinal hernia repair had a greater than twofold risk of developmental or behavioral disorders than did age-matched control children.[49] A potential bias of this study is that children undergoing surgery at a young age may

also be predisposed to learning or cognitive disorders. Bartels et al attempted to address this issue by using the Netherlands Twin Registry to evaluate monozygotic concordant-discordant twins. In a study of 1143 monozygotic twin pairs, exposure to anesthesia before 3 years of age was associated with reduced educational achievement.[50] However, there was no difference in outcome between twin pairs when one twin had undergone anesthesia and the other had not. The authors concluded that there is no causal relationship between anesthesia exposure and learning disabilities. Hansen et al recently compared ninth-grade test scores of nearly 2700 Swedish children who had undergone inguinal hernia repair as infants with those of randomly selected age-matched controls and found no difference in test performance.[51] Clearly, the issue of whether anesthetic exposure as an infant affects long-term neurodevelopment is unsettled. Two large clinical studies are under way to address this issue.[52]

Ultimately, the timing of preterm infant inguinal hernia repair varies widely in practice. In a 2005 survey of members of the American Academy of Pediatrics Section on Surgery, 63% reported routinely performing hernia repairs just before discharge from the NICU, 18% performed repairs at a specific corrected gestational age, and 5% performed repairs when it was convenient.[53] If a hernia was discovered after discharge, 53% of respondents would repair the hernia when it was convenient, and 27% of respondents would wait to repair until the infant was between 38 and 60 weeks' corrected gestational age (mean, 53.1 weeks' corrected gestational age). In a previous survey performed in 1993, surgeons were more likely to repair an inguinal hernia when convenient.[54]

Timing of inguinal hernia repair in preterm and term infants represents a balance of the risks of inguinal hernia incarceration and of postoperative respiratory complications. At present, the literature does not clearly define what these risks are and how they should be balanced.

CONTRALATERAL INGUINAL EXPLORATION

The utility of contralateral inguinal exploration in children is an area of active debate. The rationale for attempting to diagnose a contralateral PPV is that repair can be performed to prevent any potential contralateral incarceration with no additive anesthetic risk. Historically, surgeons performed routine open contralateral inguinal explorations to identify PPV in either all children or in selected populations (ie, former preterm infants or children younger than 2 years). Marulaiah et al suggested that routine contralateral exploration is not indicated, given the risks associated with such exploration, such as spermatic cord injury.[55] Alternatively, given the high incidence of subsequent hernias if a contralateral PPV is encountered, others support routine exploration.[13,56,57] Lee et al indicated that it is cost-effective to perform routine contralateral groin explorations.[58] Results from the aforementioned 2005 survey of American Academy of Pediatrics Section on Surgery members revealed a variety of practices; 15% of respondents indicated that they never explore the contralateral side in a male patient, 12% responded that they always do, and 73% responded that they had an age cutoff beyond which they would not explore.[53] Respondents also had a wide variation of practices when caring for a girl with a unilateral hernia. For both male and female patients with hernias, however, results of the survey revealed that there were significant reductions in the routine explorations of the contralateral side compared with results from the same survey performed in 1996.[54] Various diagnostic modalities, such as the physical examination, herniography, or ultrasonographic examination are not particularly sensitive or specific, thus making these efforts unreliable.[56,59] With the advent of laparoscopic techniques, inspection of the contralateral internal ring has become increasingly popular as the method of choice for evaluating for a PPV. According to survey responses, use of laparoscopy as the modality with which to explore the contralateral ring has increased from 6% in 1996 to 37% in 2005.[53,54] Use of laparoscopy to explore the contralateral groin has likely increased since then.

LAPAROSCOPIC APPROACH TO INGUINAL HERNIA REPAIR IN INFANTS

Laparoscopic repair has been used effectively in preterm infants. Various techniques have been described, but all routinely use a port placed in the umbilicus to visualize the internal ring. Reported hernia recurrence rates are comparable to those associated with open repair.[60,61] However, data regarding the risk of testicular atrophy are not available.[62,63] A prospective, randomized, single-blinded trial comparing laparoscopic to open repair of inguinal hernias showed that children who were older than 3 months of age when laparoscopic repair was performed required significantly fewer doses of pain medication.[64] The utility of laparoscopic repair of inguinal hernias in younger infants remains undetermined to date.

CONCLUSIONS

- Inguinal hernias are common in the infant population. The risk of hernia incarceration drives the preference to pursue surgical repair.
- Data regarding optimal timing of repair are conflicting and inadequate.

- There is no consensus on when or if contralateral inguinal exploration is necessary.
- Data regarding a laparoscopic approach to inguinal hernia repairs suggest that it is comparable to the standard open technique.
- Given the lack of data supporting evidence-based approaches to inguinal hernias in infants, consideration should be given to large, prospective, randomized, controlled trials to answer these important questions.

Baseball and softball are among the most popular and safest sports in which children and adolescents participate. Nevertheless, traumatic and overuse injuries occur regularly, including occasional catastrophic injury and even death. Safety of the athlete is a constant focus of attention among those responsible for modifying rules. Understanding the stresses placed on the arm, especially while pitching, led to the institution of rules controlling the quantity of pitches thrown in youth baseball and established rest periods between pitching assignments. Similarly, field maintenance and awareness of environmental conditions as well as equipment maintenance and creative prevention strategies are critically important in minimizing the risk of injury. This statement serves as a basis for encouraging safe participation in baseball and softball. This statement has been endorsed by the Canadian Paediatric Society. *Pediatrics* 2012;129:e842–e856

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

The pediatrician needs to have an understanding of baseball and softball. This will allow the pediatrician to offer appropriate counseling and guidance to the many boys and girls, their parents, and members of the sporting community who participate in baseball and softball each year.

Baseball is one of the most popular sports in the United States, with an estimated 8.6 million children ages 6 to 17 participating annually in organized and recreational baseball.[1] Although baseball is a relatively safe sport in comparison with many other athletic activities, highly publicized catastrophic impact injuries from contact with a ball or a bat frequently raise safety concerns.[2,3] These incidents, as well as the high frequency of shoulder and elbow injuries resulting from overload and overuse, provide the impetus for this review and new guidance to reduce injury risk and improve safety in baseball for 5- to 18-year-old participants. This policy statement replaces the previous statement written in 2001.[4] This statement has been endorsed by the Canadian Paediatric Society.

Beginning in the early 1990s, epidemiological and injury surveillance research in baseball and softball intensified. Data from these scientific efforts paved the way for organized baseball to create medical advisory committees, which generated policies designed to reduce the risks of injury in baseball and softball. Advances in equipment also continue to offer new opportunities to make the game safer for youth athletes; similarly, the dissemination and use of automatic lightning detectors (which produce a clear and loud warning signal) and automated external defibrillators (AEDs) provide additional means of reducing catastrophic events on the baseball field.[5,6] Moreover, organized youth baseball coaches, officials, and administrators must remain knowledgeable and

sensitive to the developmental and skill levels of young baseball players and continue to modify the rules, when necessary, for the safety of the players. This policy statement focuses principally on baseball, but softball will also be considered where relevant literature is available.

PARTICIPATION

There are over a dozen youth baseball organizations whose combined annual participation is nearly 5 million. Little League Baseball reports baseball participation at approximately 2.3 million annually and softball participation at 400 000 per year[7]; the Babe Ruth League (and its 12-and-under Cal Ripken Baseball division) has more than 1 million youth participants annually.[8] Over 2 million girls between the ages of 12 and 18 compete in fast pitch softball annually. The National Federation of State High School Associations 2009–2010 participation data counted 473 503 baseball players (ages 14–18) and 393 578 softball athletes.[9]

INJURY DATA

There are a variety of sources of data for injuries in youth baseball, which include hospital emergency departments, insurance claims, national catastrophic injury reporting system, and independent researchers.[1,10–13] Each of these sources captures a limited view of total injuries. Taken together, however, a fairly consistent pattern emerges on the overall injury incidence and relative frequency (prevalence) of baseball injuries compared with other sports. Comprehensive data also come from the high school level reporting systems using certified athletic trainers to record the key injury-related information on this 14- to 18-year-old population.[14–16]

Prevalence

The US Consumer Product Safety Commission (CPSC) maintains the National Electronic Injury Surveillance System (NEISS) through a network of approximately 100 participating US emergency departments. From the data collected from this cross section of national emergency departments, the CPSC extrapolates national estimates of injury prevalence in various age groups. The overall prevalence of all sports-related injuries in children younger than 15 years seen in an emergency department is just under a million per year; in 2007, the CPSC estimated that 109 202 baseball- and softball-related injuries among 5- to 14-year-old children were treated in US emergency departments nationally.[17] More specifically, in 2007, the CPSC/NEISS recorded exactly 3343 baseball injuries among 5- to 18-year-old children from the participating US emergency departments (T.J. Schroeder, MS, personal communication, 2009). The frequency distribution of injuries by age followed a bell-shaped curve for ages 5 to 18 years, with the highest number of injuries clustered in children from 11 to 14 years of age (more than 300 injuries per year of age).[17] Because 11- to 14-year-old children represent the majority of participants, valid injury risk comparisons with other age groups cannot be directly determined from these raw numbers alone. Nearly half of the 3343 injuries (44%) involved the head (25% to the face, including eyes and nose; 14% to the head and neck; and 5% to the mouth), with the highest frequency in children 9 to 11 years of age.[17] According to several years of annual NEISS reports, approximately one-fourth to one-third of all youth baseball injuries are to the upper extremities, including the fingers (10%–13%), wrists (4%–5%), and hands (4%–5%). Just under 20% of injuries were to the lower extremities, with knees (5%) and ankles (6%–7%) almost equally affected. Injuries to the trunk and pubic area accounted for approximately 6% to 10% of all injuries.[1,11,17]

Also in 2007, the NEISS recorded exactly 1188 youth softball injuries in the same 100 participating emergency departments. Girls accounted for 1062 injuries, and boys accounted for 126.[17] For girls, the frequency of injuries by age also followed a bell-shaped curve for ages 5 to 18 years, with the highest numbers of injuries clustered in children from 13 to 16 years of age (more than 130 injuries per year of age). The distribution of injuries by body region was more evenly distributed for girls playing softball compared with boys playing baseball, with 28% of girls' softball injuries involving the head and neck, 35% involving the upper extremities, 31% involving the lower extremities, and 5% involving the trunk and pubic area. The 5 most common areas for injury were the face (14%), ankle (14%), finger (13%), knee (11%), and head and neck (11%).[17] Thirty-nine percent of injuries were classified as contusions, abrasions, lacerations, or hematomas/hemorrhages; 31% were classified as sprains or strains; 21% were classified as fractures, dislocations, or avulsions; 4% were classified as internal organ injuries; and 4% were classified as concussions.[17]

Baseball is one of the safest high school sports in the United States with a reported injury rate of 1.26 injuries per 1000 athletic exposures.[14] Baseball athletes have the third lowest rates of injury lasting longer than 1 week among 18 different sports played in high school. However, although the overall injury rate is low, the degree of injury severity is relatively high. In baseball, fractures represent a larger percentage of total injuries than in other sports. Baseball also ranks second highest for the percentage of injuries resulting in a time loss from sport participation longer than 7 days.[14,15] In high school baseball and softball, as in youth baseball, most injuries to the head and face (48%) and mouth

and teeth (16.0%) are attributed to being hit by a batted ball.[14] More of these head and facial injuries also required surgery (18.0%), compared with other baseball-related injuries (6.8%).

USA Baseball, through its Medical and Safety Advisory Committee, sponsored injury-surveillance research and produced a report on injury patterns in youth baseball in 2008 which concluded that, in younger players, injuries are more often associated with lack of skill, whereas in older players, the greater skill, muscle power, and body size become injurious forces.[13] More detailed study findings were as follows:
