6. Fellowship training programs must provide a career mentor(s) for each trainee who will assist the trainee in developing an individualized learning plan for the entire training period. This mentor must be responsible for providing the ongoing formative feedback that is essential to the trainee's attainment of competence in clinical care, teaching, and scholarship. The mentor may come from a division or department other than the one offering the fellowship.
7. Fellowship training programs must be periodically reviewed and evaluated to improve the quality of the trainee's experiences in clinical care, education, and investigation. Tracking trainee career outcomes must be part of this review. The reports of these evaluations must be used to judge whether a program has met predetermined standards for fellowship training and to identify areas in need of improvement. The reports must be made available to trainee applicants and trainees.

Policy Statement—Pediatric Organ Donation and Transplantation

abstract

Pediatric organ donation and organ transplantation can have a significant life-extending benefit to the young recipients of these organs and a high emotional impact on donor and recipient families. Pediatricians, pediatric medical specialists, and pediatric transplant surgeons need to be better acquainted with evolving national strategies that involve organ procurement and organ transplantation to help acquaint families with the benefits and risks of organ donation and transplantation. Efforts of pediatric professionals are needed to shape public policies to provide a system in which procurement, distribution, and cost are fair and equitable to children and adults. Major issues of concern are availability of and access to donor organs; oversight and control of the process; pediatric medical and surgical consultation and continued care throughout the organ-donation and transplantation process; ethical, social, financial, and follow-up issues; insurance-coverage issues; and public awareness of the need for organ donors of all ages. *Pediatrics* 2010;125:822–828

OPO—organ-procurement organization
OPTN—Organ Procurement and Transplantation Network
DCD—donation after cardiac death
UNOS—United Network for Organ Sharing

BACKGROUND

In 1998, the Centers for Medicare and Medicaid Services changed the federal conditions of participation to require that hospitals participating in Medicare and Medicaid programs refer potential organ donors to their local organ-procurement organization (OPO) in a timely manner.[1] The Centers for Medicare and Medicaid Services mandates that all families of potential organ donors be made aware of their option to donate. Legislation further requires all hospitals to have trained "designated requestors" available to discuss organ donation with families of potential donors. Even with these mandates, organ availability remains inadequate. The number of individuals who are on the national transplant waiting list remains far in excess of the number of organs recovered and transplanted.[2] Children from birth to 17 years of age account for approximately 2% to 3% of the national waiting list. More than 70% of the children on the list are waiting for a liver or a kidney, and the small bowel is the organ with the greatest increase in need.[3,4] Ongoing debates attempt to identify the best ways to manage the existing supply of organs and how to improve organ procurement in general.[5]

The Organ Procurement and Transplantation Network (OPTN) is the nation's organ procurement, donation, and transplantation system. The United Network for Organ Sharing (UNOS) is the nonprofit organization that operates under the OPTN under a contract from the federal

government. All organ procurement organizations (OPOs) and transplant programs are OPTN/UNOS members and follow OPTN policies. The OPTN is overseen by the US Department of Health and Human Services, Health Resources and Services Administration. The Children's Health Act,[6] which was passed in October 2000, called on the OPTN to develop specific criteria, policies, and procedures to address the unique needs of children and adults. To overcome the ethical dilemma of organ distribution based on time on the waiting list versus benefit to the patient, the OPTN developed new criteria for organ transplantation for children and adolescents. Included is a new lung-allocation score to maximize benefits and fairness for allocation of donor lungs to potential transplant recipients. This lung-allocation score for patients aged 12 years and older is based on multiple factors, not just the length of time on the transplant waiting list, and allows children to receive priority for pediatric donor lungs before they can be offered to adults. Liver allocation to children on the transplant waiting list is based on the pediatric end-stage liver disease (PELD) and model for end-stage liver disease (MELD) scores and not only on the length of time on the transplant waiting list.[7,8] Kidney-allocation policies are revised so that kidneys from donors younger than 35 years are offered preferentially to pediatric candidates. Children younger than 11 years on the kidney transplant waiting list are given additional priority because of the greater impact of kidney failure on development.[3] Pediatric heart transplantation candidates receive preference over adult candidates in the allocation of adolescent donor hearts depending on the urgency of each case.[3]

ORGAN DONATION

This discussion of organ donation and transplantation acknowledges that this is a most difficult time for 2 families: one with a loved one who has suffered an untimely death and another with a child with a terminal condition. Organ donation is a process that starts when the family begins receiving information about their critically ill child.

The American Academy of Pediatrics supports the role of OPOs by recommending that all potential donor families be approached in a systematic method by individuals trained in the psychological, social, and medical aspects of organ donation. OPOs exist throughout the country. They evaluate potential donors, discuss donation with family members, arrange for surgical removal of donated organs, and arrange for distribution of the organs according to national organ-sharing policies. The rate of families that consent to donation can be increased significantly by using hospital or OPO staff who are specifically trained in organ procurement and by separating or "decoupling" the death notification and organ-donation consent processes.[4,9–11] Timely referral and the use of staff trained in organ procurement are federal requirements for participation in the Medicare program. Timely referral is crucial to ensure that a rushed approach regarding donation is avoided with the family. This may start in the emergency department with the admission of a critically injured child, and staff may start the process at that time.[12] Timely referral provides active communication with the health care team and the OPO, which enhances the chances that the family will agree to organ donation. Deliberation with the OPO should occur before or when initial brain-death testing is occurring or "withdrawal-of-care" or "do-not-resuscitate" options are being discussed. Collaboration with physicians, the health care team, and the OPO is critical to ensure that every family is provided the opportunity to discuss organ donation during end-of-life discussions.[13] Accurate determination of death is essential before efforts to actively recover organs can proceed. One must ensure that death has occurred; if there is any question, additional testing or extending the observation period between neurologic examinations is warranted. Just as important is the timely declaration of neurologic death. Therefore, timely and definitive treatment of the donor is critical.[10] The timely declaration of neurologic death has important benefits. First, it allows the grieving process to begin for the family, which makes a point of closure more likely to be achieved by the family. Second, it improves the success associated with the acquisition of organs. Aggressive medical management of the potential donor to keep organs perfused can increase organ yield. Progression of organ failure secondary to hemodynamic instability after neurologic death results in the loss of up to 25% of potential donors. Third, it avoids continued life support for a person who has died and is no longer a potential donor. Care of the pediatric donor is a natural extension of care for a critically ill and injured child and the family. This continuum of care of the potential pediatric donor and the family is crucial in helping families understand what has transpired with their child. Likewise, support and advice of the child's primary caregiver provides further continuity of care.

Pediatric donors become eligible for organ procurement after the determination of neurologic death has been made. Although most pediatric donors will meet standard criteria for declaration of brain death, donation after cardiac death (DCD)—or non–heart-beating organ donation—has the potential to increase organ donation.[14] Contrary to the belief that DCD is a new way to recover organs, DCD is, in fact,

the foundation of modern transplantation. Organs were routinely recovered from deceased donors by this method before development of brain-death guidelines. For patients with severe brain injury for whom neurologic death is unlikely to occur, DCD enters the end-of-life continuum of care. Discussions regarding DCD can occur only after the family and the medical team have made the decision to withdraw support or terminate care. Comfort measures are provided for the patient as would normally be instituted anytime withdrawal of support occurs. Once life support is withdrawn and the donor develops circulatory arrest, apnea, and unresponsiveness, the patient is observed for a period of 2 to 5 minutes before certification of death. Organs can be recovered for transplantation if death occurs within a short period of time, usually 1 hour, after withdrawal of support. DCD is slowly gaining acceptance in the pediatric community, as evidenced by an increase in organs from pediatric non–heart-beating organ donors over the past few years.[3,4] DCD enables the ability to recover 2 of the most needed organs for children—kidney and liver. Concerns regarding prolonged ischemia time and graft dysfunction have been raised; however, several reports have indicated that renal and liver grafts from DCD donors have graft function and transplant recipient survival rates comparable to those with organs recovered from brain-dead donors.[15–19] In addition, lungs from DCD donors are now being recovered with good success.[9] The Institute of Medicine and the American College of Critical Care Medicine both endorse DCD as a means to recover organs for transplantation.[20,21]

TRANSPLANTATION

The process of organ transplantation begins when the child is referred to a transplant center. When it is determined that the child is a suitable candidate, he or she is added to that transplant center's waiting list through the United Network for Organ Sharing (UNOS) computer, and access information for organ-matching is listed. The UNOS is contracted with the Health Services and Resources Administration to maintain a centralized computer network linking OPOs with transplant centers. When a potential organ donor is identified, a transplant coordinator accesses the UNOS computer. The computer generates a ranked list of potential recipients for each organ that may be procured according to organ-allocation policies, which differ for each organ. These policies were developed by patients and transplant professionals to ensure fair and equitable distribution of organs. There are no criteria based on gender, religion, celebrity status, or financial status. The organ is offered to the transplant team of the first person on the list. The transplant surgeon then determines if that person is appropriate for that particular organ, and if so, the transplant takes place. If not, the organ is offered to the next person on the list.

OPOs are the link between organ donors and recipients. They are responsible for coordinating the recovery of organs, ensuring that there is informed consent, managing the clinical care of the donor once consent is obtained, ensuring the viability of the donated organs until transplant, and transporting the organ to the transplant team. They also provide follow-up information to the donor family and hospital staff. Pediatric transplant programs are smaller than adult programs, because fewer children require transplantation, and they must offer special expertise in children's health care (eg, critical care, dialysis, and interventional radiology). Pediatric transplantations should be performed in only the most experienced of institutions.

The family should be involved in every aspect of transplantation. There are unique consequences of transplantation in childhood that require ongoing evaluation and care besides the functioning of the transplanted organ. Special attention must be given to growth and developmental issues to ensure an optimal neurodevelopmental outcome.[22–24] Some considerations for the medical team caring for the pediatric organ recipient include support (emotional and spiritual) for the recipient, other siblings (eg, social aspects relating to their care), and parents or guardians (eg, maintaining employment status) and the availability of pediatric subspecialty support (critical care, dialysis, anesthesia, interventional radiology, etc).[25,26] Children are much harder to relocate to a transplant center for care, because their families must accompany them and siblings must be cared for at the same time. Involvement of the child's primary care physician and local subspecialist can be beneficial in providing follow-up visits and laboratory monitoring where these capabilities exist.[26] This decreases transportation costs and improves patient access to medical intervention. Keeping the family unit intact reduces stress on the family and improves the outcome for the child.

ETHICAL ISSUES

There are numerous ethical issues involved in the area of organ transplantation. Three general topics are deciding when human beings are dead, deciding when it is ethical to procure organs, and deciding how to allocate organs once they are procured.[27] Additional questions that are raised include: Who should pay for transplantation? Is it ever appropriate to pay for organs? Is transplantation worth the

tremendous cost? Are the benefits justified for all conditions? Is the distribution system as fair as it can be? Should we allow second transplants? It is not the purpose of this policy statement to answer those questions but to raise awareness of them. Donation and procurement of vital organs after cardiac death is ethical, provided informed consent is obtained ahead of time. Organ procurement must not cause death, and death must precede procurement of unpaired organs or both paired organs. Death must be certified by using standardized, objective, and auditable criteria, and death determination must follow state law. All decisions about children are made by parents or guardians on the basis of the best interests of minor children and not on the basis of preservation of patient autonomy per se. It is reasonable for any child for whom a do-not-resuscitate or withdrawal-of-care decision is made in the course of management, or any child who has a nonneurologic death, to be considered a DCD candidate. Unless parents or guardians initiate donation conversations first, discussions regarding donation should occur only after the decision to withdraw support or terminate care has been established. The medical and forensic investigation of the death of a child attributable to trauma (unintentional or resulting from abuse), sudden infant death syndrome, or poisonings presents unique issues related to organ procurement. Close cooperation between the forensic system, transplant team, treating physicians, and OPO facilitates evaluation, guidance, and successful organ procurement in most cases. Cooperation ensures that evidence will not be destroyed and that any injuries noted during organ recovery will be documented and reported. The surgeon also has the responsibility to testify to the condition of the organs at the time of recovery. Some medical examiners believe that individuals who died as a result of abuse should not be organ donors. However, if protocols are developed through which the historical data, surgical and autopsy findings, and laboratory studies are cooperatively examined, most individuals whose death requires investigation can be donors.[28–30] The National Association of Medical Examiners supports organ donation and is working to achieve zero medical examiner denials.[11]

FAMILY SUPPORT

The American Academy of Pediatrics supports the key role of OPO professionals to provide family support during the donation process and in long-term follow-up of the donor family. The success of these efforts is an integral part of increasing organ donation within the local community. In addition to OPOs, the broader medical community must also provide support to the donor family. This includes nurses, clergy, pediatricians and family physicians, child life specialists, and social workers. Involvement of the child's primary care physician and treating subspecialist during organ procurement and transplantation can be beneficial in bedside management, discussion of complex or unusual diseases, and addressing broader medical issues with the donor family. Education of the primary care pediatrician and other health care professionals about approaching the emotional and physical health of the donor's family can be provided by the OPOs. Sensitivity to the needs, beliefs, and desires of each individual family is an important aspect of organ donation, and these family issues must be considered in each circumstance. Each local medical community must evaluate its resources and have procedures in place to support the family during and after the death of a child. The primary care physician is an integral part of the care of the family and should be involved in support and follow-up of the donor family. In addition to family support, the staff at the local medical center should also receive training in dealing with the death of a child, including confidentiality and religious, cultural, and ethical issues. Hospital ethics committees are beneficial in the development of staff support and for discussion of difficult cases.[31,32]

FINANCIAL ISSUES

The cost of organ donation is borne entirely by the OPO. Transplant costs are the responsibility of the recipient. Organ transplantation is one of the most resource-intensive and expensive therapies available to children. The costs are higher for children because of a longer expected life span after transplantation and loss of work for parents or guardians.

Despite these increased costs, the significant benefits of organ and tissue transplantation should outweigh financial concerns.

Payment for organ transplantation and subsequent follow-up care may be covered by employer and individual insurance policies. However, the coverage of certain organ transplants, second transplants, and long-term care is variable, and most policies have a lifetime maximum amount or "cap."[33] Once this amount has been reached, the insurance company has no obligation to pay for additional benefits. The amount of the cap varies greatly and may apply to just 1 procedure or to all procedures and treatments combined. The ongoing cost of transplantation plus ongoing long-term care may exceed the cap. Improved long-term survival in younger transplant recipients places them at high risk of reaching this cap. Medicaid rules vary from state to state, but most transplant procedures are now included. Because

publicly funded programs such as Medicaid, the State Children's Health Insurance Program, TRICARE, and others are insurers of a large segment of the pediatric population, transplantation financial issues must be addressed by state and federally funded health care programs.

PUBLIC AWARENESS

Because the death of a child is often unforeseen, many families have not considered the possibility of organ donation. Pediatricians, children's advocacy groups, and institutions that care for children need to increase awareness of the need for organs with the same enthusiasm with which blood donations and immunization programs are promoted, through the use of posters in waiting rooms, handouts, and other public campaigns. Educational programs have begun with a classroom program titled "Decision: Donation," developed as a part of the US Department Health and Human Services Gift of Life Donation Initiative.[34] Options also exist for the promotion of living donation and bone marrow transplantation. An opportunity to discuss these options within the context of anticipatory guidance during adolescent visits might arise when reviewing the risks of driving.[35] This interaction would better prepare the adolescent for future decisions that he or she may have to make regarding family members and serve to educate the parents of their own organ-donation options. Organ donation is a decision made by families, not by physicians. Every family should be given the opportunity to allow their loved one to become an organ donor. Organ donation should be an option for any family with a loved one for whom end-of-life issues are being discussed.

RECOMMENDATIONS

1. Pediatricians at local, regional, and national levels should promote the awareness for increased organ donation and support regional transplant programs.
2. Organ donation is an integral part of end-of-life care that provides families with a final decision to make concerning a loved one. Every family should be given the opportunity for organ donation if it is medically appropriate, and it should be the expectation that the family will be approached in a professional, compassionate manner. The decision to donate is one made by the family, not by physicians.
3. Accurate and timely declaration of neurologic death is essential to ensure that viable organs are not lost because of a delay in declaration of death.
4. DCD is a reasonable way to increase the number of organs recovered for pediatric transplantation, especially much-needed livers and kidneys.
5. Timely referral to OPOs can increase organ-donation rates by providing active communication with the health care team and the OPO. Timely notification decreases the likeliness of a rushed approach to donation, which enhances the chances of the family agreeing to organ donation. Collaboration with physicians, the health care team, and the OPO is critical to ensure that every family is provided the opportunity to discuss organ donation during end-of-life discussions.
6. The consent procedure for organ donation should be handled by a trained professional, and the death notification and consent for organ-donation processes should be separated or "decoupled."
7. Education of staff should include medical, ethical, social, cultural, and religious issues related to the potential donor and recipient families.
8. Programs for support of donor families should be in place and coordinated with the child's primary care physician.
9. The treating physician should continue to be involved in cooperative medical decision-making and support of the family after the determination of brain death and cardiac death in the patient who has become an organ donor. Care of the pediatric donor is a natural extension of care for a critically ill or injured child and the child's family. Involvement of pediatric critical care specialists as early as possible can increase organ availability and improve the quality of organs recovered for transplantation.
10. Protocols should be developed that allow cooperative examination of evidence and injuries so that organ donation can successfully proceed in cases in which forensic investigation is required.
11. The US Department of Health and Human Services and the medical community must closely examine all transplant and organ-donation regulations and work to ensure that children are fairly served by their policies.
12. An organ-distribution system should recognize the following:
    - Health care for children who need transplantation is best provided in centers of excellence by a health care system that provides medical care delivered by pediatricians, pediatric medical subspecialists, and surgical specialists with expertise in pediatric organ transplantation.
    - Issues related to relocation of the child and family to a transplant center for care, transpor-

tation, and family support must be addressed at all centers that provide transplantations for children.

13. Adequate financial resources and payment for pediatric organ transplantation and lifetime follow-up care must be available.
14. Pediatricians should be informed of the possibility of transplantation for certain patients, be educated about the process of transplantation, be familiar with the transplant center in their region, and be advocates for their patients and their families in the transplant-listing process.

Pediatric Primary Health Care (RE9262)

AMERICAN ACADEMY OF PEDIATRICS

PRIMARY HEALTH CARE is described as accessible and affordable, first contact, continuous and comprehensive, and coordinated to meet the health needs of the individual and the family being served.

PEDIATRIC PRIMARY HEALTH CARE encompasses health supervision and anticipatory guidance; monitoring physical and psychosocial growth and development; ageappropriate screening; diagnosis and treatment of acute and chronic disorders; management of serious and life-threatening illness and, when appropriate, referral of more complex conditions; and provision of first contact care as well as coordinated management of health problems requiring multiple professional services. PEDIATRIC PRIMARY HEALTH CARE for children and adolescents is family oriented and incorporates community resources and strengths, needs and risk factors, and sociocultural sensitivities into strategies for care delivery and clinical practice. PEDIATRIC PRIMARY HEALTH CARE is best delivered within the context of a "medical home," where comprehensive, continuously accessible and affordable care is available and delivered or supervised by qualified child health specialists.

The PEDIATRICIAN, because of training (which includes four years of medical school education, plus an additional three or more years of intensive training devoted solely to all aspects of medical care for children and adolescents), coupled with the demonstrated interest in and total professional commitment to the health care of infants, children, adolescents and young adults, is the most appropriate provider of PEDIATRIC PRIMARY HEALTH CARE.

The Medical Home (RE9262)

The recommendations in this statement do not indicate an exclusive course of treatment or standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Psychosocial Aspects of Child and Family Health

The Pediatrician and Childhood Bereavement

ABSTRACT. Pediatricians should understand and evaluate children's reactions to the death of a person important to them by using age-appropriate and culturally sensitive guidance while being alert for normal and complicated grief responses. Pediatricians also should advise and assist families in responding to the child's needs. Sharing, family support, and communication have been associated with positive long-term bereavement adjustment.

The death of an important person in a child's life is among the most stressful events that a youngster can experience.[1–3] Adults in the midst of their own grief often are confused and uncertain about how to respond supportively to a child.[3,4] When the death involves a parent or a sibling, the potential for an adverse response by the child is compounded.[5] During such a crisis, the pediatrician can be an important source of education and support for a child and family.[1]

By already knowing something of the family interactions and individual coping skills, the pediatrician is in a position to help evaluate and understand a child's reactions and to advise and assist the family in responding to the child's needs.[1–3] Awareness of the child's temperament and typical responses to stress can help the pediatrician counsel the child and family.[2] Cultural and religious background are important considerations in dealing with the bereaved family.[2,6,7] Knowledge of previous significant losses and parent and child responses to them are helpful in understanding and predicting how a death may affect the child and family.[2] Circumstances (eg, prolonged illness, sudden unexpected death, or violent death) are important additional considerations.[6–8] In instances of disasters with multiple deaths, the pediatrician is likely to be called on as a resource by rescue teams, school personnel, and others. The pediatrician should describe to families and personnel the normal childhood emotional reactions to such an abnormal incident and offer support and counsel to the children and to the adults caring for them.[9]

The child should be told about a death honestly and in language that is developmentally appropriate. When advising an adult about informing the child of the death, the pediatrician needs to be aware that a child's concept of death varies with age (Table 1) and needs to be able to tailor the specific advice given to a parent.[3,5,10] The family can be reassured that their showing of feelings, such as shock, disbelief, guilt, sadness, and anger, is normal and helpful.[2] A bereaved parent or other close family member who shares these feelings and memories (eg, with pictures and stories) with a child reduces the child's sense of isolation.[5,11] Children need reassurance that they will be cared for and loved by a consistent adult who attends sensitively to their needs. In addition, they must be assured that they did not cause the death, could not have prevented it, and cannot bring back the deceased.[1,5,8] Parents should be encouraged to continue family routines and discipline.[2,8,12]

The funeral services can provide even a young child with an important way to grieve a loved one if such involvement is supportive, appropriately explained, and compatible with the family's values and approach.[2,8] Children need to be prepared if they are to participate in the funeral process.[12] The participation should be tailored according to the developmental level of the child. For instance, the younger child may have the process broken down into shorter, more manageable, intervals. A trusted person should be with a child to explain what is happening and to offer support.[3] Older children and adolescents may want to participate by speaking at the funeral or memorial service. Encouraging a child to commemorate loss through some form of participation, such as drawing pictures, planting a tree, or giving a favorite object, will promote inclusion in the process and provide a meaningful ritual.[5]

Grief for a child is a process that unfolds over time. The initial shock and denial of death may evolve into sadness and anger that can last for weeks to months and eventually end, in the best of circumstances, with acceptance and readjustment.[13] Some children may seem emotionally unmoved, thus causing concern to family members.[5,8] It is important for the pediatrician to be aware of the range of manifestations of childhood grief (Table 2) and to be alert to prolonged or severe behavior change that signals the need for more intensive intervention.[1,4,8] A number of age-appropriate books can be read by or to a child as support for understanding and dealing with the grieving process (Table 3). The pediatrician should remain alert to the resurfacing of the child's concerns at the anniversary of the death, at holidays, or at times of other losses as the child progresses through subsequent developmental stages.[5,11]

Recognition of one's own attitudes and reactions to death is essential for objectively and supportively counseling the family.[1] Pediatricians must realize that grief counseling is an emotionally demanding,

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

PEDIATRICS (ISSN 0031 4005).

TABLE 1. Overview of Children's Concepts of Death

Age Range, Years	Concept
0 to 2	Death is perceived as separation or abandonment Protest and despair from disruption in care-taking No cognitive understanding of death
2 to 6	Death is reversible or temporary Death is personified and often seen as punishment Magical thinking that wishes can come true
6 to 11	Gradual awareness of irreversibility and finality Specific death of self or loved one difficult to understand Concrete reasoning with ability to see cause-and-effect relationships
Older than 11	Death is irreversible, universal, and inevitable All people and self must die, although latter is far off Abstract and philosophical reasoning

time-consuming, and potentially frustrating endeavor.[3] *The Classification of Child and Adolescent Mental Diagnoses in Primary Care: Diagnostic and Statistical Manual for Primary Care (DSM-PC) Child and Adolescent Version*[14] identifies diagnoses and conditions and may help the pediatrician evaluate the degree of severity of the child's behavior. Use of *DSM-PC* coding also may help the pediatrician deal with third-party payers. Referral to a mental health specialist or clergy (pastoral counselor) should be considered when the pediatrician believes that progress is not being made or would feel more comfortable having someone else work with the family.

RECOMMENDATIONS

1. The pediatrician should provide support and anticipatory guidance for children and families who face death. The pediatrician is in a position to encourage open discussion of reactions, thoughts, and feelings in the family, thereby increasing the sense of mutual support and cohesion.
2. The pediatrician must use age-appropriate and culturally sensitive guidance while being alert for

TABLE 2. Range of Common Grief Manifestations in Children and Adolescents

Normal or Variant Behavior	Sign of Problem or Disorder*
Shock or numbness	Long-term denial and avoidance of feelings
Crying	Repeated crying spells
Sadness	Disabling depression and suicidal ideation
Anger	Persistent anger
Feeling guilty	Believing guilty
Transient unhappiness	Persistent unhappiness
Keeping concerns inside	Social withdrawal
Increased clinging	Separation anxiety
Disobedience	Oppositional or conduct disorder
Lack of interest in school	Decline in school performance
Transient sleep disturbance	Persistent sleep problems
Physical complaints	Physical symptoms of deceased
Decreased appetite	Eating disorder
Temporary regression	Disabling or persistent regression
Being good or bad	Being much too good or bad
Believing deceased is still alive	Persistent belief that deceased is still alive
Adolescent relating better to friend than to family	Promiscuity or delinquent behavior
Behavior lasts days to weeks	Behavior lasts weeks to months

* Should prompt investigation by pediatrician; mental health referral is probable.

normal and complicated grief responses. The ability to share, reliance on family members, and good communication have been associated with positive long-term bereavement adjustment.

ABSTRACT

Emergency departments are vital in the management of pediatric patients with mental health emergencies. Pediatric mental health emergencies are an increasing part of emergency medical practice because emergency departments have become the safety net for a fragmented mental health infrastructure that is experiencing critical shortages in services in all sectors. Emergency departments must safely, humanely, and in a culturally and developmentally appropriate manner manage pediatric patients with undiagnosed and known mental illnesses, including those with mental retardation, autistic spectrum disorders, and attention-deficit/hyperactivity disorder and those experiencing a behavioral crisis. Emergency departments also manage patients with suicidal ideation, depression, escalating aggression, substance abuse, posttraumatic stress disorder, and maltreatment and those exposed to violence and unexpected deaths. Emergency departments must address not only the physical but also the mental health needs of patients during and after mass-casualty incidents and disasters. The American Academy of Pediatrics and the American College of Emergency Physicians support advocacy for increased mental health resources, including improved pediatric mental health tools for the emergency department, increased mental health insurance coverage, and adequate reimbursement at all levels; acknowledgment of the importance of the child's medical home; and promotion of education and research for mental health emergencies.

STATEMENT

PEDIATRIC mental health emergencies constitute a large and growing segment of pediatric emergency medical care. Emergency departments (EDs) play a critical role in the evaluation and management of child and adolescent patients with mental health emergencies. Community mental health resources have diminished and, in some regions, even disappeared through inpatient bed shortages, private and public health insurance changes, reorganization of state mental health programs, and shortages of pediatric-trained mental health specialists. These changes have resulted in critical shortages of inpatient and outpatient mental health services for children.[1] The ED has increasingly become the safety net for a fragmented mental health infrastructure in which the needs of children and adolescents, among the most vulnerable populations, have been insufficiently addressed.

ED staff must safely, humanely, and in a culturally sensitive manner manage patients with exacerbations of known diagnosed mental illnesses as well as those

with mental retardation, autistic spectrum disorders, and attention-deficit/hyperactivity disorder or those who are having a behavioral crisis. They also must identify and manage patients with previously undiagnosed and/or undetected conditions such as suicidal ideation, depression, escalating aggression, substance abuse, and posttraumatic stress disorder.[2] ED personnel evaluate and treat trauma patients, physically and sexually maltreated children, and children exposed to community and domestic violence and also must deal with unexpected deaths of children in the ED. Violence-related situations may involve pediatric victims and/or pediatric-aged perpetrators of violence. In many states, adolescents can seek and receive care for mental health issues and drug/alcohol use without parental involvement, and confidentiality must be maintained unless the child is at risk of harming himself/herself or others. The ED staff must also recognize the primary support role of the family and caregivers in all phases of pediatric mental illness.

EDs play a critical role in mass-casualty occurrences and disasters, and staff must address the unique mental health needs of children during and after these events. A strong and growing body of evidence indicates that emotional and physical trauma to children can cause neurochemical and structural brain changes resulting in posttraumatic stress disorder and can affect some children into their adult lives.[1–12] Emotional trauma may be ameliorated by timely, culturally appropriate, pediatric-specific stress intervention that may be implemented in the initial hours after the trauma.[13,14]

The epidemiologic and outcome data on pediatric mental health emergencies are insufficient, but there is evidence that pediatric mental health concerns are commonly unaddressed.[15,16] Pediatric mental health emergencies are frequently not recognized as such, presenting initially as trauma or somatic complaints, and are, therefore, underrepresented in the existing data.[17–20] The challenges to an already overburdened ED "safety net" are to provide safe, humane, and culturally and developmentally sensitive triage, diagnosis, stabilization, initial management, and treatment and referral for a broad spectrum of mental health emergencies, working within a mental health infrastructure in crisis.

Pediatric mental health emergencies are best managed by a skilled, multidisciplinary team approach, including specialized screening tools, pediatric-trained mental health consultants, the availability of pediatric psychiatric facilities when hospitalization is necessary, and an outpatient infrastructure that supports pediatric mental health care, including communication back to the primary care physician and timely and appropriate ED referrals to mental health professionals.[21]

The American Academy of Pediatrics and American College of Emergency Physicians support the following actions:

1. Advocacy for adequate pediatric mental health resources in both inpatient and outpatient settings, including the availability of prompt psychiatric consultation for ED psychiatric patients and school and community mental health services, including adequate mental health screening.
2. Development of mechanisms for the ED to deal with unique pediatric mental health issues including violence in the community, physical trauma, domestic violence, child maltreatment, mass-casualty incidents and disasters, suicides and suicide attempts, and the death of a child in the ED.
3. Appropriate payment for both inpatient and outpatient pediatric mental health services.
4. Acknowledgment of the importance of the child's medical home* to his or her continued well-being, including prevention, screening, and treatment of mental health issues.[22]
5. Advocacy for comprehensive pediatric mental health insurance coverage to include provision of mental health services for the uninsured and expansion of coverage to include mental health services for those who are insured.
6. Advocacy for additional research funding dedicated to pediatric emergency mental health issues.
7. Promotion of education and research for mental health emergencies and specifically to

   - expand the data on epidemiology, best practices, treatment outcomes, and cost/benefit issues for pediatric mental health emergencies in the ED;
   - evaluate the adequacy of patient access to pediatric mental health services;
   - evaluate children with behavioral crisis to understand gaps in primary care and community resources;
   - develop mental health support networks that minimize reliance on acute crisis management;
   - develop and validate accurate pediatric mental health screening tools for use in various settings and best practices for follow-up programs for pediatric mental health patients; and
   - enhance the pediatric mental health curriculum for emergency medicine and pediatric residency training programs and pediatric emergency medicine fellowships.

* A medical home is defined as primary care that is accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective.

The Pediatrician and Disaster Preparedness

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine
Committee on Medical Liability
Task Force on Terrorism

ABSTRACT

Recent natural disasters and events of terrorism and war have heightened society's recognition of the need for emergency preparedness. In addition to the unique pediatric issues involved in general emergency preparedness, several additional issues related to terrorism preparedness must be considered, including the unique vulnerabilities of children to various agents as well as the limited availability of age- and weight-appropriate antidotes and treatments. Although children may respond more rapidly to therapeutic intervention, they are at the same time more susceptible to various agents and conditions and more likely to deteriorate if not monitored carefully.

The challenge of dealing with the threat of terrorism, natural disasters, and public health emergencies in the United States is daunting not only for disaster planners but also for our medical system and health professionals of all types, including pediatricians. As part of the network of health responders, pediatricians need to be able to answer concerns of patients and families, recognize signs of possible exposure to a weapon of terror, understand first-line response to such attacks, and sufficiently participate in disaster planning to ensure that the unique needs of children are addressed satisfactorily in the overall process. Pediatricians play a central role in disaster and terrorism preparedness with families, children, and their communities. This applies not only to the general pediatrician but also to the pediatric medical subspecialist and pediatric surgical specialist. Families view pediatricians as their expert resource, and most of them expect the pediatrician to be knowledgeable in areas of concern. Providing expert guidance entails educating families in anticipation of events and responding to questions during and after actual events. It is essential that pediatricians educate themselves regarding these issues of emergency preparedness.

For pediatricians, some information is currently available on virtually all of these issues in recently produced printed materials, at special conferences, in broadcasts of various types, and on the Internet. However, selecting appropriate, accurate sources of information and determining how much information is sufficient remain difficult challenges. Similarly, guidance is needed with respect to developing relevant curricula for medical students and postdoctoral clinical trainees.

INTRODUCTION

Recent natural disasters and events of terrorism and war have heightened society's recognition of the need for emergency preparedness. Moreover, the possibility of

additional terrorism on US soil has become increasingly likely, so much so that billions of dollars have been allocated to massive investments in homeland security and public health readiness. The challenge of dealing with the threat of terrorism, natural disasters, and public health emergencies in the United States is daunting not only for disaster planners but also for our medical system and health professionals of all types, especially pediatricians. Pediatricians need to be able to answer concerns of patients or families, know when to recognize signs of possible exposure to a weapon of terror, understand first-line response to such attacks, and sufficiently participate in disaster planning to ensure that the unique needs of children are addressed satisfactorily in the overall process.

THE ROLE OF THE PEDIATRICIAN

Managing Family Concerns About Disaster and Terrorism Preparedness

Pediatricians play a central role in disaster and terrorism preparedness with families, children, and their communities. This applies not only to the general pediatrician but also to the pediatric medical subspecialist and pediatric surgical specialist. Families view pediatricians as their expert resource, and most of them expect the pediatrician to be knowledgeable in areas of concern. Providing expert guidance entails educating families in anticipation of events and responding to questions during and after actual events. It is essential that pediatricians educate themselves regarding these issues of emergency preparedness. The American Academy of Pediatrics has an extensive set of emergency-preparedness resources for pediatricians. In addition, many other resources for pediatricians regarding emergency preparedness exist and can be found in "Suggested Resources for Additional Information."

As part of anticipatory guidance, pediatricians should discuss issues related to family emergency preparedness. They should provide families with information on creating a family emergency plan, discussing this plan with their children, and practicing the plan. There are several good resources for pediatricians to use in educating families regarding emergency preparedness. They can be found in "Suggested Resources for Additional Information."

Although adults can actively seek help, children cannot; they depend on the adults in their lives to get them the assistance that they need. With appropriate support and guidance, children can develop the skills and resiliency needed to deal with, overcome, and possibly even grow from these traumatic experiences. As part of anticipatory guidance, pediatricians should ask parents about their child's awareness of natural disasters and previous or potential future terrorist attacks, their degree of exposure (including television) to these issues, and their previous and current reactions. Such queries may provide an opportunity to advise parents about how best to discuss terrorist attacks with their child. Pediatricians should encourage parents to present information to children honestly, using language that is appropriate to the child's developmental level and cognitive abilities. Parents can be encouraged to talk with their children about a specific plan that includes things to do in case of a disaster, terrorist incident, or other emergency, such as to whom to go for help, safe places to seek, and other concrete steps that can be taken at home, at school, and in the community. The approach may be similar to that taken to prepare children for other potential threats such as fire or approach by a stranger. By using specific plans to ensure safety, the goal of these discussions should be to help the child to potentially feel in control of a threatening situation and also to convey that the parents are in control.

In addition to handling the needs of all their patients and discussing family emergency planning, pediatricians need to address the unique needs of children with special health care needs. Pediatricians should provide guidance to families of children with special health care needs regarding:

- notification of utility companies to provide emergency support during a disaster;
- maintenance of medications and equipment should supply be disrupted during a disaster;
- knowledge of how to obtain additional medications and equipment during times of disaster;
- training for family members to assume the role of in-home health care providers, who may not be available during a disaster; and
- keeping an up-to-date emergency information form (available from ref 1) to provide health care workers with the patient's medical information should the regular care provider be unavailable.

Office-Based Preparedness

After a disaster, offices or clinics may become sites for care if area hospitals are unable to provide services. If even local offices are unusable, alternative sites for primary care must be identified. If necessary, medical care may be provided in schools, public buildings, malls, and/or makeshift facilities, such as tents, using limited power and water sources. Pediatricians should prepare, regularly update, and practice an office disaster plan that addresses response and recovery issues. This office plan should be coordinated with local hospital and community emergency-response plans. Office training programs in emergency procedures, including first aid, cardiopulmonary resuscitation, evacuation, search and rescue (as appropriate), the use of fire extinguishers, and participation in community disaster drills, should be a routine part of the office's overall emergency preparedness.

Emergency preparations should include plans for storage of temperature-sensitive vaccines, medications, and supplies during extended periods of absent or limited power supply.

Community Preparedness

Pediatricians in the community can assist in both triage and treatment of patients. Important questions to ask include: (1) Where should the pediatrician go during the disaster? (2) How should pediatricians be notified that they are needed to respond to the disaster? (3) How should hospital physicians be identified and notified to go to the scene to attend to victims of the disaster? and (4) How should transfers of pediatric patients in the hospital and discharges be handled? In areas in which pediatricians cover several hospitals, pools should be initiated through the local medical or pediatric society to provide uniform pediatric coverage of area hospitals. Pediatricians can aid schools, child care centers, and other child congregate facilities in developing disaster plans. At the local level, the agency that will have the responsibility for the overall coordination during a disaster or terrorism event will be the office of emergency management (OEM). The specific role of coordination and preplanning for the health care needs of the community will be coordinated by the office of emergency management but assigned to the local department of public health.

Currently, the 2 major programs that provide departments of health in states and the 5 largest cities with direct funding to help fulfill this role of coordinating the health care system for terrorism preparedness are the Health Resources and Services Administration (HRSA) Bioterrorism Hospital Preparedness program and the Centers for Disease Control and Prevention (CDC) Public Health Preparedness and Response for Bioterrorism program. The CDC-funded initiative is primarily concerned with improving public health departments' ability to address bioterrorism, whereas the HRSA effort allows public health departments to provide training, guidance, and funding to hospitals to improve their preparedness. Both of these programs specifically mention pediatric considerations in their guidance, but unfortunately, the pediatric care activities in many states are minimal and often lack sufficient involvement by pediatricians. It is important for pediatricians to become familiar with the activities of these programs to ensure pediatric involvement. Information on these programs can be found on state public health department Web sites in addition to the HRSA and CDC Web sites (see "Suggested Resources for Additional Information").

The Office of the Surgeon General and USA Freedom Corps support local voluntary Medical Reserve Corps units in more than 200 American communities (www.medicalreservecorps.gov). These volunteer units provide a mechanism for health care professionals to volunteer their services during times of disaster as part of the organized response in a community. In addition, by joining a Medical Reserve Corps or other governmentally sponsored or recognized volunteer program, physicians will be provided with mechanisms for identification during times of emergencies. Because the Medical Reserve Corps program does not have pediatric capability as a requirement for their units, it is important for pediatricians to join these teams to ensure that pediatric considerations are met.

Some state health departments have begun to coordinate and link the activities of the Medical Reserve Corps units in their states. In addition, most state health departments and many large local health departments are establishing notification systems based on requirements of the HRSA and CDC grant programs. The purpose of these systems is to ensure that physicians and other health care professionals have timely access to needed information about the existence of an event (disaster, terrorism, or public health emergency), are provided with information on what their role should be, and know whom to contact with problems or for additional information. It is important that all physicians register for these notification systems so that in a time of emergency, they are notified and informed of their role.

Last, pediatricians should inquire about the emergency-preparedness plans at all the hospitals at which they work or admit patients. In times of emergency, there may be a need for transfers or discharges based on different criteria or altered admission policies. To assist hospitals with these functions and provide better care for their patients, pediatricians must understand how each hospital has planned to handle these events.

Surveillance

One of the key elements in emergency preparedness is early detection of any possible public health threat or bioterrorism event. The most likely scenario involves exposure in a community that may manifest with subtle signs and symptoms and/or unusual patient presentations. The role of the pediatrician is key. Pediatricians must be functioning constantly as part of a surveillance system to provide for early detection of any bioterrorism agent, which requires pediatricians to become familiar with the types of bioterrorism agents that may be involved. They also must become familiar with referral procedures and when to report cases to the local health department. Health department reporting is based on local requirements but should be considered for all unusual cases, any cases that are suspicious for a bioterrorist agent, or an unusual number of patients, either absolute or for the season, who present with similar symptoms.

Reporting a Disaster, Terrorism, or Public Health Emergency

It is important that health care professionals be knowledgeable about the mechanism and appropriate contacts to report an event, whether natural or man-made. In

case of any emergency, health care professionals should activate their local emergency system, which in most areas can be done by calling 911. Any suspicious or confirmed disaster situation should be reported immediately to the local 911 emergency-response number.

In addition, if a pediatrician believes that someone has been exposed deliberately to a biological, chemical, or radioactive agent or if a pediatrician believes an intentional terrorist threat will occur or is occurring, he or she should immediately involve the public health authorities. This can be done by contacting the local health department, the local police or other law enforcement agency, and the 24-hour CDC hotline at 770-488-7100.

Last, any incident related to terrorism or possible terrorist activity also requires telephone notification to local law enforcement and the National Response Center at 800-424-8802. This includes bombings, bomb threats, suspicious letters or packages, and incidents related to the intentional release of chemical, radiologic, and biological agents.

Pediatricians' Actions During a Disaster

During a disaster, pediatricians may need to serve in a variety of functions ranging from routine disaster actions for themselves and their families to providing medical care and answering questions from their patients and families and participating in the local disaster response to meet the needs of their community and the hospitals in their community. Medical responders likely will need to function unassisted until outside resources arrive, at least 6 to 8 hours after the onset. Hospitals and clinics will be flooded with affected patients and the "worried well."

To fulfill these roles during a disaster, all pediatricians need to:

- institute office and home disaster plans;
- participate in the community or hospital disaster plan, including drills and exercises;
- provide medical assistance via established disaster medical delivery systems;
- provide guidance to patients and their families;
- when volunteering to assist during or after a disaster, make every effort to work in concert with the lead organization coordinating disaster relief; and
- serve a key role in identifying sentinel cases of illness after a chemical, biological, or radiologic release.

In addition to important functions during the actual event, pediatricians' assistance will be needed after the event throughout the recovery period. The role of the pediatrician is to help patients who have been affected by the event to return to normal functioning and to assist with community efforts at return to normal activity. During the recovery period, all pediatricians need to:

- be prepared to deal with continued disruption of services (which may include medical services in the community; supplies for their patients, their office, and hospitals; limited availability of pharmacy services; and altered utilities such as telephone, electrical power, and water);
- continue providing care as part of their office emergency plan and as needed in community disaster medical programs;
- continue to provide surveillance for the effects of chemical, biological, or radiologic agent release but also during any disaster provide surveillance for unusual rates of infectious disease that may occur; and
- ensure that the mental health needs of children and their families are being addressed and, when needed, provide appropriate referral for mental health services.

Hospital Preparedness

It is important for hospitals to consider the needs of children in all aspects of emergency preparedness and all hazards plans. This will include, but is not limited to, appropriate types and numbers of pediatric-trained staff, equipment, medications, and decontamination equipment, including the ability to handle nonambulatory children. In addition, hospitals must be prepared to handle situations in which patients will be cared for as a family unit and children will not be able to be separated from adults, such as in a quarantine situation. This will require all hospitals to have the capability to handle children, and all children's hospitals must possess the ability to care for adult patients who will be staying with their children.

Pediatricians' Liability During Disasters

In the past, many pediatricians have provided care without affiliation with recognized government or volunteer agencies. When providing medical services during a disaster or terrorism event, it is important that health care professionals are part of an organized program. Lack of an oversight organization providing the service may result in services that are not in concert with the organized response and places health care professionals in a position without professional liability insurance coverage. Most malpractice coverage is limited to the health care professional's usual scope of practice and practice setting. In some states, individual malpractice insurance policies do not cover out-of-office care or the expanded scope of practice that may be required during a disaster. Good Samaritan statutes provide some liability protection when rendering medical care at the scene of an emergency to one who would not otherwise receive it. Good Samaritan statutes cover physicians at the scene of acute incidents but vary among states and may not provide liability protection during or after disasters or ter-

rorism events. These laws do not cover a physician if there is any payment for services or if there is an accusation of gross negligence. In many states, coverage for liability during a disaster requires health care professionals to practice under the umbrella of an official disaster agency such as the Federal Emergency Management Agency, the US Department of Health and Human Services, a state or local health department, a state or local office of emergency management, the local emergency medical services authority, or an other recognized government or volunteer agency.

Advocating for Children and Families in Disaster Planning

As all pediatricians know, children are often not considered in government and community activities for a multitude of reasons. Properly informed and motivated pediatricians are essential advocates for children. This role can take several forms. Grassroots advocacy can include efforts to ensure legislation and funding to support an emphasis on children in disaster planning at every level. Pediatricians can also serve as expert advisors to local, state, and federal agencies and committees. Most often, this can be done through involvement in professional organizations such as the American Academy of Pediatrics and its chapters, committees, sections, and task forces.

RECOMMENDATIONS

1. Pediatricians should advocate for the inclusion of the needs of children in all federal, state, and local disaster planning.
2. Pediatricians and pediatric trainees should become knowledgeable in issues related to pediatric disaster management, including chemical, biological, explosive, radiologic, and nuclear events and physician liability during disasters.
3. Pediatricians should participate in disaster planning by:
   - taking part in local community and hospital disaster planning, exercises, and drills through emergency medical services and public health systems;
   - preparing and regularly updating and practicing an office disaster plan;
   - working with schools and child care centers in developing disaster plans;
   - providing anticipatory guidance to families on home disaster preparedness, with consideration given to the unique problems faced by children with special health care needs;
   - participating in disease surveillance and reporting to local health departments; and
   - participating with and providing guidance to medical volunteer programs such as disaster medical assistance teams, Medical Reserve Corps, and other response teams to ensure that they are equipped and trained for the care of children.
4. Pediatricians need to educate themselves regarding liability issues during the acute and recovery phases of a disaster, including:
   - individual states' Good Samaritan statutes and protections afforded while providing emergency care during a disaster and any limitations to those protections;
   - individual liability insurance coverage protections and limitations outside of the usual scope of practice and practice settings when providing urgent and routine care; and
   - the importance of working under the auspices of an official government or disaster agency for volunteer liability protection to apply.

abstract

All professionals are concerned about maintaining the appropriate limits in their relationships with those they serve. Pediatricians should be aware that, under normal circumstances, caring for one's own children presents significant ethical issues. Pediatricians also must strive to maintain appropriate professional boundaries in their relationships with the family members of their patients. Pediatricians should avoid behavior that patients and parents might misunderstand as having sexual or inappropriate social meaning. Romantic and sexual involvement between physicians and patients is unacceptable. The acceptance of gifts or nonmonetary compensation for medical services has the potential to affect the professional relationship adversely. *Pediatrics* 2009;124:1685–1688

INTRODUCTION

Physicians and the public recognize the need for high moral standards and accountability in medicine. Most commonly, the focus of concern involves physician competence and integrity, as demonstrated by such measures as board certification, hospital credentialing, peer review of practice, participation in impaired physician programs, and malpractice litigation. Physician behavior is guided by various practice guidelines, review articles, policy statements by professional organizations, and applicable laws and regulations. Codes of ethics for physicians have a role in addressing personal and other nontechnical aspects of physician conduct, as exemplified by the American Medical Association's periodically updated code[1] and a 2008 document from the American College of Obstetricians and Gynecologists.[2] The American Academy of Pediatrics also has issued policy statements titled "The Use of Chaperones During the Physical Examination of the Pediatric Patient"[3] and "Professionalism in Pediatrics: Statement of Principles."[4]

This statement delineates the appropriate professional boundaries[5] between pediatricians who provide medical care for children (including their own) and their patients and patients' family members. The American Academy of Pediatrics believes that pediatricians must exercise substantial care in nonprofessional relationships with patients and families to promote the highest possible degree of trust in the doctor-patient-family relationship.

PROVIDING MEDICAL CARE FOR ONE'S OWN CHILDREN

Pediatricians, because of their unique expertise, often find themselves in the position of providing medical advice and treatment for their own

children (and minor relatives as well as the children of close friends). Although such activities seem to be common,[6–9] the American Medical Association[10] considers the practice of treating immediate family members inappropriate. The normal feelings that pediatricians have for their patients can be distorted when the patients are their own children. Pediatricians, when providing medical care for their own children, are more likely to lack objectivity, function with incomplete information, and have difficulty setting physician-patient boundaries. Significant confidentiality issues could arise when caring for minor relatives and the children of close friends. By providing potentially less-than-optimal care for these children, pediatricians violate a fundamental professional obligation. Exceptions to the general prohibition are limited to minor treatments and decisions (often similar to those handled by nonphysician parents) or clear emergencies and disasters and for pediatricians who practice in underserved areas in which there are no other physicians capable of providing pediatric care. If at all possible, the treating pediatrician should notify the child's primary care physician of treatment plans and prescriptions to ensure continuity of care.

GIFTS OR OTHER EXPRESSIONS OF AFFECTION OR GRATITUDE

Patients or parents sometimes give pediatricians gifts, especially after providing help for a complex or troubling health-related problem. Under most circumstances, gifts have a far more symbolic than material value.[11] For most pediatricians, accepting modest gifts does not involve a serious conflict; in fact, refusal of a gift may constitute a social or cultural affront. As the monetary worth of the gift increases, however, so does the psychological and ethical difficulty in maintaining appropriate boundaries in the professional relationship. When the pediatrician feels uncomfortable with a gift that a family insists on delivering, he or she must voice the concern and suggest acceptable alternatives, such as a charitable donation in the pediatrician's name. Highly valued gifts may indicate that these boundaries have been crossed. The patient or loved one may have misinterpreted the pediatrician's earlier behavior or may be inviting the pediatrician to engage in a relationship that could compromise medical judgment and action.

ROMANTIC AND SEXUAL RELATIONSHIPS

It is difficult to find reliable data on the prevalence of sexual contact between physicians and their patients or their patients' family members. Authors of position papers about psychiatrists[12] and obstetricians[13] have commented on the lack of well-conducted, reliable studies on professional boundary violations by physicians. Attention to the subject, in the form of complaints against practitioners and publications in professional journals, has been more prominent among psychiatrists and obstetricians/gynecologists.[14–18] Interpersonal entanglements raise at least 2 serious questions. First, can a patient or family member make clear and free choices to accept or reject affections, especially sexual, in the context of the unavoidably unequal physician-patient-family relationship? Second, once such intimacy develops, can the parties maintain a proper and effective therapeutic relationship?

Because pediatricians provide counseling services for patients and families, these concerns closely parallel those faced by mental health professionals. Pediatricians who feel sexually attracted to their patients may put the patients at risk of sexual abuse or exploitation.[19] A more common circumstance, however, is that pediatricians may be misunderstood when they first discuss sexual maturation and sexuality with patients.[20] Similarly, examination of an adolescent's maturing genitals or breasts during an office visit may be distressing or misunderstood by the patient, especially if a parent or chaperone is not in the examining room.[3] Pediatricians should develop and follow clear and consistent office policies about the presence of a chaperone during parts of the physical examination, taking into account context, local customs, families' religious and cultural traditions, and the need for patient privacy. Pediatricians should include notations in the record if they do not adhere to the documented office policy requiring the presence of a chaperone.

Pediatricians also interact with the parents or guardians of their patients, although seldom in doctor-patient relationships. Pediatricians are responsible for maintaining appropriate professional boundaries with the families of their patients, although their obligations toward them may be somewhat different from those toward their patients.

There is an inherent risk of exploitation for patients or family members who depend on the knowledge and authority of the pediatrician, especially in cases that involve nonroutine health care. The success of the doctor-patient or doctor-family relationship depends on the ability of the patient or family member to trust the pediatrician completely. Patients and family members legitimately expect to feel physically and emotionally safe in professional relationships with pediatricians. They should not feel vulnerable to romantic or sexual advances while receiving medical care for themselves or their children. In addition, children should be free from concern that their treatment may be compromised by a nonprofessional relationship between a parent and their pediatrician. Children

should not have to worry about confidentiality or have anxiety over the potential for the pediatrician to have a conflict of loyalty because of the pediatrician's involvement with the parent.

Patients or family members, to some extent, identify with and feel gratitude toward pediatricians. At times, these feelings may result in efforts to initiate a nonprofessional relationship with the physician or may leave the patient or family member consciously or otherwise unwilling or unable to reject a pediatrician's romantic or sexual advances. Any confusion between complex professional bonds and extraprofessional personal relationships may leave the patient or family member unable to exercise the best judgment or choice about medical matters.

The clinical judgment of pediatricians who become intimately involved with a patient or family member may become clouded, and they may breach their professional responsibilities. Whether this possibility extends to close family members of patients is somewhat less clear. If the intimacy develops in the context of a patient's serious illness, concerns about exploitation of the family member's dependency on the pediatrician arise. Under these circumstances, the pediatrician is well advised to end the professional relationship after ensuring the transfer of the patient's medical care to another appropriate practitioner. Nevertheless, proscriptions on pediatricians pursuing relationships with parents or adult siblings of their patients may, in unusual circumstances, result in unnecessary and inappropriate restrictions on the pediatrician's personal life.

INADVERTENT SEXUALITY IN THE PEDIATRICIAN-PATIENT RELATIONSHIP

Pediatricians usually prefer warm, friendly relationships with their patients. The need to avoid untoward personal intimacy should not lead to a cold, indifferent manner in their interactions with patients or family members. Many cultures expect physical expressions of care and concern in times of personal crisis, including sickness. Pediatricians might well be seen as unsympathetic and excessively remote if they avoid handshakes or other socially approved touching during emotional encounters with families. In most social groups in the United States, interaction with children is likely to involve appropriate physical contact such as hugging.

Pediatricians should be aware of their patients' customs and personal and religious beliefs. In addition, it may be helpful to recognize that some kinds of touching may be confusing or offensive to children, depending on their stage of physical and emotional maturation. For example, certain children may have strong preferences about whether their physical examination is performed by a male or female pediatrician or whether someone else besides the pediatrician is present during the examination. Anticipatory discussion of these issues should reduce fears and misunderstandings and lead to enhanced pediatrician, patient, and family comfort.

Pediatricians also have an obligation to recognize that physical interaction is not the only means by which humans communicate sexually. Body language and verbal expressions also convey attitudes and emotions that may provoke strong feelings. Because socioeconomic or cultural groups may differ in what they consider acceptable or expected behavior, it is usually best to ask patients and parents their preferences about how they would like to be addressed.[17] For example, pediatricians should use neutral language or names in addressing patients rather than using terms of endearment such as "honey" or "dear." Words that could be seen as evaluative or provocative when referring to body parts, such as the breasts, should be avoided. Personal questions about family history and household functioning should be asked in a way that clearly indicates that their sole purpose is to assist in optimizing the child's development.

OTHER CONSIDERATIONS

Patients or family members may want to compensate pediatricians with an exchange of services or with barter. For example, an adolescent or the adolescent's parents may offer the patient's services as a baby-sitter or gardener in lieu of monetary payment for care. Such arrangements vary legitimately with local custom and the economic circumstances of patients and families. However, problems may arise about exactly what services constitute adequate compensation for professional care and the appropriateness of increased personal contact between the patient or family member and the pediatrician. Nonmonetary payments, as with gifts, may become precursors to boundary violations and should be approached with caution.

RECOMMENDATIONS

1. Pediatricians should know that caring for one's own children and caring for the minor children of relatives and close friends, particularly outside of the doctor-patient relationship, presents significant ethical issues, including issues of confidentiality, and may lead to less-than-optimal medical care. Exceptions exist for treatment of minor conditions or during emergencies and disasters and in underserved areas in which alternatives are unavailable.
2. It may be acceptable for pediatricians to accept modest gifts from patients and their families. When the pediatrician feels uncomfortable with a gift that a family insists on delivering, he or she should suggest acceptable alternatives such

as a charitable donation in the pediatrician's name. However, caution is urged when the material value of gifts or offered services could seem to influence the pediatrician's professional judgment. Furthermore, the pediatrician must be sensitive to the possibility that the intent of the gift is, in fact, to alter behavior.

3. Pediatricians caring for children and adolescents need to be aware of the potential for conflict between their professional roles and their personal relations with their patients and their patients' family members. Romantic and/or sexual relationships with patients are always inappropriate. Romantic or sexual relationships with adult family members of patients should be avoided, given the potential for adverse effects on professional judgment and family-member behavior concerning the patient's health.
4. In providing care for children and adolescents, pediatricians need to be aware that their words, body language, and other aspects of professional conduct may inadvertently offend or insult patients and family members depending on both the context of the event and local customs. Many expressions and actions during the physical examination may have an unintended sexual connotation for the patient or parent. Pediatricians are advised to use neutral language that is acceptable to the patient and to discuss thoroughly and in advance aspects of care that may seem sexually charged. Personal questions about family history and household functioning need to be asked in the context of optimizing the child's development.
5. Medical school, residency, and continuing medical education programs should routinely discuss the importance of personal boundaries between professionals, their patients, and their patients' family members.

AMERICAN ACADEMY OF PEDIATRICS

TECHNICAL REPORT

David C. Goodman, MD, MS; and the Committee on Pediatric Workforce

The Pediatrician Workforce: Current Status and Future Prospects

ABSTRACT. The effective and efficient delivery of children's health care depends on the pediatrician workforce. The number, composition, and distribution of pediatricians necessary to deliver this care have been the subject of long-standing policy and professional debate. This technical report reviews current characteristics and recent trends in the pediatric workforce and couples the workforce to a conceptual model of improvement in children's health and well-being. Important recent changes in the workforce include (1) the growth in the number of pediatricians in relation to the child population, (2) increased numbers of female pediatricians and their attainment of majority gender status in the specialty, (3) the persistence of a large number of international medical graduates entering training programs, (4) a lack of ethnic and racial diversity in pediatricians compared with children, and (5) the persistence of marked regional variation in pediatrician supply. Supply models projecting the pediatric workforce are reviewed and generally indicate that the number of pediatricians per child will increase by 50% over the next 20 years. The differing methods of assessing workforce requirements are presented and critiqued. The report finds that the pediatric workforce is undergoing fundamental changes that will have important effects on the professional lives of pediatricians and children's health care delivery. *Pediatrics* **2005; 116:e156–e173. URL: www.pediatrics.org/cgi/doi/10.1542/peds.2005-0874;** ***child health workforce, diversity, family medicine, female pediatricians, geographic distribution, health manpower, internal medicine-pediatrics, international medical graduates, nonphysician clinicians, physician workforce, pediatrics, pediatric medical subspecialists, pediatric surgical specialists.***

INTRODUCTION

Our common mission to attain the optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults (mission statement of the American Academy of Pediatrics [AAP]) depends on the pediatrician workforce. The improvement of children's health occurs through the efforts of these professionals who draw on their training and experience to deliver within a medical home the best possible pediatric care and to serve as child advocates. How, then, can we ensure that the right number of qualified clinicians are located where needed to provide pediatric care that is effective and efficient? Market forces alone are insufficient to meet these public and professional workforce goals given the inherent imperfections in the market for health care labor and health care services.[1–6] With a continuing need to influence the number and characteristics of child health professionals, this technical report seeks to inform pediatricians and child health policy makers of the status of the child health workforce and the public policies that will influence its future.

The last AAP policy statement on the pediatric workforce, prepared by the Committee on Pediatric Workforce and published in 1998,[7] combined a status report of the workforce with policy recommendations. In this current effort, the technical report provides the background to recommendations included in the separate but companion policy statement "Pediatrician Workforce Statement."[8] To accomplish this, the report draws mostly on published sources, many of them from the AAP or the Future of Pediatric Education II (FOPE II) Project, to identify salient trends, possible future challenges to the profession, and critical domains of underdeveloped information. When published sources of data were not available, unpublished data have been cited from the Center for the Evaluative Clinical Sciences at Dartmouth Medical School (data sources and methods are available on request). The focus of the report is on general and medical subspecialty board-certified (by the American Board of Pediatrics [ABP]) pediatricians and the 99 million patients younger than 21 years whom they serve. Surgical and non–ABP-boarded pediatricians also provide essential services to children, but a detailed discussion of their status is beyond the scope of this report.

HEALTH WORKFORCE TRENDS

A full understanding of recent trends and current challenges facing the pediatric health workforce requires an examination of 4 general workforce themes.[9] First, the number of physicians in the United States continues to grow in both absolute and per-capita numbers.[10,11] In 2001 (December 31), the number of total patient-care physicians (defined by the American Medical Association [AMA] Masterfile as >50%

doi:10.1542/peds.2005-0874

of professional time spent in clinical care) was 668 939, reflecting a 28% absolute and 18% per-capita increase during the decade. The number of residency or graduate medical education (GME) positions, the best predictor of entry into practice, was virtually unchanged at 93 674, with an 11% decrease in per-capita numbers. The per-capita decrease in the number of residency positions is slow enough that the physician workforce will continue its per-capita growth for another 20 years before decreasing. These figures do not include osteopathic physicians, who increased by 41% per capita during the decade and are a particularly important provider of primary care in many regions (Center for the Evaluative Clinical Sciences, unpublished data, 1998).

The second notable trend was the continued growth in the number of female medical students.[12] Although men continued to outnumber women in some specialties in both residency programs and practice,[13] most specialties have experienced a shift in their gender mix. Overall, the per-capita number of female physicians increased 53% during the decade, reflecting an increase from 100 024 to 173 254.[10,11]

Third, the physician workforce still fails to reflect the growing racial and ethnic diversity of the nation despite efforts to broaden medical school opportunities for individuals of traditionally underrepresented minority groups (black, Hispanic, and American Indian/Alaska Native). From information primarily collected by medical schools and residencies, in 2001 the AMA Masterfile listed 20 738 black (2.5%), 28 626 Hispanic (3.4%), 73 849 Asian, (8.8%) and 504 American Indian/Alaska Native (<1%) physicians of 836 156 physicians.[11] The system of racial/ethnic designation is presumably self-designation from a list of mutually exclusive categories, a type of categorization that has limitations.[14] It is notable that race/ethnicity was missing for 256 995 physicians (31%) in the Masterfile. More complete data are known for physicians in residency programs; in 2000, 6% of all residents in programs approved by the Accreditation Council for Graduate Medical Education were black, 5.5% were Hispanic, and 22% were Asian (see Appendix II in ref 15). The racial/ethnic makeup of physicians is in contrast to the US population, of which in 2000, 12.2% were black non-Hispanic, 11.8% were Hispanic, 3.8% were Asian, and 0.7% were American Indian/Alaska Native.[16]

Physicians trained in other countries represent a fourth trend. The number of international medical graduates (IMGs) increased by 38% during the past decade, from 118 531 to 164 097.[10,11] IMGs include US citizens who graduated from medical schools outside of the United States or Canada, citizens of other countries emigrating to the United States, and those planning on returning to their native country after completing residency. The most common country of citizenship of those issued Educational Commission for Foreign Medical Graduates certificates in 2001 was the United States (25.6%), followed by India (19.6%), Pakistan (6.2%), China (2.5%), Philippines (2.5%), and Iran (2.5%).[17] Despite their ethnic diversity, IMGs leave unaddressed the need for a physician workforce reflective of and culturally competent to care for growing US minority populations.

A final important characteristic of the medical workforce is its uneven geographic distribution. Regional variation in physicians per capita, whether measured by state, county, or health service areas,[18–20] exceeds threefold for all specialties. Although the term "geographic variation" is typically used to refer to maldistribution associated with physician shortage in rural and inner-city communities, most regional variation occurs in a range of supply above that considered adequate.[21,22] To date, studies that have examined the relationship between physician supply and population health needs have found a tenuous association.[19,20,23–25] Similarly, the limited research on the association between the per-capita numbers of physicians in regions and health outcomes has found diminishing returns of improved health with higher levels of physicians per capita.[24,26–35] It should be noted that this type of research is methodologically challenging.

A MODEL OF THE CHILD HEALTH WORKFORCE

There are many factors that can influence the size and composition of the child health workforce. The workforce is not, of course, an end in and of itself but exists to provide medical services to children. Parents, the public, and pediatricians, in turn, expect that pediatric services delivered within a medical home will lead to better health and well-being for children. To bring clarity and cohesiveness to workforce-related factors discussed in this report, we present a conceptual framework that is referenced throughout (Fig 1). As complex as the model may appear at first glance, it provides a simplified map of the elements that influence the number and characteristics of pediatricians and their relation to the production of improved children's health outcomes. The model presents a sequence of "steps" using common economic and health services concepts. The medical education system (sometimes referred to by others as "the pipeline") produces pediatricians who, in turn, produce pediatric services, leading to the production of improved child health outcomes. The model severely abbreviates some critical health influences that are beyond the scope of this report. For example, the many important genetic, environmental, and social factors that bear on health outcomes are summed by the component "relative need" in box 17 of the model.

COMPOSITION AND RECENT TRENDS IN THE CHILD HEALTH WORKFORCE

The per-capita growth rate in pediatricians during the past decade has exceeded that of the overall physician supply. The total number of active patient-care pediatricians (including medical subspecialists but excluding those in residency) increased from 33 691 to 51 675 (53%) over the past decade (January 1, 1992, through December 31, 2001), and the number of children younger than 18 years increased 11%; on a per-child basis, this represents a 38% increase. The numbers of general pediatricians increased at a slightly slower pace, from 29 931 to 42 214, a 41%

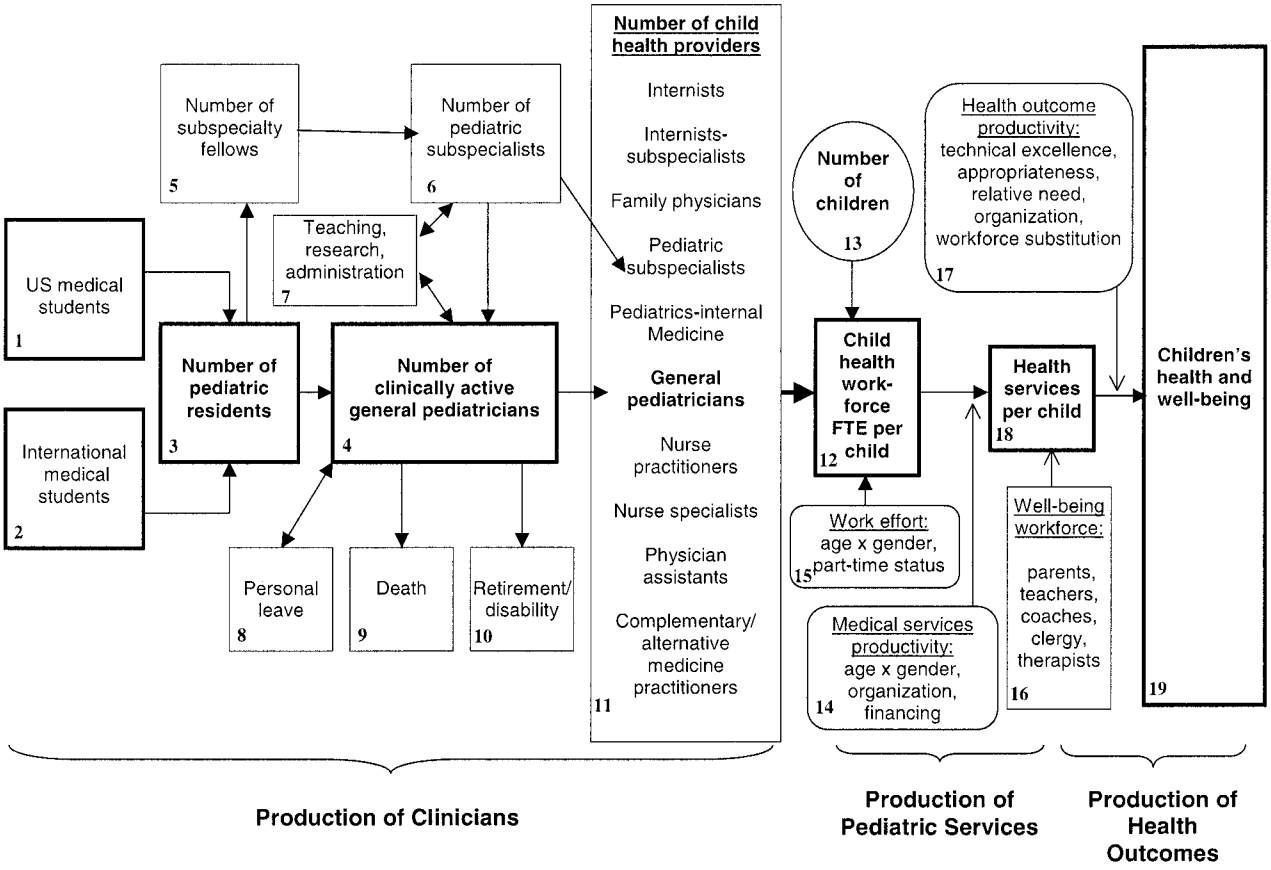

Fig 1. The child health workforce and the production of improved health outcomes.

increase or a 27% per-child increase. This increase in general pediatricians is higher than the per-capita (total population) growth in general internal medicine (20%) and family medicine (11%).[10,11] Although concerns remain that the current number of pediatric residency positions is insufficient to meet patient and research needs for certain subspecialties,[36] the overall per-capita number of pediatric medical subspecialists increased by 127% during the past decade.

Gender

The most notable change in the composition of the child health workforce has been the accelerating entry of women into pediatric residency programs. Women constituted 65.2% of the 7629 pediatric residents in 2000, a proportion exceeded only by few other specialties such as obstetrics and gynecology (69.6%).[15] In the past decade, the number of women in patient-care pediatrics increased from 17 219 to 31 276 (82% increase), and now women constitute 50% of all pediatricians.[10,11] By the time this report is published, women will represent the majority of pediatricians, a historic first for any specialty in the United States. Information specific to pediatrics is lacking, but generally a woman's choice to enter a primary care specialty is influenced by children and other family responsibilities, volunteer or clerkship experiences with the underserved, personal social values, and factors related to marriage and spouse. In contrast, men are more influenced by income potential, parental preferences, and role models before medical school.[37]

There are many implications of this gender shift for pediatric health care delivery. The pediatrician workforce has begun to approach the gender mix of pediatric patients, better meeting the preferences of female adolescents for a clinician of the same gender. If the current gender mix of residents continues, male pediatricians will eventually make up approximately one third of the workforce. This trend is unlikely to stimulate increased demand for male clinicians. Although 50% of girls prefer a female clinician, only 23% of boys prefer a male clinician.[38]

Another implication of more female pediatricians is that, all else held equal, additional physicians will be needed as more women choose to work part-time, particularly when their children are young.[39] The most useful source of information to assess these factors is the AAP Periodic Survey of Fellows, administered to 6400 active members annually. An excellent analysis of gender differences in 1993 was published by Brotherton and colleagues,[40] which this technical report will briefly summarize. First, the proportion of women practicing as general rather than subspecialty pediatricians was higher (61.4% female vs 55.4% male) and was particularly low for some subspecialties such as cardiology (0.9% of all pediatricians were female cardiologists vs 4.3% male); the proportion of female residents in 2000 remains less than 40% in pediatric cardiology and

gastroenterology.[15] Male physicians, compared with female physicians, work more hours per week (average: 57 vs 48 hours, respectively) and spend more time delivering direct patient care (average: 42 vs 35 hours, respectively); thus, female physicians work, on average, 17% fewer patient-care hours than do male physicians over the course of their work lives. These figures include overall hours of both part-time and full-time pediatricians and are similar to data from the most recent AAP Periodic Survey of Fellows as well as previous reports.[41]

Analysis of the AAP Periodic Survey of Fellows has shown that the gender differences in work hours is explained by more women working part-time. The work hours of full-time men and women were similar, but 26% of women worked part-time, compared with 4% of men (Table 1). Pediatricians in part-time employment worked, on average, 15 fewer hours per week than did full-time pediatricians.

These data contradict any notions that women are less productive than men (productivity defined as "medical services productivity" and discussed later in the report [Fig 1, box 14]). More pediatricians will be needed as the proportion of female pediatricians increases, because women choose to work part-time or not at all during certain periods of their life but not because they do not work as hard as men when they are working full-time. Differing retirement rates by gender could also affect the numbers of pediatricians required, but no published studies are available to date.

Other gender differences merit mention. Overall, male and female pediatricians both spend approximately 17 minutes with patients for preventive care visits from birth through 11 years of age. However, female pediatricians spend 22 minutes with patients 12 years and older, compared with male pediatricians, who spend 19 minutes with patients 12 years and older.[40] In a study of a university-based pediatric primary care practice, female pediatrician visits were 29% longer than those with male pediatricians.[42] These findings differ from those reported by McMurray et al[43] in data from the Physician Work Life Study. In this study, women and men allocated similar time for patient visits, but a discrepancy was reported between perceived and actual time needed by female physicians for complete physical examination/consultation.

Frank and Meacham[44] found that female pediatricians worked less and had lower incomes compared with other female physicians but also reported less stress and career dissatisfaction. Female physician income was also reported to be consistently lower for both generalists and subspecialists compared with men, a difference that persists even when controlling for employment status. McMurray et al[43] also found a similar disparity when studying the combined specialties of pediatrics, family medicine, and internal medicine. Female pediatricians also face significant barriers in achieving advancement in academic medicine.[45] These disparities are troubling and have not been explained to date, although it would not be surprising if the gender discrimination in income and advancement that is pervasive in other professions was also found in pediatrics.[46,47]

International Medical Graduates

Approximately one third of practicing pediatricians attended medical schools outside of the United States and Canada,[10,11] a proportion that has changed little during the past 10 years. US medical students generally fill residency positions first and constitute a higher proportion of pediatric residency positions than most other specialties. In 2003, 28.7% of offered first-year pediatric residency positions were filled by IMGs, a lower proportion than for internal medicine (44.8%) or family medicine (58%).[48] IMGs remain an important and relatively stable part of the pediatrician workforce.

IMG residents and practicing physicians are heterogeneous in their national origin and their intentions to remain in the United States. The majority (58%) of first-year pediatric IMG residents are either US citizens, native or naturalized, or are permanent US residents with the right to apply for citizenship.[15] The remaining IMGs hold a variety of visas that usually require a return to their country of origin after residency unless they accept employment in an underserved area of the United States. Their stay in the United States can be prolonged as long as they are in Accreditation Council for Graduate Medical Education–approved residency programs, including subspecialty education. This is a strong incentive to enter pediatric subspecialty residency programs, but when this training is completed, the final choices are still to practice primary care in an underserved area for several years or return to their country of origin. For example, an analysis of New York State IMGs by citizenship and visa status shows that IMGs with temporary visas were more likely to initially enter a primary care residency but that they planned to continue on to subspecialty education. Most planned to

TABLE 1. Mean Number of Hours and Part-time Status of Pediatricians According to Age and Gender: 2000

Age, y	Hours per Week (SD)		Percentage Working Full-time	
	Female	Male	Female	Male
≤35	42.6 (14.3)	46.9 (17.3)	77.1	91.1
36–45	38.8 (16.9)	46.0 (17.2)	66.9	99.0
46–55	36.2 (19.8)	47.3 (15.8)	70.9	97.9
≥56	45.5 (16.0)	43.1 (16.7)	93.3	92.2

remain in the United States for additional education or by working with underserved populations.[49] In the end, a majority of IMGs remain in the United States.[50]

The social value of the continuing flow of IMGs into residency positions, and ultimately into practice, is one of the most contentious issues among health workforce policy leaders. The debate is largely centered on the services they provide for indigent patients while in residency and the care they provide in practice to patients who are medically disenfranchised for geographic, cultural, or financial reasons.[50–52] Some have argued that IMGs exacerbate an existing relative surplus of physicians, particularly specialists, and that in some instances they seem to add to regional disparities in the workforce. There are also concerns that international workforce migration of foreign-born physicians exacerbates health problems in developing countries by draining the supply of their physicians.[53,54] Mullan[55] makes a similar point and argues that IMGs deny opportunities to US citizens aspiring to a career in medicine. In truth, many of the US citizens denied medical school admission in this country do travel overseas and return as one tributary of the IMG river. A fair reading of the policy research in this area does not support any simple conclusions. Foreign-born IMGs preferentially locate in areas with established IMG physicians, and IMGs of Hispanic and Asian descent tend to settle in areas with a higher proportion of these populations.[56] IMGs also disproportionately locate in high-need and underserved counties, and community health centers depend on them; at the same time, the data also indicate that they tend to locate in states with large numbers of physicians.[57–60] In some instances, the presence of IMGs seems to exacerbate regional disparities in physician supply.[61]

IMGs receive their medical education in varied settings. The differences in education and training have raised concerns about the technical and cultural competencies of IMGs. Although data are incomplete about practicing IMGs, training-examination results provide some limited information. US IMGs and non–US IMGs have comparable pass rates in steps 1 and 2 of the US Medical Licensing Examination, but both fall short of US medical graduates. In the Clinical Skills Assessment Examination, overall pass rates of non–US IMGs are 79.7%, compared with 88.6% for US IMGs.[62] ABP scores of first-time takers reveal a bimodal distribution with more low and high scores compared with US medical graduates (G. McGuinness, MD, ABP, written communication, January 16, 2003). These differences in scores may have implications for patient care; a recent study from Canada found a strong association between certification scores of primary care physicians and subsequent practice performance.[63]

The number of foreign-trained physicians is a critical variable that affects growth in the physician workforce. Although the total number of residency positions, largely supported by funds from Medicare and the Health Resources and Services Administration, determines the GME maximum training capacity,[64] filling these positions depends on IMGs. The number of physicians entering practice, therefore, is not determined by a national workforce policy linked to the need for physicians but by the vagaries of visa regulations, federal GME funding, and the perceived needs of teaching hospitals. Together, these factors, which determine the size of the GME pipeline, remain the most salient example of an absent national workforce policy in the United States.

Racial/Ethnic Diversity

The more general issue of people of minority groups in medicine is explored extensively in the 12th report of the Council on Graduate Medical Education.[65] The Committee on Pediatric Workforce has also published 2 relevant policy statements, "Enhancing the Racial Diversity of the Pediatric Workforce"[66] and "Culturally Effective Pediatric Care: Education and Training Issues,"[67] that are essential reading for those concerned with child health workforce policy issues. Although this technical report is partly duplicative of these efforts, the pressing nature of this topic warrants, at the very least, a summary of the factual basis of the policy recommendations. Additional information can also be found in 2 recent papers.[68,69]

The overall racial/ethnic composition of pediatricians little resembles the populations they seek to serve. In 1996, for example, the number of black pediatricians per black children was less than one third that of white pediatricians per white children.[68] The proportion of third-year residents from underrepresented minority groups (black, Hispanic, or American Indian/Alaska Native) increased from 6% in 1997 to 12% in 2002.[70] Still, the disparity in race and ethnicity is anticipated to grow substantially by 2025,[68] reflecting the combination of high minority-population growth rates and an assumption of slow increases in enrollment rates of individuals of minority groups in medical education.

Given that physicians are never likely to be completely reflective of their patients, why should racial/ethnic diversity be a particular concern in planning the workforce for children? The disparities in health status and health services by race and ethnicity are well documented and incontrovertible.[71] These disparities can only be partly attributed to an associated income gradient.[72,73] Ronsaville and Hakim[74] found in a recent analysis of the 1991 National Maternal and Infant Survey that 35% of black infants and 37% of Hispanic infants obtained adequate well care, compared with 58% of white infants; these findings persisted after controlling for socioeconomic status.

Greater minority representation in the workforce seems to be one important way of improving health outcomes in children of minority groups. Physicians from underrepresented minority groups are known to preferentially provide care for patients from minority and underserved groups.[75–79] Furthermore, many individuals of minority groups prefer physicians of similar racial or ethnic background and are more likely to seek care when such a clinician is available.[80] Other necessary measures to improve the delivery of care include the development of greater

cultural competence in current and new physicians[81] and better identification of health system–specific disparities.[82] Neither of these measures addresses the reasons for low rates of minority entrance into medical education, which in and of itself is a fundamental issue of societal equity.[83]

Internal Medicine-Pediatrics

Although internists have assumed a relatively minor role in the care of children, the combined specialty of internal medicine-pediatrics (med-peds) has emerged in the past 30 years as an important alternative to family medicine for physicians interested in providing primary care to all age groups.[84] At present, there are 109 approved programs with a total of 1558 residents.[85] Growth in residency positions was rapid in the 1990s but has now slowed. In 1999, 432 positions were offered in the match and 88.4% were filled, 80.3% of them by US medical graduates. In 2003, 385 positions were offered and 82.3% were filled, 67% of them by US medical graduates.[48] After completing the 4-year program, approximately 90% achieve board certification in one discipline, and 80% achieve board certification in both. Fifty-four percent of med-peds physicians practice in community office settings, usually in primary care serving adults and children.[86] Med-peds is an important component of the pediatrician workforce, but its implications for projecting the workforce supply are less clear. Similar to family physicians, med-peds physicians can adjust their practices to the availability of patients without additional training. As the US population continues to age, med-peds physicians may accommodate a relative decrease in the local pediatric population by seeing more adults.

Nonpediatrician Providers of Pediatric Care

Pediatricians provide only a portion of the care received by pediatric patients. The extent of future pediatric primary care that is delivered by pediatricians will not be determined solely by the pediatrician's extensive education and training in children's health, the fact that they are the largest group of clinicians exclusively caring for children, or that their professional competency and availability may be preferred by families. Influential market forces that will shape the role of pediatricians include the (1) availability and rates of growth of other clinicians, particularly nurse practitioners and physician assistants, (2) salaries and productivity of all pediatric clinicians, (3) practice independence of nonphysician clinicians, and (4) hiring practices of health plans and existing pediatric practices, which hire nonphysician clinicians in increasing numbers.

The number of family physicians (post-GME clinically active) increased from 63 209 to 76 409 in the past decade (1992–2002), a per-child (younger than 18 years) increase of 9%.[10,11] These numbers overstate the growth of family physicians who, unlike pediatricians, care for a rapidly growing population: the elderly. The number of first-year residency positions in family medicine was unchanged in the later part of the decade, and the number filled by US medical graduates decreased.[13] Family physicians view themselves as the primary care providers for families, including children, and their important role in this regard is evidenced by their providing 17% of primary care office visits for children younger than 5 years, 28% for children 5 to 9 years of age, 43% for children 10 to 14 years of age, and 61% for adolescents 15 to 17 years of age (Table 2). The fact that family physicians provide the majority of primary care office visits for older adolescents may translate into new opportunities for pediatricians as the aging population creates additional demand on family physician services. Recent trends indicate that pediatricians are, in fact, providing an increasing proportion of children's primary care visits.[87]

Family physicians currently have a high interest in children's health care,[88] as demonstrated by a recent search of the Web site of the American Academy of Family Physicians. Twenty pediatric policy statements were identified, including clinical recommendations for breastfeeding and otitis media with effusion (see www.aafp.org/x6595.xml). Family physicians are vigorous advocates for the further expansion of their residency programs and are active in all aspects of workforce public policy.[88]

Nurse practitioners and physician assistants have emerged as a health workforce larger than many physician specialties, including pediatrics. Precise figures for the total number of nurse practitioners are not available, but estimates of those practicing in primary care vary from 52 000 to 71 000.[90–92] Approximately 90% of all nurse practitioners deliver primary care services,[90] and others such as neonatal nurse practitioners provide highly specialized tertiary care.[93] Approximately 46% of physician assistants (42 000), in contrast, work in primary care settings, including 14 734 in family practice and 1110 in general pediatrics.[90,94,95]

Nurse practitioners and physician assistants have a particularly important role in rural underserved communities, the setting least likely to attract or support a pediatrician. In 1977, the Rural Health Clinics Services Act (Pub L No. 95-210) established rural health clinics to improve primary care availability in rural underserved areas through favorable Medicare and Medicaid reimbursements. The 2 most salient criteria for rural health clinic designation are location within a health profession–shortage area or

TABLE 2. Number of Primary Care Office Visits According to Specialty of Physician

Age of Patient, y	Primary Care Specialty, No. of Visits (%)	
	General Pediatricians	Family Physicians
0–4	40 480 000 (83)	8 163 529 (17)
5–9	15 960 000 (72)	6 058 195 (28)
10–14	10 660 000 (57)	8 073 828 (43)
15–17	3 422 674 (39)	5 327 585 (61)
Total	71 860 000 (72)	27 620 000 (28)

Office visits by internists are excluded because of the small number of observations.

medically underserved area and the employment of a nurse practitioner or physician assistant. Although the clinic must be under the supervision of a physician, the physician needs to be on site only once every 2 weeks. It is not surprising that many physician assistants and nurse practitioners who practice underserved areas seem to serve as physician substitutes.[96–98] The proportion, however, of nonphysician clinicians located in underserved areas is small, and the overall location of nurse practitioners measured across states has been shown to be correlated closely with that of physicians.[99]

The growth in training programs for both physician assistants and nurse practitioners greatly exceeds primary care physician residency growth, and therefore the availability of nonphysician clinicians will also grow faster than that of pediatricians.[90–92] The growth in numbers has also been accompanied by an expansion of practice independence and prescription authority.[100–102] Both greater numbers and practice autonomy are likely to lead to much larger roles of nonphysician clinicians in pediatric medical care.

Geographic Variation in Child Health Clinician Supply

The study of geographic variation in health care resources and utilization, termed "small-area analysis," emerged in the late 1960s and remains one of the most active and provocative areas of health services research.[103,104] Whether measured at a state, county, or health-market area level, the per-capita numbers of physicians and the use of medical care vary substantially from place to place. There is now an extensive literature of small-area variation in health care resources, although few studies are concerned with children and their clinicians.[19,105]

The study of regional variation in child health clinicians, and pediatricians specifically, remains today an underdeveloped field of research. Almost without exception, pediatrician-workforce analysts have viewed the variation phenomenon as an aspect of underservice in rural and inner-city areas.[7,61,106–108] Some of these locales are underserved in terms of all primary care clinicians (ie, health profession shortage areas[109]), and others have an adequate number of primary care clinicians per capita but no pediatrician. For example, more than 7 million children live in 2935 primary care service areas (of a total of 6102) without a pediatrician. A small but important number of children (290 000) live in 313 primary care service areas without either a pediatrician or a family physician (Primary Care Service Area Project, Dartmouth Medical School, unpublished data, 1999).[110] A recent study by Cull and colleagues[70] found a decreasing number of third-year residents accepting positions in rural areas.

There are myriad public programs that seek to address low clinician availability,[109,111–113] including state and federal programs that run the gamut from subsidizing physicians to practice in designated areas (eg, National Health Service Corps), to providing incentives for nonphysician clinicians (eg, rural health clinics), to selectively recruiting medical students from rural areas.[113] By and large, these programs have increased the availability of primary care physicians, although less is known about the availability and quality of clinicians for children.

Recently, a few studies have examined the geographic variation in child health clinicians across the full distribution of supply, ranging from areas of underservice to areas of perceived high supply.[20,25,30,31,61] Although not without controversy, these studies challenge several long-held assumptions. All these studies demonstrate that the regional per-capita (ie, per-child or per-newborn) supply of general pediatricians or neonatologists varies more than fourfold. Chang and Halfon[20] examined pediatrician-to-child populations across the 50 US states between 1982 and 1992 and found a range of 18.5 (Idaho) to 84.3 (Maryland) clinical pediatricians per 100 000 population (children younger than 18 years). Pediatricians were the least well-distributed primary care specialty in relation to the child population and had the smallest reduction in regional variation between 1982 and 1992. LeBaron et al[30] found a similar degree of state variation in pediatrician supply for 1997. Politzer et al[61] used county aggregates as units of analysis and found a similarly high relative degree of geographic variation in pediatricians compared with other primary care physicians and no decrease in regional disparities between 1989 and 1994. A recent study examined the per-newborn supply of neonatologists across 246 market-based neonatal intensive care regions and also observed a greater than fourfold variation. These differences in neonatologists could not be explained by the substitution of nonphysician clinicians or the presence of academic medical centers.[114] Although capturing only a fraction of the total pediatrician workforce, the studies of neonatologists offer important methodologic advantages: geographic accuracy in physician enumeration and in the ascertainment of patient health care needs.

None of these studies provide evidence that areas with a higher supply of general pediatricians or neonatologists have populations with greater health needs. Across states, the supply of pediatricians, but not family physicians, is positively correlated with median household and per-capita income.[20,30] Higher supply is associated also with the presence of pediatric residency programs[20] and minority populations.[30] State-based analyses are limited methodologically, because important within-state variation of physician supply and population risk are obscured. No work has been published examining the relation of general pediatricians to child health needs in health-market–based areas. Analyses of neonatologists and newborn risk address a narrower population but with greater measurement accuracy. By using vital record data to measure newborn risk and neonatal intensive care regions to measure supply, virtually no relationship was observed between the regional supply of neonatologists and low birth weight rates or any other commonly used measure of perinatal risk.[25,31] Additional study is needed on the relation of supply and child-population needs, but these initial efforts do not suggest that current market forces and public policy lead to

an equitable distribution of child health physicians with respect to their health needs.

The final aspect of regional variation in pediatrician supply that has received some recent attention is the relation between the supply of pediatricians and the outcomes of infants and children. To date, no study has examined health outcomes of children in relation to the supply or availability of general pediatricians, and substantial methodologic challenges would confront any such research effort. These difficulties are evident in cross-sectional studies examining adult populations, which have shown a weak association between higher primary care physician supply and lower mortality. The analyses rely on large-area summations of population characteristics (ie, states, metropolitan statistical areas, or counties) and limited measures for controlling population health-risk differences (eg, income, race).[28,35] Causal direction is also ambiguous. Do more physicians lead to lower mortality, or do physicians tend to locate in areas with healthier and wealthier populations? A recent study showing an association between the supply of pediatricians, but not family physicians, and immunization rates using states as the units of analysis had similar limitations.[30]

A retrospective cohort study of the 1995 birth cohort found higher neonatal mortality in neonatal intensive care regions with a very low supply of neonatologists compared with those with a low supply but no difference in mortality between regions with low and very high supply. These findings suggest that there is indeed a threshold of supply beneath which poorer newborn outcomes are evident. On the other hand, the absence of any additional mortality decrease as supply increases suggests that many areas have more neonatologists than required for minimizing neonatal deaths. This study did not examine whether neonatologist supply was associated with decreased morbidity or better quality of care.[31]

Pediatric Subspecialists

Using the broadest criteria, there are 19 areas of pediatric medical subspecialization,[115] 16 of which offer certification through the ABP.[116] On the basis of physician report to AMA surveys on December 31, 2001, there were 9461 post-GME clinical (>50% of professional time spent directly caring for patients) pediatric subspecialists and an additional 740 researchers, 331 teachers, and 260 administrators (Table 3).[11] Many of these pediatricians, of course, have more than one professional role.

AMA data are also likely to undercount subspecialists, because physicians will retain their initial GME specialty in the database until updated by a response to a survey. The alternative to AMA data has its own weakness. The ABP reports granting 14 699 subspecialty diplomas since 1961,[116] but the current practice status of these pediatricians is not known.

Pediatric subspecialists are a heterogeneous group of pediatricians that eludes generalizations with respect to their type of practice, workforce size, and future opportunities. Some subspecialists such as neonatologists provide services not offered by other specialties, and others such as pediatric allergists provide care for conditions that are within the scope of practice of general pediatricians, pulmonologists, or internist-allergists. New specialties continue to develop and establish their role in caring for children before formal fellowships and board certification are established. Hospitalists are the most recent example. Certain subspecialists may have decreased the patient load of general pediatricians (neonatologists and hospitalists, for example) as they assume care for infants and children that were formerly central to the practice of many general pediatricians. Most important are the differences in the sizes of the subspecialties. At one extreme are neonatologists and pediatric cardiologists, who number 2847 (post-GME clinically active) and 1310, respectively, using AMA data, and at the other extreme are pediatric endocrinologists and rheumatologists, which, by the AMA system of enumeration, number less than 100 each in full-time clinical practice.[11] The number of board-certified subspecialists is higher.[117] The ABP has certified 828 infectious-disease subspecialists and 192 rheumatologist subspecialists,[116] but these figures do not identify those returning to general pediatrics and those with research, teaching, or administration as their primary focus. The proportion of professional time devoted to academic work also varies across these specialties, adding another factor to be considered in workforce planning.

The heterogeneity in pediatric subspecialists has 2 important implications. The first is that workforce statistics, forecasting models, and health services studies that report the general experience of pediatric subspecialists will be driven by the largest subspe-

TABLE 3. Professional Activities of Allopathic Pediatricians: December 31, 2001

	Total	Patient Care		Other Professional Activities			
		Post-GME Patient Care	Resident/ Fellows	Administration	Medical Teaching	Research	Other
Pediatricians	66 636	51 675	10 924	1270	1128	1435	204
Generalists	52 888	42 214	8006	1010	797	695	166
Subspecialists	13 748	9461	2918	260	331	740	38

cialties. These generalizations may lead to policies that suit no particular group of children's health services needs. Pediatric subspecialists, as a whole, have already suffered this fate by being subject to the same policy brush as have adult subspecialists, an extremely large group of physicians who, unlike pediatricians, are largely nonacademically based and more highly remunerated. The second implication is that workforce analysts must recognize, from a measurement viewpoint, that many pediatric subspecialists qualify in epidemiologic terms as "rare events." Enumeration, workforce models, and measures of local availability have relatively low precision and, for the smallest subspecialties, great uncertainty. The geographic variation in subspecialists can lead to additional confusion about the overall adequacy of supply.

Pediatric subspecialists are more likely to be based academically than as general pediatricians or adult subspecialists,[118,119] although this differs by specialty. Most pediatric subspecialists, nevertheless, spend most of their professional time in patient care. Pediatric departments have difficulty recruiting subspecialists, at the same time that subspecialists interested in nonacademic practices have trouble finding positions, and those in practice may experience significant competition.[117,120] Failure to differentiate the academic and community labor markets for pediatric subspecialists perpetuates shortages of academic subspecialists who have unique roles in education and research. These shortages may be exacerbated in the future if there is a decrease in the number of IMGs and a greater number of female pediatricians, trends that are likely to lead to fewer pediatricians seeking subspecialty education.[121] Notwithstanding these possible future influences, the recent trend is toward a greater interest in subspecialty education by third-year residents.[70] It is the pediatrician-scientist supply that remains at highest risk, facing particularly long training periods and shrinking clinical revenues while competing with PhD-trained investigators for research funding.

For these reasons, subspecialty workforce policy and planning need to occur by specialty, with an eye to finding commonality when it is present and rejecting it when it is not. Although the recommendations of the recent FOPE II report are not universally accepted,[36] FOPE II has produced an important literature about pediatric medical subspecialists and surgical specialists through the review of primary literature and surveys of pediatricians.[117–120,122–126]

FORECASTING THE CHILD HEALTH WORKFORCE SUPPLY

The 2 fundamental questions in any consideration of the child health workforce are: How many will we have in the future, and will that number be enough or too many? As the previous discussion suggests, future child health workforce supply and requirements are related to many factors, each with their own uncertainties (Fig 1). Methods of projecting the number of pediatricians are on safest ground. Using simple actuarial models with assumptions about training (box 3), retirement (box 10), and death rates (box 9 [the last 2 are sometimes combined as a separation rate]), the models have finite solutions. The robustness of forecasting models using these 3 rates can be tested with simple sensitivity analysis.

Training rates depend on the number of pediatric GME positions (Fig 1, boxes 3 and 5). Changes in the size of US medical schools (Fig 1, box 1) alter the makeup of the workforce but not the number of pediatricians. Positions unfilled by US medical school graduates[48,127] are filled by physicians trained in other countries (Fig 1, box 2). Since 1997, the number of categorical pediatric residency positions offered in the match has increased by 11% and the number filled has increased by 6%.[48] ABP data indicate a 5% increase in the number of categorical first-year positions from 1997 to 2002.[116] Changes in GME funding could quickly alter the size of this pipeline, although none are on the immediate horizon.

We can expect that death rates will continue their downward drift for physicians, but these rates are already low in the preretirement years and a further decrease will not appreciably alter supply-projection models. There are many opinions about trends in retirement rates,[128] but there is no dominant a priori direction that can be asserted. Much has been made of physician frustration with managed care, greater administrative tasks, and increasingly litigious families. Without a doubt, these are less attractive sides of the medical profession. On the other hand, health care professionals are retiring later, not earlier, as they follow a general labor trend to a longer work life. Pediatricians and their employers are also faced with the same dramatic short-term challenges of decreasing financial markets that devalue pension funds and 401(k) accounts alike. This inevitably will lead to postponed retirement, at least in the short run. By the time this report is published, it is hoped that the country's economic health along with the rate of return of financial investments will have improved. Still, no credible economist predicts a return to the "irrational exuberance" of the 1990 equity markets, as attractive as that might be for retirement expectations.

In a model forecasting the number of clinically active pediatricians, 2 additional gender-related variables are of increasing importance: personal leave (Fig 1, box 8) and part-time employment (Fig 1, box 15), typically for child care responsibilities. The former affects the number of clinically active pediatricians employed at any given time, and the latter modifies the full-time equivalence of those physicians. The dominant influence on these event rates will be the number of women entering pediatric residencies. Current rates are known and can be added to actuarial models with assumptions about future changes in these rates.

Forecasting becomes increasingly complex as we incorporate additional parameters into the model. Many of the desired variables are difficult to measure, requiring the substitution of proxies. Other measures lack a theoretic or definitional consensus within the health policy and medical community. Even with perfect measurement, simply adding

more variables to the model introduces additional uncertainty to the results.

One domain that bedevils child health workforce-supply forecasting is workforce productivity, how it is defined and measured.[12,129–132] For the moment, we will restrict productivity to its common measures that are more aptly named medical services productivity (Fig 1, box 14). Examples include visits or hours of clinical activity per week per physician full-time equivalent (FTE). These measures are not equivalent. As previously discussed, the hours worked per week are not strongly related to pediatrician gender. Full-time female and male pediatricians work similar clinical hours.[39] Data are not available about gender differences in patient visits per week.

Organizational factors are increasingly important in medical productivity as pediatricians continue to shift from solo and partnership practice to employee-based work arrangements. Employee pediatricians work an average of 6.4 fewer hours per week compared with those practicing solo or in partnerships.[133] Financial incentives related to patient insurance types or the compensation plans by physician employers can also affect the number of medical services delivered per physician FTE.[134,135] For all of these factors, the consistent trend is for pediatricians to work fewer hours and provide fewer visits per week. In 1989, pediatricians (those working at least 20 hours per week in patient care) worked an average of 53 hours per week in patient-care activities; by 1999, they worked 50 hours. During the same period, the average number of office visits decreased from 102 visits per week to 95 (Table 4).[136,137] The numbers indicate a decrease in the medical services productivity of pediatricians but do not account for possible but still unmeasured changes in patient complexity. It is also not known if these trends stem from fewer patients, lifestyle choices of pediatricians, or both. How will medical services productivity change in the future? Answers offered to this question are highly speculative.

Medical services productivity ignores the very purpose of the profession. The difficulty becomes obvious when one is reminded that the unit of production (in an economic sense) in health care is improvement in health outcomes (Fig 1). Therefore, a strict measure of productivity would be the labor input required per unit of greater health outcomes. In this instance, "health outcomes" is defined broadly to include the maintenance of health, the care and cure of illness, and the restoration of a sense of well-being in children and families through education and counseling. Although operationalizing the theory of health outcomes productivity with actual measurements is difficult, it should at least be understood that the number of hours worked or patients seen per week is not always related to the health status, reduction of risk, or sense of well-being of a physician's patient population.

Many workforce-supply models have been developed,[138–140] but few have been for pediatrics and only one is recent. Shipman and colleagues[141] developed an interactive general pediatrician–supply model using software developed for modeling scientific and business systems. The actuarial model estimates future pediatrician FTEs by using parameters for GME output, gender mix, and retirement patterns. Other parameters incorporated into the model include rates of subspecialization, mortality, and the proportion of IMGs returning to their home countries. Although not intended to fully represent workforce requirements, the model also calculates pediatrician-to-child ratios by using low-, middle-, and high-census projections. The supply projections are compared with a user-selected benchmark or reference value, the default being the current supply of

TABLE 4. Characteristics of Allopathic Pediatricians (General Pediatrics, Pediatric Cardiology, and Pediatric Allergy Included): 1989 and 1999

Pediatrician Characteristic	1989	1999	Percent Change 1989–1999
Net income	$93 000	$126 000	35.5
Adjusted for inflation*	—	$93 750	0.8
Professional activities			
Weeks of practice per year	47.4	47.6	0.4
Hours of professional activities per week	58.0	54.5	−6.0
Hours of patient care per week	53.4	49.5	−7.3
Office hours per week	31.8	29.8	−6.3
Office visits per week	101.8	95.0	−6.7
Revenue sources			
Medicaid	—	20%	—
Private insurance	—	65%	—
Patients	—	10%	—
Time spent in primary care activities	—	95%	—
Wait for new patient appointment	—	2 days	—
Employment type	—		—
Self-employed solo	—	19.2%	—
Self-employed group	—	27.5%	—
Employee	—	50.5%	—

49.0 per 100 000 population. The benchmark can also be adjusted for the different future demand as the age structure shifts (infants require more visits than do adolescents) as well as the greater need for pediatricians if family physicians see fewer children. The program has a simple-to-use interface, and the user can adjust the default values. The effects of varying model parameters can be tested quickly by comparing projection curves of the number of pediatrician FTEs. The model is available at www.dartmouthatlas.org/workforce_model.php, and AAP members are encouraged to test their own assumptions about the relative importance of the factors discussed in this report.

By using default assumptions, the model forecasts a 36% increase (from 38 457 to 52 169) in general pediatricians in 10 years and a 64% increase (62 952) in 20 years. Using middle-census estimates, the number of general pediatricians per 100 000 children will increase 31% in 10 years and 50% in 20 years. Adjusting the number of future pediatricians for age and gender productivity will require 4% more pediatricians in 20 years, in large part to compensate for part-time status. This assumes that the current gender mix of residents continues into the future. Sensitivity testing included retirement rates, ranging from a 20% decrease to a doubling of current rates within all age and gender strata, decreased productivity of at least 30% for pediatricians older than 50 years, GME downsizing to 110% of US medical graduates, increase in pediatric residency positions by 1% per year, and substituting low- or high-census child-population estimates. At 20 years, these resulted in differences from the default model pediatrician-to-child ratio of less than 16%. This model demonstrates that the growth in the pediatrician-to-child ratio is robust to varied alternative-forecasting scenarios.

PEDIATRICIAN-WORKFORCE REQUIREMENTS

Workforce analyses usually run aground when forecasting the physician requirements of populations. The most important parameter is simply the size of the population or its age definition, in this instance the number of children (Fig 1, box 13); from this, future FTEs per child (or per capita) are calculated. Population projections may seem straightforward, but there are uncertainties in both the number and composition of the future population, leading to contentious and seemingly arcane arguments among forecasters.[138,139,142]

Requirements for general pediatricians are also related to substitution within the broader child health workforce (Fig 1, box 11). As discussed in this report, the number of child health professionals includes a complex mix of physicians and nonphysician clinicians with differing training and education, skills, and knowledge that provide, at times, similar services. Two examples come to mind. Within pediatrics, subspecialists such as neonatologists and hospitalists provide care that once was part of nearly every pediatrician's daily professional life. For whatever factors that may increase the need for pediatric services in the future, rearrangement of clinical work within pediatrics decreases the need for general pediatricians. Similarly, the growth in numbers of nonphysician clinicians may spare the efforts of pediatricians within a practice while decreasing the need for pediatricians in aggregate.

More difficult to measure, and usually ignored, are the rich and complex factors that relate the number of health services delivered per child to children's health and well-being, termed health outcome productivity (Fig 1, box 17). A short list of factors includes the technical excellence and appropriateness of the service and the division of labor across the many possible clinicians (Fig 1, box 11) or even across the nonmedical workforce—parents, teachers, coaches, clergy, and therapists (Fig 1, box 16). Relative health needs are also of central importance (Fig 1, box 17). All else held equal, we would also expect a greater production of health (ie, improvement in health status or well-being) when care is delivered to a less healthy child. The organizational and community milieu can also modify the efforts of the child health workforce (Fig 1, box 14). When these factors are considered together, it becomes apparent that successful health outcomes might occur with a widely differing number of pediatricians. Workforce forecasters have accounted for these factors through 5 different models.[130,139,143,144] Each model requires particular theoretic assumptions and data, and none of these methods should be viewed as mutually exclusive of the others. The acceptance of a particular framework partly depends on the definition of "requirement" and the policy goal of the forecasting process. Another way of looking at the task of assessing requirements is that it is not a science in the traditional sense but is intertwined with the values expressed in the assumptions. Is the goal to optimize health or the perception of access to physicians or to maximize employment opportunities for physicians? Is reducing disparities in the access and use of medical services one goal? What level of public funding in education and payment of health services is assumed, and what is the rationale for public funding at all if it is thought that markets will drive the health care system to desirable outcomes? Although the values inherent in different requirement models may not be explicitly stated, the careful reader will find them implicit in the models' assumptions.

Employment Opportunities for Pediatricians

The most basic approach to assess the requirements for pediatricians is to determine their employment opportunities and competition for patients. Both measures are indicative of the pediatrician's short-term prospects, although no forecasting models have been constructed that formally incorporate these economic signals.

Studies from the mid- to late 1990s show that although there were wide employment opportunities for general pediatricians, there was also significant competition for jobs and patients. In 1996, 17% of residents finishing training had difficulty finding a position, 15% received only 1 job offer, 9% accepted positions that were not their first choice, 17% accepted a position in a location that was not their first choice, and 18% accepted a job with a salary that was less than expected. Although discouraging at first

glance, pediatricians had less difficulty finding a position than did physicians in 25 of the 32 specialties examined. The specialty with the most favorable employment prospects was family medicine; job prospects in general internal medicine were slightly less favorable than in general pediatrics. The specialties with the poorest job prospects were pathology, adult pulmonary disease/critical care medicine, and adult infectious disease.[145] Another study found that between 1990 and 1995, the number of employment ads for pediatricians decreased, and ads for pediatric subspecialists remained nearly constant. At the same time, the number of ads for family physicians grew close to 25%.[146] Perhaps the most pessimistic view of general pediatrics was reported to the Council on Graduate Medical Education by the Center for Workforce Studies in Albany, NY.[147] In exit surveys of residents completing training in New York State and Texas, 6 measures were used to assess relative demand by specialty; general pediatrics was second to last of the 28 specialties studied.

The most recent information comes from Cull et al,[70] who used survey data from third-year pediatric residents. Over a 5-year period ending in 2002, the proportion of residents with a general pediatrics goal without a position increased from 5% to 15%, and the proportion reporting that their position was their first choice decreased from 86% to 80%.

Our information about the competition experienced by practicing pediatricians is limited to subspecialists. Competition is highest for pediatric allergy/immunology, cardiology, pulmonary medicine, and critical care medicine; lower levels of competition were perceived by infectious disease, genetics, and adolescent medicine pediatricians. The strongest predictors of competition were working in solo, group, or medical school practices in contrast to staff- or group-model health maintenance organizations (HMOs) or community hospitals. Pediatricians working in the Midwest or southern regions also experienced the strongest competition. Less competition was felt by IMGs, those working in rural areas, and female physicians.[120]

Salary information also indicates a weak demand for pediatricians compared with other primary care specialties. In one nationally representative survey conducted between 1996 and 1998, general pediatricians reported an average income of $126 000 compared with $144 000 for general internists; pediatric subspecialists reported an average salary of $156 000, whereas the average salary of internal medicine subspecialists was $192 000.[148] When adjusted for inflation, the salary of pediatricians changed little between 1989 and 1999 (Table 4).[136,137] Starting salaries for graduating residents entering general pediatric practices decreased (in 2002 dollars) from $103 161 in 1997 to $99 123 in 2002.[70]

Data from the National Resident Matching Program indicated that pediatric residency positions are among the most highly sought by medical students. At its peak in 1998, 98.9% of pediatric positions offered through the match were filled, with 82.2% filled by US medical graduates; these match rates exceeded internal medicine and family medicine. By 2002, the overall pediatric match rate had fallen to 90.5%, with 70.7% filled by US medical graduates, and then increased slightly in 2003 to 93.8%, with 71.3% filled by US medical graduates. Other primary care specialties experienced similar decreases, particularly with respect to the proportion of US medical graduates matching: 55.2% for internal medicine and 42.0% for family medicine in 2003. For all first-year positions in 2003, 89.9% were match-filled, 63.9% by US medical graduates.[48,127,149,150]

Despite these marketplace signals, it is worth noting that once in practice, general pediatricians have higher satisfaction with their job, career, and specialty than do general internists. Satisfaction, job stress, and burnout for pediatric subspecialists were less favorable and similar to general and subspecialty internal medicine physicians. These findings show a lack of correlation with salary levels and attitudes about practice and also identify stress experienced by pediatric subspecialists.[148]

Needs-Based Models

One formal model for forecasting future physician requirements was that developed by the Graduate Medical Education National Advisory Committee (GMENAC).[151] GMENAC estimated physician requirements in the late 1970s through a complicated process of defining the need for efficient medical services to optimize health. For each specialty, clinicians and epidemiologists estimated the future disease burden, the necessary treatments, and the workforce required to provide those services. The GMENAC report predicted a physician surplus for both generalists and specialists, pediatricians included. From the standpoint of physician employment, this obviously did not occur, and in the absence of unemployed physicians, GMENAC predictions have generally been rejected.[9,152]

What went wrong with GMENAC? First, the data requirements of the models were unrealistic. Needs-based planning assumes that the disease burdens of populations are measurable and that it is known which medical interventions can most effectively and efficiently improve health today and in the future.[153] In actuality, the measurement of health status in populations is imperfect, and knowledge of medical care effectiveness is incomplete and likely to remain so as technologic developments outpace effectiveness studies.[154,155] Second, there was an assumption by the readers of GMENAC that as physician supply approached levels needed for populations to be healthy, demand would attenuate. In this instance, surplus would be evidenced in unemployment or, at the very least, pressure on physician salaries. Populations with higher health status, however, do not consume necessarily less health care, as might be expected, but continue to demand (in an economic sense) services to address an ever-elusive definition of "health." With most health care costs borne by third parties and the general sense that more medical care always leads to better health, physicians continue to be fully employed even as health status improves. This would be of little public policy interest except that societal resources for medical care

reimbursement are not without limits, and many populations remain with unmet health care needs, even as the healthy seek more care. The lesson learned from GMENAC is that in the complex market for medical care and physician labor, population needs are poorly related to demand for physicians.

Demand-Based Models

Demand-based forecasting uses current medical services utilization as an indication of medical need and projects future utilization to determine the required number of physicians under different conditions of productivity. In its most elegant form, utilization is measured for many different combinations of population characteristics such as age, gender, and race and for different medical care settings and financing. These include the mixture of fee-for-service or managed care penetration and patient insurance status. Once these are measured in the present, then populations for each of these characteristics are projected into the future, and the number of required pediatricians can be calculated.

Demand-based models are the most common type of forecasting.[138,139,156] Medical service utilization data are available for many populations and types of service delivery. The model assumes that current delivery patterns are rational and desirable and that similar populations in the future will require utilization rates close to those delivered today. The acceptance of current utilization patterns as normative measures also assumes that the current market for health care services maximizes the well-being of children.

The 2 merits of demand forecasting are the availability of data and the simple assumption that the medical marketplace reasonably delivers health care consistent with societal values and expectations. Among the many criticisms that can be leveled, the most obvious is that the supply of physicians, as seen with general pediatricians and neonatologists, is not located where child health needs are greater[20,114] and that medical utilization similarly varies widely across regions without detectable population differences. Current demand for health care cannot be used as a normative standard when the location of resources is idiosyncratic. The health services literature is replete with studies that show the irrationality of health care delivery.[18,157–160] Critics of demand-based planning ask: Why would we want to perpetuate these delivery patterns into the future?

Trend Analysis

Recently, a new method of projecting physician requirements was proposed: trend analysis.[144,152] The method uses a macroeconomic conceptual framework that asserts that growth in physician requirements is tightly linked with increases in the gross domestic product (GDP). In addition to long-term trends in GDP, 8 "macro" trends are emphasized in the model, some that can be reasonably measured and others that are highly speculative. The model attempts to separate trends that are "the natural evolution of the current fiscal and organizational characteristics of the health care system and the societal fabric in which it exists" (attrition, productivity, substitution, geographic distribution, technology, demographics, health systems, and economic dependency) from trends that are "value judgments" (technology controls, specialist controls, volume controls, and cost controls).[161] The developers of this model have used it to advance the idea of an "impending" physician shortage. Although the method forecasts physicians in aggregate, they have interpreted trends as indicating a future shortage in specialists and an "abundance of generalists."[162,163]

Trend analysis has been criticized for its view that the macroeconomic association of GDP and the workforce is causal, inevitable, and a self-evident expression of societal wants. Many other criticisms have also been vigorously advanced.[164–170]

When this model is applied to the pediatrician workforce, a contradiction emerges. Just as Cooper et al[162] have observed a correlation between the growth of GDP per capita and total physicians per capita, Freed et al[171] have presented a similar correlation with pediatricians per 100 000 children. Projecting this trend into the future, Freed et al[171] find, instead of Cooper et al's "abundance of generalists," that "the current net inflow of pediatricians will not be sufficient to meet future demand as expressed by the trend line." These conclusions need to be considered in the context of the estimate of Shipman et al[141] that the per-child number of pediatricians will grow more than 5 times faster than the per-capita number of internists or family physicians. One interpretation is that there is an impending shortage of primary care as well as specialist physicians. Another interpretation is that macroeconomic correlations are an overly simple estimator of workforce requirements. A potential weakness with these models is that the number of physicians per capita has increased over time and will correlate highly with any other upward trend. Bivariate time-series analyses are subject to the same limitations as any other observational study, with the added problems of a small number of observations (n = number of time periods) and difficulty in identifying and measuring time-dependent confounders. When the models are technically correct,[172] health care planners still must decide whether previous patterns of physician growth should be used as the primary guide of the child health workforce in the future.

Benchmarking

Benchmarking is a final method of determining workforce requirements. Benchmarking exploits natural experiments in workforce levels by using physician-to-population ratios found in regions of the United States or within health care systems as indications of real life and attainable physician levels.[19,139,143,173,174] Benchmarking seeks to find regions in which workforce deployment is efficient and effective in delivering health care. A slightly different approach is to use the staffing levels in efficient capitated health systems that deliver high-quality care as measured by medical care processes, family satisfaction, and health outcomes. Benchmarking rejects the notion that the current national physician

labor or health services markets have any particular normative value in terms of optimizing health outcomes and offers a variety of available reference points to help guide physicians' employment decisions. In the short term, benchmarks can caution a health plan about adding additional specialists to an area with a high per-capita number or point to areas with a low supply that may be an opportunity for expanded services. As the marginal effects of physician supply on patient satisfaction and outcomes are better understood, benchmarks may provide a means of improving systems of care for populations enrolled in health plans or residing within regions. To the degree we fall short of the need or desire to develop effective delivery systems with constrained resources, benchmarking will fail to predict physician employment opportunities.

Requirements for Pediatricians

In Table 5 we present published projections of pediatrician supply and requirements. It is evident from this list that relatively little work has been done in this area. The supply of general pediatricians forecasted by Shipman et al[141] for 2010 is similar to the earlier predictions of Kletke et al.[175]

The current supply (53 general pediatricians per 100 000 children younger than 18 years) exceeds the requirement suggested by GMENAC in 1980 (49 per 100 000) and by Abt Associates in 1991[176] (41 per 100 000). The only other estimates of requirements that are available are from the AAP Pediatric Research in Office Settings Network (71 per 100 000) and various group and HMO practices (49–89 per 100 000). These figures assume that children receive care only within pediatrician-dominated practices with staffing levels observed in practices serving largely employer-insured populations.[107,177] Even with these assumptions, Shipman et al[141] and Kletke et al[175] forecast a supply in 2010 (72 per 100 000) that exceeds staffing levels observed in most of these groups.

As discussed elsewhere in this report, a level of supply judged sufficient for the United States as a whole still leaves pockets of underservice or possible pediatrician excess. In addition, the effects of the growing supply of pediatricians on employment opportunities will depend on both the financing and organization of health care. General pediatrician unemployment would most likely occur if pediatric care were delivered entirely under the organizational systems that carefully manage panel size, the mix of physicians and nonphysician clinicians, and utilization, such as staff- or group-model HMOs. To the extent that pediatric care is less explicitly planned and financed, there are likely to be substantial regional differences in future opportunities for pediatricians.

TABLE 5. General Pediatrician Current Supply, Projected Supply, and Requirements

Supply	Date	Children per General Pediatrician*	General Pediatricians per 100 000 Children*	No. of General Pediatricians
Current				
Shipman et al[141]				
Population age <18 y	2000	1886	53	38 457
Population age <20 y	2000	2041	49	38 457
Kletke et al[175] (estimated)	2000	—	—	41 600
Projected				
Shipman et al[141]				
Population age < 18 y	2010	1390	72	52 169
Population age < 20 y	2010	1555	64	52 169
Population age < 18 y	2020	1293	77	62 900
Population age < 20 y	2020	1362	73	62 900
Kletke et al[175] (ratios assume age <18 y)	2010	1408	71	51 500
Estimated Requirements				
Population-based				
GMENAC[151]	1980	2034	49	NA
Abt Associates and the Bureau of Health Professions[176]	1991	2430	41	NA
Practice-based†				
AAP PROS Network[166]	1996	1400	71	NA
Managed care staffing				
Group Health Association of America[178] (age not stated)	1993	2222	45	NA
New England IPA (0–17 y)	—	1300	77	NA
33 HMOs (0–14 y)	1992	1157	86	NA
Group-model HMO 1 (age not stated)	—	1125	89	NA
Group-model HMO 2 (age not stated)	—	1750	57	NA
Group-model HMO 3 (age not stated)	—	1200	83	NA
FOPE II "ideal"[107]				
High	2000	1200	83	NA
Low	2000	1400	71	NA

PROS indicates Pediatric Research in Office Settings; IPA, independent practice association; NA, not applicable.

* Assumes middle-US estimates.

† These practice-based measures need to be viewed cautiously. They assume that all children are cared for exclusively by pediatric practices and that most have employer-based insurance.

Which Supply of Pediatricians Is "Right?"

This report does not recommend a particular supply of pediatricians but instead challenges the reader to consider the values worth promoting through workforce policy. Much of the disagreement about physician requirements is seen as a consequence of uncertainty in the data and analytic methods when, in fact, these debates are driven by fundamental, and often unstated, conflicts in values. The differences in values are embedded in both the means and ends of the pediatrician workforce.

With respect to the "means," there are significant disagreements among pediatricians, health care planners, and families about the appropriate and effective mix of market-based and publicly funded programs in the education and deployment of the workforce. Should public funding of medical education (eg, GME Medicare and Health Resources and Services Administration monies) be accompanied by an obligation to care for underserved populations? Who should decide on the size of the pediatrician pipeline? Should it continue to be residency programs or a quasi-public entity? How much of medical education should be funded publicly if markets are considered the best arbiter of workforce supply?

As far as the "ends" of workforce policy, should the workforce be equitably available to children? If not, how much disparity is acceptable, and who should pay the associated uneven costs? How much should workforce policy be influenced by the interest in tempering pediatric competition and thereby ensuring practice opportunities and stable incomes? If this is ignored, will we able to attract the best and the brightest of rising medical talent to pediatrics? These are only a few of the questions that need to be considered in developing workforce policy, including the target supply. The answers are linked to the values held as individuals and jointly as a profession.

If producing better health and well-being of children remains the goal of pediatricians and associated workforce policy, there are still areas in which sound policy is hindered by inadequate data. The 2 related and unanswered questions in pediatrician-workforce research are: How much of an improvement in child health outcomes is derived from a given increase in the number of pediatricians, and would an equal investment in an alternative input provide a greater benefit? Past investments in pediatricians have brought good value in children's health outcomes improvement. At the same time, there is a need to evaluate the effectiveness of additional growth in pediatrician supply.

abstract

FREE

It is the pediatrician's role to promote the child's well-being and to help parents raise healthy, well-adjusted children. Pediatricians, therefore, can play an important role in the prevention of child maltreatment. Previous clinical reports and policy statements from the American Academy of Pediatrics have focused on improving the identification and management of child maltreatment. This clinical report outlines how the pediatrician can help to strengthen families and promote safe, stable, nurturing relationships with the aim of preventing maltreatment. After describing some of the triggers and factors that place children at risk for maltreatment, the report describes how pediatricians can identify family strengths, recognize risk factors, provide helpful guidance, and refer families to programs and other resources with the goal of strengthening families, preventing child maltreatment, and enhancing child development. *Pediatrics* 2010;126:833–841

INTRODUCTION

Since Kempe et al[1] published their description of the battered-child syndrome in 1962, the medical profession has made great strides in recognizing and intervening in cases of child maltreatment. Child maltreatment is now recognized to be part of a continuum of family violence that includes child maltreatment, intimate partner violence, and the abuse of animals and the elderly. A great deal is known about the factors that contribute to the abuse of a child and about those that may prove protective. Despite the progress made, the problem remains widespread and serious in its costs, whether reckoned in dollars[2–4] or human potential.[5] Child maltreatment, however, is a preventable problem, and pediatricians have a role in its prevention.[6]

Pediatricians, because of their unique relationship with families, are in an excellent position to help families enhance their ability to protect children and to address factors that put them at increased risk of abuse. Because pediatricians have contact with families during challenging and stressful times (eg, when a child is ill), they can become familiar with a family's stressors and strengths. As a trusting relationship evolves, families and patients develop comfort discussing personal issues with their pediatrician.[7] Pediatricians are often connected to community resources that have the welfare of the child and family as a priority. Families tend to trust their pediatricians' guidance and referral to these resources. The literature shows that parents view pediatricians as respected advisors and counselors.[8]

Pediatricians accept this role as well. The majority of pediatricians (70%) who participated in the 2002–2003 American Academy of Pedi-

atrics (AAP) periodic survey agreed that they can help prevent child abuse by providing anticipatory guidance.[9] Almost all the respondents to this survey (91%) agreed that pediatricians should screen for parenting problems during health supervision visits.

Triggers

Pediatricians can play a role in preventing child maltreatment if they understand the situations that commonly trigger maltreatment and if they identify and address some of the factors that may make a child more vulnerable to maltreatment.

Certain elements of normal child development are often the triggers for child maltreatment. Schmitt[10] described what he called the "7 deadly sins" of childhood. He described normal developmental phases that may cause difficulty for some parents, specifically colic, awakening at night, separation anxiety, normal exploratory behavior, normal negativism, normal poor appetite, and toilet-training resistance. He suggested that pediatricians anticipate these normal developmental stages and provide guidance to families about how to best manage potentially difficult situations.

Crying is a common trigger for child abuse[11] and is the most common trigger of abusive head trauma.[12,13] In 1 study of infants who suffered abusive head trauma, almost all of the parents had sought help for their infant's crying previously from their primary care physician.[14] All infants cry; crying generally begins in the first month of life, and the duration of crying increases and peaks between 2 and 4 months of age. That the incidence of abusive head trauma parallels this normal developmental crying curve may serve as additional corroboration of the association between crying and abuse.[15,16]

The severity and frequency of caregivers' adverse responses to crying have largely been underappreciated. In 1 study, almost 6% of parents of 6-month-old infants admitted that they had smothered, slapped, or shaken their infant at least once because of his or her crying.[17]

Discipline can become abusive, as when punishment is used inappropriately in response to a child's developmentally normal behaviors. Unprepared parents may mistake separation anxiety, normal exploratory play, and normal negativism, for example, for abnormal behaviors or unacceptable behavior and resort to punitive measures to correct them. Apart from its possible effects on emotional development, corporal punishment may result in serious physical injuries for the child. When mothers in the Carolinas were interviewed, 4.3% of them admitted using harsh physical techniques when disciplining their children. These practices included beating, burning, kicking, or hitting a child with an object somewhere other than on the buttocks; 2.3% of the mothers said that they shook children younger than 2 years as a form of discipline.[18]

Toilet-training and toilet accidents are another common trigger for child abuse.[19] Immersion burns are frequently inflicted in response to soiling and enuresis by caregivers who believe that the children should be able to control these behaviors.[20,21] Genital bruising and immersion burns are common child abuse injuries associated with toilet-training. The average age of children who have been intentionally burned is 32 months, which is about the same age many children are being toilet trained and, thus, the same age at which some are accidentally soiling or wetting themselves.

TABLE 1 Factors and Characteristics That Place a Child at Risk for Child Maltreatment

Child	Parent	Environment (Community and Society)
Emotional/behavioral difficulties	Low self-esteem	Social isolation
Chronic illness	Poor impulse control	Poverty
Physical disabilities	Substance abuse/alcohol abuse	Unemployment
Developmental disabilities	Young maternal or paternal age	Low educational achievement
Preterm birth	Abused as a child	Single-parent home
Unwanted	Depression or other mental illness	Non–biologically related male living in the home
Unplanned	Poor knowledge of child development or unrealistic expectations for child	Family or intimate partner violence
	Negative perception of normal child behavior	

Factors That Place a Child at Risk for Child Maltreatment

Many disparate factors may combine to make a child more likely to be abused or neglected.[22] Using an ecologic model as a framework for considering risk,[23] certain characteristics of the child, the parent, and the environment may place a child at risk, as shown in Table 1. Often, multiple factors coexist and are interrelated, which increases the risk for the child.

Child characteristics that could predispose a child to maltreatment include anything that makes a child more difficult to care for or makes a child different from the parent's expectation. For example, a demanding infant or a child with special health care needs may test the parent's patience. As a result, children with physical, developmental, or emotional/behavioral disability are at an increased risk of being maltreated.[24,25]

Children with disabilities are approximately 3 times more likely to be maltreated than are children without disabilities.[26] A number of characteristics

may make children with disabilities more vulnerable to maltreatment.[27] The child's disability may place additional emotional or financial demands on the family. A child who is heavily dependent on others beyond infancy may engender resentment. Further complicating matters, the child with disabilities may be conditioned to obey caregivers without question and, thus, may lack the ability to disclose abuse. If children have been taught to accept painful touch as normal, they may not be able to distinguish when boundaries are crossed.

Children born prematurely may also be at increased risk of being maltreated.[28–30] Some preterm infants may be more at risk for abuse, because the infants are perceived as less attractive and more demanding by their parents.[28] Some experts have suggested that the early and sometimes prolonged separation of these infants from their parents may contribute to their vulnerability. Some preterm children may be more vulnerable because they have special needs or require special care, including additional physician visits or special therapy. All of this care may place an additional financial and/or emotional strain on the family.

Likewise, the child who is unplanned or unwanted is at risk for maltreatment.[31] An unplanned pregnancy may place an extra financial and/or emotional burden on the family.[30]

Parent factors also may make a child more vulnerable to being maltreated. Factors that may decrease a parent's ability to cope with the stresses of parenting include low self-esteem; poor impulse control, including a tendency to lash out in response to stress; substance use; and alcohol abuse.[30,32] Young maternal and paternal age are risk factors for maltreatment,[33,34] and young maternal age is strongly associated with infant homicide.[35] Parents who were abused or neglected themselves as children may parent in the only style they have learned.[30,31]

A parent's depression or other mental illnesses,[34,36] particularly postpartum depression, affect a child's growth and development and may place the child at risk for maltreatment. Depression is a significant problem for both fathers and mothers.[37]

Parents who have a negative view of themselves and their children and parents who devalue their children are at risk of maltreating their children. Oates et al[30] found that mothers who had maltreated their children tended to rate their children as below average, whereas control mothers viewed their infants as normal or above average.

Lack of knowledge about child-rearing can increase the caregiver's level of frustration with the child's behavior. Parents vary widely in their knowledge of child development and what they should reasonably expect from a child at a given age. Parents who maltreat their children are more likely to have developmentally inappropriate and unrealistic expectations for their child's behavior and to have a negative perception of normal behaviors.[28]

Oates et al[30] also found that parents who maltreated their children were more likely to have a punitive child-rearing style and were stricter. When the maltreated children behaved well, they were rarely praised, compared with the children in the control group, who were praised for good behavior.

Environmental factors can add to parents' stress. Parents who are isolated and who have low levels of social support are at increased risk of maltreating their child.[38] Poverty, unemployment, low maternal education, and single parenting are risk factors associated with physical child abuse.[36,39–42] Having a non–biologically related male living in a single-female–headed home is a risk factor for child maltreatment and for fatal child maltreatment.[43–45]

Adult intimate partner violence and child maltreatment are closely linked.[46] Children who live with an adult victim of intimate partner violence are at an increased risk of being physically abused. In addition, children who are exposed to violence in the home are affected emotionally, cognitively, and behaviorally.[47] Exposure to this toxic environment is often considered a form of child maltreatment.

These factors may interact and increase the child's vulnerability to maltreatment. Infants who are not nurtured properly in their first months may not learn to regulate their emotions, because development of this vital task is enhanced by early parental attention and support.[48] As the infants become more challenging to their parents, this complex interplay may increase their risk for abuse. Adults who are socially isolated may lack standards for comparison of their child's behaviors, or role models and resources for themselves. Food or employment insecurity, poor access to community services, or simply the lack of community feedback can exacerbate stress and anxiety. Even if no single factor would be sufficient to overwhelm the caregiver, the combination of stresses may precipitate an abusive crisis.[49,50]

Protective Factors

Besides assessing a child's risk for maltreatment, the pediatrician should identify and consider the child's and family's strengths. Maltreatment occurs when factors specifically pertinent to the child and factors relevant to the parent, the community, and to the environment interact, which creates a "perfect storm" for abuse and/or neglect.[51–53] In other words,

maltreatment occurs when risk factors are greater than protective factors and stressors exceed the supports.

Several factors seem to both protect a child from maltreatment and provide children with resilience to the effects of child maltreatment, as shown in Table 2.[54–56] Using the same ecologic framework, protective factors include attributes of the child and the family as well as support from outside the family. Although many studies have focused on how these behaviors may trigger a physical response or physical abuse, it is likely that these behaviors also trigger other forms of maltreatment, including sexual abuse. Prevention may require changing some cultural beliefs and social policy and improving education and economic opportunities.

PREVENTION AND INTERVENTION PROGRAMS

It is not the intent of this report to review and evaluate all of the available prevention and intervention programs. Instead, the report will discuss some of the programs as examples and, when available, cite any evidence for their effectiveness.

Hospital- and Office-Based Intervention Programs

Programs have been developed to help parents to better cope with a child's crying. Dias et al[57] implemented a program in nurseries in western New York designed to teach new parents about violent infant-shaking and alternatives to use when infants cried. They found that the incidence of abusive head injuries decreased by 47% during the first 5 years of the program. A similar program, the Period of PURPLE Crying, also uses a brief video and written material to educate new parents about normal crying and how to cope with an infant's crying. This program has been shown to improve mothers' knowledge about crying and to improve their behavioral response to it.[58,59] Although both of these programs represent promising models, neither program has yet demonstrated strong evidence that they are effective as a primary prevention of abusive head trauma.

One office-based prevention model, the Safe Environment for Every Child (SEEK) model, was tested in a resident continuity clinic over a 3-year period.[60] Residents were trained to recognize factors that placed a family at risk for maltreatment. Study families were screened for risk factors, and a team that consisted of a resident and a social worker addressed any identified risk factors. When the families were compared with a control group, the prevention program resulted in fewer reports of child maltreatment made to child protective services, fewer incidents of medical noncompliance and delayed immunizations, and less harsh punishment by parents. Although some of the differences between the control group and intervention group were of modest significance, participation in this program improved the residents' sense of competence and comfort when addressing risk behaviors.

The AAP developed Connected Kids: Safe, Strong, Secure, an office intervention originally known as the Violence Intervention and Prevention Program (VIPP). This program was modeled after The Injury Prevention Program (TIPP), also from the AAP.[61] The Connected Kids program uses a resilience-based approach to anticipatory guidance and is designed to help primary care physicians use their therapeutic relationship to support families as a means of violence prevention. The Connected Kids program includes a clinical guide, online training materials, and parent education materials and educates both pediatricians and parents about discipline, parenting, and other issues. Brochures on child development show parents that normal problematic child behaviors—from crying to climbing—arise from the child's normal growth and development and advocate that these behaviors be addressed with guidance rather than punishment. The Connected Kids program has not been

TABLE 2 Protective Factors

Dispositional/Temperamental Attributes of the Child	Warm and Secure Family Relationships	Availability of Extrafamilial Support
Above-average cognitive ability	Presence of a caring and supportive adult	Structured school environment
High ego control (high degree of impulse control and modulation)	Positive family changes (eg, family interventions, father no longer allowed on visitations)	Involvement with a religious community
Internal locus of control (belief in one's ability to control own destiny)		Involvement in extracurricular activities or hobbies
External attribution of blame (attribute cause to something outside oneself [eg, some external pressure])		Access to good health, educational, and social welfare services
Presence of spirituality		
Ego control and ego resilience (able to modify impulses and insulate themselves from environmental distracters)		
High self-esteem or sense of self-worth		

evaluated formally, but a study on implementation of Connected Kids was conducted in 2007 with 27 pediatricians over a 6-month period, with a focus on improving parental supervision and monitoring during middle childhood. Findings from the project indicate that the Connected Kids program is appealing to pediatricians, implementation is feasible, and use is sustainable over a period of 6 months. More information about the Connected Kids program is available at www.aap.org/connectedkids.

Practicing Safety, a program conducted by the AAP and funded by the Doris Duke Charitable Foundation, developed expanded anticipatory guidance modules for use in primary care offices. The 7 modules provide pediatricians with suggested assessment, guidance, and resources to help parents cope with crying, help them parent, ensure their children's safety when they are in the care of others, improve the family environment, provide effective discipline, assist with sleeping and eating, and help with toilet-training (www.aap.org/practicingsafety). The program was tested in 8 practices in New Jersey and Pennsylvania, and parent and staff reports showed a significant increase in maternal depression screening. Staff reports also showed an increase in discussion and use of resources on coping with crying, discipline, and toilet-training. The toolkit was revised and was implemented by 14 practices in the AAP Quality Improvement Innovation Network (QuIIN); the next steps are being developed.

Community Prevention Programs and Resources

Home-visitation programs, in which targeted families receive regular contact with trained personnel, are a prevention model that has been widely used and are supported by the AAP.[62] The Nurse-Family Partnership model developed by Olds et al has been rigorously tested.[63] The model, which uses trained nurses, has demonstrated improvements in maternal and child functioning and showed a trend toward reduced childhood mortality rates from preventable causes.[64] On the other hand, Healthy Families, a home-visitation program that uses trained paraprofessionals, has been tested in a number of states, but it has not been shown to reduce child abuse or child abuse risk factors.[65–67] Cincinnati's "Every Child Succeeds" program used both the Nurse-Family Partnership model and the Healthy Families model and provided home-visiting to mothers at high risk (adolescent, unmarried, low income, or suboptimal education) and first-time mothers. They found that intensive home-visiting reduced the risk of infant death during the first year of life.[68] The Task Force on Community Preventive Services found that, in the 21 programs for which records were available, home-visiting was associated with a median reduction in child abuse of more than 50%.[69–71]

Although pediatricians have long been familiar with therapeutic preschools and with parenting programs, study results have suggested that these interventions are more effective when multiple modalities are combined with those that target the entire family. Reynolds and Robertson[72] reported that participation in school-based child-parent centers, which provided extensive family education and support, reduced maltreatment by 50% in a population at high risk. Other study results have shown significant effects when community-based parent-child interventions are targeted at specific populations, combine peer and professional support, and provide some services directly to the children.[73]

Parent-training programs, such as the Triple P program, Sure Start, Family Connections, Healthy Families America, and Together for Kids, aim to improve parenting skills and parents' emotional adjustment. The quality of the programs, however, is variable. The Triple P program resulted in a positive reduction of maltreatment in 1 study,[74] but the program needs to be replicated and reassessed to determine its effectiveness.[63] A comparison of the effectiveness of parent-training programs is available through the *Cochrane Database of Systematic Reviews*.[75,76] More information about child abuse—prevention programs, local resources, and program evaluation can be found at www.childwelfare.gov/preventing/programs/types/homevisit.cfm.

The Role of Pediatricians

It is important for pediatricians to recognize and respond to ongoing maltreatment. Universal prevention of child maltreatment must begin with an approach that assesses the caregivers' strengths and deficits and connects the family with community resources that will protect the dependent children before abuse or neglect occurs. The schedule of routine health care visits recommended by the AAP provides ample opportunity for the clinician to observe and assess parenting practices at the very times when a child would be expected to initiate new and possibly challenging behaviors.[77]

The third edition of *Bright Futures* (http://brightfutures.aap.org/about.html) from the AAP provides pediatricians with guidelines for anticipatory guidance and prioritizes topics for discussion at each health supervision visit. This multimedia program includes the *Bright Futures* guidelines in a manual format, pocket guide, and personal digital assistant (PDA) version in addition to toolkits, PowerPoint presentations, and health-promotion information sheets.

A clinician may receive answers or observe behaviors that suggest the family's resilience is compromised in some significant way. Such compromise may derive from child factors, parental deficits, or environmental stressors. If the family's ability to nurture and protect the child is compromised, that child must be considered at risk for abuse, and action should be taken. Unless the child is felt to have been abused in some way, such action rarely entails referral to child protective services but frequently goes beyond the scope of a typical office visit. Efforts may be as straightforward as taking the time to elicit a more comprehensive history or counseling a frustrated parent. A more complicated case may involve referral to a community agency for evidence-based parent training or for intervention for intimate partner violence. If there is significant doubt about the child's safety, the caregivers' ability to protect, or maltreatment is suspected, the pediatrician should, of course, contact child protective services.

TABLE 3 Incorporating Primary Child Maltreatment Prevention Into the Health Supervision Visit

	Parent Coping Skills and Support System
Prenatal or first visit	Who lives in the home? History of mental health problems, substance abuse/alcohol abuse, or intimate partner violence?
	How were the parents parented and disciplined?
	What were the parents' experience(s) with trauma?
	Are there financial problems and/or poverty?
	Was the pregnancy planned?
	Who will care for the infant?
Newborn	Infant crying
	Expectations
	Identify 3 friends or family members who can help (safety line)
First months	Infant crying
	Normal development and expectations
	Maternal depression
	Identify 3 friends or family members who can help (safety line)
	Loving is not "spoiling"
Cruiser/toddler	Discipline = teaching
	Toilet-training
	Normal development and age-appropriate expectations
Preschool	Teach child names for genitalia
	Safe touch/unsafe touch
	Normal sexual behavior
	Normal development and age-appropriate expectations
	Discipline = teaching
	Model nonviolent anger management and conflict resolution
School	Discipline = teaching
	Model nonviolent anger management and conflict resolution
	Appropriate supervision
	Respect private parts of others and others to do the same
	Personal safety; peer pressure; Internet use
Adolescence	Discipline = teaching
	Dating violence
	Model nonviolent anger management and conflict resolution

Note that topics may be reintroduced at successive visits

GUIDANCE FOR THE PEDIATRICIAN

1. Obtain a thorough social history, initially and periodically, throughout a patient's childhood. The parent-screening tool included in the *Bright Futures* tool and resource kit (available at http://brightfutures.aap.org) can be used to help screen for risk factors and problems; identify and build on family strengths, resilience, and mediating factors; identify and address parents' concerns; and reinforce effective parenting.[78] Reinforcement builds strength and a sense of competence.
2. Acknowledge the frustration and anger that often accompany parenting. Provide anticipatory guidance about developmental stages that may be stressful or serve as a trigger for child maltreatment. A health visit framework can be helpful (see Table 3) or refer to the Connected Kids counseling schedule (http://aap.org/connectedkids).
3. Talk with parents about their infant's crying and how they are coping with it. Learn their perception of their infant's crying and which strategies they use to cope. The pediatrician should provide parents with insight into the infant's behavior and teach alternative responses.
4. When caring for children with disabilities, be cognizant of their increased vulnerability and watch for signs of maltreatment.[79,80] Provide families with information about the child's condition. Activities may include giving out handouts or having group instructional sessions with parents. Validate the parent's stresses and provide them with techniques to manage the stress. Provide the family with information about respite care, which allows someone else to care for the child so that the parents or other family members can take a break. Identify families at greater risk of abusing their child. Help educate older children about how to protect themselves against abuse and that they should share uncomfortable, abusive, or concerning experiences with a trusted adult.
5. Be alert to signs and symptoms of parental intimate partner violence[81] and postpartum depression. Instruments are available

that can be used by clinicians to identify depression in mothers and fathers.[37,82] Familiarize yourself with appropriate community resources, and know how to respond if a caregiver reports intimate partner violence or depression.

6. Guide parents in providing effective discipline.[83] Encourage parents to use alternatives to corporal punishment, such as time out techniques and positive reinforcement. Brochures such as those developed for the Connected Kids program (http://aap.org/connectedkids) and *Bright Futures* (http://brightfutures.aap.org) can be used to supplement this discussion.
7. Talk to parents about normal sexual development and counsel them about how to prevent sexual abuse. The AAP has developed an educational toolkit that helps health care professionals talk to parents and patients about sexual violence topics and provides them with educational materials and other resources (www.aap.org/pubserv/PSVpreview/start.html).
8. Encourage caregivers to use the pediatric office as a conduit to needed expertise. Become knowledgeable about resources in the community, and, when appropriate, refer families, especially stressed parents, to these resources.
9. Advocate for community programs and resources that will provide effective prevention, intervention, research, and treatment for child maltreatment and for programs that address the underlying problems that contribute to child maltreatment (eg, poverty, substance abuse, mental health issues, and poor parenting skills).
10. Advocate for positive behavioral interventions and supports in schools. Encourage schools to implement effective and supportive behavioral expectations and interventions. (More information about school-based positive behavioral interventions and support can be found at www.pbis.org.)
11. Recognize signs and symptoms of maltreatment and report suspected maltreatment to the appropriate authorities.

AMERICAN ACADEMY OF PEDIATRICS

POLICY STATEMENT

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Community Health Services

The Pediatrician's Role in Community Pediatrics

ABSTRACT. This policy statement reaffirms the pediatrician's role in community pediatrics. It offers pediatricians a definition of community pediatrics and provides a set of specific recommendations that underscore the critical nature of this important dimension of the profession. ***Pediatrics*** **2005;115:1092–1094;** ***community, pediatrics, pediatrician, role of, definition of, profession.***

ABBREVIATION. AAP, American Academy of Pediatrics.

INTRODUCTION

Today's children and families live in a period of rapid social change. The economic organization of the health care and other human service systems in the United States is undergoing profound changes. Pediatric training programs are searching for the optimal blend of knowledge, skill, attitudes, and experience to prepare tomorrow's pediatricians for the new challenges and morbidities that they will face.[1–3] As clinicians and educators encounter new demands on their expertise and resources, it is important to reaffirm the vital and long-standing role of pediatricians in promoting the physical, mental, and social health and well-being of all children in the communities they serve.

DEFINITION OF COMMUNITY PEDIATRICS

The American Academy of Pediatrics (AAP) offers a definition of community pediatrics to remind all pediatricians, generalists and specialists alike, of the profound importance of the community dimension in pediatric practice. Community pediatrics is all of the following:

- A perspective that enlarges the pediatrician's focus from one child to all children in the community;
- A recognition that family, educational, social, cultural, spiritual, economic, environmental, and political forces act favorably or unfavorably, but always significantly, on the health and functioning of children;
- A synthesis of clinical practice and public health principles directed toward providing health care to a given child and promoting the health of all children within the context of the family, school, and community[4];
- A commitment to use a community's resources in collaboration with other professionals, agencies, and parents to achieve optimal accessibility, appropriateness, and quality of services[5] for all children and to advocate especially for those who lack access to care because of social, cultural, geographic, or economic conditions or special health care needs[6,7]; and
- An integral part of the professional role and duty of the pediatrician.

For many pediatricians, efforts to promote the health of children have been directed at attending to the needs of particular children in a practice setting, on an individual basis, and providing them with a medical home.[8] This approach, in combination with pediatricians' own personal community interests and commitments, has proven to be very successful. Increasingly, however, the major threats to the health of America's children, the new morbidities,[9] arise from problems that cannot be addressed adequately by the practice model alone.[10] These problems include high infant mortality rates, children with chronic health care needs, obesity, disproportionately high levels of intentional and unintentional injuries, exposure to lead and other environmental hazards, substance abuse, behavioral and developmental consequences of inappropriate care and experience, mental health conditions, poor school readiness,[11]family dysfunction, sexually transmitted diseases, unwanted pregnancies, and lack of access to medical homes.[12] An integral component of a community-pediatrics approach incorporates interdisciplinary practice. As former AAP president Robert Haggerty, MD, FAAP, reminded us in 1995, "we must become partners with others, or we will become increasingly irrelevant to the health of children."[13]

Communities should impart a sense of health, safety, and well-being and promote a supportive environment for families of all types. Just as children depend on the interaction of families in which they live, the communities that support them affect families. The health and welfare of children depend on the ability of families and the community support system to foster positive emotional and physical development.[14] Recently the AAP's Task Force on the Family examined the concept of family pediatrics and the discipline that must be practiced within the context[15] of the community.[16,17]

doi:10.1542/peds.2004-2680

Pediatricians remain instrumental in efforts to create, organize, and implement changes in communities' efforts that can substantially improve the health of children. As far back as Abraham Jacobi, MD (1830–1919), a leading child advocate of his time and a founder of the discipline of pediatrics, pediatricians recognized that children are best understood, and their needs attended to, within interlinking contexts of biology, family, and community.[18] More recently, Haggerty identified the unique contribution and focus of community pediatrics:

> Community pediatrics [has sought] to provide a far more realistic and complete clinical picture by taking responsibility for all children in a community, providing preventive and curative services, and understanding the determinants and consequences of child health and illness, as well as the effectiveness of services provided. Thus, the unique feature of community pediatrics is its concern for all of the population—those who remain well but need preventive services, those who have symptoms but do not receive effective care, and those who do seek medical care either in a physician's office or in a hospital.[19]

With the sweeping changes occurring in medicine and other human services, it is especially important now for pediatricians to reexamine and reaffirm their role as professionals in the community, as community pediatricians, and prepare themselves for it just as diligently as they prepare for traditional clinical roles.

RECOMMENDATIONS

1. Pediatricians should use community data (epidemiologic, demographic, and economic) to increase their understanding of the health and social risks on child outcomes and of the opportunities for successful collaboration with other child advocates.
2. Pediatricians should work collaboratively with public health departments and colleagues in related professions to identify and decrease barriers to the health and well-being of children in the communities they serve.[20,21]
3. Pediatricians should become comfortable with an interdisciplinary collaborative approach and advocacy effort to child health. Pediatricians can play an important role in coordinating and focusing new and existing services to realize maximum benefit for all children.[22,23]
4. Pediatricians and other members of the community should interact and advocate to improve all settings and organizations in which children spend time (eg, child care facilities, schools, youth programs). School and community resources should be considered as assets in developing strategies for the problems that children will face now and throughout their lives.
5. Pediatricians should nurture and advocate for neighborhood structures that support healthy families capable of promoting optimal health, safety, and development in their children.
6. Pediatricians should advocate improving the effectiveness and efficiency of health care for all children, striving to ensure that every child in the community has a medical home.
7. Pediatricians should educate themselves concerning the availability of community resources that affect the health and well-being of the children they serve.
8. Pediatricians are encouraged to become involved in the education of residents and medical students in community settings. Pediatricians have the unique opportunity to model roles outside the traditional clinical roles that students and residents encounter. Pediatric academicians should use resources from the AAP and the Ambulatory Pediatric Association to engage the community pediatrician as an educator, both in the care of individual patients in community-based practice and in roles related to promotion of the well-being of all children in the community. Community-based resources outside the bounds of the traditional hospital and outpatient office setting should be used to instruct residents in the effect of the community on child health status and the positive effect of interdependent collaboration of community agencies with health professionals on child health.[24]
9. Medical student, resident, and continuing medical education programs should consider and periodically review basic community pediatric competencies to be included in training and maintenance of certification efforts for pediatricians.[25]
10. AAP chapters and their members should provide leadership for furthering the understanding of community pediatrics and encourage participation in creative, community-based, integrated models such as those supported through the Community Access to Child Health program and the Healthy Tomorrows Partnership for Children.
11. AAP chapters should provide leadership, support, and recognition for pediatricians involved in advocacy efforts at the local, state, and national levels to ensure that children have access to care and to foster integration of these activities as an integral part of the professional role and duty of the pediatrician.

Caring, compassionate, and knowledgeable pediatricians should address the needs of their patients and all children in the context of the community.

Committee on Children With Disabilities

The Pediatrician's Role in Development and Implementation of an Individual Education Plan (IEP) and/or an Individual Family Service Plan (IFSP)

ABSTRACT. The Individual Education Plan and Individual Family Service Plan are legally mandated documents developed by a multidisciplinary team assessment that specifies goals and services for each child eligible for special educational services or early intervention services. Pediatricians need to be knowledgeable of federal, state, and local requirements; establish linkages with early intervention, educational professionals, and parent support groups; and collaborate with the team working with individual children.

ABBREVIATIONS. IDEA, Individuals With Disabilities Education Act; IEP, Individual Education Plan; IFSP, Individual Family Service Plan; OHI, Other Health Impaired.

Special education in each local school district is protected and regulated by strong legislative and judicial safeguards created by the federal Education for All Handicapped Children Act (PL 94–142). This act was reauthorized in the 1991 legislation PL 101–476 under the new title, Individuals With Disabilities Education Act (IDEA), which has four key components: 1) identification of children with learning-related problems; 2) evaluation of the health and developmental status of the child with special needs, determining current and future intervention requirements, and developing a plan to match services to needs; 3) provision of services that include educational and related services; and 4) guaranteed due process.[1] These federally legislated safeguards establish that children with disabilities and their parents share the same legal right to a free and appropriate education as children without disabilities.

Federal legislation requires that each child recognized as having a disability that interferes with learning has a written plan of service: an Individual Education Plan (IEP) for children aged 3 through 21 years, an Individual Family Service Plan (IFSP) for infants and toddlers birth through 3 years, and a Transitional Services Outcome Plan for young adults at 16 years of age. Federal legislation defines transition from school as a coordinated set of activities for a student designed to promote movement from school to postschool activities, including postsecondary education, vocational training, integrated employment, continuing and adult education, adult services, independent living, and community participation. This transition plan highlights and validates the lifelong needs of individuals with disabilities and is the beginning of an integrated program that enables adults with disabilities to live, work, and play in our towns and cities.[2] The pediatrician is in a key position to participate in planning services and to provide care for these children and young adults.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

BACKGROUND

The Individual Education Plan (IEP)

In 1975 Congress enacted PL 94–142, the Education for All Handicapped Children Act, as an educational bill of rights to assure children with disabilities a free and appropriate education in the least restrictive environment. In 1977 implementation of services was extended to children 3 to 21 years old, although services for children aged 3 to 5 years remained optional. States were also requested to identify children who had not previously received services.

PL 94–142 (currently Part B) allowed children with mental retardation, hearing deficiencies, speech and language impairments, specific learning disabilities, visual impairments, emotional disturbances, orthopedic impairments, and a variety of medical conditions that may interfere with education (categorized as Other Health Impaired [OHI]) to receive special education services. To meet the eligibility criteria, a child's disability must interfere with the educational process and normal school performance to the extent that special education assistance is needed.

Other portions of the law provide the following:

1. Every child must have a multidisciplinary evaluation by a team. This team, working in collaboration with the family, is responsible for designing an IEP that has specific education and therapeutic strategies and objectives. Each plan must be reviewed annually.
2. Every child must be educated in the least restrictive environment. This criterion supports the concept of integrating children with and without disabilities as much as possible and with extra supports and services when necessary to facilitate inclusion.
3. The evaluation team may recommend the following related services: transportation; developmental, corrective, and other supportive services (in-

cluding speech pathology, audiology, psychological services, and physical and occupational therapy); recreation (including therapeutic recreation); and social work services (including rehabilitative counseling) and medical services (for diagnostic and evaluative purposes only). These services may be required to assist a child to benefit from special education and include early identification and assessment of disabling conditions.[3] If the parents approve the IEP, they sign a document and the school is committed to providing these outlined services.

4. The rights of the parents and child to "due process" shall be protected. This ensures the parents' rights to be involved in developing the educational plan and for the meeting to be conducted in their native language or other mode of communication if it is not a written language understandable to the general public. The IEP/IFSP team leader is responsible for arranging and paying for an interpreter if English is not the native language of the home or if the parent has a hearing impairment. Furthermore, parents have the right to appeal when they view the team's decision as inappropriate or harmful.

The Individual Family Service Plan (IFSP)

In 1986 Congress enacted the Education of the Handicapped Act Amendments, PL 99–457.[4] It was reauthorized in PL 105–17 in 1997. Part C of this reauthorization legislation, formerly known as Part H, called for the creation of statewide, coordinated, multidisciplinary, interagency programs for the provision of early intervention services for all infants and toddlers with disabilities. Although the law did not mandate these services, partial reimbursement of costs was made readily available to states that wished to participate. All states have established programs for children birth to 3 years. These developmental services are designed to meet needs in the areas of physical, cognitive, communicative, and psychological development, and in self-help skills. The purpose of these services is to enhance the development of the infant and toddlers with disabilities; to minimize their potential for developmental delay; and to optimize the abilities of the families to meet the special needs of their children. It was also hoped that this would minimize the cost over time of special education services when youngsters attained school age, decrease the need for institutionalization, and enhance the potential for independent living.

The law requires each state to create its own definition of developmental delay as a basis for determining eligibility for services. Pediatricians played a significant role in determining this eligibility by advocating for a broad definition of developmental delay. Services are provided for children with developmental delay, as well as for those whose biological conditions have a high probability of having a delay. In addition, states have the option to provide services to those children who are at risk of manifesting developmental delays attributable to environmental factors.

A major difference between Part C of PL105–17 and Part B of PL94–142 is that Part C focuses on the involvement of the family and supports for the family. Under this law, the evaluation, assessment, and planning take place with family participation and approval. Early intervention services are all optional, subject to family approval, and are provided in natural settings such as the parents' home and child care settings as well as more formal child development programs. The current discussions about early brain development center around children from birth to 3 years. It is during this period that the growth and organization of the brain is most influenced by environmental factors that Part C strives to make optimal.

Children referred as potentially eligible receive a comprehensive multidisciplinary assessment. The assessment describes the abilities and needs of the child and family. Following assessment, an IFSP is created, to include the following:

- the child's present attainments,
- family strengths,
- how to enhance development of the child,
- major outcomes expected, including the outcome measures and criteria, and time lines to achieve specific goals,
- specific early intervention services that the child and family will receive,
- projected dates for initiating services and their duration,
- name of the service coordinator responsible for coordinating and helping the family implement the plan,
- steps to help the child and family with the transition to school services at an appropriate time.

The statute specifies a wide array of other services, but the only health services included are those that are "necessary for the infant or toddler to benefit from other early intervention services." Diagnostic and consultative medical services are also included, but the extent to which these services are funded by the early intervention program varies.

MEDICAL ROLE AND RECOMMENDATIONS

Several roles for the pediatrician exist under IDEA. All pediatricians should ensure that in their practices, every child with a disability has access to the following services:

1. A medical home.[5,6] A medical home provides care that is accessible, continuous, comprehensive, family-centered, coordinated, and compassionate. For children with special health care needs, many of whom have an IEP or an IFSP, the pediatrician's central role as the provider of primary care means that he or she would participate in the plan development. In addition, the pediatrician should collaborate with community resources in treatment planning and in promoting early intervention programs that work.
2. Screening, surveillance, and diagnosis.[7,8] The pediatrician should screen all children from the first encounter, checking for risk or existence of a disability or developmental delay. Pediatricians are

in key positions to identify at the earliest possible age those children who may benefit from services under IDEA. Pediatricians should provide screening and surveillance using a combination of methods best designed to take advantage of multiple sources of information.

3. Referral. The pediatrician should be knowledgeable about the referral process to early intervention programs in his or her community and knowledgeable about the parents' right for multidisciplinary team evaluation by the school- or state-designated agency if a disabling condition may be present. In addition, some of the best support of parents comes from other parents who are able to offer emotional and social support and practical advice. Many communities have programs in which parents support each other and help parents new to the system better navigate the system.[9] Family Voices, a nationwide grassroots network of families and friends speaking on behalf of children with special health care needs, is a creditable organization that can assist parents and pediatricians and is accessible by telephone and the Internet (1–888-835–5669; www.familyvoices.org).
4. Diagnosis and eligibility. For early intervention, the pediatrician has an important role in the identification of children with established delays and in the diagnosis of conditions with a high probability of developmental delay, which will qualify a child for this program. Each state has developed a definition of these conditions, which should be obtained from the state's lead agency for this infant and toddler program. In addition, some states include "at risk" conditions as defined by the state as eligible for services. Further information about these issues can be obtained from the single point of entry into Part C locally or the state's lead agency. A list of lead agencies for state early intervention services can be obtained from the National Childhood Technical Assistance System (919/962-2001; www.nectas.unc.edu/).
5. Participation in assessment. A child identified through screening or observation as meeting the definition for developmental delay should receive a comprehensive multidisciplinary assessment. The pediatrician has an important role as a referral source or, if more extensive participation is elected, as a member of the multidisciplinary team. Few pediatricians have the flexibility in their schedules to participate in person in lengthy team meetings. Usually, these meetings are scheduled with a short lead time and at the convenience of the educators arranging them. However, all pediatricians should offer to be available by written communication or participate by conference call or other means to offer input to and receive feedback from the assessment team. Ideally, the pediatrician should be a member of the team and attend the IEP/IFSP meeting.
6. Counsel and advice. During the assessment process, families will need a knowledgeable person for medical advice and counsel. Pediatricians can alert parents to the benefits of a pre-IFSP or pre-IEP conference; of their right to sign the IFSP or IEP only when they are comfortable with the recommendations; and their right to have a friend or other advocate at the IFSP and IEP conference. Although a parent may bring their personal attorney to the conference, most parents do not. If an attorney is going to attend on behalf of the family, the family should notify the school agency of that fact before the meeting to give the school an opportunity to have their legal counsel or top administrator scheduled for the conference. The appeal process begins at the district school board where the child resides. The president of the school board and superintendent of schools should receive the written appeal document. If appeal at the district level fails to satisfy the family's concerns, their next appeal is to the State Board of Education. Rarely does an appeal by either the school district or family go to state or federal supreme courts. Each district school board has a published document that advises parents of procedural safeguards, which can be obtained at no cost to the family. Most assessment teams nominate a member as service coordinator to work with the families. A strong link should be developed between the assessment team and the primary care pediatrician, as well as an open sharing of concerns between parents, the pediatrician, and the assessment team.
7. Creation of the IEP and IFSP. Pediatricians who participate in the assessment process should be consulted by the assessment team when these documents are created. Such consultation is vital to preparing an appropriate and effective plan. The pediatrician should review the plan developed, counsel the family, and comment on health-related issues as needed. The pediatrician should determine if the health-related services proposed are appropriate and sufficiently comprehensive and assist parents in performing their advocacy tasks when there is evidence of inappropriate planning. Ideally, when schools or educational agencies are developing the IEP or IFSP, a pediatrician should serve as a member of the assessment team.
8. Coordinated medical services. When medical services are part of the IEP or IFSP, they should be conducted by the primary care pediatrician or an appropriate pediatric subspecialist. Medical services and communication should be coordinated by the primary care pediatrician or his or her designee in those cases in which the children have complex medical needs involving several physicians or centers. Special education personnel should be made aware of the restrictions of health care insurance including limited referral options and the role of the primary physician as "the gatekeeper" in some programs.
9. Advocacy. Pediatricians have many local and state opportunities to serve as knowledgeable, thoughtful advocates for improved community and educational services for children with disabilities. Pediatricians who select this role need to be aware of the structure of services in the commu-

nity and the key persons who implement them. Examples of advocacy roles for pediatricians include participation in the local or state early intervention interagency council, consulting with the local school system or state department of education, or becoming a school board member.

CONCLUSION

Participation in interdisciplinary efforts for children with disabilities can help the pediatrician focus on the needs of the child with disabilities or developmental delay and improve the coordination of all forms of service and care for the child and the child's family.[10] The pediatrician's role in IEP and IFSP development and implementation includes knowledge of federal statutes and state and local mandates and regulations; establishing linkages with local early intervention and education professionals and parental support groups; and collaborating with the team serving the individual child. Collaboration among parents, pediatricians, and educators can lead to better quality of care and paves the way for a better quality of life for the child and young adult with a disability.

POLICY STATEMENT

The Pediatrician's Role in Family Support and Family Support Programs

abstract

FREE

Children's social, emotional, and physical health; their developmental trajectory; and the neurocircuits that are being created and reinforced in their developing brains are all directly influenced by their relationships during early childhood. The stresses associated with contemporary American life can challenge families' abilities to promote successful developmental outcomes and emotional health for their children. Pediatricians are positioned to serve as partners with families and other community providers in supporting the well-being of children and their families. The structure and support of families involve forces that are often outside the agenda of the usual pediatric health supervision visits. Pediatricians must ensure that their medical home efforts promote a holistically healthy family environment for all children. This statement recommends opportunities for pediatricians to develop their expertise in assessing the strengths and stresses in families, in counseling families about strategies and resources, and in collaborating with others in their communities to support family relationships. *Pediatrics* 2011;128:e1680–e1684

family support, social emotional health, counseling, community resources

ABBREVIATION
AAP—American Academy of Pediatrics

INTRODUCTION

The health and welfare of children depend on the ability of their families, supported by systems in their communities, to foster positive emotional and physical development. Recent scientific research confirms that brain growth and neurophysiologic development during the first years of life respond directly to the environmental influences of early emotional relationships. The neurologic pathways produced then have profound effects on the behaviors of children and adolescents and affect their interactions within their families and extended society across the life course. The enormous effect the family has on this developmental process led the American Academy of Pediatrics (AAP) to make the "promotion of nurturing families for all children" a priority among AAP resolutions in 1993 and 1994 and, subsequently, to develop the AAP Task Force on the Family. The task force published a thorough and extensive report in 2003 that informs pediatricians and guides policy-makers regarding the effect that family has on children's functioning and the expectations for pediatricians to promote optimal family functioning for their patients.[1] Pediatricians play a unique role as family health advisors during the formative period of a child's development and during crucial developmental stages throughout childhood and adolescence. Pediatricians need expertise in working with families to identify strengths, stresses, and needs and to identify priorities and

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

goals with families. They also need to develop expertise in counseling skills and knowledge regarding community-based resources to offer strategies and resources to families. The structure and support of families involve forces that are often outside the agenda of the usual pediatric health supervision visits. Pediatricians must ensure that their medical home efforts promote a holistically healthy family environment for all children.[2]

CHANGES IN FAMILIES

Stresses accompanying contemporary American life can challenge families' efforts to promote successful developmental and emotional outcomes for their children. The structure of families and patterns of family life in the United States have changed profoundly in the past quarter century. Five percent of all births in 1960 were to unmarried women; this figure increased to almost 37% by 2005.[3] Since 1960, the divorce rate has more than doubled[4]; 40% to 50% of all first-time marriages end in divorce.[5] Divorce rates seem to have leveled overall since the 1980s, but factors exist that increase the risk for some couples (eg, lower educational level or younger age at the time of marriage).[6] Although remarriage rates are high, more than one-third of remarried couples divorce again.[7] As a consequence, approximately 14% more children are now living in 1-parent households than approximately 40 years ago (25.8% in 2007 versus 11.8% in 1968).[8]

Another change in family life is that, by 2005, approximately 63% of all mothers with preschool-aged children were in the labor force, which reflects a twofold increase since 1970.[9] Three-fourths of the mothers of school-aged children work.[10] In 2-parent households, this means a marked increase in homes in which both parents work. Despite the majority of American mothers being in the workforce, half of female-led single-parent households lived below the poverty level in 2004.[9] A decline in the purchasing power of family income and the lack of comparable wages for women have added to the stress on families. Social disparities have also contributed to the growing percentage of children who live in poverty, and poverty is the strongest predictor of poorer health and well-being for children.[1,11] Residential mobility has separated many families from the natural support systems provided by their extended families, which may leave parents feeling socially isolated and prevents the intergenerational transmission of cultural and community-specific advice and support. Economic and social inequalities have led to increasingly impoverished neighborhoods, more working families living in or near poverty, and weakening of community ties. Longer hours away from their children, disconnection from close extended family support, and disintegration of traditional community interdependence all reduce the time, energy, and external supports available for rearing healthy children. The stress and speed of social change has weakened the support systems for many American families.[12]

RESILIENCE IN FAMILIES

Despite these enormous pressures working against families, intact and successful families do exist. Although it is evident that the risk of poorer outcomes for children is lowest among 2-parent households,[13] there is not a specific family constellation that makes poor outcomes inevitable. How a family influences children's outcomes is embedded within the interactions among its members. Table 1 lists characteristics that positively contribute to a family's success in raising children and, ultimately, to communities and society.[14]

TABLE 1 Characteristics of Successful Families[14]

Clear, open, and frequent communication
Encouragement of individual members
Expressing appreciation
Commitment to family
Religious or spiritual orientation
Social connectedness to external resources
Ability to adapt to stressors
Clear roles within the family
Time together that is of high quality and quantity

SUPPORT PROGRAMS: WHAT PEDIATRICIANS NEED TO KNOW

Social institutions have begun to offer various family support services to help parents carry out essential functions on behalf of their children. Many pediatricians have perinatal exposure to families who need community-based support for a variety of reasons, and all community pediatricians begin providing comprehensive health services for children as soon as they are discharged from the newborn nursery. Many pediatricians are already familiar with some types of family support programs. Examples of successful programs include prenatal and infant home visitor programs, comprehensive early childhood education programs (eg, Early Head Start, Head Start), early screening and referral programs, crisis care programs, parent support and/or education groups, early reading and parental literacy, and early intervention programs for children with special needs (eg, Individuals With Disabilities Education Act, Part C).[1,10,15–18] Because of significant variability regarding the effectiveness of available support programs, pediatricians should be aware of the evidence base for different types of programs and, specifically, the programs available in their communities. Home visitation programs, for example, can lead to improvements for families (eg, detecting postpartum depression, reducing the frequency of unintentional injury, improving parenting skills), but the relative effect depends on the qual-

ities of the program; for example, programs that use professionals (ie, nurses) rather than paraprofessionals[19] and programs targeted at specific populations (eg, infants born prematurely) have more measurable effects on child outcomes.[20]

Many comprehensive, community-based family support programs have been established around the country. These programs aim to support family relationships and promote parental competencies and behaviors that contribute to parental and infant/child/adolescent health and development. The best programs offer a spectrum of services that involve informal and structured groups. Topics may include information on child development, personal growth, family relationships, parenting education, peer support groups, parent-child activities, early developmental screening, community referral and follow-up, job skills training, and/or adult education, especially language and literacy education.[21,22] Services should be available to all families regardless of economic or ethnic background. The programs operate on the premise that no family is entirely self-sufficient and that most can benefit from some external support.[23] Pediatricians should search for, become familiar with, and refer families to high-quality family support services in their communities.

Some schools are providing after-school programs for children whose parents cannot be at home when classes end; others are providing school-based or associated health services to ensure that children receive timely health care and counseling. School curricula have expanded to include topics such as conflict resolution, sex education, and community service. Some employers offer family-oriented benefits such as flexible work hours, shared jobs, and child care. Religious congregations in some communities have developed a full array of social services and supports. The Family and Medical Leave Act of 1993 is an example of government acting in support of families, as are more established programs such as the Supplemental Nutrition Program for Women, Infants, and Children (WIC) and Temporary Assistance for Needy Families (TANF).

PRINCIPLES OF FAMILY SUPPORT PROGRAMS

High-quality programs operate on the following principles[1,24,25]:

- The primary responsibility for the development and well-being of children lies within the family.
- Families are part of a community, and support should be provided in the context of community life and through collaborative links with community resources.
- The kinds of support provided should be determined by individual and community needs. Although participation should be voluntary, it should be encouraged for at-risk families such as those led by single and/or socially isolated parents and those living in poverty.
- Support offered by friends, neighbors, and community-based resources is as vital as access to professional support services. Families are resources for themselves, for other families, and for communities and programs.
- The support given should enhance the strengths found within the family unit and among family members and empower families to use those strengths. The aim of support is to strengthen the family unit and the community while preventing alienation and family dysfunction.
- Support is available for all families and provided with an awareness of and sensitivity toward the culture, race, and native language of families and communities.

Family support programs play an important and, in some instances, essential role in promoting the positive functioning of families and ensuring the well-being of children. Their effectiveness, at least with certain populations (eg, low-income families, young single mothers, low birth weight infants, children with behavioral problems, children with special health care needs) is well documented.[17,20,26] All families need knowledge, skills, and support to raise their children and to foster normal growth, development, and learning. The AAP encourages public policies, professional practices, and personal behavior that support the caregiving role of families, advocate comprehensive approaches to child health and encourage prevention and early intervention strategies oriented toward the family.

RECOMMENDATIONS

1. Pediatricians should be aware of the increasing number of families experiencing stress and should learn to recognize situations (eg, maternal depression) that interfere with successful child rearing. The AAP *Bright Futures* guidelines recommend using open-ended questions to screen for and assess family stress during health supervision visits, with sample questions provided to probe for stressors such as parental depression, domestic violence, separation/divorce, and substance abuse. In addition, *Bright Futures* has a chapter titled "Promoting Family Support," which outlines the importance of family development to a child's overall growth and development.[27]
2. As medical homes, pediatric practices should collaborate with patients and their caregivers and provide family-centered care with an

awareness of cultural diversity. By having open and ongoing relationships with parents, pediatricians can facilitate discussions; monitor and guide developmental progress; address parental concerns; and support parental care, capacities, and needs. Focus should be on fostering those characteristics (Table 1) known to be associated with successful family functioning.

3. Pediatricians should interview families with a real awareness of the significant influence that family factors (socioeconomic status, discipline style, cultural beliefs, parental health and mental health, etc) have on children's development and behavior.[28] Continuing medical education programs on pediatric family interviewing and psychosocial issues in pediatric practice can enhance the pediatrician's skills and opportunities for counseling families. As recommended by the Task Force on the Family, the AAP advocates for pediatricians to have "adequate time, resources, billing options, and reimbursement to provide family-oriented care."[1]
4. Pediatricians can provide family support by engaging in a relationship with parents based on collaboration and shared decision-making so that parents feel and become more competent. The AAP provides pediatricians with guidance for supporting families in the prevention of violence and injury and the enhancement of parent-child communication on the basis of individual families' needs in the Connected Kids program (www.aap.org/ConnectedKids/ClinicalGuide.pdf). This collaboration with parents might also be in the form of parent councils and other partnerships that allow parents to provide input to practices and programs.
5. Pediatrician counseling of parents should include considering the needs and resources of the family and helping them benefit from the support of members of extended family and the community.
6. Pediatricians should work to identify, develop, refer to, and participate in community-based family support programs to help parents secure the knowledge, skills, support and strategies they need to raise their children. Having information easily available for families within the pediatric office that includes information and schedules of parenting classes, volunteer and community organizations incorporating family participation, and child care resources is also extremely helpful. The Maternal and Child Health Library provides an online directory to assist families and health providers to locate services within their own communities (www.mchlibrary.info/KnowledgePaths/kp_community.html).
7. Pediatricians should actively participate in sustaining the social capacity of their communities through their personal participation in local recreational, social, educational, civic, or philanthropic activities and associations. By participating in community-based family support programs, pediatricians can provide technical advice on health and safety aspects of services, serve as a source of professional information for families, and learn from these programs how best to contribute to the healthy development of children, families, and communities.
8. Pediatricians need to work within their communities to develop plans for identifying and coordinating care for families in need of more extensive social support services. An opportunity the AAP provides that might support pediatricians in this endeavor is the Community Access to Child Health (CATCH) program. CATCH provides pediatricians funding, training, technical assistance, and networking opportunities to ensure that all children have access to needed health care services within their communities.[29]

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Barbara J. Howard, MD, Daniel D. Broughton, MD, and the Committee on Psychosocial Aspects of Child and Family Health

The Pediatrician's Role in the Prevention of Missing Children

ABSTRACT. In 2002, the *Second National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children* report was released by the US Department of Justice, providing new data on a problem that our nation continues to face. This clinical report describes the categories of missing children, the prevalence of each, and prevention strategies that primary care pediatricians can share with parents to increase awareness and education about the safety of their children. *Pediatrics* 2004;114: 1100–1105; *missing children, runaway children, thrownaway children, family abduction, nonfamily abduction.*

ABBREVIATIONS. NISMART-2, Second National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children, AMBER, American's Missing: Broadcast Emergency Response.

INTRODUCTION

Missing children are of considerable concern to parents, children, and the nation. In one study, nearly 75% of parents acknowledged worrying about their children being kidnapped, and 35% said they were very concerned.[1] The issue of missing children is complex and needs to be dealt with in the appropriate context. When considering how to counsel parents about this issue, it is important for pediatricians to have a good understanding of the problem.

Of the 837 055 missing persons reported in 2001,[2] it is estimated that 80% of them were children.[3] Fortunately, approximately 99% were found within hours or days by usual law-enforcement response. However, 7115 to 7534 children nationwide were missing for prolonged periods.

There are several categories of missing children. Most children reported missing are runaways and children taken by noncustodial parents, both of which are preventable events. A small but indeterminate number of children are abducted by nonfamily members. Most of these nonfamily abductions occur as a result of direct contact between the perpetrator and the child. However, with the increase in Internet use, an increasing number of children have been reported as missing through contact with people they have met only through this medium. Abduction of newborn infants has been nearly eliminated through additional security and educational measures implemented in hospitals.

Pediatricians have an important role in helping parents put the problem of missing children in perspective, recommending general safety measures to be discussed without frightening children or adults, advocating for services for dysfunctional families and for children after runaway events, and condemning the use of commercial techniques that exploit fears about missing children.

CATEGORIES OF MISSING CHILDREN

In 2002, the US Department of Justice released the *Second National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children (NISMART-2)*.[4] Children who had been missing according to their families in 1999 were put into one of several categories: nonfamily abductions; family abductions; runaways or thrownaways (children forced to leave their homes by their parents); missing involuntary, lost, or missing; and missing benign explanation.

Nonfamily Abductions

According to the US Department of Justice, nonfamily abduction occurs when a nonfamily perpetrator takes a child by the use of physical force or threat of bodily harm or detains a child for at least 1 hour in an isolated place by the use of physical force or threat of bodily harm without lawful authority or parental permission or when a child who is younger than 15 years or is mentally incompetent, without lawful authority or parental permission, is taken or detained by or voluntarily accompanies a nonfamily perpetrator who conceals the child's whereabouts, demands ransom, or expresses the intention to keep the child permanently.[5] According to NISMART-2, more than 50 000 children and adolescents were taken in this manner in 1999.[6] Most victims of nonfamily abductions were girls (65%), and most were 12 years old or older (58%). Forty-six percent of the victims were sexually assaulted while missing. Most nonfamily abductions lasted less than 1 day (91%), with 29% lasting 2 hours or less. Less than 1% of children were not yet returned at the time of the study. Although much less common, classic nonfamily kidnappings pose the greatest risk of death or serious harm. According to law-enforcement statis-

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

doi:10.1542/peds.2004-1397

tics, a few more than 100 children were kidnapped in this sense in 1999.[4] Although these numbers are small, the effects on the child, family, and community are enormous. All nonfamily abductions are part of a continuum. On one end are relatively brief episodes in which there is no physical harm to the victim. At the other extreme are the horrific cases of classic kidnappings that often grab the nation's attention.

The statistics on abductions are powerful reasons for teaching safety principles to older children, especially girls. As an example, the National Center for Missing and Exploited Children has developed a campaign to get kids to "know the rules"[7] when going out:

- Don't go out alone.
- Always tell an adult where you are going.
- Say "no" if you feel threatened.

These are good rules, because they lessen the risk for children and adolescents to develop serious problems from getting into situations in which they are most vulnerable to exploitation and harm, whether with unfamiliar people or as in "date rape."

We all can remember our parents and teachers giving admonitions such as "don't take candy from strangers," hoping to keep us safe. Unfortunately, we now know that most people who perpetrate these crimes on children are not strangers in the eye and mind of the child. A neighbor, a familiar face in a child's daily routine, or someone the child's parents know well enough to speak to or whose name the child knows is probably not viewed as a stranger by the child. The perpetrators usually understand and practice seduction techniques that make themselves appear nonthreatening to children. Such techniques include calling the child by name, becoming familiar with their family or friends to provide a sense of familiarity, and providing toys or sweets for enticement. Often, these perpetrators will ask the child for assistance in looking for something such as an address or a lost puppy, thus becoming a new "friend" or ally. In cases of long-term kidnappings in which the child was found alive, 85% of the victims did not consider the kidnapper to be a stranger. In at least 65% of the cases in which a child was found dead and the perpetrator was identified, it was clear that the child would not have considered the person a stranger.[8] These strategies make it ineffective to give simple instructions to children not to talk to or go with strangers, because these people do not seem to be strangers by the time the abduction occurs. Use of an "appropriate stranger" such as a police officer or a store clerk or manager may be of great assistance to a lost child. Careful supervision of children, screening of references of potential caregivers, and excellent communication between parent and child are the best defense. Children sense unease in inappropriate relationships and can report this as long as parents routinely take all of their concerns in life seriously rather than downplaying or shaming them. Children should also be taught from an early age that they need not kiss, hug, touch, or sit on the lap of anyone, relative or not, if they do not wish to. This respect for their comfort and wishes translates into self-respect and the ability to differentiate unwanted contacts without generating fear.

Runaways and Thrownaways

Most children reported as missing left of their own accord, often from adverse family or living situations. In fact, leaving home as an impulsive act of protest is very common, occurring in an estimated 1 of 7 children younger than 16 years in England, with 11% being younger than 11 years,[9] with girls leaving twice as often as boys.[10] Traditionally, most of these children were not reported as missing to national authorities, however, and were not included in national statistics from earlier surveys. In 1983, the Inspector General of the Department of Health and Human Services estimated that there were as many as 1 million and possibly more than 2 million runaways annually in the United States.[11] Children who run away commonly live in difficult situations such as poverty or reconstituted homes. Many of them were truant previously.

Runaway or thrownaway children missing for a prolonged time commonly were subject to physical abuse (up to 75%), sexual abuse (up to 20%),[12] or other harsh treatment from which they were seeking escape and felt they had no other way out. A variety of additional risk factors are more common among runaways than among other children and adolescents, including psychological problems, strained family relationships, school difficulties, and adverse peer-group pressure.[13] Up to 30% of runaway children ran away from foster care.[9] Runaways gone for a prolonged time are at risk of many medical and psychological problems including disease, crime (both as victims and perpetrators), injuries, alcohol use, illegal drug use (one third)[10] and selling, sexual contact, and death. They may pose for pornography or prostitute themselves to provide income to survive or be taken into prostitution as a form of "sheltering" relationship. As a result of this activity, they are at high risk of pregnancy and sexually transmitted diseases including human immunodeficiency virus infection. In urban areas, these children often join gangs or are involved in burglary or armed robbery and other crimes. The psychological effect of the coercive parenting they were receiving and their subsequent experiences can be severe. Many have learning disabilities and school failure and belong to deviant peer groups preceding the runaway event, which makes recovery more difficult.

NISMART-2 data about runaways show that 68% of runaways were 15 to 17 years of age, 28% were 12 to 14 years of age, and 4% were 7 to 11 years of age.[14] Runaway episodes are most likely to occur during summer (39%), with the runaway going more than 10 but no more than 50 miles from home (31%), and most were gone from 24 hours to 1 week (58%). Although many such episodes seem minor, 7% of runaways were missing from 1 to 6 months, 23% traveled more than 50 miles from home, and at least 9% traveled out of state. Many of the runaways are harmed during the episode, with 1% having been sexually assaulted or having had someone attempt to

do so and 4% having been physically assaulted or having had someone attempt to do so.

Preventing children from becoming runaways and thrownaways lies in detecting family situations that include behavior problems or coercive interactions, especially when discipline is inappropriately harsh. Early and ongoing intervention for these families can promote more positive understanding of their children and better strategies for coexisting. Often, these children are targeted for punishment for the act of running away or for the associated misdeeds of substance use, theft, or prostitution when what is really needed is medical and psychological treatment, family realignment, or foster placement. Pediatricians should support community shelter and hot-line programs for runaways (eg, the National Runaway Switchboard at l-800-621-4000) that provide comprehensive medical and psychological care. Quality follow-up care is also needed to monitor for psychological and family adjustment and long-term sequelae. Problems that warrant treatment include skin, respiratory, gastrointestinal, and genital infections; dental disease; accidental or inflicted trauma; lack of immunizations; poor nutrition; and pregnancy in addition to preexisting and subsequent learning and psychological disorders.[13] On reunion, if it is possible, the entire troubled family needs to be addressed. The pediatrician needs to work as part of a team with the goal of long-term recovery for these children.

Family Abductions

One of the most prevalent categories of missing children is abduction by a noncustodial parent or unauthorized extended visits with family members. NISMART-2 research found that 203 900 children each year were victims of family abduction.[15] Thirty-five percent of these children were 6 to 11 years of age, 23% were 3 to 5 years of age, 21% were younger than 2 years, and 17% were 12 to 14 years of age. Thirty-five percent of abductions occurred in the summer, 26% occurred in the fall, 24% occurred in the winter, and 15% occurred in the spring. Twenty-four percent of these abductions lasted 1 week to 1 month, and less than 1% of children were still absent at the time of the research. Police were contacted in 60% of the cases.

Pediatricians have an important but difficult role to play in preventing family abduction through monitoring for marital difficulties or substance abuse in the family. It is important to offer early advice on ways to protect the child from marital discord and prompt referral to counseling or mediation. In the case of parental separation, the pediatrician may need to give advice on how to manage affected children.[16]

Children abducted by family members may be at increased risk of physical and sexual abuse or neglect.[17] However, data from NISMART-1 indicate that sexual abuse of children may be relatively uncommon in parental kidnapping. Although children abducted by family members can be with familiar and loving caregivers, emotional trauma still occurs. The children are separated from other loved ones and exposed to uncertainty and secrecy, and care is provided by an adult who is usually experiencing his or her own pain or anger. The goal of the adult taking the child generally is revenge or manipulation toward the ex-partner rather than the benefit of the child. In one study[18] of children after family abduction, 16 of 18 had emotional effects including severe fright, mental indoctrination, grief or rage about parental abandonment, rejection of the offending parent, and exaggerated identification with one parent. The 2 children abducted by fathers without any apparent reaction were told the truth, maintained contact with the mother, and came from such lifestyle chaos that this event seemed insignificant.

Missing Benign Explanations

A very large number of children who have not been abducted nor run away end up missing with benign explanations. In fact, this is the second largest category of missing children. "A missing benign explanation episode occurs when a child's whereabouts are unknown to the child's caretaker and this causes the caretaker to 1) be alarmed, 2) try to locate the child, and 3) contact the police about the episode for any reason, as long as the child was not lost, injured, abducted, victimized, or classified as runaway/thrownaway."[5] NISMART-2 data show that 374 000 or 28% of missing children were in this category. NISMART-1 included a category called "otherwise missing" to include those who were missing but did not fit into any of the other categories. There were nearly 440 000 children in this category with one third of the episodes being concerning enough for the parents to have reported them to the police. Children who have wandered off or disappeared in this way are at significant risk even though they have not been abducted or run away. They are vulnerable to abuse and exploitation, may become disoriented, or may be injured unintentionally. One in five suffered some type of physical harm, and 1 in 7 was abused or assaulted while missing, which emphasizes the point that every case in which a child is missing must be taken seriously regardless of the reason or perceived reason the child is gone.

Neonatal Abductions

From 1983 to 2001, the number of neonatal abductions per year ranged from 0 to 12. The perpetrators of this crime were typically females of childbearing age who had had a miscarriage or had been unable to conceive and had carefully planned an abduction to replace the lost child or maintain a relationship with a lover. The infant was usually kept in the area within 25 miles of the hospital[19] and in 95% of cases was returned to the parents.[20] Prevention of infant abductions has been successful through a combination of increased security measures in hospitals, including video cameras and alarm devices, and education of staff and parents about precautions to take while in the hospital. It is critical not to allow anyone without identification to take an infant for any reason and to keep the infant within sight of the parent or nursery staff at all times. These measures should be largely invisible and create a sense of security rather than increasing parental fears about abduc-

tion. Apparently as a result of these measures, there were no reported infant abductions from hospitals in the United States in 1999.[21] Infant abductions did occur in 2000 and 2001, but at a lower rate than in previous years. The National Center for Missing and Exploited Children provides free security and training consultations (1-800-843-5678). Pediatricians should support appropriate safeguards in the hospitals they serve but should also reassure parents of the rarity of this crime in a sensitive way so as not to promote a sense of vulnerability at this especially sensitive time of family formation.

Internet Issues

Although still relatively uncommon, the practice of pedophiles and child molesters approaching children on the Internet is occurring more frequently. In some cases, pedophiles and/or child molesters have arranged meetings with children. Nineteen percent of children using the Internet had received unwanted online requests to engage in sexual activities or provide intimate sexual information. Almost half of these solicitations were from other children. However, at least one quarter of them were from adults.[22] The National Center for Missing and Exploited Children reports that approximately 840 cases of people (of unspecified ages) "traveling to or luring" children they had contacted on the Internet are "proven or under investigation." Parents need to be advised to supervise Internet use by their children, discuss Internet experiences with their children, and set clear rules about contacts with people met via the Internet. Any computer with access to the Internet should always be kept in an open place (eg, living room, family room) in any home with children and should not be in a room in which the door can be closed or locked. It is important to monitor where children and adolescents have been surfing on the Internet. Parents may find it desirable to use filtering or censoring devices on the computer or limit access to restricted passwords. Eighty-five percent of parents in a national survey indicated that they had warned their children about the dangers of chats on the Internet, but only one third had used any blocking devices. Children need realistic education about the potential of the Internet as part of their media education but without generating fears for their safety.

IN THE EVENT OF A MISSING CHILD

In the event of a missing child, parents should:

- immediately call local law enforcement.
- provide police and/or the Federal Bureau of Investigation with a detailed description of the child, including clothing or jewelry worn at the time of the disappearance, and medical and dental information.
- be sure that the child is entered into National Crime Information Center logs by their local police.
- report abductions or suspected abductions to the National Center for Missing and Exploited Children (1-800-THE-LOST or www.missingkids.com) by parents or law enforcement.
- report runaways to the hot line (1-800-621-4000) of the federal Runaway and Homeless Youth Program.

PREVENTION

The pediatrician's advice for preventing missing children, as for many other health issues, needs to be a balance of safeguarding children while avoiding generating fear. None of this information needs to be taught specifically as abduction safeguarding, with all its overtones of danger and threat. Instead, it should be taught as developmental achievements to be praised for their own value in the growing child. The appropriate message allows the child to go forward with skill and confidence rather than fear and avoidance.

Pediatricians can help safeguard children older than 5 years by encouraging parents to teach them to memorize their name, address, and phone number, including area code, so that they can be identified readily if separated from their families. Older children can learn numbers for contacting parents at home or at work. Because abductions are rarely conducted by strangers, even in nonfamily abductions, teaching children not to talk to strangers frightens them without any proven benefit. Passive methods of identifying children such as the placement of microchips in the teeth and fingerprinting are primarily techniques for identification of bodies. Their use has become common for fund raising and as a "service to the community" often without considering the potential effect in frightening children and inappropriately raising fears in adults without any perspective provided on the real nature or rareness of abduction.[23,24] On the other hand, keeping recent photographs of children and promptly reporting incidences to the police are extremely helpful measures. Law-enforcement officials consider photographs the number one tool in finding missing children. In addition, photograph campaigns such as direct mail cards and "rogues' galleries" in magazines have resulted in 1 in 6 children being located as a direct result of the photograph. Parents should be instructed to keep a high-quality photograph of each child, updated at least every 6 months. School photographs serve this purpose with only positive connotations.

The importance of a prompt response in missing-children cases is demonstrated in the AMBER (American's Missing: Broadcast Emergency Response) Plan. Patterned after the emergency weather warnings, the AMBER Plan is intended to flood a region with information regarding high-risk missing children when time is of the essence. Strict criteria are in place to initiate an AMBER Plan response. It was introduced in Dallas, Texas, in 1997 and became a national program in 2002. Since its inception, the AMBER Plan has been credited with successfully recovering more than 130 children. When combined with the success of the photograph-distribution campaigns (1 in 6 featured long-term missing children found as a direct result of these programs), we see the value of both a prompt response and persistence in searching in missing-child cases.

Learning about personal safety is an important part of a child's education. Schools should be encouraged to include such a program as part of their K-12 curriculum. Many such programs exist but vary greatly in quality and effectiveness. The National Center for Missing and Exploited Children, in cooperation with the American Academy of Pediatrics and other child-advocacy groups, has developed a tool to help school districts evaluate these programs and select one that best fits their individual needs (*Guidelines for Programs to Reduce Child Victimization: A Resource for Communities When Choosing a Program to Teach Personal Safety to Children*[25]).

ADVICE FOR PEDIATRICIANS

1. Help parents and children put the risk of becoming missing in perspective.
2. Encourage families to teach children self-identifying information without connecting it to a threat of becoming missing.
3. Encourage families to keep a high-quality and current photograph of each child.
4. Encourage families to teach children to accept only touches that are comfortable to them regardless of the toucher's relationship to them.
5. Encourage families to teach older children, especially girls, to "know the rules":
   - When going out, don't go out alone.
   - Always tell an adult where you are going.
   - Say "no" if you feel threatened.
6. Consider advocating for an appropriate personal-safety curriculum to be taught in schools and check its approach.
7. Continually screen for risk factors for missing children (ie, family discord, divorce, coercive parenting, substance abuse, school failure, deviant peer group, etc) and intervene early with appropriate work-up and referrals.
8. Assess whether adolescents consider themselves to have several sources of support, including the pediatrician, so that they need not resort to running away.
9. Be skeptical of new patients presenting with vague stories about absent parents or children who report mysterious parent deaths or separations without contact, because they may represent abductions.
10. Insist on prompt transfer of medical records as a routine practice.
11. Support programs that serve runaways.
12. Consider providing or coordinating comprehensive care to any families who have just had a missing child returned.
13. Expose programs spuriously generating fear of abduction.
14. Look at and encourage others to look at pictures of missing children.

Personal Watercraft Use by Children and Adolescents (RE9925)

AMERICAN ACADEMY OF PEDIATRICS

Committee on Injury and Poison Prevention

ABSTRACT. The use of personal watercraft (PWC) has increased dramatically during the past decade as have the speed and mobility of the watercraft. A similar dramatic increase in PWC-related injury and death has occurred simultaneously. No one younger than 16 years should operate a PWC. The operator and all passengers must wear US Coast Guard-approved personal flotation devices. Other safety recommendations are suggested for parents and pediatricians.

ABBREVIATION. PWC, personal watercraft.

Personal watercraft (PWC) became commercially available during the 1970s when Kawasaki Motors Corporation introduced the Jet Ski. This craft allowed 1 person to maneuver a small (<4 m) boat while standing up. Newer sit-down models made by several manufacturers allow as many as 3 people on board, can pull a water skier, and may be able to reach speeds of 60 mph with engines ranging from 60 to 135 hp. The lure of speed and mobility at a relatively inexpensive price has proven irresistible to many recreational boaters.

The use of PWC has increased dramatically during the past decade. Between 1990 and 1995, the number of PWC in operation more than tripled from 240 000 to 760 000.[1] Annual sales of PWC rose from 29 000 in 1987 to 200 000 in 1995.[2] Current estimates suggest that more than 1 million PWC are now in use. Despite the increased popularity of PWC, many communities are limiting or banning their use because of environmental concerns and the risk of injury.[3]

Until recently only scattered case reports of injury associated with PWC use have been published.[4-6] However, several regional reports[7-10] and 2 national reports[1,2] suggest a fairly uniform and substantial increase in the number of injuries associated with the use of PWC. Data from the National Electronic Injury Surveillance System used in 1 study estimate that nearly 12 000 people were treated in hospital emergency departments during 1995. This represents a fourfold increase from 1990, when 2860 injuries were treated.[1] The Coast Guard reports an even greater increase in fatalities, from 5 during 1987 to 57 during 1996. Preliminary data from the National Association of State Boating Law Administrators show at least 83 fatalities for 1997.[2]

According to the National Electronic Injury Surveillance System data, 7% of injuries occurred to children 14 years and younger; 38% of those injured were 15 to 24 years old.[1] In the National Transportation Safety Board study, 9% of operators involved in PWC incidents were younger than 16 years, and 46% were 16 through 24 years old.[2] Finally, in the report by Hamman et al,[7] 27% of the injured were younger than 17 years, and 61% were 25 years of age or younger. In an even more telling set of statistics, in California, children younger than 18 years accounted for 14% of all boating incidents, 18% of all boating injuries, and 5% of boating fatalities, but 93% of these incidents involved PWC.[8] Conversely, PWC in California represented 16% of all registered vessels but accounted for 55% of all boating injuries.[2,8]

PWC are the only recreational boats for which the leading cause of death is not drowning; most fatalities result from blunt trauma. When the cause of death is drowning, most victims are not wearing personal flotation devices. The types of nonfatal injury are quite varied. Lacerations represent 30% to 57% of the injuries. There are 3 case reports of significant vaginal laceration while riding a PWC.[4-6] Fractures are the next most commonly recorded injury (12% to 26%). The lower extremity is injured more commonly than is the upper extremity. Branche et al[1] and Hamman et al[7] report a significant incidence of head injury (17% to 29%).

Most injuries seem to occur when PWC collideï either with other vessels including other PWC or with fixed objects such as docks or tree stumps. Behavioral factors cited in 3 studies include operator inexperience (most operators had <20 hours of experience in boat operation), operator inattention, and excess speed or reckless operation.[2,9,10] Operators who rent the watercraft seem to be at especially high risk. Operating characteristics of the PWC contribute to these problems. They are maneuverable only when the throttle is open. Contrary to experience in every other motor vehicle, an obstruction is not avoided by slowing and turning but by maintaining or increasing speed and turning to avoid the hazard. In addition, as with any other watercraft, there is no ability to brake. Stopping is achieved only by cutting the throttle and by coasting; while coasting, no steering is possible.[2]

No published studies exist dealing with the effectiveness of protective equipment to prevent injury sustained while riding PWC. Just as wearing a personal flotation device should be mandatory for any boat operator or passenger, personal flotation devices must be worn by anyone riding PWC. The Personal Watercraft Industry Association recommends wearing eye protection, a wet suit, footwear, and gloves. Helmets are worn by some professional PWC riders. Although it makes intuitive sense that a helmet would be protective, it is unclear which type of helmet would provide the best protection. No studies have been performed to assess the effectiveness of these equipment interventions, and industry standards are not available for this gear.

RECOMMENDATIONS

1. No one younger than 16 years should operate PWC.
2. The operator and every passenger must wear a US Coast Guard-approved personal flotation device.
3. Alcohol or other drug use should be avoided before and while operating PWC.

4. Participation in a safe boater course with specific information about PWC should be required before operating PWC.
5. Safe operating practices, such as no operation between sunset and sunrise, no wake jumping, and observing posted speed limits or no-wake zones, should be followed. (No-wake zone means the craft speed is slow enough that no wake is formed behind the craft as it crosses a specific area.)
6. PWC should not be operated where swimmers are in the water.
7. If a PWC is being used to tow another person on skis, knee boards, tubes, or other devices, a second person must face the rear to monitor the person being towed.
8. All persons who rent PWC should be required to comply with these recommendations.
9. Protective equipment such as wet suits, gloves, boots, eyewear, and helmets may be appropriate to wear.
10. Pediatricians should work within their communities to pass legislation that supports the previously mentioned recommendations.[11] Included in such legislation should be funding to support adequate enforcement of regulations such as alcohol consumption, speed limits, and the use of personal flotation devices.
11. Additional research into appropriate protective equipment and modification of PWC to improve safety should be supported by pediatricians.

Special Article

CME Practice Parameter: Pharmacological treatment of migraine headache in children and adolescents

Report of the American Academy of Neurology Quality Standards Subcommittee and the Practice Committee of the Child Neurology Society

D. Lewis, MD; S. Ashwal, MD; A. Hershey, MD; D. Hirtz, MD; M. Yonker, MD; and S. Silberstein, MD

Abstract—*Objective:* To review evidence on the pharmacologic treatment of the child with migraine headache. *Methods:* The authors reviewed, abstracted, and classified relevant literature. Recommendations were based on a four-tiered scheme of evidence classification. Treatment options were separated into medications for acute headache and preventive medications. *Results:* The authors identified and reviewed 166 articles. For acute treatment, five agents were reviewed. Sumatriptan nasal spray and ibuprofen are effective and are well tolerated vs placebo. Acetaminophen is probably effective and is well tolerated vs placebo. Rizatriptan and zolmitriptan were safe and well tolerated but were not superior to placebo. For preventive therapy, 12 agents were evaluated. Flunarizine is probably effective. The data concerning cyproheptadine, amitriptyline, divalproex sodium, topiramate, and levetiracetam were insufficient. Conflicting data were found concerning propranolol and trazodone. Pizotifen, nimodipine, and clonidine did not show efficacy. *Conclusions:* For children (>age 6 years), ibuprofen is effective and acetaminophen is probably effective and either can be considered for the acute treatment of migraine. For adolescents (>12 years of age), sumatriptan nasal spray is effective and should be considered for the acute treatment of migraine. For preventive therapy, flunarizine is probably effective and can be considered, but is not available in the United States. There are conflicting or insufficient data to make any other recommendations for the preventive therapy of migraine in children and adolescents. For a clinical problem so prevalent in children and adolescents, there is a disappointing lack of evidence from controlled, randomized, and masked trials.

NEUROLOGY 2004;63:2215–2224

Migraine headaches are common in children and occur with increasing frequency through adolescence.[1-6] The reported prevalence increases from 3% (age 3 to 7 years) to 4 to 11% (age 7 to 11) to 8 to 23% (age 11 to 15+) with the mean age at onset being 7.2 years for boys and 10.9 years for girls.[7,8]

The evaluation of a child with recurrent headaches begins with a thorough medical and family history followed by a complete physical examination with measurement of vital signs, particularly blood pressure, and complete neurologic examination including examination of the optic fundi. Recently, a

Endorsed by the American Academy of Pediatrics and the American Headache Society.

Approved by the QSS on April 27, 2004; by the Practice Committee on August 7, 2004; and by the AAN Board of Directors on October 16, 2004.

Table 1 *2004 International Headache Society classification of headache disorders: Criteria for pediatric migraine without aura*[11]

A. ≥5 attacks fulfilling features B–D
B. Headache attack lasting 1 to 72 hours
C. Headache has at least 2 of the following 4 features:
1. Either bilateral or unilateral (frontal/temporal) location
2. Pulsating quality
3. Moderate to severe intensity
4. Aggravated by routine physical activities
D. At least 1 of the following accompanies headache:
1. Nausea and/or vomiting
2. Photophobia and phonophobia (may be inferred from their behavior)

practice parameter that outlined guidelines for the clinical and laboratory evaluation of children and adolescents with recurrent headaches was published.[9]

Diagnosis of primary headache disorders of children rests principally on clinical criteria as set forth by the International Headache Society (IHS, 1988).[10] In 2004, the IHS published a modified International Classification of Headache Disorders (ICHD) for primary (e.g., including migraine, with and without aura) and secondary headache disorders (table 1).[11] For young children, the 1988 IHS criteria were too restrictive, and the second edition ICHD criteria have incorporated more developmentally sensitive criteria.[12-16] Consensus-based criteria for pediatric migraine are essential for the conduct of future clinical treatment trials.

Appropriate treatment for children and adolescents with migraine requires an individually tailored strategy giving due consideration to both pharmacologic and nonpharmacologic measures in the context of the degree of disability produced by the headache. Not all children require pharmacologic intervention. Treatment of migraine headaches in children has remained difficult for both parents and physicians. In young children, accurate diagnosis, assessment of the severity of symptoms, and recognition of associated symptoms is complicated by the inability of children to articulate their complaints. In addition, other infectious, allergic, or gastrointestinal disorders of childhood may mimic symptoms of migraine. Therefore, medications directed specifically for the treatment of childhood migraine may be of limited value if there are other conditions present that mimic or even precipitate migraine. Of equal importance has been the difficulty in using medications either acutely or for preventive purposes in children and adolescents that have shown efficacy in adults, as the appropriate safety and efficacy studies have not been conducted.

This practice parameter reviews the evidence on the pharmacologic treatment of migraine in children and adolescents. Nonpharmacologic treatments and biobehavioral measures are not addressed.

Description of process. Three organizations participated in the development of this practice parameter, including the American Academy of Neurology (AAN), the Child Neurology Society, and the American Headache Society. The American Academy of Pediatrics reviewed the manuscript. Computer-assisted literature searches were conducted with the help of the AAN and the University of Minnesota Biomedical Information Services Research Librarian for relevant articles published from 1980 through December 2003. Databases searched included Medline and Current Contents using the following key words: headache, migraine, children and adolescents, and treatment. The age qualifier of 3 years to 18 years was selected, as this is the age group, based on previous literature, when most children are seen for pediatric or neurologic evaluation. Searches included titles from English and non-English language journals. Only those articles reporting studies with ≥10 patients were included. A bibliography of the 166 articles and abstracts identified and reviewed for preparation of this parameter is available at the AAN Web site (http://www.aan.com/). Relevant position papers from professional organizations were also reviewed.

Individual committee members reviewed titles and abstracts for content and relevance. Those articles dealing with aspects of treatment of pediatric headache were selected for further detailed review. Bibliographies of the articles cited were checked for additional pertinent references. Each of the selected articles was reviewed, abstracted, and classified by at least two committee members. Abstracted data included the number of patients, age, sex, nature of subject selection, case-finding methods (prospective, retrospective, or referral), inclusion and exclusion criteria, headache type and characteristics, and study design and statistical analysis employed.

A four-tiered classification scheme for therapeutic evidence approved by the Quality Standards Subcommittee was utilized (Appendix 1). Depending on the strength of this evidence it was decided whether specific recommendations could be made, and if so, the strength of these recommendations. Evidence pertinent to treatment with the committee's evidence-based recommendations is presented.

General principles of treatment. General principles of management of adults with migraine headaches have been established by the previously published AAN practice parameter (Appendix 2). Likewise, fundamental goals of long-term migraine treatment have been established that include 1) reduction of headache frequency, severity, duration, and disability; 2) reduction of reliance on poorly tolerated, ineffective, or unwanted acute pharmacotherapies; 3) improvement in quality of life; 4) avoidance of acute headache medication escalation; 5) education and enablement of patients to manage their disease to enhance personal control of their migraine; and 6) reduction of headache-related distress and

NSAIDs = non-steroidal anti-inflammatory drugs; NS = nonsignificant.

psychological symptoms.[17] These general principles of management and fundamental goals of treatment also apply to children and adolescents and once the diagnosis of migraine headache is established a comprehensive treatment program should be implemented. Treatment options include use of 1) acute or episodic medications; 2) prophylactic or preventive agents; and 3) nonpharmacologic or biobehavioral interventions.

Modalities selected must be individually tailored to a particular patient's pattern and must also be flexible enough to accommodate a changing headache frequency. Fundamental to this process is assessment of a patient's degree of disability or headache "burden," which reflects an individual patient's frequency, duration, intensity, functional disability, qualify of life, comorbidity, and pain tolerance. The extent of medical management should be determined by assessment of the headache burden.

Pharmacologic treatment. As in adults, treatment in children and adolescents can be employed on an acute basis as well as daily to prevent frequent recurring migraine attacks.

Acute treatment. Recommended general principles for treatment of acute migraine headache as established in the previously published AAN practice parameter include the following: 1) treat attacks rapidly and consistently without recurrence; 2) restore the patient's ability to function; 3) minimize the use of back-up and rescue medications; 4) optimize self-care and reduce subsequent use of resources; 5) be cost-effective for overall management; and 6) have minimal or no adverse events.[17]

Evidence-based recommendations for the acute treatment of migraine headaches. There is a paucity of controlled data regarding the treatment of primary headache disorders in children and adolescents. The data that exist focus on the most frequent of the primary headache disorders, migraine with and without aura. A summary of the evidence for treatment of acute attacks of migraine is presented in table 2. These data are reviewed according to the different medications used and directed at answering the following questions: 1) How safe and tolerable are acute migraine medications in children and adolescents? 2) What are the effects on acute headache pain of medications taken during the attack?

Nonsteroidal anti-inflammatory agents (NSAIDs) and acetaminophen. Ibuprofen has been the most rigorously studied medication. Two double-blind, placebo-controlled class I trials have shown that ibuprofen (7.5 to 10 mg/kg) in childhood migraine is safe and effective.[18,19]

The first study (n = 88) compared ibuprofen (10 mg/kg) to acetaminophen (15 mg/kg) and a placebo.[18] At the 1- and 2-hour endpoints, both ibuprofen and

acetaminophen were significantly more effective than placebo in providing pain relief as defined by a ≥2-point reduction of pain on a 5-point pain scale ($p < 0.05$). At the 2-hour intent to treat endpoint, ibuprofen provided alleviation of headache in 56% of treated patients compared to 53% for acetaminophen and 36% for the placebo group. Differences between ibuprofen compared to acetaminophen were not statistically significant at this end point. Complete resolution of headache was found in 60% of ibuprofen-treated children and 39% of the acetaminophen group vs 28% of those who received placebo. Reduction in moderate to severe headache by at least two grades after 2 hours was twice as likely with acetaminophen and three times as likely with ibuprofen as placebo. Acetaminophen was considered effective and well tolerated. Acetaminophen was observed to have a faster onset of action than ibuprofen.

The second class I study of ibuprofen (7.5 mg/kg) in 84 children ages 6 to 12 years found that there was a significant reduction in headache severity in 76% of those on active drug vs 53% in the placebo group at the primary 2-hour endpoint ($p = 0.006$). Reduction in pain score, absence of nausea, and reduced need for rescue medications all reached statistical significance. However, the primary endpoint effect seen in the study was accounted for by the results in boys only (84% ibuprofen vs 43% placebo) whereas results for girls were 65% reduction in severity with ibuprofen and 67% with placebo.

There were no statistically significant adverse effects of ibuprofen or acetaminophen reported in either study.

5-Hydroxytryptamine receptor agonists ("triptan agents"). Sumatriptan, available in nasal spray, subcutaneous injection, and tablet forms, has been subjected to several double-blind, placebo–controlled trials. Three controlled trials (class I) have demonstrated both efficacy and safety of sumatriptan nasal spray in adolescent migraineurs. The first study (class I; n = 14) found significant headache relief at 2 hours in 85.7% vs 42.9% in the placebo group ($p = 0.03$).[20] Headache-associated symptoms were also significantly improved in the sumatriptan group; nausea decreased by 36% and phonophobia by 57%.

The second study was multicentered, double-blind, and placebo-controlled (class I) and included 510 adolescents (ages 12 to 17 years) comparing 5 mg, 10 mg, and 20 mg sumatriptan nasal spray to placebo.[21] The 2-hour response rate (reduction in headache severity from severe or moderate to mild or no headache) was 66% for the 5 mg dose ($p < 0.05$), 63% for the 20 mg dose ($p = 0.059$), and 53% for placebo. Significant relief ($p < 0.05$) was noted at 1 hour in the 5 mg and 20 mg dosing arms. A pain-free state at 2 hours was achieved to a statistically significant degree with 20 mg nasal spray ($p < 0.05$). Both photophobia and phonophobia were reduced with the 20 mg dose ($p < 0.05$). The only adverse effect was taste disturbance (26%).

The third trial, a double-blind, placebo-controlled, two-way crossover design (class 1; n = 83), included children ages 8 to 17 years (median 12.4 years). Doses of 10 mg nasal spray were provided for children weighing 20 to 39 kg and 20 mg for children weighing >40 kg. The primary endpoint was headache relief as defined by a 2-point improvement in headache severity based upon a 5-point pain scale at 2 hours. At 2 hours, the primary endpoint was met in 64% of patients receiving sumatriptan and in 39% of those receiving matching placebo ($p = 0.003$). At 1 hour, headache relief was found in 51% of children receiving sumatriptan and in 29% receiving placebo ($p = 0.014$). Complete pain relief was experienced by 31% of those treated with sumatriptan and 19% receiving placebo ($p = 0.14$). Secondary endpoints including use of rescue medications and patient preference also favored sumatriptan (NS). Bad taste was again the most common side effect (29%).[22]

Subcutaneous sumatriptan has been studied in two open label trials (class IV). The first trial in children 6 to 16 years (n = 17) used the 6 mg dose in children weighing >30 kg and 3 mg in children <30 kg.[23] The injection was effective in 64% with side effects including chest pressure, neck pressure, or tingling, lasting 15 minutes, occurring in 15/17 patients.

A second subcutaneous trial in 50 patients, ages 6 to 18 years (class IV), using a dose of 0.06 mg/kg, found an efficacy of 78% with 26% responding within 30 minutes, 46% within 60 minutes, and 6% between 1 to 2 hours.[24] Headache recurrence rate was low at 6%. Ninety-one percent of boys responded, whereas 68% of girls responded. Eighty percent of patients experienced transient adverse effects including head, neck, or chest discomfort.

One class I clinical trial including children aged 8.3 to 16.4 years (n = 23) examining oral sumatriptan tablet (50 to 100 mg) failed to clearly demonstrate efficacy greater than matched placebo at the primary endpoint of pain relief at 2 hours (difference 9%, 95% CI for difference 21 to 38%, p = NS).[25]

Rizatriptan. Studies of rizatriptan in children are limited. A single class I report (n = 296) found no difference compared to placebo in pain relief in children ages 12 to 17 years at the 2-hour primary endpoint (rizatriptan 66%; placebo 56%; $p = 0.79$).[26] These results may have been influenced by the high placebo responder rate. Rizatriptan did demonstrate good tolerability and safety with adverse events (asthenia, dizziness, and dry mouth) being comparable to placebo (3 to 5%).

Zolmitriptan. A class IV open-labeled multicenter trial of oral zolmitriptan (2.5 to 5 mg) in 12- to 17-year-old adolescents (n = 38) who had 276 migraine attacks found that treatment was well tolerated. Overall improvement in headache symptoms at 2 hours was 88% with the 2.5 mg dose and 70% with the 5 mg dose.[27] A pain-free state was achieved in 66% of patients.

Conclusions. For the acute treatment of migraine headaches in children, both ibuprofen and acetaminophen have been shown to be safe and effec-

tive (class I). Sumatriptan is the only 5HT1 agonist that has proven effective for the treatment of children and adolescents with migraine with the 5 mg and 20 mg nasal spray having the most favorable profile (class I). There is only class IV evidence for effectiveness of subcutaneous sumatriptan. Oral triptan agents have not demonstrated efficacy in class I studies. There are currently no agents approved by the Food and Drug Administration for the acute treatment of migraine in children or adolescents.

Recommendations for the acute treatment of migraine in children and adolescents.

1. Ibuprofen is effective and should be considered for the acute treatment of migraine in children (Level A).
2. Acetaminophen is probably effective and should be considered for the acute treatment of migraine in children (Level B).
3. Sumatriptan nasal spray is effective and should be considered for the acute treatment of migraine in adolescents (Level A).
4. There are no data to support or refute use of any oral triptan preparations in children or adolescents (Level U).
5. There are inadequate data to make a judgment on the efficacy of subcutaneous sumatriptan (Level U).

Preventive treatments. General principles related to the goals of migraine preventive therapies are to 1) reduce attack frequency, severity, and duration; 2) improve responsiveness to treatment of acute attacks; and 3) improve function, reduce disability, and improve the patient's quality of life. Rationales for institution of preventive therapies and principles of care have been published in the AAN practice parameter on the treatment of headaches in adults. The following questions are addressed in the review of medications listed below: 1) What are the effects on the frequency and/or severity of migraine attacks of medications taken on a daily basis for prevention of migraine? 2) How safe and tolerable are preventive migraine medications in children and adolescents? 3) How do the efficacy and tolerability of preventive medications for migraine compare to those for placebo?

Cyproheptadine. One class IV retrospective study of the use of preventive agents for children and adolescents within one child neurology practice found that headache frequency was reduced from a mean baseline of 8.4 headaches/month to 3.7 headaches per month at a dose of 2 to 8 mg/day.[28] A positive response rate, defined as an overall favorable decrease in headache frequency and intensity plus acceptability of the agent, occurred in 83% of children receiving cyproheptadine (n = 30). Common side effects of cyproheptadine included sedation and increased appetite. No Class I to III studies were found in children regarding the use of cyproheptadine in children.

Antihypertensive agents. Beta-blockers. The nonselective beta-blocker propranolol has been evaluated in three class II trials with conflicting results. One double-blind, crossover trial in children ages 7 to 16 years (n = 28) using 60 to 120 mg per day found that 20 of 28 (71%) had complete remission from headaches and another 3 patients (10%) experienced a 66% reduction in headache frequency among the propranolol treated patients ($p < 0.001$). In the placebo group, 3/28 had complete remission and 1 of the 28 experienced a 66% improvement.[29] A second trial (n = 39) failed to demonstrate preventive efficacy at doses of 80 to 120 mg/day and, in fact, significantly increased the average duration of headache in the propranolol group.[30] A third trial compared propranolol at a dose of 3 mg/kg/day vs self-hypnosis and found no benefit from propranolol but significant improvement with hypnotherapy.[31]

Clonidine. The alpha-adrenergic agonist clonidine was assessed in two studies. The first study had two phases. The initial pilot phase (n = 50) had an open-label design and 40% of the children experienced extended relief from migraine attacks. The second phase, a follow-up, double blind, crossover design in 43 children, failed to demonstrate significant difference from placebo (class II).[32] Side effects of sedation and enuresis were more common in the placebo group. The second study compared clonidine to placebo in parallel-group trial (class II) at doses of 25 to 50 μg for 2 months (n = 57).[33] There was no statistical significance between the two groups with 9 of 28 patients in the clonidine group and 9 of 26 in the placebo group experiencing freedom from headache attacks.

Antidepressants. Antidepressants have become a mainstay of migraine prophylaxis, although limited controlled data exist in children to validate this convention.

Amitriptyline. In one open labeled class IV trial of 192 children with frequent headache, 70% had migraine and were treated with amitriptyline up to 1 mg/kg/day.[34] The average age was 12 years and the patients had more than three headaches per month. Over 80% of patients reported a significant reduction in headache frequency and severity but no change in headache duration. Side effects were "minimal," but not specified.

One class IV retrospective study of the use of preventive agents for children and adolescents within one child neurology practice found that amitriptyline produced a "positive response rate" of 89% (n = 73). Positive response rate was defined as an overall decrease in headache frequency and intensity plus acceptability of the agent. Headache frequency was reduced from a mean baseline of 11 to 4.1 headaches per month.[28] The principal side effect was mild sedation.

There are no comparative data for the tricyclic antidepressants nortriptyline and desipramine.

Trazodone. Trazodone hydrochloride, a triazolopyridine derivative antidepressant, was studied in

one class II, placebo-controlled, crossover study (n = 35) in patients ages 7 to 18 years.[35] The results were mixed between the two crossover phases. During the first crossover phase, both groups had a significant reduction in headache frequency and there was no significant difference between the placebo and the trazodone treated group. During the second phase, the trazodone treated group (1 mg/kg/day divided TID) experienced "further" reduction in headache frequency compared to the placebo group. No side effects were observed in either group.

The serotonin-blocking agent pizotifen, unavailable in the United States, was studied in a randomized, crossover class I trial (n = 47) with two 12-week treatment phases and no washout period between phases.[36] There was no significant difference in either headache frequency or headache duration between the placebo and pizotifen-treated groups. Side effects occurred in 17% of patients, but there was no significant difference between the two groups.

No studies have been performed in children or adolescents using the serotonin reuptake inhibitors.

Anticonvulsants. Considering current views concerning the pathophysiology of migraine involving a primary neuronal initiation and a cortical spreading depression, anticonvulsants have received increasing attention as an alternative therapeutic option.

Divalproex sodium. One class IV study in 42 children (ages 7 to 16 years) found that over 80% were able to discontinue their abortive medications when treated with divalproex sodium (15 to 45 mg/kg/day).[37] After 4 months of treatment, 75.8% of patients reported a 50% reduction in headache frequency; 14.2% had a 75% reduction and 14.2% achieved a headache-free status. Side effects included gastrointestinal upset, weight gain, somnolence dizziness, and tremor, similar to those seen for patients with epilepsy.

A second study using divalproex sodium included children ages 9 to 17 years (n = 10) who were treated in an open label fashion (class IV) with doses between 500 and 1,000 mg. Both headache severity and frequency were reduced. Mean severity at baseline using a visual analog scale was reduced from 6.8 to 0.7 at the end of treatment ($p = 0$). Mean headache attacks per month were reduced from 6/month to 0.7/month and mean duration of headache attacks was reduced from 5.5 hours to 1.1 hour following treatment. Side effects included dizziness, drowsiness, and increased appetite, but no serious side effects were noted in this small study.[38]

Caution must be exercised with the use of divalproex sodium in women of childbearing potential.

Topiramate. One retrospective study (class IV) assessing the efficacy of topiramate for pediatric headache included 75 patients of whom 41 were available at a second follow-up visit. Daily doses of 1.4 (±0.74) mg/kg/day were reached and headache frequency was reduced from 16.5 (±10) headaches/month to 11.6 (±10) headaches/month ($p < 0.001$). Mean headache severity, duration, and accompanying disability were also reduced. Side effects included cognitive changes (12.5%), weight loss (5.6%), and sensory symptoms (2.8%).[39] This study population was predominantly children with very frequent migraine headaches approaching the spectrum of chronic daily headache as defined by ≥15 headaches per month.

Levetiracetam. One retrospective study (class IV) assessed the efficacy and safety of levetiracetam for pediatric migraine at doses of 125 to 250 mg twice daily and included 19 patients (mean age 12 years) treated for a mean duration of 4.1 months. The mean frequency of headache attacks before treatment was 6.3/month and after treatment, fell to 1.7/month ($p < 0.0001$). Fifty-two percent of patients experienced elimination of migraine attacks during treatment. No side effects were reported in 82.4% but 10.5% discontinued treatment because of side effects including somnolence, dizziness, and irritability.[40]

Calcium channel blockers. Calcium channel blockers are thought to exert their effects through selective inhibition of vasoactive substances on cerebrovascular smooth muscle.

Nimodipine. One controlled, crossover trial including children ages 7 to 18 years (n = 37) found inconsistent effects with nimodipine (10 to 20 mg TID) compared to placebo between the two treatment phases (class I). During the first treatment period, there was no difference between active and placebo. Headache frequency per month fell from 3.3 to 2.8 in the active group and from 3.0 to 2.5 in the placebo group (NS). During the second treatment phase, there was a significant reduction in headache frequency in the nimodipine group, but no effect on headache duration. Side effects were limited to mild abdominal discomfort in 0.08%.[41]

Flunarizine. Unavailable in the United States, flunarizine is a calcium channel blocker that has been evaluated in several trials for the prevention of childhood migraine. A double blind, placebo-controlled, crossover trial (class I) using 5 mg/day doses of flunarizine (n = 63) demonstrated significant reduction in headache frequency ($p < 0.001$) and decreased average headache duration ($p < 0.01$) compared to the placebo group.[42] The main side effects were drowsiness (9.5%) and weight gain (22.2%).

An open label (class IV) study of 12 patients showed decreased headache frequency with 8/12 experiencing a 75 to 100% reduction in headache frequency during a 6-month follow-up.[43] Another randomized trial compared flunarizine, dimethothiazine, and placebo and showed clinical improvement in 80 to 93% of patients without statistical significance among the three groups.[44]

A class II trial compared flunarizine to propranolol. Headache frequency was decreased in both treatment groups, but no statistically significant difference was detected between the trial agents.[45]

Only two of the trials detailed side effects, which included sedation (9.5%) and weight gain (22.2%) but extrapyramidal side effects (e.g., tremor) have been reported in postmarketing trials.[42,43]

Table 3 *Preventive therapies for migraine*

Therapies	Class	n	Efficacy	Adverse effects	Ref.
Antiepileptic medications					
Divalproex sodium				Occasional to frequent	
15–45 mg/kg/d (7–16 y)	IV	42	76% had >50% reduction headache frequency		37
500–1,000 mg/d (9–17 y)	IV	10	$p = 0$		38
Topiramate 12.5–225 mg (8–15 y)	IV	75	$p < 0.001$	Occasional to frequent	39
Levetiracetam 250–500 mg (3–17 y)	IV	19	$p < 0.0001$	Occasional to frequent	40
Antidepressant medications					
Trazodone 1 mg/kg/d (7–18 y)	II	35	NS	Occasional to frequent	35
Pizotifen 1–1.5 mg (7–14 y)	I	47	NS	Occasional to frequent	36
Tricyclic antidepressants amitriptyline					
1 mg/kg (9–15 y)	IV	192	80%	Occasional to frequent	34
10 mg (3–12 y)	IV	73	89%		28
Antihistamines					
Cyproheptadine 4 mg (3–12 y)	IV	30	83%	Occasional to frequent	28
Calcium channel blockers					
Flunarizine 5 mg (5–11 y)	I	63	$p < 0.001$	Occasional	42
5 mg (10–13 y)	IV	12	75% had 75–100% reduction headache frequency		43
Nimodipine 10–20 mg (7–18 y)	I	37	NS	Occasional	41
Antihypertensive agents					
Propranolol					
80 mg (3–12 y)	II	39	81%	Occasional to frequent	30
6–120 mg (7–16 y)	II	28	NS		29
3 mg/kg/d (6–12 y)	II	28	NS		31
Clonidine					
0.07–0.1 mg (7–14 y)	II	43	NS	Occasional to frequent	32
0.025–0.05 mg (≤15 y)	II	57	32%: 34%—NS		33

Conclusions. The calcium channel blocker flunarizine was studied in one class I trial and is probably effective but is unavailable in the United States. The evidence is insufficient (class IV) to determine efficacy for the antihistamine cyproheptadine, the antidepressant amitriptyline, and the anticonvulsant agents valproic acid, topiramate, and levetiracetam for prevention of pediatric migraine. There is conflicting class II evidence regarding propranolol and trazodone. Clonidine (class II), pizotifen (class I), and nimodipine (class I) were not shown to be more effective than placebo (table 3).

A recent Cochrane Database review of the medical literature also concluded that the calcium channel blocker flunarizine is the only agent that has been studied in rigorous controlled trials and found to be effective.[46] The authors conclude with the statement that there is a "clear and urgent need" for methodologically sound randomized controlled trials for the use of prophylactic drugs in pediatric migraine.

Recommendations for preventive therapy of migraine in children and adolescents.

1. Flunarizine is probably effective for preventive therapy and can be considered for this purpose but is not available in the United States (Level B).
2. There is insufficient evidence to make any recommendations concerning the use of cyproheptadine, amitriptyline, divalproex sodium, topiramate, or levetiracetam (Level U).
3. Recommendations cannot be made concerning propranolol or trazodone for preventive therapy as the evidence is conflicting (Level U).
4. Pizotifen and nimodipine (Level B) and clonidine (Level B) did not show efficacy and are not recommended.

Future directions.

1. Standardized criteria for the diagnosis of migraine headaches in children and adolescents are

needed in order to facilitate proper diagnosis and for the purpose of providing a case definition that could be used as part of therapeutic clinical trials.
2. Standardized criteria of the response to treatment of migraine in children/adolescents need to be established that are related to the frequency, duration, severity, and disability of headaches.
3. The safety and efficacy of currently available medications used to treat migraine headaches in adults need to be established in children and adolescents, particularly the dose and age range in which these medications are deemed safe and effective to use. Failure of an agent for acute or preventive therapy to demonstrate efficacy to a statistically significant degree does not imply that these medications have no role in the pediatric population and their use must be based upon good clinical judgment.
4. It is essential that multicentered, placebo-controlled clinical trials be conducted to assess the safety, tolerability, and efficacy of medications used for the acute and preventive treatment of pediatric and adolescent migraine.
5. Efforts must be made to develop novel and innovative study designs that will address the critical issue of high placebo response rates encountered in clinical trials in children and adolescents, which has proven to be the major impediment to demonstration of efficacy.
6. There are no epidemiologic studies of the incidence or prevalence of status migraine (defined by the International Headache Society as a prolonged attack [≥72 hours] of unremitting headache) in children or adolescents. These epidemiologic studies are needed, as well as treatment studies directed at this clinical entity.
7. It will be important to understand the variations in effects of treatments by age and sex.

Mission statement. The Quality Standards Subcommittee (QSS) of the American Academy of Neurology is charged with developing practice parameters for physicians. This practice parameter summarizes the results from the two evidence-based reviews on the management of pediatric patients with migraine: specifically, acute and preventive treatments for pediatric and adolescent migraine.

Disclaimer. This statement is provided as an educational service of the American Academy of Neurology. It is based on an assessment of current scientific and clinical information. It is not intended to include all possible proper methods of

Appendix 1 *AAN evidence classification scheme for a therapeutic article and linkage to level of recommendation*

Rating of therapeutic article	Rating of recommendation	Translation of evidence to recommendations
Class I: Prospective, randomized, controlled clinical trial with masked outcome assessment, in a representative population. The following are required: a) primary outcome(s) is/are clearly defined b) exclusion/inclusion criteria are clearly defined c) adequate accounting for drop-outs and cross-overs with numbers sufficiently low to have minimal potential for bias d) relevant baseline characteristics are presented and substantially equivalent among treatment groups or there is appropriate statistical adjustment for differences.	Level A = Established as effective, ineffective or harmful (or established as useful/predictive or not useful/predictive) for the given condition in the specified population	Level A rating requires at least two consistent class I studies*
Class II: Prospective matched group cohort study in a representative population with masked outcome assessment that meets a–d above OR a RCT in a representative population that lacks one criteria a–d.	Level B = Probably effective, ineffective or harmful (or probably useful/predictive or not useful/predictive) for the given condition in the specified population	Level B rating requires at least one class I study or two consistent class II studies
Class III: All other controlled trials (including well-defined natural history controls or patients serving as own controls) in a representative population, where outcome is independently assessed, or independently derived by objective outcome measurement.†	Level C = Possibly effective, ineffective or harmful (or possibly useful/predictive or not useful/predictive) for the given condition in the specified population	Level C rating requires at least one class II study or two consistent class III studies
Class IV: Evidence from uncontrolled studies, case series, case reports, or expert opinion.	Level U = Data inadequate or conflicting. Given current knowledge, treatment (test, predictor) is unproven	Studies not meeting criteria for class I–class III

* In exceptional cases, one convincing class I study may suffice for an "A" recommendation if 1) all criteria met, 2) magnitude of effect ≥5, and 3) narrow confidence intervals (lower limit >2).

† Objective outcome measurement—an outcome measure that is unlikely to be affected by an observer's (patient, treating physician, investigator) expectation or bias (e.g., blood tests, administrative outcome data).

Appendix 2 *Consensus-based general principles of adult migraine management*[17]

- Establish a diagnosis.
- Assess the headache burden or disability:
  - Treatment choice depends on the frequency and severity of attacks,
  - the presence and degree of temporary disability,
  - impact on the patient's quality of life, and
  - associated symptoms such as nausea and vomiting.
- Educate migraine sufferers and their families about their condition and its treatment.
- Discuss the rationale for a particular treatment, how to use it, and what adverse events are likely.
- Encourage the patient to identify and avoid triggers.
- Establish realistic patient expectations by setting appropriate goals and discussing the expected benefits of therapy and how long it will take to achieve them.
- Empower the patients to be actively involved in their own management by encouraging patients to track their own progress through the use of:
  - diary cards, flow charts, headache calendars, and
  - methods for tracking days of disability or missed work, school, or family activities.
- Create a formal management plan and individualize management: consider the patient's response to, and tolerance for, specific medications.
- Consider co-morbidity/coexisting conditions that need to be ascertained as they may influence treatment choices.
  - Co-morbid conditions: depression, anxiety, obsessive-compulsive disorders
  - Co-existing conditions (such as reactive airway disease, hypertension).

To meet these goals:

- Use migraine-specific agents (e.g. triptans) in patients whose headaches respond poorly to nonsteroidal anti-inflammatory drugs (NSAIDs) or acetaminophen.

Failure to use an effective treatment promptly may increase pain, disability, and the impact of the headache. Aspirin containing compounds should not be used in children under the age of 15 due to the risk of Reye syndrome.

- Select a non-oral route of administration for patients with migraine associated with severe nausea or vomiting where the nausea and vomiting restrict the use of oral medications.

Antiemetics should not be restricted to patients who are vomiting or likely to vomit. Nausea itself is one of the most aversive and disabling symptoms of a migraine attack and should be treated appropriately.

- Consider a self-administered rescue medication for patients with severe migraine who do not respond to (or fail) other treatments.

A rescue medication is used when other treatments fail and permits the patient to achieve relief without the discomfort and expense of a visit to the physician's office or emergency department.

- Guard against medication-overuse headache ("rebound headache" or "drug-induced headache").

Frequent use of acute medications (including but not limited to opiates, triptans, simple analgesics, and mixed analgesics containing butalbital, caffeine, or isometheptene) is generally thought to cause medication-overuse headache. Many experts limit acute therapy to two headache days per week on a regular basis. Patients with medication overuse should use preventive therapy.

care for a particular neurologic problem or all legitimate criteria for choosing to use a specific procedure. Neither is it intended to exclude any reasonable alternative methodologies. The AAN recognizes that specific patient care decisions are the prerogative of the patient and the physician caring for the patient, based on all of the circumstances involved.

TECHNICAL REPORT

Phototherapy to Prevent Severe Neonatal Hyperbilirubinemia in the Newborn Infant 35 or More Weeks of Gestation

abstract

FREE

OBJECTIVE: To standardize the use of phototherapy consistent with the American Academy of Pediatrics clinical practice guideline for the management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation.

METHODS: Relevant literature was reviewed. Phototherapy devices currently marketed in the United States that incorporate fluorescent, halogen, fiber-optic, or blue light-emitting diode light sources were assessed in the laboratory.

RESULTS: The efficacy of phototherapy units varies widely because of differences in light source and configuration. The following characteristics of a device contribute to its effectiveness: (1) emission of light in the blue-to-green range that overlaps the in vivo plasma bilirubin absorption spectrum (~460–490 nm); (2) irradiance of at least 30 $\mu W \cdot cm^{-2} \cdot nm^{-1}$ (confirmed with an appropriate irradiance meter calibrated over the appropriate wavelength range); (3) illumination of maximal body surface; and (4) demonstration of a decrease in total bilirubin concentrations during the first 4 to 6 hours of exposure.

RECOMMENDATIONS (SEE APPENDIX FOR GRADING DEFINITION): The intensity and spectral output of phototherapy devices is useful in predicting potential effectiveness in treating hyperbilirubinemia (group B recommendation). Clinical effectiveness should be evaluated before and monitored during use (group B recommendation). Blocking the light source or reducing exposed body surface should be avoided (group B recommendation). Standardization of irradiance meters, improvements in device design, and lower-upper limits of light intensity for phototherapy units merit further study. Comparing the in vivo performance of devices is not practical, in general, and alternative procedures need to be explored. *Pediatrics* 2011;128:e1046–e1052

INTRODUCTION

Clinical trials have validated the efficacy of phototherapy in reducing excessive unconjugated hyperbilirubinemia, and its implementation has drastically curtailed the use of exchange transfusions.[1] The initiation and duration of phototherapy is defined by a specific range of total bilirubin values based on an infant's postnatal age and the potential risk for bilirubin neurotoxicity.[1] Clinical response to phototherapy depends on the efficacy of the phototherapy device as well as the balance between an infant's rates of bilirubin production and elimination. The active agent in phototherapy is light delivered in measurable doses, which makes phototherapy conceptually similar to pharmacotherapy. This report standardizes the use of phototherapy consistent with the American Academy of Pediatrics clinical practice guideline for the management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation.

I. COMMERCIAL LIGHT SOURCES

A wide selection of commercial phototherapy devices is available in the United States. A complete discussion of devices is beyond the scope of this review; some are described in Tables 1 and 2. Phototherapy devices can be categorized according to their light source as follows: (1) fluorescent-tube devices that emit different colors (cool white daylight, blue [B], special blue [BB], turquoise, and green) and are straight (F20 T12, 60 cm, 20 W), U-shaped, or spiral-shaped; (2) metal halide bulbs, used in spotlights and incubator lights; (3) light-emitting diodes (LEDs) or metal halide bulbs, used with fiber-optic light guides in pads, blankets, or spotlights; and (4) high-intensity LEDs, used as over- and under-the-body devices.

Data in Table 1 are expanded and updated from that previously reported by Vreman et al.[3] The definitions and standards for device assessment are explained below.

EMISSION SPECTRAL QUALITIES. Measured data of the light delivered by each of the light sources are presented as the minimum, maximum and range. Light source emission spectra within the range of 300–700 nm were recorded after the device had reached stable light emission, using a miniature fiberoptic radiometer (IRRAD2000, Ocean Optics, Inc, Dunedin, FL). For precision based device assessment, the spectral bandwidth (*), which is defined as the width of the emission spectrum in nm at 50% of peak light intensity, is the preferred method to distinguish and compare instead of the total range emission spectrum (data usually provided by manufacturers). Emission peak values are also used to characterize the quality of light emitted by a given light source.

IRRADIANCE: Measured data are presented as mean ± standard deviation (SD), representing the irradiance of blue light (including spectral bandwidth), for each device's light footprint at the manufacturer-recommended distance. To compare diverse devices, the spectral irradiance ($\mu W/cm2/nm$) measurements were made using calibrated BiliBlanket Meters I and II (Ohmeda, GE Healthcare, Fairfield, CT), which were found to yield identical results with stable output phototherapy devices. This type of meter was selected from the several devices with different photonic characteristics that are commercially available, because it has a wide sensitivity range (400–520 nm with peak sensitivity at 450 nm), which overlaps the bilirubin absorption spectrum and which renders it suitable for the evaluation of narrow and broad wavelength band light sources. The devices have been found exceptionally stable during several years of use and agree closely after each annual calibration.

FOOTPRINT: The minimum and maximum irradiance measured (at the intervals provided or defined) in the given irradiance footprint of the device (length × width). The footprint of a device is that area which is occupied by a patient to receive phototherapy. The irradiance footprint has greater dimensions than the emission surface, which is measured at the point where the light exits a phototherapy device. The minimum and maximum values are shown to indicate the range of irradiances encountered with a device and can be used as an indication of the uniformity of the emitted light. Most devices conform to an international standard to deliver a minimum/maximum footprint light ratio of no lower than 0.4.

BSA: BODY SURFACE AREA refers to percent (%) exposure of either the ventral or dorsal planar surface exposed to light and Irradiance measurements are accurate to ±0.5.

All of the reported devices are marketed in the United States except the PortaBed, which is a non-licensed Stanford-developed research device and the Dutch Crigler-Najjar Association (used by Crigler-Najjar patients).

TABLE 2 Maximum Spectral Irradiance of Phototherapy Devices (Using Commercial Light Meters at Manufacturer Recommended Distances) Compared to Clear-Sky Sunlight

Data in Table 2 were tested and compiled by Hendrik J. Vreman (June 2007 and reverified December 2010).

** Irradiance presented to this meter exceeded its range. Measurement was made through a stainless-steel screen that attenuated the measured irradiance to 57%, which was subsequently corrected by this factor.

[a] Solar Light Company, Inc., Glenside, PA 19038.

[b] Oriel Instruments, Stratford, CT 06615 and SmartMeter GRP-1 with UV-A probe. GRP-1 measures UV-A light as μW/cm^2. No artificial light source delivered significant (<0.04 μW/cm^2) UV-A radiation at the distances measured.

II. STANDARDS FOR PHOTOTHERAPY DEVICES

Methods for reporting and measuring phototherapy doses are not standardized. Comparisons of commercially available phototherapy devices that use in vitro photodegradation techniques may not accurately predict clinical efficacy.[2] A recent report explored an approach to standardizing and quantifying the magnitude of phototherapy delivered by various devices.[3] Table 1 lists technical data for some of the devices marketed in the United States.[3] Factors to consider in prescribing and implementing phototherapy are (1) emission range of the light source, (2) the light intensity (irradiance), (3) the exposed ("treatable") body surface area illuminated, and (4) the decrease in total bilirubin concentration. A measure of the effectiveness of phototherapy to rapidly configure the bilirubin molecule to less toxic photoisomers (measured in seconds) is not yet clinically available.

A. Light Wavelength

The visible white light spectrum ranges from approximately 350 to 800 nm. Bilirubin absorbs visible light most strongly in the blue region of the spectrum (~460 nm). Absorption of light transforms unconjugated bilirubin molecules bound to human serum albumin in solution into bilirubin photoproducts (predominantly isomers of bilirubin).[2,4,5] Because of the photophysical properties of skin, the most effective light in vivo is probably in the blue-to-green region (~460–490 nm).[2] The first prototype phototherapy device to result in a clinically significant rate of bilirubin decrease used a blue (B) fluorescent-tube light source with 420- to 480-nm emission.[6,7] More effective narrow-band special blue bulbs (F20T12/BB [General Electric, Westinghouse, Sylvania] or TL52/20W [Phillips]) were subsequently used.[8,9] Most recently, commercial compact fluorescent-tube light sources and devices that use LEDs of narrow spectral bandwidth have been used.[9–14] Unless specified otherwise, plastic covers or optical filters need to be used to remove potentially harmful ultraviolet light.

Clinical Context

Devices with maximum emission within the 460- to 490-nm (blue-green) region of the visible spectrum are probably the most effective for treating hyperbilirubinemia.[2,4] Lights with broader emission also will work, although not as effectively. Special blue (BB) fluorescent lights are effective but should not be confused with white lights painted blue or covered with blue plastic sheaths, which should not be used. Devices that contain high-intensity gallium nitride LEDs with emission within the 460- to 490-nm regions are also effective and have a longer lifetime (>20 000 hours), lower heat output, low infrared emission, and no ultraviolet emission.

B. Measuring Light Irradiance

Light intensity or energy output is defined by irradiance and refers to the number of photons (spectral energy) that are delivered per unit area (cm^2) of exposed skin.[1] The dose of phototherapy is a measure of the irradiance delivered for a specific duration and adjusted to the exposed body surface area. Determination of an in vivo dose-response relationship is confounded by the optical properties of skin and the rates of bilirubin production and elimination.[1] Irradiance is measured with a radiometer (W·cm^{-2}) or spectroradiometer (μW·cm^{-2}·nm^{-1}) over a given wavelength band. Table 2 compares the spectral irradiance of some of the devices in the US market, as measured with different brands of me-

ters. Often, radiometers measure wavelengths that do not penetrate skin well or that are far from optimal for phototherapy and, therefore, may be of little value for predicting the clinical efficacy of phototherapy units. A direct relationship between irradiance and the rate of in vivo total bilirubin concentration decrease was described in the report of a study of term "healthy" infants with nonhemolytic hyperbilirubinemia (peak values: 15–18 mg/dL) using fluorescent Philips daylight (TL20W/54, TL20W/52) and special blue (TLAK 40W/03) lamps.[15,16] The American Academy of Pediatrics has recommended that the irradiance for intensive phototherapy be at least 30 $\mu W \cdot cm^{-2} \cdot nm^{-1}$ over the waveband interval 460 to 490 nm.[1] Devices that emit lower irradiance may be supplemented with auxiliary devices. Much higher doses (>65 $\mu W \cdot cm^{-2} \cdot nm^{-1}$) might have (as-yet-unidentified) adverse effects. Currently, no single method is in general use for measuring phototherapy dosages. In addition, the calibration methods, wavelength responses, and geometries of instruments are not standardized. Consequently, different radiometers may show different values for the same light source.[2]

Clinical Context

For routine measurements, clinicians are limited by reliance on irradiance meters supplied or recommended by the manufacturer. Visual estimations of brightness and use of ordinary photometric or colorimetric light meters are inappropriate.[1,2] Maximal irradiance can be achieved by bringing the light source close to the infant[1]; however, this should not be done with halogen or tungsten lights, because the heat generated can cause a burn. Furthermore, with some fixtures, increasing the proximity may reduce the exposed body surface area. Irradiance distribution in the illuminated area (footprint) is rarely uniform; measurements at the center of the footprint may greatly exceed those at the periphery and are variable among phototherapy devices.[1] Thus, irradiance should be measured at several sites on the infant's body surface. The ideal distance and orientation of the light source should be maintained according to the manufacturer's recommendations. The irradiance of all lamps decreases with use; manufacturers may provide useful-lifetime estimates, which should not be exceeded.

C. Optimal Body Surface Area

An infant's total body surface area[17] can be influenced by the disproportionate head size, especially in the more preterm infant. Complete (100%) exposure of the total body surface to light is impractical and limited by use of eye masks and diapers. Circumferential illumination (total body surface exposure from multiple directions) achieves exposure of approximately 80% of the total body surface. In clinical practice, exposure is usually planar: ventral with overhead light sources and dorsal with lighted mattresses. Approximately 35% of the total body surface (ventral or dorsal) is exposed with either method. Changing the infant's posture every 2 to 3 hours may maximize the area exposed to light. Exposed body surface area treated rather than the number of devices (double, triple, etc) used is clinically more important. Maximal skin surface illumination allows for a more intensive exposure and may require combined use of more than 1 phototherapy device.[1]

Clinical Context

Physical obstruction of light by equipment, such as radiant warmers, head covers, large diapers, eye masks that enclose large areas of the scalp, tape, electrode patches, and insulating plastic covers, decrease the exposed skin surface area. Circumferential phototherapy maximizes the exposed area. Combining several devices, such as fluorescent tubes with fiber-optic pads or LED mattresses placed below the infant or bassinet, will increase the surface area exposed. If the infant is in an incubator, the light rays should be perpendicular to the surface of the incubator to minimize reflectance and loss of efficacy.[1,2]

D. Rate of Response Measured by Decrease in Serum Bilirubin Concentration

The clinical impact of phototherapy should be evident within 4 to 6 hours of initiation with an anticipated decrease of more than 2 mg/dL (34 μmol/L) in serum bilirubin concentration.[1] The clinical response depends on the rates of bilirubin production, enterohepatic circulation, and bilirubin elimination; the degree of tissue bilirubin deposition[15,16,18]; and the rates of the photochemical reactions of bilirubin. Aggressive implementation of phototherapy for excessive hyperbilirubinemia, sometimes referred to as the "crash-cart" approach,[19,20] has been reported to reduce the need for exchange transfusion and possibly reduce the severity of bilirubin neurotoxicity.

Clinical Context

Serial measurements of bilirubin concentration are used to monitor the effectiveness of phototherapy, but the value of these measurements can be confounded by changes in bilirubin production or elimination and by a sudden increase in bilirubin concentration (rebound) if phototherapy is stopped. Periodicity of serial measurements is based on clinical judgment.

III. EVIDENCE FOR EFFECTIVE PHOTOTHERAPY

Light-emission characteristics of phototherapy devices help in predicting

TABLE 3 Practice Considerations for Optimal Administration of Phototherapy

Checklist	Recommendation	Implementation
Light source (nm)	Wavelength spectrum in ~460- 490-nm blue-green light region	Know the spectral output of the light source
Light irradiance ($\mu W \cdot cm^{-2} \cdot nm^{-1}$)	Use optimal irradiance: >30 $\mu W \cdot cm^{-2} \cdot nm^{-1}$ within the 460- to 490-nm waveband	Ensure uniformity over the light footprint area
Body surface area (cm^2)	Expose maximal skin area	Reduce blocking of light
Timeliness of implementation	Urgent or "crash-cart" intervention for excessive hyperbilirubinemia	May conduct procedures while infant is on phototherapy
Continuity of therapy	Briefly interrupt for feeding, parental bonding, nursing care	After confirmation of adequate bilirubin concentration decrease
Efficacy of intervention	Periodically measure rate of response in bilirubin load reduction	Degree of total serum/plasma bilirubin concentration decrease
Duration of therapy	Discontinue at desired bilirubin threshold; be aware of possible rebound increase	Serial bilirubin measurements based on rate of decrease

their effectiveness (group B recommendation) (see Appendix). The clinical effectiveness of the device should be known before and monitored during clinical application (group B recommendation). Local guidelines (instructions) for routine clinical use should be available. Important factors that need to be considered are listed in Table 3. Obstructing the light source and reducing the exposed body surface area must be avoided (group B recommendation).

These recommendations are appropriate for clinical care in high-resource settings. In low-resource settings the use of improvised technologies and affordable phototherapy device choices need to meet minimum efficacy and safety standards.

IV. SAFETY AND PROTECTIVE MEASURES

A clinician skilled in newborn care should assess the neonate's clinical status during phototherapy to ensure adequate hydration, nutrition, and temperature control. Clinical improvement or progression of jaundice should also be assessed, including signs suggestive of early bilirubin encephalopathy such as changes in sleeping pattern, deteriorating feeding pattern, or inability to be consoled while crying.[1] Staff should be educated regarding the importance of safely minimizing the distance of the phototherapy device from the infant. They should be aware that the intensity of light decreases at the outer perimeter of the light footprint and recognize the effects of physical factors that could impede or obstruct light exposure. Staff should be aware that phototherapy does not use ultraviolet light and that exposure to the lights is mostly harmless. Four decades of neonatal phototherapy use has revealed no serious adverse clinical effects in newborn infants 35 or more weeks of gestation. For more preterm infants, who are usually treated with prophylactic rather than therapeutic phototherapy, this may not be true. Informed staff should educate parents regarding the care of their newborn infant undergoing phototherapy. Devices must comply with general safety standards listed by the International Electrotechnical Commission.[21] Other clinical considerations include:

a. Interruption of phototherapy: After a documented decrease in bilirubin concentration, continuous exposure to the light source may be interrupted and the eye mask removed to allow for feeding and maternal-infant bonding.[1]
b. Use of eye masks: Eye masks to prevent retinal damage are used routinely, although there is no evidence to support this recommendation. Retinal damage has been documented in the unpatched eyes of newborn monkeys exposed to phototherapy, but there are no similar data available from human newborns, because eye patches have always been used.[22–24] Purulent eye discharge and conjunctivitis in term infants have been reported with prolonged use of eye patches.[25,26]
c. Use of diapers: Concerns for the long-term effects of continuous phototherapy exposure of the reproductive system have been raised but not substantiated.[27–29] Diapers may be used for hygiene but are not essential.
d. Other protective considerations: Devices used in environments with high humidity and oxygen must meet electrical and fire hazard safety standards.[21] Phototherapy is contraindicated in infants with congenital porphyria or those treated with photosensitizing drugs.[1] Prolonged phototherapy has been associated with increased oxidant stress and lipid peroxidation[30] and riboflavin deficiency.[31] Recent clinical reports of other adverse outcomes (eg, malignant melanoma, DNA damage, and skin changes) have yet to be validated.[1,2,32,33] Phototherapy does not exacerbate hemolysis.[34]

V. RESEARCH NEEDS

Among the gaps in knowledge that remain regarding the use of phototherapy to prevent severe neonatal hyperbilirubinemia, the following are among the most important:

1. The ability to measure the actual wavelength and irradiance delivered by a phototherapy device is urgently needed to assess the efficiency of

phototherapy in reducing total serum bilirubin concentrations.

2. The safety and efficacy of home phototherapy remains a research priority.
3. Further delineation of the short- and long-term consequences of exposing infants with conjugated and unconjugated hyperbilirubinemia to phototherapy is needed.
4. Whether use of phototherapy reduces the risk of bilirubin neurotoxicity in a timely and effective manner needs further exploration.

SUMMARY

Clinicians and hospitals should ensure that the phototherapy devices they use fully illuminate the patient's body surface area, have an irradiance level of $\geq 30\ \mu W \cdot cm^{-2} \cdot nm^{-1}$ (confirmed with accuracy with an appropriate spectral radiometer) over the waveband of approximately 460 to 490 nm, and are implemented in a timely manner. Standard procedures should be documented for their safe deployment.

APPENDIX Definition of Grades for Recommendation and Suggestion for Practice

Grade	Definition	Suggestion for Practice
A	This intervention is recommended. There is a high certainty that the net benefit is substantial	Offer and administer this intervention
B	This intervention is recommended. There is a moderate certainty that the net benefit is moderate to substantial	Offer and administer this intervention
C	This intervention is recommended. There may be considerations that support the use of this intervention in an individual patient. There is a moderate to high certainty that the net benefit is small	Offer and administer this intervention only if other considerations support this intervention in an individual patient
D	This intervention is not recommended. There is a moderate to high certainty that the intervention has no net benefit and that the harms outweigh the benefits	Discourage use of this intervention
I	The current evidence is insufficient to assess the balance of benefits against and harms of this intervention. There is a moderate to high certainty that the intervention has no net benefit and that the harms outweigh the benefits. Evidence is lacking, of poor quality, or conflicting, and the balance of benefits and harms cannot be determined	If this intervention is conducted, the patient should understand the uncertainty about the balance of benefits and harms

abstract

Health care professionals may have moral objections to particular medical interventions. They may refuse to provide or cooperate in the provision of these interventions. Such objections are referred to as conscientious objections. Although it may be difficult to characterize or validate claims of conscience, respecting the individual physician's moral integrity is important. Conflicts arise when claims of conscience impede a patient's access to medical information or care. A physician's conscientious objection to certain interventions or treatments may be constrained in some situations. Physicians have a duty to disclose to prospective patients treatments they refuse to perform. As part of informed consent, physicians also have a duty to inform their patients of all relevant and legally available treatment options, including options to which they object. They have a moral obligation to refer patients to other health care professionals who are willing to provide those services when failing to do so would cause harm to the patient, and they have a duty to treat patients in emergencies when referral would significantly increase the probability of mortality or serious morbidity. Conversely, the health care system should make reasonable accommodations for physicians with conscientious objections. *Pediatrics* 2009;124:1689–1693

INTRODUCTION

Health care professionals may morally object to particular treatments and refuse to provide them. This practice is referred to as "conscientious objection."[1–3] This statement will not address claims of conscience on behalf of institutions. Possible examples of conscientious objection in pediatric practice include refusals to prescribe contraception, specifically emergency contraception[4]; perform routine neonatal male circumcision[5]; or administer vaccines developed with virus strains or cell lines derived from voluntarily aborted human fetuses.[6] Such objections may limit patients' access to information or treatment. Given this ethical dilemma, the legitimacy of such objections has become an important issue. Legislation has been proposed both to protect health care providers' ability to conscientiously object and to ensure patients' access to health care.[7]

Conscience

There are morally important reasons to protect the individual's exercise of conscience even if one disagrees with the content of the consci-

entious belief. Conscience is closely related to integrity. Performing an action that violates one's conscience undermines one's sense of integrity and self-respect and produces guilt, remorse, or shame.[8,9] Integrity is valuable, and harms associated with the loss of self-respect should be avoided. This view of conscience provides a justification for respecting conscience independent of particular religious beliefs about conscience or morality. Claims of conscience are generally negative (the right to not perform an action) rather than positive (the right to perform an action).[10]

There are potential social benefits to protecting individuals' ability to act according to their consciences. These benefits include empowering individuals to think and act morally, encouraging the use of reason rather than force, exemplifying and encouraging tolerance, and encouraging moral action. For example, people are more likely to act morally if they are permitted to act on their own decisions.[11]

What constitutes a violation of conscience may be difficult to identify or validate. In some situations, claims of conscientious objection may hide self-serving motives.[12] For example, a potential military recruit may illegitimately assert conscientious objection not because of moral objections to killing but because of a concern for his or her personal safety. Personal affiliation with an organization that publicly proscribes certain actions makes it easier to identify true claims of conscience. Confirmation may also be difficult regarding actions that are not intrinsically immoral but only immoral under certain conditions. Whereas some traditions view war as intrinsically immoral, others view the use of lethal force as morally appropriate if certain criteria are fulfilled. Whether the criteria are fulfilled may depend on empirical claims about which there is controversy. Objectors have an obligation to explain and defend their position and may be required to demonstrate the sincerity and importance of their belief.[11]

There are, however, a number of difficulties in characterizing and validating claims of conscience. The boundary between legitimate conscientious objection and unjust discrimination is particularly problematic. For example, the medical profession would not tolerate a physician's refusal to treat patients of a particular racial group because the physician considered members of this group inferior. Discrimination is an affront to the dignity of the individual discriminated against and may impose significant practical burdens on the individual. Alternatively, clinicians might claim that an action is not intrinsically immoral but only immoral when performed by certain categories of persons. For example, a clinician might object to prescribing contraception to unmarried people because the clinician believes it facilitates immoral sexual activity. In such situations, clinicians should be careful not to violate patients' privacy by asking personal questions only to satisfy their own interests.[13] Legally, when claims of conscience conflict with claims of nondiscrimination in public accommodations, such as hotels and restaurants, nondiscrimination claims take precedence. Whether private physician practices should be considered public accommodations, and which groups of individuals should be protected against discrimination, are subjects of continuing societal debate.[14] The American Academy of Pediatrics opposes discrimination in the care of any patient or against any physician.[15]

Evaluating claims of conscience is also difficult, because some individuals object not only to performing an action themselves but also to assisting someone else to perform the action. Physicians who object to emergency contraception do not use it themselves and also refuse to prescribe it to others. They argue that assisting others to do something they themselves consider immoral makes them morally culpable. For example, a physician whose patient makes a credible threat against a third party would be morally culpable if he or she refused to warn the third party or to notify the police and the patient harmed the other individual.

Whether assisting someone else to perform an act that you consider immoral is wrong depends on a number of factors including intention. It would be wrong if you intend for the wrong to be committed and share the intention of the person you are helping. In other cases you might cooperate in the act but not share the other person's intention, and your assistance might be appropriate. Using a bank robbery as a nonmedical example, the getaway driver shares the robber's intention, but the bank manager who is forced to open the vault does not. The getaway driver's actions are wrong, whereas those of the manager may be excusable. The moral evaluation of assisting another without sharing his or her intention depends on a variety of practical considerations including the seriousness of the wrong, the causal relationship between the assistance and the act, the necessity of the assistance for completing the act, and the reason for providing the assistance. There is also the concern that cooperation may be misinterpreted as approval and might cause another to act wrongly.[16] Often, these relative determinations do not permit clear lines to be drawn between morally acceptable and immoral assistance. Questions regarding cooperation can become issues of conscience.

Conscientious Objection in Health Care

Claims regarding conscientious objection in medicine should be evaluated on the health care system rather than the individual level, because neither the clinicians' nor the patients' claims clearly trump the others' in all situations. Conflicts are often framed in terms of an individual provider and a single patient. Both of these individuals have morally significant interests.[17] Consider a pediatrician who refuses to prescribe emergency contraception for a patient whose partner's condom broke during intercourse. A health care professional might choose to leave medicine rather than violate his or her conscience. This decision could have secondary effects not only for the professional and his or her family but also for patients. It might limit their access to other services. Alternatively, the health care professional might violate his or her conscience and experience significant guilt and shame and their secondary effects. Constrained access to health care may also have significant effects for patients, such as an unintended but possibly preventable pregnancy. Benefits and harms to patients should be evaluated from the patients' points of view. The frequency of particular outcomes is difficult to predict, and the type and magnitude of these outcomes do not lend themselves to weighing and balancing. Therefore, it is not possible to state in the abstract that either the health care professional's claim to conscientious objection or the patient's claim to access should always prevail.

Some refusals constitute an imposition of the physician's moral beliefs on the patient. Refusing to transfer a patient's medical records, for example, unfairly constrains a patient's subsequent action and is morally unacceptable.[9] More egregious actions, such as berating or humiliating patients, violate the respect that objectors themselves are seeking and are clearly morally wrong. It is not clear, however, that refusing to cooperate is morally equivalent to imposing one's views. Physicians, except in emergencies, have significant latitude in selecting patients, and pharmacies may not stock dedicated emergency contraceptives for reasons unrelated to conscience. Those who refuse on the basis of conscience should not be held to higher standards than those who refuse treatment on the basis of other accepted grounds.

Constraints on claims of conscience can, nonetheless, be justified on the basis of health care professionals' role responsibilities and the power differential created by licensure. Health care professionals fulfill a particular societal role with associated expectations and responsibilities. For example, physicians' primary focus should be on their patients' rather than their own benefit. These role expectations are based in part on the power differential between physicians and patients, which is the result of physicians' knowledge and patients' conditions.

Role obligations are generally voluntarily accepted; therefore, health care professionals' claims of conscientious objection may justifiably be limited. It is unreasonable for an individual to enter a profession or specialty with primary activities that conflict with his or her central values.[18] Individuals, however, may change their moral points of view after having accepted a role, or the role may be redefined during the course of their professional practice. The debate over physician-assisted suicide, for example, has evolved during many practicing physicians' careers.[8] The boundaries of medical practice, both in terms of what constitutes disease and the scope of available treatments, may also evolve over time. Although individuals should not knowingly enter a specialty with core activities that they are unwilling to perform, changes in medical practice over time should also be acknowledged.

Some have argued that the exercise of conscience is integral to being a professional, but this claim confuses professional and nonprofessional commitments. Physicians generally can refuse to perform actions that they consider medically inappropriate. A pediatrician may, for example, refuse to prescribe antibiotics for a viral respiratory infection or perform a surgery that has an unacceptable mortality rate. In contrast, conscientious objections are typically based not on medical knowledge but on moral, religious, or political beliefs.[9,11] The ability to refuse to provide a service or treatment on these other bases is not part of being a physician.

One responsibility of the physician's role is providing medical information, including risks, benefits, and alternatives, during the informed-consent process. This role responsibility is supported by the value of autonomy and patients' need for information to make autonomous decisions.[12] Permitting physicians, on the basis of a claim of conscience, not to disclose a legally available treatment option of which the patient is unaware but might otherwise choose would significantly undermine the practice of medicine. For example, it would be unfair for a victim of sexual assault who was unfamiliar with emergency contraception not to be informed of its existence. Acknowledging that language is not value neutral, the information disclosed should be accurate, complete, easily understood, and focused on the patients' decision-making needs. Physicians should document the informed-consent process in the patient's medical record.

As previously mentioned, clinical information should be provided in a respectful manner.[19] Physicians can ex-

plain the reasons why they do not provide certain treatments or services while respecting patients' autonomy. The power differential between physicians and patients may, however, create unintended coercion. Patients should be able to refuse to listen to physicians' reasons.

Similar considerations require clinicians to provide prospective disclosure and referral. Physicians who, on the basis of conscience, refuse to provide particular treatments or services within the usual scope of practice for their specialty have an obligation to disclose this to potential patients. This knowledge may be important to patients in selecting physicians. In some situations, it may be feasible to transfer care. Although some clinicians object that referring makes them morally complicit,[8] patients may be harmed by the lack of referral. Patients, particularly adolescents, may not know how to identify a willing health care professional. Patients may also face a significant delay in obtaining a new-patient appointment. The power differential in the physician-patient relationship is based not only on physicians' greater medical knowledge but also on their greater knowledge about the health care system. In situations of potential harm to patients, physicians have a duty to refer in a timely manner. This duty may be fulfilled by informing patients about referral services such as those provided by hospitals or insurance companies. Physicians should provide other, ongoing care while transferring patient care responsibilities. For example, a physician who decides not to see unimmunized patients should continue to treat an established, unimmunized patient's asthma until a new primary care provider can be established.

Special obligations on the part of health care professionals also result from the system of licensure.[17,20] Licensure requirements constrain others from providing similar services and limit patients' access. Physicians' relative monopoly on health care services and their fiduciary obligations to patients create an obligation to treat, irrespective of conscientious objection, in emergencies. Health care providers have a duty to perform procedures within the scope of their training when the patient's health is at significant risk and an alternative health care professional is unavailable.[11,13]

Protection of physicians' conscience and provision of legal health care services are both goods that the health care system should protect. A variety of accommodations are feasible. For example, alternative modes of providing emergency contraception include advance prescription, pharmacist provision, and over-the-counter sales.[21] Employers have important legal obligations and can provide an essential coordinating function within the health care system. They should provide reasonable accommodations, such as job restructuring or modified work schedules.[18] Referral services may also be created to provide resources for patients seeking care.[21] Accommodation efforts should recognize a wide variety of potential barriers for patients, including education level, income, and geography. Local variation in circumstance makes broad policy recommendations difficult.[17]

Conversely, physicians have obligations to their patients. These obligations include disclosure, provision of informed consent, referral, and emergency treatment.[22] Physicians have a moral obligation to disclose their beliefs to employers and to accept reasonable accommodations from them.[18] Physicians should avoid placing undue burdens on their colleagues. Self-employed physicians should avoid creating situations that inordinately constrain patients' access to legal treatments. For example, a physician with a conscientious objection to a particular procedure should avoid intentionally displacing the only willing provider of that procedure for a large geographic area.

RECOMMENDATIONS

1. The American Academy of Pediatrics supports a balance between the individual physician's moral integrity and his or her fiduciary obligations to patients. A physician's duty to perform a procedure within the scope of his or her training increases as the availability of alternative providers decreases and the risk to the patient increases.
2. Physicians should work to ensure that health care–delivery systems enable physicians to act according to their consciences and patients to obtain desired health care.
3. Physicians have a duty to prospective patients to disclose standard treatments and procedures that they refuse to provide but are normally provided by other health care professionals.
4. Physicians have a moral obligation to inform their patients of relevant alternatives as part of the informed-consent process. Physicians should convey information relevant to the patient's decision-making in a timely manner, using widely accepted and easily understood medical terminology, and should document this process in the patient's medical record.
5. Physicians who consider certain treatments immoral have a duty to refer patients who desire these treatments in a timely manner when failing to do so would harm the patients. Such physicians must also provide appropriate ongoing care in the interim.

6. Physicians should work to ensure that employers make reasonable accommodations for employees' conscientiously held views and that responsibilities are equitably distributed among colleagues.
7. In emergencies, when referral would significantly increase the probability of mortality or serious morbidity, physicians have a moral obligation to provide treatment.

abstract

FREE

The care of hospitalized children and adolescents has become increasingly complex and often involves multiple physicians beyond the traditional primary care pediatrician. Hospitalists, medical subspecialists, surgical specialists, and hospital attending physicians may all participate in the care of hospitalized children and youth. This report summarizes the responsibilities of the pediatrician and other involved physicians in ensuring that children receive coordinated and comprehensive medical care delivered within the context of their medical homes as inpatients, and that care is appropriately continued on an outpatient basis. *Pediatrics* 2010;126:829–832

BACKGROUND

Although an infrequent occurrence for most children and their families, hospitalization is a significant event in the life of a child and his or her family. Most children are hospitalized for an acute illness or injury. Children with disabilities are more likely to be hospitalized and experience 8 times as many hospital days as other children.[1] Care coordination is an important aspect of caring for children with special health care needs and has been emphasized by the American Academy of Pediatrics as part of the medical home concept.[2] Care coordination is essential for safe care and includes developing and guiding diagnostic and therapeutic plans with integration of input from the medical team, patients, and families toward the goal of discharging a healthier child back to his or her medical home.[3]

Patient and family satisfaction with the hospital experience is an important element of quality of care. Parents in 1 review, on average, were very satisfied with the overall care of their child; however, information shared with the child and coordination of care had the highest problem scores. In addition, problems with information provided to the parents correlated most strongly with overall negative perception of care received.[4]

As the care that is delivered to children on an outpatient basis becomes more sophisticated, illnesses that warrant hospitalization are becoming more complex and severe and often require specialty consultation(s). Although the primary care pediatrician may be the attending physician directly responsible for clinical management of the hospitalized child, this is becoming much less common.[5,6] In community hospitals, pediatric hospitalists, medical subspecialists, and surgical specialists may be unavailable, and a physician whose primary practice is adult medicine may provide general, specialty, and/or surgical care and function as the attending physician for pediatric patients. Alternatively, a pediatric hospitalist, full-time teaching attending pediatrician, pediatric medical subspecialist, or

surgical specialist may be responsible for the supervision and care of the child. Coordination and oversight of care must be provided by the attending physician who is caring for the patient, regardless of whether that is the primary care pediatrician and/or other physicians as described above. The following functions are the essential components of this coordination and oversight role.

INITIAL ASSESSMENT

For any child who requires hospital admission, an initial assessment made before or at the time of hospitalization allows for the child to be admitted to the inpatient setting that is best suited to his or her specific problem(s). At times, authorization may be needed from the child's insurance carrier before admission. In addition, attention must be directed to the safest way for the child to travel to the hospital (family car, ambulance, or specialized pediatric transport). A safe transport plan is particularly important if the child's destination is distant. Referring and receiving physicians should work together to advocate and direct a timely, well-coordinated, and safe transfer.

A complete initial evaluation includes a history of the present illness; complete medical history; pain assessment; drug and food allergies; review of systems; review of immunizations; medication reconciliation; assessment of growth (including BMI), nutritional, developmental, educational, and emotional status; review of family and social history, including review of behavioral and environmental risk factors and cultural or ethnic issues; and a physical examination.[7] The effects of the child's condition on his or her family and the effects of the family on the child's condition need to be evaluated to initiate family-centered care. These assessments may be performed just before or concurrent with hospitalization and routinely involve collaboration with other health care professionals such as nursing staff, child life specialists, social workers, and others.

It is especially important that the child's medical history be obtained if the primary care pediatrician is not the attending physician. Hospitalists, medical subspecialists, and surgical specialists who care for hospitalized children must communicate with the child's primary care pediatrician for overall coordination of care. Pertinent previous health information must be available on admission for the inpatient health care team to review, including a list of prescribed medications and therapies. Access to this information prevents unnecessary duplication of previous diagnostic and therapeutic measures; reduces the risk of errors in medication dosing; allows primary care and hospital-based physicians to update the status of past conditions that may not be obvious on the current admission; provides an opportunity to address identified deficiencies while the child is hospitalized, such as catching up on immunizations; provides insight into psychosocial issues facing the patient and family; and facilitates monitoring of the child's growth and development. Inpatient and outpatient facilities must be able to provide and receive necessary medical records in a reliable, timely, safe, and confidential manner. An accessible electronic health record may provide more timely and accurate data. In some settings, equipment from home (eg, a home bilevel positive airway pressure [BIPAP] device, insulin pump, or specialized wheelchair) can be critical, even if only to bridge the gap in transition from home to hospital.

DURING THE HOSPITAL STAY

The attending physician integrates and coordinates the input of all physicians and other ancillary providers when multiple providers are involved in the patient's care. Duties include directing the overall care of the child, coordinating input from consultants, confirming that the child and the family understand the information from all consultants, considering the options when consultants disagree, planning for discharge from the hospital, and efficiently using inpatient resources.

Family-centered care is linked to improved health outcomes[8] and has been recommended by many key constituents for children's health care. Family-centered rounds is a system that emphasizes the essential role of the family in coordinating the care of hospitalized children.[9] Communication with the patient, family, bedside nurse, and other members of the inpatient care team can improve coordination of the daily plan, which leads to fewer misunderstandings and more timely completion of the daily plan. In a nonteaching hospital, family-centered rounds can be as simple as rounding together with the nurse, patient, and family and trying to coordinate this time with the visit of other involved subspecialists and/or surgeons.

Increasing emphasis is being placed on ways to reduce medication errors.[10] Children are more at risk for medication errors than adults, and the potential for harm is higher.[11,12] Errors are likely to occur during transitions of care, including admission, handoffs from 1 team to another, and discharge. In academic medical centers, resident work-hour restrictions have led to increasing numbers of sign-outs, another time at which errors may occur.[13] The process for handoffs and sign-outs should be standardized and include opportunities for verbal interchange and links to the hospital information system to ensure up-to-date and accurate information.

When the attending physician does not routinely care for pediatric patients, pediatric consultation can help with

the physiologic, pharmacologic, and psychosocial issues; discharge planning; and identifying and arranging for home care resources unique to younger and smaller patients. Hospitals are encouraged to set criteria for pediatric consultation, depending on local resources. Formal consultation is recommended for any hospitalized child with complex medical or psychosocial problems. Some hospitals have set age or weight criteria for mandatory consultation, such as age younger than 14 years or body weight less than 40 kg.

When physicians other than the primary care pediatrician participate in the care of the hospitalized child, the primary care pediatrician can help ensure continuity of care and help the family develop trust in providers who have no preexisting relationship with the family. As the hospitalization progresses, the primary care pediatrician can provide valuable insight into the patient's changing medical condition and the patient's and family's psychosocial status and response. For patients and families facing end-of-life issues, the involvement of the primary care pediatrician and community resources, such as pastoral care, is particularly valuable.

DISCHARGE PLANS AND COORDINATION

Preparation for discharge needs to begin at admission and engage the family at all stages. Discharge criteria are set at admission and reviewed at least daily by members of the team and the patient and family. When going home, an assessment of the child's needs should be made; plans should be formulated; medications should be reconciled, including clarifying that some medications may purposely be discontinued at the time of discharge; and appropriate training and education should be completed. Treatment plans must be made in accordance with the child's developmental, educational, and emotional level and available resources. The continued involvement of the primary care pediatrician ensures that discharge planning is proceeding effectively. It improves the primary care pediatrician's understanding of the patient's hospital course to facilitate optimal transitional and ongoing outpatient care.[14] Family members or guardians must be involved with formulation of the treatment plan, because they are ultimately responsible for decisions about the care their child receives.[15]

If treatment is not completed during hospitalization, appropriate outpatient management must be arranged. The attending physician, together with other members of the health care team and the family, is responsible for evaluating whether the outpatient treatment plan seems feasible for the child's family to undertake and modifying the plan if needed. At the time of discharge, a legible summary, including medications, appropriate follow-up, and assignment of care responsibilities, must be available to all personnel and institutions involved in the subsequent care of the child.[16] Timely electronic reports should be available to ensure that a complete and legible record of events is provided. Laboratory, imaging, and consultative reports that are pending at the time of discharge should be identified, and the physician responsible for checking these results should be clearly specified. Referrals must be provided for all needed outpatient services, including a source of primary care if the child does not have a medical home. In such instances or when the primary care pediatrician was not directly involved in the child's hospitalization, the provider responsible for ongoing care should be contacted directly by the inpatient team to ensure prompt initiation of outpatient care; ideally, this would occur at the time of discharge. All referrals for outpatient services should be arranged with providers who are familiar with the special needs of children.[17]

CONCLUSIONS

Most inpatient care represents an episodic incident of care and must be viewed and managed within the context of the child's medical home. To accomplish this requires ongoing communication between the primary care pediatrician and the hospital attending physician. Care coordination must include continual involvement of the family, timely legible communication between inpatient and outpatient physicians, meticulous handoffs at every transition, and clear delineation of the responsibilities of all involved physicians during the hospital stay and when the child returns home.

abstract

FREE

Despite marked progress in global polio eradication, the threat of polio importation into the United States remains; therefore, all children should be protected against the disease. The standard schedule for poliovirus immunization remains 4 doses of inactivated poliovirus vaccine at 2, 4, and 6 through 18 months and 4 through 6 years of age. The minimum interval between doses 1 and 2 and between doses 2 and 3 is 4 weeks, and the minimum interval between doses 3 and 4 is 6 months. The minimum age for dose 1 is 6 weeks. Minimal age and intervals should be used when there is imminent threat of exposure, such as travel to an area in which polio is endemic or epidemic. The final dose in the inactivated poliovirus vaccine series should be administered at 4 through 6 years of age, regardless of the previous number of doses administered before the fourth birthday, and at least 6 months since the last dose was received. *Pediatrics* 2011;128:805–808

INTRODUCTION

Despite marked progress in global efforts to eradicate polio, wild polioviruses still persist in a small number of Asian and African countries. Thus, it is essential to ensure high poliovirus immunity levels in US children to prevent outbreaks should poliovirus be imported into this country. In 2000, inactivated poliovirus vaccine (IPV) became the poliovirus vaccine of choice for routine immunization in the United States; it replaced oral poliovirus vaccine (OPV), which had been in use since the 1960s.[1] The rationale behind the change to IPV was to prevent the rare occurrence of vaccine-associated paralytic polio caused by OPV. Since 2000, 3 combination vaccines containing IPV have been licensed.[2] This brief policy statement provides guidance on the optimal use of such combinations. In addition, the appropriate intervals between doses, particularly for catch-up schedules, and the importance of the dose at 4 through 6 years of age for maintaining long-term immunity to polio are addressed.

BACKGROUND AND RATIONALE

Before the introduction of IPV in 1955, more than 15 000 cases of paralytic polio occurred annually in the United States. During the early 1960s, OPVs replaced IPV as the vaccine of choice because of their ease of use and because, at the time, it was believed that OPV would provide better community protection and produce long-lasting immunity. Use of OPV led to the elimination of indigenous polio in this country; the last reported outbreak was in 1979.[3] Although the use of OPV was highly effective, there were rare but serious cases of vaccine-associated paralytic polio (~8 cases per year) in both healthy and immunocompro-

mised recipients and contacts of recipients of OPV.[4] In addition, data accumulated to show that IPV-induced immunity was long-term and that IPV alone had interrupted poliovirus transmission in several industrialized countries.[5] Thus, in 2000, IPV replaced OPV for preventing vaccine-associated paralytic polio cases while maintaining high levels of individual and community protection against wild polioviruses. The current IPV immunization schedule was designed to induce immunity to polio early in life; it calls for 3 doses administered at 2, 4, and 6 through 18 months of age and a booster dose at 4 through 6 years of age.[1] The 3-dose primary series of IPV leads to more than 95% seroconversion to all 3 poliovirus serotypes.

In 1988, the World Health Assembly adopted a goal to eradicate polio. At the time, there were an estimated 350 000 cases worldwide, and polio was indigenous to 125 countries.[6] By 2009, the number of cases caused by wild polioviruses was reduced to 1604, and only 4 countries (Afghanistan, India, Nigeria, and Pakistan) had never interrupted indigenous virus transmission (www.polioeradication.org). However, these 4 countries exported virus to at least 19 other countries, which reported cases of polio in 2009, which indicates the potential for continuing spread outside the currently affected areas. Although the number of reported cases during 2010 was reduced compared with 2009 (1349 vs 1604), polio had been reported from 20 countries during 2010. As of August 23, 333 cases were reported from 14 countries, compared with 618 cases during the same period in 2010.

The need for increased investment in implementation of strategies for eradicating polio was recently well articulated, and both donor and affected countries should be encouraged to continue to make progress toward this goal.

OPV is the vaccine used in most of the world.[7] Rarely, circulation of oral vaccine viruses has been associated with acquisition of a wild virus phenotype (comparable neurovirulence and transmissibility to wild polioviruses) leading to outbreaks of polio.[6] The medical care costs of even 1 case of polio are substantial. A recent study estimated that such costs were on the order of $520 000 per case (range: $250 000–$1 500 000).[8] These costs are exclusive of the costs that would be incurred trying to contain an outbreak. Thus, the United States remains at risk of importation of pathogenic polioviruses, which indicates the need, into the foreseeable future, to maintain high levels of polio immunity in the population through widespread use of IPV. Individual protection is important, because even within the United States, there are pockets of underimmunized children who might sustain polio transmission if the virus is introduced.[9,10]

EVIDENCE TO SUPPORT POLICY/ RECOMMENDATION

Seroconversion rates and geometric mean titers (GMTs) after receipt of IPV are influenced by preexisting maternal antibody, the age at which doses are administered, and the intervals between doses. For example, a study from Puerto Rico reported seroconversion rates of 99.6%, 100%, and 99.1% against serotypes 1, 2, and 3, respectively, when administered at 2, 4, and 6 months of age, compared with 85.8%, 86.2%, and 96.9%, respectively, when administered at 6, 10, and 14 weeks of age.[11] In each schedule, children with higher maternal antibodies tended to have lower GMTs and lower seroconversion rates; maternal antibodies decrease with increasing age. For example, infants vaccinated during the first 6 months of life using 1-month intervals at 2, 3, and 4 months or 3, 4, and 5 months of age tend to produce lower antibody levels than do infants vaccinated using 2-month intervals.[7,11,12]

The duration of immunity after receipt of the IPV series is long-term, possibly lifelong. A study in Sweden revealed persistent levels of antibody for the 12-year duration of follow-up for children who received a 4-dose series beginning in the first year of life with a booster at 4 through 5 years of age.[13] A review of IPV schedules in 36 countries that used IPV in 2009 revealed that 34 countries included a booster dose at 4 or more years of age.[14] Thus, there is substantial experience showing that countries that provide such a booster dose at that age have been able to sustain polio elimination. On the other hand, the experience in countries that do not provide the booster has been limited.

Four preparations of IPV are available in the United States (Table 1),[2] including a stand-alone preparation and 3 combination vaccines: DTaP-HepB-IPV (diphtheria and tetanus toxoids and acellular pertussis adsorbed, hepatitis B [recombinant], and IPV combined [Pediarix (GlaxoSmithKline Biologicals, Rixensart, Belgium)]), licensed for the first 3 doses of the IPV series through 6 years of age; DTaP-IPV/Hib (diphtheria-tetanus-acellular pertussis [DTaP], IPV, and *Haemophilus influenzae* type b [Hib] conjugate [tetanus toxoid conjugate] vaccine [Pentacel (Sanofi Pasteur, Swiftwater, PA)]), licensed for 4 doses of the IPV series through 4 years of age; and DTaP-IPV (Kinrix [GlaxoSmithKline Biologicals]), licensed for the booster dose at 4 through 6 years of age.

RECOMMENDATIONS

1. The standard schedule for IPV should be 4 doses administered at 2 months, 4 months, 6 through 18 months, and 4 through 6 years of age.
2. If there is risk of imminent exposure to circulating polioviruses, such as travel to a country in which

polio is endemic or there is an outbreak, then the minimum age and intervals for the first 3 doses of IPV should be followed. Maternal antibodies can interfere with seroconversion in the first 6 months of life. For this reason, the standard schedule in recommendation 1, which calls for vaccine administration during periods when maternal antibodies are likely to have waned substantially, should be implemented unless there is imminent exposure risk. Although not ideal, the great majority of infants vaccinated at the minimum age with minimal intervals are protected from polio, and with imminent risk of exposure, the benefits of using the abbreviated schedule far outweigh any risks of failure to induce a protective immune response.

- The minimum interval from doses 3 to 4 should be 6 months.
- The minimum interval from doses 1 to 2 and from doses 2 to 3 should be 4 weeks.
- The minimum age for dose 1 is 6 weeks.

3. The final dose of IPV should be administered at 4 through 6 years of age regardless of the number of doses administered before 4 years of age. The final dose should be given at least 6 months after the preceding dose.
4. When DTaP-IPV/Hib is used for the first 4 doses, a fifth dose of an IPV-containing preparation (IPV alone or DTaP-IPV) should be administered on or after the fourth birthday. The minimal interval between doses 4 and 5 of IPV in this case should be 6 months.
5. IPV should be administered to immunocompromised and immunodeficient children using the same schedule as that for children with normal immune systems. Because the vaccine is inactivated, it is safe in children with abnormal immune systems. IPV might not be as effective in such children, depending on the disorder and degree of immunocompromise, compared with protection rates in children with normal immune systems.
6. Adults who are at an increased risk of exposure to wild-type poliovirus and who previously completed primary immunization with OPV or IPV can receive a single dose of IPV.

Planning for Children Whose Parents Are Dying of HIV/AIDS

ABSTRACT. Although the character of acquired immunodeficiency syndrome is changing into a chronic illness, it is estimated that by the end of this century, 80 000 children and adolescents in the United States will be orphaned by parental death caused by human immunodeficiency virus infection. Plans for these children need to be made to ensure not only a stable, consistent environment that provides love and nurturing, but also the medical and social interventions necessary to cope with the tragic loss. Pediatricians should become aware of local laws and community resources and initiate discussion early in the course of parental illness to facilitate planning for the future care and custody of the children. States need to adopt laws and regulations that provide flexible approaches to guardianship and placement of children orphaned by acquired immunodeficiency syndrome.

ABBREVIATIONS. AIDS, acquired immunodeficiency syndrome; HIV, human immunodeficiency virus.

THE PROBLEM

Health care professionals caring for children of parents who are chronically or terminally ill with acquired immunodeficiency syndrome (AIDS) should consider raising the issue of planning for the future of these children at an appropriate time in the course of the parents' illness. It is estimated that by the end of this century, parental death caused by human immunodeficiency virus (HIV) infection or AIDS will result in as many as 80 000 orphaned children and adolescents in the United States.[1,2] For parents who face worsening illness and impending death, one of the most painful realizations is the inability to care for their children, plan their futures, and see them grow to maturity. In the context of HIV infection, both parents are likely to be infected and possibly ill or dying, and the mother may be quite isolated and not have assistance from the father of the children, who may have died or is unavailable. Future planning for the children can create peace of mind for parents by assuring that the children will be cared for according to the parents' wishes concerning their future. Future planning is a difficult and complex process that requires considerable time and effort and should be initiated in a sensitive manner early in the course of illness. Parents often are reluctant to initiate such planning because of a sense of guilt, denial of the seriousness of the illness, or fear that others may learn about the diagnosis.

Planning for the future of a child or adolescent who will be orphaned includes creating a stable, nurturing environment providing love and stability. At the same time, the legal framework and social interventions necessary must be provided for the child to cope with the loss of their parents and to receive necessary medical, mental health, and educational services.

BACKGROUND

Children and adolescents who are orphaned by the HIV/AIDS epidemic are generally from families who have experienced the consequences of poverty, lack of access to services, discrimination, and family disruption. They are most often cared for solely by their mother, with or without the assistance of other family members such as a grandmother.[3] It is, therefore, not surprising that parent(s) may be somewhat reluctant to discuss the issue of their own death and the planning for their children.[4,5] Parents with HIV/AIDS may fear the potential stigmatization and isolation from family and community that is associated with revealing the diagnosis. In addition, they may fear losing custody or parental rights to direct their child's future when they reveal concern about their future loss of capacity.[6] They also may be concerned about the burden imposed on potential guardians such as a grandmother, sister, or aunt, and may be reluctant to raise the issue of planning for their children. Most poignantly, the parents may be reluctant to face their own potential death and be unwilling to discuss their child's future with the child or with anyone else.[7]

A legal guardian is appointed by a court and is empowered, in lieu of a parent, to make day-to-day decisions for a child, including issues involving health care, housing, and education. Once a guardian has been appointed, that person assumes legal authority for the child even if the chronically ill parent and guardian have agreed informally that the guardian will not assume responsibility until the parent is no longer able. A parent can ask the court to designate a guardian for a child, but the other parent, if alive, must agree to the appointment or be judged to be unknown, unavailable, or determined to have relinquished parental rights. A parent can designate a guardian in a will, but the authority comes into effect only after the completion of the approval of the guardianship petition by the court after the death of the parent.[8–10] Some states have created flexible laws and regulations that aid ill parents in planning for

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

their children's future. New York, New Jersey, Illinois, Florida, North Carolina, and California have instituted a stand-by guardianship law to authorize a guardian to be temporarily or permanently designated by a chronically ill parent to make decisions for the child at a specified time such as at the death of the parent or when the parent becomes physically debilitated or mentally incapacitated. This guardianship arrangement can allow the parent to resume custody if sufficient health returns.[9] This approach allows maximal involvement of the parent while alive, and immediate clarification of guardianship for the child after the death of the parent.

Foster care agencies generally have not developed flexible policies for placement of children during episodes of parental illness and rapid return of the children to the parent when sufficient health warrants resumption of custody. This is particularly important as HIV infection becomes a chronic disease with multiple acute episodes of serious illness. Agencies also should make efforts to keep siblings from being separated or losing regular contact with one another when making foster care arrangements.

Children and adolescents who have experienced the death or face the impending death of a parent require sensitive bereavement counseling services including information, long-term emotional support, and preventive services.[11–13] Pediatricians should be aware of community and financial resources to assist such children and families and should monitor the grief process and provide appropriate anticipatory guidance and referral when needed.[14]

CONCLUSION

Because an increasing number of children and adolescents are being orphaned because of the death of their parents from HIV/AIDS, health care professionals should assist chronically ill and dying parents to plan for the future of their children. Creating loving and nurturing environments for such children by providing the legal framework; the counseling and other necessary social and financial services; and the stability of a clear, consistent family structure enhances the outcome for children while assuring that chronically ill parents participate actively in the planning process.

RECOMMENDATIONS

1. Health care professionals caring for the children and adolescents of chronically and terminally ill parents with AIDS should assist families to create a plan for the future care and custody of their children. This discussion should be initiated in a sensitive manner early in the course of parental illness and take place over an appropriate period consistent with disease severity and the course of the parents' illness.
2. Pediatricians should refer families for assistance with planning for the future well-being of their children to social service agencies that provide these services. When pediatricians are not aware of such agencies, they should advise parents to contact the HIV Resource Center or the Pediatric AIDS Foundation.
3. Pediatricians should advocate for laws that include provisions to authorize flexible and stand-by guardianship and that provide specific funding to facilitate planning for children with parents with HIV/AIDS who will become ill and have limited life expectancy.
4. Pediatricians should ask state and local child welfare agencies to develop flexible policies that permit temporary placement of children during parental illness and return of the children if the parent regains sufficient health. Whenever possible, such policies should not separate siblings. For those children who are HIV-infected themselves, policies should address the special concerns about the continuity of health care during placement.
5. Pediatricians should advocate for and assist in the development of state-funded programs that provide economic and social support to family members who care for children orphaned by HIV infection. Permanent adoption should be encouraged through the provision of social services and by decreasing economic disincentives.
6. Pediatricians should advocate for state-funded model programs that provide comprehensive mental health care, social support, and legal services for chronically ill HIV infected parents, their children, and future caregivers and guardians to enhance the well-being of the children and their families. Additional research is necessary and should be promoted by pediatricians to learn more about program effectiveness and the long-term outcomes of the children and their foster and adoptive families.

CLINICAL REPORT

Postdischarge Follow-up of Infants With Congenital Diaphragmatic Hernia

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Section on Surgery and the Committee on Fetus and Newborn

ABSTRACT

Infants with congenital diaphragmatic hernia often require intensive treatment after birth, have prolonged hospitalizations, and have other congenital anomalies. After discharge from the hospital, they may have long-term sequelae such as respiratory insufficiency, gastroesophageal reflux, poor growth, neurodevelopmental delay, behavior problems, hearing loss, hernia recurrence, and orthopedic deformities. Structured follow-up for these patients facilitates early recognition and treatment of these complications. In this report, follow-up of infants with congenital diaphragmatic hernia is outlined.

Key Words
congenital diaphragmatic hernia, gastroesophageal reflux, pulmonary hypoplasia, follow-up

Abbreviations
CDH— congenital diaphragmatic hernia
ECMO— extracorporeal membrane oxygenation

INTRODUCTION

Survival rates for patients with congenital diaphragmatic hernia (CDH) have increased during the past decade with the implementation of more "gentle" ventilation and physiology-specific strategies, high-frequency ventilation, extracorporeal membrane oxygenation (ECMO), and improved supportive care.[1–3] Improvement in survival rates has occurred for infants with CDH complicated by severe pulmonary hypoplasia, pulmonary hypertension, and chronic lung disease.[4] However, other significant morbidities, such as neurocognitive delay, gastroesophageal reflux, hearing loss, chest wall deformity, poor growth, hernia recurrence, and complications attributable to associated congenital anomalies, continue to affect the lives of many infants with CDH beyond the neonatal period.[1,5,6]

Coordination of the complex medical and surgical needs of these infants is challenging. Comprehensive multispecialty clinics that aggregate specialty physicians and services are family-friendly and provide for collaborative evaluation and management planning. Same-site multidisciplinary service teams also improve coordination, communication, and support for the medical home pediatrician who is responsible for managing the general health care needs of the infant. Unfortunately, such multispecialty clinics are not available to all infants with CDH. The following information is intended to provide clinicians who care for infants with CDH with a template to organize a comprehensive plan for detection and management of associated morbidities.

PULMONARY MORBIDITY

Survivors with CDH may require treatment beyond the initial hospitalization for chronic lung disease, bronchospasm, pulmonary hypertension, aspiration, pneumonia, and pulmonary hypoplasia. Oxygen treatment beyond the initial hospitalization may be needed for many of these infants, especially those who are treated with ECMO and a prosthetic patch.[7–9] Many survivors not treated with ECMO also receive bronchodilators and inhaled steroids.[8] At least 4% of survivors require a long-term tracheostomy.[9,10] Nearly one fourth of infants with CDH who survive have obstructive airway disease at 5 years of age,[10,11] and some have pulmonary hypertension that persists for months or years. Pulmonary hypertension that persists for more than the first few weeks after birth is a risk factor for early death.[12] Persistent abnormalities in lung function also have been demonstrated on ventilation/perfusion scans.[8,12–15]

Pneumonia occurs in approximately 7% of infants with CDH during the first year after birth.[5,16,17] Aspiration-associated pneumonia and bronchospasm may be reduced in frequency by avoiding oral feeding if oromotor incoordination is significant and by early detection and treatment of gastroesophageal reflux. Pneumonia may be prevented in part by treatment for chronic lung disease, effective management of pulmonary secretions, and immunization with recommended childhood vaccines (such as pneumococcal, influenza, and other recommended vaccines). Palivizumab (respiratory syncytial virus monoclonal antibody; Synagis [MedImmune, Inc, Gaithersburg,

MD]) also is suggested for infants with CDH who have chronic lung disease, as described in the "Revised Indications for the Use of Palivizumab and Respiratory Syncytial Virus Immune Globulin Intravenous for the Prevention of Respiratory Syncytial Virus Infections" technical report and policy statement by the American Academy of Pediatrics.[18,19]

Although the incidence of chronic lung disease is 33% to 52% at discharge, most infants who survive CDH have clinical improvement over time.[6,16,17] Nevertheless, nearly 50% of adult survivors have impairment on pulmonary function testing.[16]

GASTROESOPHAGEAL REFLUX/FOREGUT DYSMOTILITY

Gastroesophageal reflux or some form of foregut dysmotility occurs in 45% to 90% of infants with CDH.[20–24] Abnormal hiatal anatomy at the gastroesophageal junction, lack of an angle of His in some patients, and herniation of the stomach into the chest with distortion are possible mechanisms to explain this high incidence of gastroesophageal reflux. Esophageal dilation or ectasia also has been described in some infants with CDH, and as many as 70% of such infants have severe gastroesophageal reflux.[21] The incidence of gastroesophageal reflux also correlates with defect size and need for patch repair.[20,25] Pulmonary morbidity may be worsened by aspiration associated with gastroesophageal reflux. Importantly, a high incidence of esophagitis in adult survivors with CDH suggests that long-term surveillance is needed.[26] For all patients with CDH, it is important to have a high index of suspicion for gastroesophageal reflux. Antireflux surgery may be an option for patients with failed medical therapy, although the long-term success rate of this procedure has yet to be proven.

GROWTH FAILURE

Many survivors with CDH fail to grow as well as healthy term infants do and require close nutritional surveillance and intervention.[6,9,20] Infants with CDH and chronic lung disease often have poor oral feeding skills. Gastroesophageal reflux is common, and oral aversion is frequent; both contribute to growth deficiency. In 1 clinical series, more than 50% of infants with CDH had weight below the 25th percentile.[20] Gastrostomy tube placement was performed in 33% of infants in this series. Van Meurs et al[6] showed that more than 40% of CDH survivors had weight below the 5th percentile at 2 years of age. Gastrostomy tube feeding is suggested by some experts who hypothesize that nasogastric or orogastric tube feeding impairs oral feeding. Others suggest use of nasogastric or orogastric tube feeding for a period of time, especially when success with oral feeding is anticipated within several months. Despite controversy about the most appropriate mode of feeding the infant with CDH at discharge, almost 33% do not orally feed enough fluid volume to support growth and receive feedings through nasogastric or gastrostomy tubes.[6,20] Early recognition and intervention is essential for optimizing both somatic and alveolar growth and long-term outcomes for infants with CDH.

NEUROCOGNITIVE DELAY AND BEHAVIORAL DISORDERS

Significant developmental delay and behavioral disorders have been reported for a large number of infants with CDH. The infant with a large diaphragmatic defect or need for ECMO is at greatest risk.[27–36] Nobuhara et al[27] reported developmental delay in more than 33% of their CDH survivors. McGahren et al[30] described neurologic abnormalities in 67% of infants with CDH who were treated with ECMO compared with 24% of infants with CDH who were not as ill and did not receive ECMO.

The critical illness and physiologic disruption of high-risk infants with CDH places them at risk of neurologic and developmental disabilities. Many infants who present with symptoms of CDH soon after birth are clinically unstable and hypoxemic and require high levels of extraordinary life support such as ECMO and other invasive therapies. Although severity of illness is most predictive of long-term outcome, complications associated with invasive therapies may contribute to morbidity in CDH survivors. In a study by Bernbaum et al[37] of survivors receiving ECMO, infants with CDH treated with ECMO had a higher risk of significant neurodevelopmental delays than did infants without CDH. The higher risk of disability in ECMO-treated survivors with CDH compared with ECMO-treated survivors without CDH suggests that at least 3 potential factors may contribute to neurodevelopmental disability in infants with CDH: (1) an intrinsic neurologic abnormality, (2) greater number and severity of morbidities that impair development in infants who require ECMO, (3) and a greater number of ECMO-associated complications.

HEARING LOSS

Sensorineural hearing loss has been described in a number of case series of CDH survivors[27,28,33,35] and seems to occur in infants regardless of whether they were treated with ECMO. The cause remains unknown, but it is speculated to be related to treatments for respiratory failure (such as hyperventilation, ototoxic medications, or neuromuscular blockade).[38] Severe hypoxemia, prolonged ventilation, and ECMO also are risk factors. Approximately half of infants with initially normal hearing assessments develop hearing loss later in infancy.[39–41]

HERNIA RECURRENCE

Recurrent diaphragmatic hernias have been reported in 8% to 50% of patients with CDH. The single-most important predictor of hernia recurrence is the presence of a large defect that requires a patch to repair.[2,6,42,43] Recurrences can present from months to years after the initial hospitalization, or the patient can remain asymptomatic. Detection of recurrences may be discovered incidentally on chest radiographs performed for surveillance or other reasons.[6,43] The lifetime risk of recurrence for a patient with a patch repair is unknown.

ORTHOPEDIC DEFORMITIES

Pectus deformities and progressive asymmetry of the chest wall have been described in CDH survivors.[27,28,44] The incidence of these orthopedic disorders ranges from

TABLE 1 **Recommended Schedule of Follow-up for Infants With CDH**

	Before Discharge	1–3 mo After Birth	4–6 mo After Birth	9–12 mo After Birth	15–18 mo After Birth	Annual Through 16 y
Weight, length, occipital-frontal circumference	X	X	X	X	X	X
Chest radiograph	X	If patched	If patched	If patched	If patched	If patched
Pulmonary function testing			If indicated		If indicated	If indicated
Childhood immunizations	As indicated throughout childhood	X	X	X	X	X
RSV prophylaxis	RSV season during first 2 years after birth (if evidence of chronic lung disease)	X	X	X	X	X
Echocardiogram and cardiology follow-up	X	If previously abnormal or if on supplemental oxygen	If previously abnormal or if on supplemental oxygen	If previously abnormal or if on supplemental oxygen	If previously abnormal or if on supplemental oxygen	If previously abnormal or if on supplemental oxygen
Head computed tomography or MRI	If (1) abnormal finding on head ultrasound; (2) seizures/abnormal neurologic findings[a]; or (3) ECMO or patch repair	As indicated	As indicated	As indicated	As indicated	As indicated
Hearing evaluation[44]	Auditory brainstem evoked response or otoacoustic emissions screen	X	X	X	X	Every 6 mo to age 3 y, then annually to age 5 y
Developmental screening evaluation	X	X	X	X		Annually to age 5 y
Neurodevelopmental evaluation	X			X		Annually to age 5 y
Assessment for oral feeding problems	X	X	If oral feeding problems	If oral feeding problems	If oral feeding problems	If oral feeding problems
Upper gastrointestinal study, pH probe, and/or gastric scintiscan	Consider for all patients	If symptoms	If symptoms	Consider for all patients	If symptoms	If symptoms
Esophagoscopy		If symptoms	If symptoms	If symptoms or if abnormal gastrointestinal evaluations	If symptoms	If symptoms
Scoliosis and chest wall deformity screening (physical examination, chest radiograph, and/or computed tomography of the chest)				X		X

The neurosensory tests performed and frequency of surveillance may differ among infants with CDH because of variability in neurologic, developmental, and physiologic impairments. Follow-up should be tailored to each infant. RSV indicates respiratory syncytial virus.

[a] Muscle weakness, hypotonia, hypertonia, or other abnormal neurologic sign or symptom.

21% to 48%. Many of them are mild and do not require surgical intervention. Scoliosis also has been found in these patients, with an incidence of 10% to 27%.[27,44] The incidence of both of these morbidities is higher in patients who have large defects and a patch repair. Periodic and regular follow-up is suggested to detect and prevent development of functionally significant deformities from developing.

OTHER CONGENITAL ABNORMALITIES

Additional congenital anomalies are present in approximately 40% of infants with CDH.[45–48] Congenital heart lesions account for nearly two thirds of these anomalies and have a major effect on risk of mortality.[45,48] Anomalies of the central nervous system, esophageal atresia, and omphalocele also are relatively prevalent compared with other organ systems. A number of syndromes and chromosomal anomalies (such as trisomies 21, 13, and 18; Fryns syndrome; Brachmann-de Lange syndrome; and Pallister-Killian syndrome) include CDH as one of the associated anomalies. Each of these anomalies and syndromes adds to the complexity and specialty care needs for affected infants. The care requirements for such infants necessitate individualized, multidisciplinary care plans.

SUMMARY

Survivors with CDH are at risk of a number of morbidities that may affect development and function. Infants with large defects, those who have received ECMO, or those with a patch repair are at highest risk. These unique patients, especially those at highest risk, require long-term periodic follow-up by a multidisciplinary team of medical, surgical, and developmental specialists to identify and treat morbidities before additional disability results. Preventive pediatric health care according to guidelines developed by the American Academy of Pediatrics is recommended for all children, including those with CDH.[49–52] To emphasize the importance of follow-up for specific morbidities associated with CDH, additional suggestions are provided (Table 1). These are most applicable to children with extraordinary medical and surgical complications associated with CDH and should be individualized depending on the specific needs of each infant.

Policy Statement—Postnatal Corticosteroids to Prevent or Treat Bronchopulmonary Dysplasia

abstract

FREE

The purpose of this revised statement is to review current information on the use of postnatal glucocorticoids to prevent or treat bronchopulmonary dysplasia in the preterm infant and to make updated recommendations regarding their use. High-dose dexamethasone (0.5 mg/kg per day) does not seem to confer additional therapeutic benefit over lower doses and is not recommended. Evidence is insufficient to make a recommendation regarding other glucocorticoid doses and preparations. The clinician must use clinical judgment when attempting to balance the potential adverse effects of glucocorticoid treatment with those of bronchopulmonary dysplasia. *Pediatrics* 2010;126:800–808

INTRODUCTION

Chronic lung disease (CLD) after preterm birth, also known as bronchopulmonary dysplasia (BPD), a major morbidity of the very preterm infant, is remarkably resistant to therapeutic interventions and negatively affects neurodevelopmental outcomes.[1–4] In 2002, the American Academy of Pediatrics (AAP), in a policy statement regarding the use of postnatal corticosteroids for prevention or treatment of CLD in preterm infants, concluded that routine dexamethasone therapy for the prevention or treatment of CLD could not be recommended.[5] Instead, the AAP recommended that (1) use of dexamethasone for the prevention or treatment of CLD be limited to randomized, controlled trials (RCTs) with long-term follow-up, (2) alternative corticosteroids undergo further study, and (3) infants currently enrolled in RCTs of corticosteroids receive long-term neurodevelopmental follow-up. The statement added that outside the context of such trials, "the use of corticosteroids should be limited to exceptional clinical circumstances (eg, an infant on maximal ventilatory and oxygen support). In those circumstances, parents should be fully informed about the known short- and long-term risks and agree to treatment."[5]

Postnatal use of dexamethasone for BPD has decreased since the publication of the AAP statement; however, the incidence of BPD has not decreased.[6] Instead, several reports have suggested that the incidence or severity of BPD may have increased.[4,7,8] Moreover, results of additional clinical trials, meta-analyses, and follow-up studies have been published, warranting a review of the new information and revision of the statement. The objectives of this revised statement are to review data published since the 2002 AAP statement and to reexamine previous recommendations for the use of glucocorticoid therapy in view of new information.

LITERATURE REVIEW

Dexamethasone

Reviews and meta-analyses cited in the previous AAP statement indicated that dexamethasone may decrease mortality rates, facilitate extubation, and generally decrease the incidence of BPD but that it carries a significant risk for short- and long-term adverse effects, especially impairment of growth and neurodevelopment.[5,9–12] In recently updated systematic reviews, the Cochrane Collaboration continues to conclude that the benefits of dexamethasone therapy in the first week of life may not outweigh its many adverse effects.[13] In contrast, it concludes that treatment after the first postnatal week may reduce mortality rates without increasing adverse long-term neurodevelopmental outcomes, although long-term follow-up data remain limited.[14] Therefore, it has been suggested that "it appears prudent to reserve the use of late corticosteroids to infants who cannot be weaned from mechanical ventilation and to minimize the dose and duration of any course of treatment."[14]

Two other systematic reviews have added different perspectives on dexamethasone and BPD. In the first review, a risk-weighted meta-analysis, the authors emphasized the importance of the a priori risk of death or BPD in different study populations.[15] In this analysis, the incidence of death or cerebral palsy (CP) was increased among dexamethasone-treated infants compared with placebo-treated infants in studies that enrolled patients at low risk (<35%) of BPD. In contrast, dexamethasone treatment decreased the risk of death or CP when infants at high risk of BPD (≥65%) were studied.[15] Thus, for infants at the highest risk of BPD, the beneficial effect of dexamethasone in reducing lung disease seemed to outweigh its adverse effect of increasing the risk of CP. In the second meta-analysis, the authors compared outcomes for trials with different cumulative doses of dexamethasone and concluded that a higher cumulative dose improved rates of survival without BPD and did not increase adverse long-term effects.[16] However, 3 small individual RCTs that directly compared high versus low dexamethasone doses, variably defined, have revealed no differences in efficacy (Table 1).[17–19] These studies have generally been small and heterogeneous, which makes them difficult to compare.

The results of 3 RCTs that compared dexamethasone to placebo have been published since the previous AAP statement (Table 1); 1 was small and the other 2 were stopped early and are, therefore, underpowered.[20–22] One trial compared an early, short course

TABLE 1 RCTs of Dexamethasone to Prevent or Treat BPD Reported Since 2001

Study, No. of Centers	*n*	Eligibility Criteria (All on Mechanical Ventilation)	Dexamethasone Dosing Regimen	Outcome
McEvoy et al,[17] 1 center	62	500–1500 g BW; ≤32 wk gestation; 7–21 postnatal days	5 mg/kg per d tapered over 7 d vs 0.2 mg/kg tapered over 7 d	Rate of survival without BPD[a] 76% vs 73% (NS); no benefit to higher dose
Odd et al,[18] 1 center	33	≤1250 g BW; 1–3 wk of age	0.5 mg/kg per d tapered over 42 d vs "individualized" (same dose, shorter course)	Rate of survival without BPD: 24% vs 30% (NS); no difference in 18-mo outcomes
Malloy et al,[19] 1 center	16[b]	<1501 g BW; <34 wk gestation; <28 postnatal days	0.5 mg/kg per d tapered over 7 d vs 0.08 mg/kg per d for 7 d	Rate of survival without BPD: 11% vs 38% (NS); higher dose had more adverse effects, no apparent benefit
Walther et al,[20] 1 center	36	≥600 g BW; 24–32 wk gestation; 7–14 d postnatal age	0.2 mg/kg per d tapered over 14 d vs placebo	Rate of survival without BPD: 65% vs 47% (NS); extubation: 76% vs 42% ($P < .05$)
Anttila et al,[21] 6 centers	109[b]	500–999 g BW; ≤31 wk gestation; eligible at 4 h of age	0.25 mg/kg every 12 h × 4 doses vs placebo	Rate of survival without BPD: 58% vs 52% (NS)
Doyle et al,[22] 11 centers	70[b]	<1000 g BW; <28 wk gestation; >1 wk postnatal age	0.15 mg/kg per d tapered over 10 d vs placebo	Rate of survival without BPD: 14% vs 9% (NS); extubation: 60% vs 12% (odds ratio: 11.2 [95% confidence interval: 3.2–39.0])
Rozycki et al,[23] 1 center	61	650–2000 g BW; ≥ 14 d postnatal age	0.5 mg/kg per d tapered over 42 d vs inhaled beclomethasone at 3 different doses for 7 d followed by above-listed dexamethasone course, if still mechanically ventilated	Rate of survival without BPD: 53% vs 46% (NS); extubation by 7 d: 7 of 15 vs 6 of 46 ($P < .01$)

BW indicates birth weight; NS, not significant.

[a] BPD defined as receiving supplemental oxygen at 36 weeks postmenstrual age.

[b] Patient enrollment terminated early.

of dexamethasone to placebo and revealed no significant difference in mortality or BPD rates.[21] The other 2 trials evaluated the efficacy of a later, lower-dose course of dexamethasone for facilitating extubation, and the authors reported that significantly more dexamethasone-treated infants were successfully extubated during the treatment period.[20,22] Similar results were reported from an additional study that compared systemic dexamethasone to inhaled beclomethasone for extubation: significantly more dexamethasone-treated infants were successfully extubated within 7 days (Table 1).[23] These extubation trials were not powered to evaluate the effect of the treatment on rates of survival without BPD.

Many short-term adverse effects of dexamethasone therapy have been described; however, the main reason for the decline in its use is an adverse effect on neurodevelopment, particularly higher rates of CP. Since publication of the previous AAP statement, additional follow-up data on the adverse effects of dexamethasone have become available from RCTs (Table 2).[17,24–32] The heterogeneity of these reports makes it problematic to combine them meaningfully. Some studies revealed no adverse effects on neurodevelopmental outcomes at various ages, whereas others did. Most of the studies were small, which reduced their ability to either prove or disprove causation. Two RCTs that used low doses of dexamethasone revealed no significant increase in CP or other neurodevelopmental impairments when compared with placebo. Because only a total of 96 dexamethasone-treated infants were evaluated in these studies, the results must be interpreted with caution.[25,26]

Cohort studies of dexamethasone have revealed an association of its use with

TABLE 2 Neurodevelopmental Follow-up of Dexamethasone RCTs Reported After 2001

Study, Planned Age at Follow-up	Follow-up, % (No. of Infants Seen)	Treatment Start Time	Dexamethasone Dosing Regimen	Primary Neurodevelopmental Findings
McEvoy et al,[17] 1 y	66 (39)	At 7–21 d	High vs low dose: 7-d taper from 0.5 mg/kg per d vs 0.2 mg/kg per d	MDI < 70: 24% (high) vs 17% (low) (NS); CP: 10% vs 11% (NS)
Armstrong et al,[24] 18 mo chronological age	96 (64)	On day 7	42-d taper vs 3-d pulse	No difference in 18-mo outcomes No disability: 34% vs 31% (NS)
Doyle et al,[25] 2 y corrected age	98 (58)	After 7 d	0.15 mg/kg per d tapered over 10 d	Death or major disability: 46% vs 43% (NS); death or CP: 23% vs 37% (NS); CP: 14% vs 22% (NS); major disability 41% vs 31% (NS)
Stark et al,[26] 18–22 mo corrected age	74 (123)	On day 1	0.15 mg/kg per d tapered over 7 d	MDI < 70: 51% vs 43% (NS); PDI < 70: 30% vs 35% (NS); abnormal neurologic exam: 25% each group
Romagnoli et al,[27] 3 y	100 (30)	On day 4	0.5 mg/kg per d tapered over 1 wk	No differences in any parameter; CP: 9% vs 14% (NS)
Wilson et al,[28] 7 y	84 (127)	Before 3 d	4 groups: 0.5 mg/kg per d tapered over 12 d vs late (15 d) selective, vs inhaled early or late selective	No difference in cognitive, behavioral, CP, or combined outcomes
Yeh et al,[29] school age (mean: 8 y)	92 (146)	On day 1	0.5 mg/kg per d for 1 wk, then tapered for a total of 28 d	Treated children were shorter ($P = .03$), had smaller head circumference ($P = .04$), lower IQ scores ($P = .008$), and more significant disabilities (CP, IQ < 5th percentile, vision or hearing impairment): 39% vs 22% ($P = .04$)
O'Shea et al,[30] 4–11 y	89 (84)	On day 15–25	0.5 mg/kg per d tapered over 42 d vs placebo	Death or major NDI[a]: 47% vs 41% (NS); major NDI alone: 36% vs 14% ($P = .01$)
Gross et al,[31] 15 y	100 (22)	On day 14	0.5 mg/kg per d tapered over 42 d vs 18-d taper vs placebo	Intact survival (IQ > 70, normal neurologic exam, regular classroom): 69% vs 25% (18-d course) vs 18% (placebo) ($P < .05$)
Jones and the Collaborative Dexamethasone Trial Follow-up Group,[32] 13–17 y	95 (150)	At 2–12 wk	0.5 mg/kg per d for 7 d	No difference in moderate/severe disability (defined as IQ > 2 SDs < mean, CP, hearing or vision loss); CP: 24% vs 15% (relative risk: 1.58 [95% confidence interval: 0.81–3.07])

MDI indicates Bayley Mental Developmental Index; NS, not significant. PDI, Bayley Psychomotor Development Index; NDI, neurodevelopmental impairment.

[a] Major neurodevelopmental impairment included CP and/or an IQ score of <70.

impaired neurodevelopmental outcomes[3,4,33]; however, such an association cannot be construed as definitive evidence of harm. A clinician's decision to use a therapy incorporates numerous undocumented factors and varies from one clinician to the next, which may seriously confound the interpretation of such studies. Patients who receive dexamethasone for BPD are likely to be perceived as having more severe respiratory disease than infants who are not treated; such infants may have worse overall outcomes regardless of dexamethasone therapy. Authors of small series have also reported that infants treated with dexamethasone have more abnormalities on MRI than those not treated; again, causation cannot be attributed in the absence of an RCT.[34,35] Two previously reported RCTs revealed more cranial ultrasound abnormalities in dexamethasone-treated infants compared with those treated with placebo, but the patient numbers were quite small.[36,37]

In summary, high daily doses of dexamethasone have been linked frequently to adverse neurodevelopmental outcomes, and this therapy is discouraged. Because an increase in adverse neurodevelopmental outcomes in treatment studies that used low doses of dexamethasone has not been reported, further studies of low-dose dexamethasone to facilitate extubation are warranted.

Hydrocortisone

Results of 4 RCTs designed to evaluate the ability of early hydrocortisone therapy to improve rates of survival without BPD have been published (Table 3).[38–41] These studies were based on the premise that extremely preterm infants may have immature adrenal gland function, predisposing them to a relative adrenal insufficiency and inadequate anti-inflammatory capability during the first several weeks of life.[42–46] In contrast to the heterogeneous nature of previous dexamethasone trials, these studies were similar in design, time of initiation, duration, and dose. The direction of effect favored the hydrocortisone-treated infants in all 4 studies, and a significant increase in rate of survival without BPD in the hydrocortisone-treated infants was reported for 2 of the studies. The largest trial ($n = 360$) did not reveal a significant benefit of hydrocortisone treatment in the overall study group; however, for infants exposed to prenatal inflammation ($n = 149$), identified before the trial as a specific group for analysis, hydrocortisone treatment resulted in a significant decrease in mortality rate and an increase in rate of survival without BPD.[39]

Patient enrollment was halted early in 3 of these 4 studies because of a significant increase in spontaneous gastrointestinal perforation discovered in the largest trial,[39] a complication also observed with early dexamethasone.[47,48] The perforations may have resulted from an interaction between high endogenous cortisol concentrations and indomethacin therapy in the first 48 hours; however, because administration of indomethacin was not randomized, this hypothesis remains to be tested.

Neurodevelopmental outcomes at 18 to 22 months' corrected age have been published for 3 of these trials, and no adverse effects of hydrocortisone treatment were found.[49,50] In the largest multicenter trial, the incidence of death or major neurodevelopmental impairment (52% [hydrocortisone-treated] vs 56% [placebo]), major neurodevelopmental impairment alone (39% vs 44%), and CP (16% vs 18%) were similar.[49] The only significant findings favored the hydrocortisone-treated group and included a decreased incidence of a Bayley Scales of Infant Development (2nd ed) Mental Developmental Index (MDI) 2 SDs below the mean (MDI $<$ 70, 27% vs 37%;

TABLE 3 RCTs of Early Hydrocortisone to Prevent BPD

Study, No. of Centers	*n*	Population: Mechanically Ventilated Infants	Hydrocortisone Dosing Regimen	Rate of Survival Without BPD[a] HC vs Placebo, %
Watterberg et al,[38] 2 centers	40	500–999 g BW; <48 h postnatal age	0.5 mg/kg every 12 h for 9 d 0.25 mg/kg every 12 h for 3 d	60 vs 35 ($P = .04$)
Watterberg et al,[39] 9 centers	360[b]	500–999 g BW; <48 h postnatal age	0.5 mg/kg every 12 h for 12 d 0.25 mg/kg every 12 h for 3 d	35 vs 34 (aOR[c]: 1.20 [95% CI: 0.72–1.99])
Peltoniemi et al,[40] 3 centers	51[b]	501–1250 g BW; <36 h postnatal age	2.0 mg/kg per d tapered to 0.75 mg/kg per d over 10 d	64 vs 46 (OR: 1.48 [95% CI: 0.49–4.48])

BW indicates birth weight; aOR, adjusted odds ratio; OR, odds ratio; CI, confidence interval.

[a] BPD was defined as receiving supplemental oxygen at 36 weeks' postmenstrual age.

[b] Study enrollment was terminated early because of concern for spontaneous gastrointestinal perforation.

[c] Adjusted for center, birth weight, risk factors (gender, "outborn" [infants who were born at an outlying institution and transported into the study center], white race, vaginal delivery, no prenatal steroids, hydrocortisone, and/or vasopressor support at study entry).

odds ratio: 0.47 [95% confidence interval: 0.25–0.87]) and a higher incidence of awareness of object permanence (an early test of working memory and prefrontal executive function) (89% vs 79%; odds ratio: 2.19 [95% confidence interval: 1.06–4.52]).

Two other RCTs have evaluated administration of hydrocortisone to preterm infants during the first week of life with the objective of reducing respiratory morbidity. The first, published in 1974, had the objective of decreasing the severity of respiratory distress syndrome.[51] The investigators used a much higher dose (25 mg/kg per day on the first day of postnatal life), which showed no effect on respiratory distress syndrome. The second, published in 2003, was based on the hypothesis that extremely preterm infants have immature sodium channels and, therefore, cannot clear their lung liquid after birth.[52] Triiodothyronine (T_3) was given together with hydrocortisone to stimulate maturation of the sodium channels. The medications were started within 5 hours of birth and given as a constant infusion for 7 days. The investigators enrolled 253 infants and found no difference in their primary outcome variables of death or ventilator dependence at 7 days and at 14 days. At 36 weeks' postmenstrual age, 47% of the treated survivors and 51% of the placebo group remained on oxygen.

Reports of hydrocortisone therapy given to facilitate extubation have been limited to cohort studies. In the first reported study, 25 infants treated with hydrocortisone at 1 hospital (5 mg/kg per day, tapered over 3 weeks) were compared with 25 untreated infants at the same hospital and additionally with a cohort of 23 infants treated with dexamethasone (0.5 mg/kg per day, tapered over 3 weeks) at a separate hospital.[53] The investigators found that hydrocortisone was as effective as dexamethasone in weaning infants from the ventilator and in decreasing supplemental oxygen therapy, with fewer short-term adverse effects. Follow-up of these children at school age revealed no differences in neurodevelopmental outcomes between hydrocortisone-treated infants and their comparison group, whereas dexamethasone-treated infants more often had an abnormal neurologic examination and less favorable school performance than their comparison cohort.[53,54] Subsequently, several large cohort studies from the same institution reported that, although hydrocortisone-treated children were younger, smaller, and sicker than their untreated comparison groups, there were no adverse effects of hydrocortisone treatment on IQ, visual motor integration, memory testing, CP, or findings on MRI.[55–57] Investigators from this institution have also reported that neonatal dexamethasone but not hydrocortisone therapy resulted in long-lasting changes in hypothalamic-pituitary-adrenal axis and T-cell function.[58]

Other Glucocorticoids (Systemic or Inhaled)

Since the previous AAP statement, no RCTs of other systemic glucocorticoids, such as prednisone or methylprednisolone, to treat or prevent BPD have been published. No additional evidence has been published to support the efficacy of inhaled glucocorticoids to prevent or decrease the severity of BPD.[59,60]

DISCUSSION: DIFFERENCES BETWEEN DEXAMETHASONE AND HYDROCORTISONE

As described previously, many RCTs have shown adverse neurodevelopmental outcomes after postnatal dexamethasone treatment for BPD, but neither multicenter RCTs nor cohort studies have revealed adverse effects on functional or structural neurologic outcomes after neonatal hydrocortisone therapy. One possible explanation for the observed differences between dexamethasone and hydrocortisone is the difference in effective glucocorticoid dose. Neonatal animal studies have consistently revealed adverse effects on brain growth after high doses of glucocorticoid,[61,62] and results of evaluation of 22 patients who received high-dose hydrocortisone in a study from the early 1970s were suggestive of harm.[63,64] High-dose dexamethasone (0.5 mg/kg per day) is equivalent to at least 15 to 20 mg/kg per day of hydrocortisone,[65] far higher than the doses of hydrocortisone given in the recent studies described previously. Low-dose dexamethasone (0.1–0.15 mg/kg per day) may be equivalent to 3 to 6 mg/kg per day of hydrocortisone; however, because of its much longer biological half-life, it could have a much higher relative potency.[66] Lowering the dose of dexamethasone may, therefore, decrease its adverse effects, as is suggested by the 2 studies of outcome after lower-dose dexamethasone therapy.[25,26]

Second, the observed differences in neurodevelopmental outcomes may result from the different effects of these agents on the hippocampus, an area of the brain critical to learning, memory, and spatial processing.[67,68] The hippocampus contains a high density of both mineralocorticoid and glucocorticoid receptors.[69,70] Hydrocortisone, which is identical to native cortisol, can bind to both classes of receptors. In contrast, dexamethasone binds only to glucocorticoid receptors, which, in animal models, has been shown to result in degeneration and necrosis of hippocampal neurons.[71,72] This effect of dexamethasone is blocked by simultaneous administration of corticosterone (the cortisol equivalent in the rat).[71] In humans,

neonatal treatment with dexamethasone, but not hydrocortisone, has been shown to alter hippocampal synaptic plasticity and associative memory formation in later life.[73] Dexamethasone exposure has also been linked to decreased hippocampal volume in 1 cohort study,[74] but cohort studies of infants treated with hydrocortisone have revealed no decrease in hippocampal volume,[55] no adverse effect on hippocampal metabolism, and no adverse effect on memory at school age[57] when compared with a larger, more mature group of nontreated infants.

Whatever the underlying explanation(s) for the observed differences in short- and long-term outcomes may be, further RCTs are needed to answer the many remaining questions, including whether lower doses of dexamethasone can avoid previously observed adverse effects, whether hydrocortisone is efficacious for extubation, whether specific groups of infants may derive particular benefit from hydrocortisone therapy, and whether the incidence of spontaneous gastrointestinal perforation during early glucocorticoid administration can be decreased by avoiding concomitant indomethacin or ibuprofen therapy and/or by monitoring cortisol concentrations.

SUMMARY AND RECOMMENDATIONS

- BPD remains a major morbidity of the extremely preterm infant and is consistently associated with adverse effects on long-term outcomes, including neurodevelopment. Additional RCTs of postnatal glucocorticoids are warranted to optimize therapy and improve outcomes for these infants. Those who design such trials in the future should attempt to minimize the use of open-label glucocorticoid, which has confounded analysis of most previous trials, and should include assessment of long-term pulmonary and neurodevelopmental outcomes.
- High daily doses of dexamethasone (approximately 0.5 mg/kg per day) have been shown to reduce the incidence of BPD but have been associated with numerous short- and long-term adverse outcomes, including neurodevelopmental impairment, and at present there is no basis for postulating that high daily doses confer additional therapeutic benefit over lower-dose therapy. **Recommendation: in the absence of randomized trial results showing improved short- and long-term outcomes, therapy with high-dose dexamethasone cannot be recommended.**
- Low-dose dexamethasone therapy (<0.2 mg/kg per day) may facilitate extubation and may decrease the incidence of short- and long-term adverse effects observed with higher doses of dexamethasone. Additional RCTs sufficiently powered to evaluate the effects of low-dose dexamethasone therapy on rates of survival without BPD, as well as on other short- and long-term outcomes, are warranted. **Recommendation: there is insufficient evidence to make a recommendation regarding treatment with low-dose dexamethasone.**
- Low-dose hydrocortisone therapy (1 mg/kg per day) given for the first 2 weeks of life may increase rates of survival without BPD, particularly for infants delivered in a setting of prenatal inflammation, without adversely affecting neurodevelopmental outcomes. Clinicians should be aware of a possible increased risk of isolated intestinal perforation associated with early concomitant treatment with inhibitors of prostaglandin synthesis. Further RCTs powered to detect effects on neurodevelopmental outcomes, aimed at targeting patients who may derive most benefit and developing treatment strategies to reduce the incidence of isolated intestinal perforation, are warranted. **Recommendation: early hydrocortisone treatment may be beneficial in a specific population of patients; however, there is insufficient evidence to recommend its use for all infants at risk of BPD.**
- Higher doses of hydrocortisone (3–6 mg/kg per day) instituted after the first week of postnatal age have not been shown to improve rates of survival without BPD in any RCT. RCTs powered to assess the effect of this therapy on short- and long-term outcomes are needed. **Recommendation: existing data are insufficient to make a recommendation regarding treatment with high-dose hydrocortisone.**

IMPLICATIONS FOR PRACTICE

Because available data are conflicting and inconclusive, clinicians must use their own clinical judgment to balance the adverse effects of BPD with the potential adverse effects of treatments for each individual patient. Very low birth weight infants who remain on mechanical ventilation after 1 to 2 weeks of age are at very high risk of developing BPD.[14] When considering corticosteroid therapy for such an infant, clinicians might conclude that the risks of a short course of glucocorticoid therapy to mitigate BPD is warranted.[15] This individualized decision should be made in conjunction with the infant's parents.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Peter L. Havens, MD, and the Committee on Pediatric AIDS

Postexposure Prophylaxis in Children and Adolescents for Nonoccupational Exposure to Human Immunodeficiency Virus

ABSTRACT. Exposure to human immunodeficiency virus (HIV) can occur in a number of situations unique to, or more common among, children and adolescents. Guidelines for postexposure prophylaxis (PEP) for occupational and nonoccupational (eg, sexual, needle-sharing) exposures to HIV have been published by the US Public Health Service, but they do not directly address nonoccupational HIV exposures unique to children (such as accidental exposure to human milk from a woman infected with HIV or a puncture wound from a discarded needle on a playground), and they do not provide antiretroviral drug information relevant to PEP in children.

This clinical report reviews issues of potential exposure of children and adolescents to HIV and gives recommendations for PEP in those situations. The risk of HIV transmission from nonoccupational, nonperinatal exposure is generally low. Transmission risk is modified by factors related to the source and extent of exposure. Determination of the HIV infection status of the exposure source may not be possible, and data on transmission risk by exposure type may not exist. Except in the setting of perinatal transmission, no studies have demonstrated the safety and efficacy of postexposure use of antiretroviral drugs for the prevention of HIV transmission in nonoccupational settings. Antiretroviral therapy used for PEP is associated with significant toxicity. The decision to initiate prophylaxis needs to be made in consultation with the patient, the family, and a clinician with experience in treatment of persons with HIV infection. If instituted, therapy should be started as soon as possible after an exposure—no later than 72 hours—and continued for 28 days. Many clinicians would use 3 drugs for PEP regimens, although 2 drugs may be considered in certain circumstances. Instruction for avoiding secondary transmission should be given. Careful follow-up is needed for psychologic support, encouragement of medication adherence, toxicity monitoring, and serial HIV antibody testing.

ABBREVIATIONS. HIV, human immunodeficiency virus; USPHS, US Public Health Service; PEP, postexposure prophylaxis; CDC, Centers for Disease Control and Prevention; CI, confidence interval; AIDS, acquired immunodeficiency syndrome; PI, protease inhibitor; NRTI, nucleoside analog reverse transcriptase inhibitor; PCR, polymerase chain reaction; ZDV, zidovudine.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

INTRODUCTION

Exposure to human immunodeficiency virus (HIV) can occur in a number of situations unique to or more common among children and adolescents. Guidelines for prophylaxis after exposure to HIV in occupational and nonoccupational (eg, sexual, needle-sharing) settings have been published by the US Public Health Service (USPHS),[1–3] but they do not directly address nonoccupational HIV exposures unique to children (such as accidental exposure to human milk from a woman infected with HIV or a puncture wound from a discarded needle on a playground), and they do not provide antiretroviral drug information relevant to postexposure prophylaxis (PEP) in children.

This clinical report provides a review of the literature focused on issues of HIV exposure uniquely related to children and adolescents and gives recommendations for PEP in the following situations: injury from discarded needles, bite wounds, sexual exposure, and inadvertent exposure to human milk from an HIV-infected woman. In each setting, the risk of HIV transmission is directly related to the probability that the exposure source has HIV infection and that transmission of a sufficient amount of infectious virus occurred in a manner that could result in infection in the recipient. Because no studies have directly measured the effectiveness of PEP in decreasing the risk of HIV transmission in nonoccupational settings or after mucosal exposure, the potential benefit of PEP in modifying transmission risk is extrapolated from data regarding HIV pathogenesis in animals, from information about PEP for needlestick injuries in occupational settings, and from studies of vertical transmission of HIV.

Type of Source Material

Not all body fluids from persons with HIV infection are equally infectious (Table 1). Blood and fluids contaminated with blood from persons with HIV infection should be assumed to contain HIV and are associated with the highest risk of HIV transmission. Semen or vaginal secretions, cerebrospinal fluid, synovial fluid, pleural fluid, peritoneal fluid, pericardial fluid, amniotic fluid, human milk, and unfixed tissue from persons with HIV infection also may contain HIV and should be considered infectious.

TABLE 1. Materials That May Contain HIV From Persons With HIV Infection[1]

Usually Infectious Materials*	Usually Infectious Materials†	Usually Noninfectious Materials
Concentrated HIV in a laboratory specimen	Semen	Saliva
Blood[1]	Vaginal secretions	Urine
Fluid contaminated with blood	Cerebrospinal fluid	Feces
	Synovial fluid	Tears
	Pleural fluid	Sweat
	Peritoneal fluid	Vomitus
	Pericardial fluid	Nasal secretions
	Amniotic fluid	Sputum
	Human milk	
	Unfixed body tissue	

* Most likely to be associated with a risk of HIV transmission.
† May contain HIV, but less likely to be associated with risk of HIV transmission.

However, exposure to these "other potentially infectious materials"[1] is associated with a lower risk of HIV transmission. Blood-free saliva, urine, feces (including diarrhea), and vomitus are highly unlikely to transmit HIV.

Volume of Source Material

Exposure to a large volume of infectious material carries a greater risk of HIV transmission than does exposure to a smaller volume. For example, in studies of health care professionals with percutaneous exposure to blood from persons with HIV infection (Table 2),[4] injuries with large-gauge, hollow-bore needles were 14 times as likely to result in HIV transmission as were injuries with smaller-gauge, hollow needles; solid suture needles; or solid objects (such as a scalpel; Table 2).[4] Risk is also greater after exposure to a needle on which blood is visible, compared with that after exposure to a needle on which blood is not visible.[4]

Concentration of Virus in Source Material

In addition to the volume of source material, the concentration of virus in the source material is an important factor in determining the risk of transmission after an exposure. The concentration of virus in blood is highest during early (primary) HIV infection, before the infected person has fully developed an immune response, and late in infection, when immunity wanes. Some persons with HIV infection have persistently high viral load. Percutaneous exposure to blood from a person with late-stage HIV infection increases transmission risk by more than fivefold (Table 2).[4] For persons 15 to 24 years of age, for each act of heterosexual intercourse, risk of HIV transmission varies from 0.01% at viral loads less than 1700 copies/mL to 0.3% at viral loads more than 38 500 copies/mL.[5] Risk of perinatal transmission is higher for mothers with late-stage HIV disease. Prenatal maternal HIV viral load is a critical factor in determining the risk of perinatal HIV transmission.[6,7] Treatment with antiretroviral drugs can decrease the concentration of virus in blood and body fluids, even in persons with primary or late-stage infection. Therefore, antiretroviral treatment of the HIV infected individual may be associated with decreased risk of sexual and perinatal HIV transmission. However, although antiretroviral therapy for an HIV-infected source patient may decrease viral load, transmission has occurred after exposure to blood or infectious body fluids from HIV-infected persons with plasma viral loads below the level of detection, perhaps from cell-associated virus. Although there is a correlation between plasma and genital viral load, HIV may be present in genital secretions even when undetectable in plasma.[8]

TABLE 2. Percutaneous Exposure to Blood Infected With HIV: Risk Factors for HIV Transmission[4]

Risk Factor	Adjusted Odds Ratio*	95% CI
Deep injury	15	6.0–41
Visible blood on device	6.2	2.2–21
Procedure involving needle in artery or vein	4.3	1.7–12
Terminal illness in source patient	5.6	2.0–16
Postexposure use of ZDV	0.19	0.06–0.52

* Based on logistic regression analysis of 33 case patients and 665 controls reported by national surveillance systems in France, Italy, the United Kingdom, and the United States.

Viability of Virus in Source Material

The viability of virus in the source material also is an important consideration when evaluating the significance of a potential exposure to HIV, especially in the setting of a puncture wound from a needle found in the community setting.[9] In most reports of HIV transmission by percutaneous injury, needlestick injury occurred shortly after needle withdrawal from the vein or artery of the source patient with HIV infection. HIV RNA was detected in only 3 (3.8%) of 80 discarded disposable syringes that had been used by health care professionals for intramuscular or subcutaneous injection of patients with HIV infection,[10] indicating that most syringes will not contain HIV even after being used to draw blood from a person with HIV infection. HIV is susceptible to drying, and when HIV is placed on a surface exposed to air, the 50% tissue culture infective dose decreases by ~6 logs in 72 hours (1 log every 9 hours).[11] The concentration of viable virus on a discarded needle will be related to the initial virus concentration and the time that contaminated material has been drying.[12] Such drying may not occur uniformly; if there are cells, tissue, or a blood clot inside the needle, drying and virus inactivation may be slower than for a thin uniform layer of fluid on the outside of a

needle, and in the laboratory setting, HIV has been shown to survive for up to 28 days in syringes containing as little as 20 μL of blood.[13] HIV survival may be less likely outside the laboratory, and HIV proviral DNA could not be found in 28 syringes discarded in public places and 10 syringes from a needle exchange program for injection drug users.[14] Two small studies have found no evidence of HIV transmission after injuries from needles of discarded syringes.[15,16] There have been no confirmed reports of HIV acquisition from percutaneous injury by a needle found in the community (M.G. Fowler, Epidemiology Branch, Division of HIV/AIDS, Centers for Disease Control and Prevention [CDC], personal communication, June 15, 2002).

Type of Contact

The type of contact between the infectious fluid and a susceptible person is an important determinant of the risk of HIV transmission (Table 3). Blood transfusion from an HIV-infected donor carries a 95% risk of HIV transmission.[17] The risk of perinatal HIV transmission is between 13% and 45% in the absence of prophylaxis with antiretroviral medications.[18,19]

The risk of HIV transmission from breastfeeding is associated with maternal stage of infection and duration of breastfeeding. For women who acquire HIV infection after giving birth, the transmission risk from breastfeeding is estimated to be 29% (95% confidence interval [CI], 16%–42%).[20] For women with chronic HIV infection, transmission risk from breastfeeding is estimated to be 10% to 16%.[20–23] The cumulative risk of transmission if breastfeeding for 5, 11, 17, and 23 months was 3.5%, 7.0%, 8.9%, and 10.3%.[21] Using these estimates of cumulative risk and assuming that a mother breastfeeds 6 to 10 times per day, the per-episode risk of HIV transmission from a single exposure to human milk is estimated at ~0.001% to 0.004% (Table 3). There are no reports of HIV transmission from a single episode of exposure to HIV-infected human milk in an individual handling human milk in a nursery or in an infant with a single enteral exposure to milk from a woman with HIV infection.[24]

Sharp percutaneous exposure (needlestick, scalpel) to blood infected with HIV is associated with a much lower risk of transmission than that for perinatal or blood transfusion exposure. Prospective evaluation of 6202 health care professionals after percutaneous exposure to HIV-infected blood identified seroconversion in 20 persons, with an overall risk estimate of 0.32% (95% CI, 0.20%–0.50%).[4,25,26] Needle sharing in the context of injection drug use is estimated to have a transmission probability of 0.67% per injection (Table 3).[27]

The risk of HIV transmission from sexual exposure is highest with unprotected receptive anal intercourse (0.5%–3.2%), intermediate with receptive vaginal intercourse (0.05%–0.15%), and lowest for insertive vaginal intercourse (0.03%–0.09%; Table 3).[28–33] The per-act risk of HIV transmission from oral sex is not known, although HIV rarely has been transmitted from orogenital sexual exposure.[34–39] The risk of sexual transmission of HIV is potentially modified by a variety of factors related to the type of sexual act and to biological variables in each partner (Table 4).[29,40] These factors may be important for younger children in the context of a single episode of sexual abuse and for adolescents who may have repeated sexual encounters that may put them at risk of HIV infection.

Transmission of HIV by human bites has been described,[41–44] although such transmission seems to be extremely rare, even when saliva is contaminated with the biter's blood,[24] on the basis of the following observations:[45]

- Saliva inhibits HIV infectivity.[46]
- HIV is rarely isolated from saliva.[47]
- Concentrations of HIV are low in the saliva of HIV-infected persons, even in the presence of periodontal disease.[48]
- None of the approximately 500 000 cases of acquired immunodeficiency syndrome (AIDS) reported to the CDC by 1997 have been attributed to exposure to saliva.
- Transmission of HIV has not been documented in studies of nonsexual household exposure,[49] although unconfirmed transmission has been reported.[50]

Risk of HIV transmission after mucous membrane exposure is low, probably near 0.1% or less.[51,52] Transmission has occurred after contact between

TABLE 3. Type of Exposure and Risk of HIV Transmission per Exposure Event When the Source is HIV Infected

Type of HIV Exposure	Risk of Transmission per Exposure Event
Blood transfusion[17]	0.95
Perinatal exposure[18,19]	0.13 to 0.45
Needle sharing (injection drug use)[27]	0.0067
Unprotected receptive anal intercourse†[5,29,31–33]	0.005 to 0.032
Needlestick (health care professional)[4,25,26]	0.0032
Unprotected receptive vaginal intercourse†[29,30]	0.0001 to 0.003
Unprotected insertive vaginal intercourse‡[29,30]	0.0003 to 0.0009
Ingestion of human milk[20–23]*	0.00001 to 0.00004

* See text for derivation of per-event risk calculation.
† Receptive anal intercourse and receptive vaginal intercourse refer to the risk of HIV acquisition for the person whose anus or vagina was entered by the penis of the exposure source.
‡ Insertive vaginal intercourse refers to the risk of HIV acquisition for the person whose penis was inserted into the vagina of the exposure source.

TABLE 4. Sexual Exposure to HIV: Factors Affecting Risk of Sexual Transmission of HIV.[40]

Biologic Factor	Effect on Risk of HIV Transmission*	Effect on Risk of HIV Acquisition†
Late stage of HIV infection	↑ ↑ ↑	Not applicable
Primary HIV infection	↑ ↑	Not applicable
Antiretroviral therapy	↓ ↓	↓ ↓
Local infection at exposure site	↑ ↑	↑ ↑
Presence of cervical ectopy	↑ ↑	↑ ↑
Presence of foreskin	↑ ↑	↑ ↑
Condoms	↓ ↓ ↓	↓ ↓ ↓
Intrauterine device contraception	↑	↑ ↑
Menstruation	↑ ↑	↑
Genital tract trauma	↑ ↑	↑ ↑

Arrows represent risk relative to baseline values in Table 3 (the more arrows pointing upward, the higher the risk; the more arrows pointing downward, the lower the risk).
* Risk of transmission: the likelihood that HIV will be passed (transmitted) from donor to recipient.
† Risk of acquisition: the likelihood that recipient, once exposed, will become infected with HIV.

blood and nonintact skin (eczema, abrasions, etc), but infectious blood in contact with intact skin has not been reported to result in HIV transmission and is not considered an exposure with risk of transmission.[1]

RATIONALE FOR PEP TO PREVENT TRANSMISSION

During acute HIV infection, the viral doubling time is approximately 10 hours, and approximately 19 newly infected cells will develop from each HIV-infected cell.[53] Therefore, within 48 hours of infection, there will be more than 1.3×10^6 HIV-infected cells. For HIV injected directly into blood, early administration of potent antiretroviral drugs may be particularly important for successful PEP.[54] For skin and mucosal exposures, dendritic cells of skin, mucosa, and submucosa may be the first sites of virus capture and containment.[55,56] Thus, rapid drug penetration to those tissues may be an important consideration in regimen efficacy. HIV is rapidly incorporated into the DNA of resting lymphocytes, where it exists in a nonduplicating state that will not be affected by antiretroviral treatment. Host genetic and immune factors may affect the susceptibility of the exposed patient to infection.

Animal Models of PEP

Animal models of PEP suggest that antiretroviral therapy initiated after virus inoculation can prevent or ameliorate infection when drugs of adequate potency are administered immediately[57] or within a few hours of exposure[58–60] and continued for a few days[61] to weeks.[62,63] PEP was most effective if begun immediately or within 24 hours[64] to 36 hours[65] and was less[65] or not[66] beneficial if begun after 72 hours. Animals developing HIV infection despite receiving PEP may have evidence of infection delayed for up to 16 weeks after virus inoculation.[65] However, even potent therapy may not be able to prevent transmission if the virus inoculum is high.[63,67,68]

In animal models of PEP, antiretroviral drugs are most efficacious when continued for 28 days, compared with shorter durations.[64] This suggests that "prophylactic" therapy is not always truly preventing transmission but rather may be modifying the course of primary infection,[69,70] allowing the host to eliminate HIV early in infection. The development of a cellular immune response in HIV-exposed but ultimately uninfected animals[71–73] and humans[74–76] lends further support to this concept. If these regimens for prophylaxis are truly acting to abort early mucosal, submucosal, or subcutaneous infection, then antiretroviral regimens chosen for prophylaxis should be similar to those that have been shown to be effective for treatment of established HIV infection.

Prevention of Perinatal HIV Transmission as a Model of PEP

Single-drug preexposure plus postexposure antiretroviral therapy can decrease perinatal HIV transmission. In a randomized, placebo-controlled trial in 477 nonbreastfeeding women in the United States and Europe, zidovudine (ZDV [formerly called azidothymidine or AZT]) was administered to women during pregnancy and labor and to their infants for 6 weeks after birth. The rate of perinatal transmission of HIV was decreased by 67%, from 25.5% in the placebo group to 8.3% in the treatment group.[77] In a placebo-controlled trial in 626 breastfeeding women in Uganda, a single dose of nevirapine given to pregnant women at labor onset followed by a single dose to the infant after birth was compared with a very short course of ZDV. At 14 to 16 weeks of age, HIV infection was present in 25.1% of the nevirapine group, compared with 13.1% of the ZDV group, a 47% decrease in the rate of perinatal HIV transmission.[78]

Prenatal use of combinations of antiretroviral agents may further decrease perinatal HIV transmission, compared with use of single-agent therapy. In a randomized, placebo-controlled trial in 1797 pregnant women with HIV infection in southern Africa, the rate of perinatal HIV transmission was decreased by 63%, from 15.3% in placebo-treated patients to 5.7% in women treated with the combination of ZDV plus lamivudine during pregnancy and labor and continued through 7 days after birth in women and their infants.[79] In an observational cohort study of 1542 pregnant women with HIV infection in the United States who delivered infants from 1990 to 2000, the rate of perinatal HIV transmission was 20.0% for women who received no antiretroviral therapy during pregnancy, 10.4% for those who received ZDV alone, 3.8% for women treated with 2-drug combination therapy, and 1.2% for women who received combination therapy that included protease inhibitors (PIs [highly active antiretroviral therapy]) during pregnancy.[80]

Treating infants of HIV-infected women with ZDV exclusively, starting within 12 to 24 hours after birth and continued for 6 weeks, was associated with a decrease in the rate of perinatal HIV transmission in an observational study in New York.[81,82] However, observational data from North Carolina did not confirm the effectiveness of only postexposure treatment

in preventing perinatal HIV transmission.[83,84] This suggests that combined pre- and postexposure therapy may more effectively prevent perinatal HIV transmission, at least when a single agent is used.

PEP: Potential for Failure

Although postexposure ZDV treatment of HIV-exposed health care professionals was associated with an 81% lower risk of HIV transmission in an analysis of observational data (Table 2),[4] failures have occurred.[85] Such failures may result from large inoculum size,[86] late institution of therapy or failure to take prescribed therapy,[87] transmission of ZDV-resistant virus,[88,89] or other as yet unidentified factors.[2]

Although the feasibility of prophylaxis after nonoccupational exposure to HIV has been demonstrated,[90] there are no data measuring the efficacy or effectiveness of PEP in the nonoccupational setting, although this therapy is being offered in various communities.[91] Failures of such prophylaxis have been reported,[92] as have apparent successes.[54] The theoretic concern that offering PEP to sexually active persons would increase risk-taking behavior has not been identified in practice.[93] However, the cost of prophylaxis after nonoccupational exposures is high,[94] and adverse effects are relatively common[95] and can rarely be fatal.[2,96]

General Considerations Regarding Recommendations for Prophylaxis

In evaluating the need for PEP, the following factors should be considered: the duration of time that has passed since the potential exposure, the likelihood of HIV infection in the exposure source, the risk of transmission given the source material and type of exposure, the effectiveness of therapy at modifying that risk, the toxicity of the therapy, and the burden of adherence to antiretroviral therapy.

Because PEP is only recommended for exposures to material from persons with HIV infection, efforts should be made to learn the infection status of the exposure source. If the HIV infection status of the exposure source is unknown, HIV testing should be requested of the person who is the source of the exposure, with consent as required by local laws or regulations. Although awaiting results of testing of the exposure source, PEP may be started for the potentially exposed person and stopped if the exposure source is found not to be infected with HIV.

According to USPHS recommendations for PEP in the nonoccupational setting,[3] PEP should not be used for persons with HIV exposures that have a low risk of HIV transmission (eg, potentially infected body fluid on intact skin) or for persons who seek care too late for the anticipated interruption of transmission (more than 72 hours after reported exposure). Clinicians considering use of PEP after a nonoccupational HIV exposure should recognize that benefits likely would be restricted to situations in which the risk of transmission is high, the intervention can be initiated promptly, and adherence to the regimen is likely. If PEP is used, physicians experienced in the management of children and adolescents with HIV infection should be consulted.[97] Because PEP needs to be started within 72 hours of exposure, often the most feasible approach is to start PEP with a 3-day supply of medications and refer the patient to be evaluated by a consultant within 72 hours.

Recommendations for PEP in children and adolescents vary and include: 1) no PEP; 2) consider PEP; and 3) recommend PEP. Because of the absence of data documenting safety and efficacy of PEP, clinicians may make different, reasonable decisions in similar clinical circumstances. In individual cases of potential exposure, the perceived risks of HIV acquisition may be great enough to justify the burden and potential toxicity of PEP. The final decision to undertake PEP in a specific patient depends on the clinician's recommendation and the exposed person's and/or parent's evaluation of the risk of transmission versus the toxicity of therapy.

If an exposure is serious enough to warrant PEP, 2-drug or 3-drug therapy can be chosen, balancing the theoretically improved efficacy of 3 drugs with the potentially lower toxicity of 2-drug regimens. The USPHS identifies the strength of their recommendations for PEP in the occupational setting by the number of drugs in the regimen.[1,97] The recommendations in this clinical report separate the decision to start PEP from the decision about the number of drugs to include in the regimen. CDC guidelines suggest that determining which agents and how many agents to use is largely empiric.[1] Complete recommendations from the CDC[97] are available online (www.hivpepregistry.org/pdf/pedipep.pdf). American Academy of Pediatrics recommendations follow.

Prophylaxis with ZDV alone or in combination with other drugs was associated with at least 1 adverse effect in 49% of 674 health care professionals treated after occupational exposure to HIV, and 20% stopped prophylaxis prematurely because of adverse effects.[98] Adverse effects can be severe, including potentially fatal lactic acidosis and hepatitis from mitochondrial toxicity of nucleoside analog reverse transcriptase inhibitors (NRTIs)[99] and fatal hypersensitivity reactions from nevirapine.[96] Concern about adverse effects may contribute to low initiation rates for PEP,[100] and difficulty in adhering to complex drug regimens may lead to premature cessation of PEP.[101]

HIV antibody testing of the exposed person is recommended at baseline and at 6 weeks, 12 weeks, and 6 months after exposure. Such diagnostic testing will identify most persons who develop HIV infection after an exposure, although a small fraction of infected persons may not develop detectable antibody until more than 6 months after exposure.[102,103] Delay in HIV seroconversion may be more common if hepatitis C virus transmission occurs at the same time as HIV transmission.

Recommendation for Prophylaxis After Nonoccupational Exposure to HIV in Children and Adolescents

The risk of HIV transmission after an exposure varies by the type and severity of exposure (Tables

1–4) and by the likelihood that the source is infected with HIV (Table 5). Evaluation of both factors allows for estimation of the risk of HIV transmission after a potential exposure (Table 6). For an exposure to a person known to be infected with HIV, the baseline risk of transmission will be modified by the viral load in the exposure fluid.[5] For an exposure to a person of unknown HIV infection status, the baseline risk of HIV transmission will be modified by the probability that the exposure source is infected with HIV (Table 5).

Once the risk of HIV transmission has been estimated, a decision whether to recommend PEP needs to be made. In the absence of specific data on efficacy of PEP outside of the health care setting, this decision is best made by experienced clinicians in collaboration with the exposed person and/or parents after a careful discussion of the risks of transmission and the burden and potential complications of antiretroviral therapy. The risk of transmission and potential benefits of PEP vary for different clinical situations, as outlined in Tables 6 through 8 and Fig 1.

Although PEP may be considered in many circumstances, it is only recommended for high-risk exposures to persons known to be infected with HIV (Table 8). No PEP is given if the exposure occurred more than72 hours previously, if the exposed person refuses PEP, or if the exposed person is unwilling or unable to commit to 28 days of therapy and appropriate follow-up (Table 7).

A careful discussion of the risks and benefits of therapy guides the decision-making regarding PEP and allows appropriate postexposure care (Table 9). If PEP is begun, it should be started as soon as possible after the exposure (within hours, and definitely within 72 hours), and therapy should be continued for 28 days. If consultation with a clinician experienced in the care of children and adolescents with HIV is not immediately possible, a supply of medications sufficient to last until consultation occurs could be dispensed to the patient.

Sexual Exposure

Sexual exposure can result in HIV infection (Tables 3 and 4), and sexual abuse has resulted in HIV transmission to children. Of 9136 children with HIV infection or AIDS reported to the CDC from 1981 through 1997, 26 were sexually abused, with confirmed HIV exposure in 17 and suspected HIV exposure in 9.[104] Of the 17 children with confirmed HIV exposure, 14 had no other risk of HIV infection, and 3 had multiple risk factors. Sexual abuse may be more likely to result in HIV transmission in girls than in women because of thin vaginal epithelium in children and cervical ectopy in adolescents and because children may be repeatedly abused by the same person over a long period.[24] In proven cases of sexual assault by a person known or suspected to have HIV infection, PEP may be considered up to 72 hours after the exposure but is likely to be most effective if given sooner, preferably within a few hours after exposure.[105–107] If the exposure source has genital ulcer disease or another sexually transmitted disease or if the exposure included tissue damage, the risk of HIV transmission is greater (Tables 3 and 4), increasing the potential benefit of PEP relative to the burden of therapy and risks of drug toxicity. Such modifying factors might strengthen the force of the recommendation in a given clinical setting.

For adolescents with a history of a single sexual exposure, PEP can be considered, and if given should be started as soon as possible after the exposure but certainly within 72 hours.[108,109] Such exposure might occur from sexual abuse or by accidental exposure in a consensual relationship (eg, a broken condom). For persons with ongoing consensual sexual exposure to HIV, PEP is not indicated, and behavioral interven-

TABLE 5. Characteristics of the Exposure Source and Risk of Human Immunodeficiency Virus (HIV) Transmission

HIV Infection Status of Exposure Source	Risk of HIV Transmission
Not HIV infected Known not to be infected with HIV*	No risk
HIV status unknown/unknown source HIV infection status unknown, HIV risk status unknown	Unquantified
HIV status unknown: low risk HIV infection status unknown, but known not to have risk factors†	Low
HIV status unknown: high risk HIV infection status unknown but known to have 1 or more risk factors†	Intermediate
HIV infected Known to be infected with HIV‡	High

* HIV infection is documented by presence of specific antibody to HIV in persons older than 18 months and by positive plasma HIV RNA polymerase chain reaction (PCR) assay results, positive cell-associated HIV DNA PCR assay results, or detection of plasma HIV p24 antigen in persons of any age.

† Risk factors for HIV infection include male homosexual activity, injection drug use, blood transfusion or blood product infusion before 1985, or sexual activity with a member of a high-risk group. Some persons who have sex with members of a high-risk group do not identify themselves as at risk, because they are unaware of the risk history of their sexual partner. Their risk of HIV infection is related to the prevalence of HIV infection in their immediate community.

‡ Absence of HIV infection is identified by laboratory documentation of negative HIV antibody or negative HIV DNA PCR assay results from a specimen collected close to the time of the exposure and in the absence of interval high-risk behavior or symptoms compatible with acute retroviral infection syndrome.

TABLE 6. Exposure Type and Exposure Risk Category for HIV

Exposure Type	Exposure Risk Category
Cutaneous exposure	
Fluid on intact skin	No risk identified
Bite without break in skin	
Skin with compromised integrity (eczema, chapped skin, dermatitis, abrasion, laceration, open wound)	Low to intermediate
Traumatic skin wound with bleeding in donor and recipient*	High
Mucous membrane exposure	
Kissing	No risk identified
Oral sex	Low
Human milk: single ingestion	
Splash to eye or mouth	
Receptive vaginal sex without trauma	Intermediate
Receptive anal intercourse	High
Traumatic sex with blood (sexual assault)	
Percutaneous exposure†	
Superficial scratch with sharp object, including a needle found in the community	No risk identified
Puncture wound with solid needle	Low
Puncture wound with hollow needle without visible blood	
Body piercing	
Bite with break in skin	
Puncture wound with hollow needle with visible blood	Intermediate
Puncture wound with large-bore hollow needle with visible blood on needle, or needle recently used in source patient artery or vein	High

* For example, in a fight, a blow to the mouth might break a tooth that bleeds and lacerate the first that also bleeds. If there was mixing of blood, both persons may be at risk.
† See text for considerations used in assigning the appropriate risk category for a percutaneous exposure.

TABLE 7. Suggested Approach to HIV (PEP) on the Basis of Characteristics of the Exposed Patient*

Characteristics of Exposed Patient	Suggested Approach
Exposure >72 h ago; or Exposed person refuses PEP; or Exposed person unwilling or unable to commit to 28 d of therapy and appropriate follow-up.	No PEP
Exposure ≤72 h ago; or Exposed person voluntarily accepts PEP; or Exposed person commits to 28 d of therapy and appropriate follow-up.	Consider PEP in appropriate exposure setting (Tables 6 and 8)

* Animal data suggest PEP started later than 72 hours after exposure is less effective in preventing infection.[64–66]

tions to decrease repeated exposure probably are more appropriate.[110,111]

Percutaneous Exposures

Risk of HIV transmission from a puncture wound from a needle found in the community is significantly lower than the 0.3% HIV transmission risk after needlestick injury in a health care professional from a person with HIV infection. Although it is unlikely that a true estimate of risk can be established, transmission will be related to:

- The probability that the person who used the needle has HIV infection (Table 5);
- The time interval since the needle was in contact with blood of the source;
- The initial concentration of HIV on the needle, presence of blood or tissue that might delay drying (and, therefore, killing of the virus), or the presence of fresh blood or material that might contain viable virus; and
- The severity of the injury (skin contact without skin breakage, abrasion without bleeding, deeper skin penetration) in the exposed individual.

In evaluating a puncture wound, the following factors are considered in assessing potential for HIV transmission (presented as lower risk category followed by higher risk category for each attribute): the depth of the wound (superficial scratch or deep puncture); the presence of blood on the needle (no visible blood or visible blood); the characteristics of the blood on the needle (dried or fresh); the type of needle (solid or hollow bore); and the location the needle was used in the source patient's body (not in artery or vein; or in artery or vein).

The risk of HIV transmission from a discarded needle in public places (often referred to as a "found" needle) seems to be low. Because data are not available on the efficacy of PEP in this circumstance for adults or children, the USPHS is unable to recommend for or against PEP in this circumstance.

TABLE 8. Suggested Approach* to PEP on the Basis of Exposure Risk Category and HIV Infection Status of the Source

Exposure Risk Category†	HIV Infection Status of Source‡	Suggested Approach
No risk identified	Any	No PEP
Any	Not HIV infected	No PEP
Low, intermediate, or high	Unknown	Consider PEP
Low or intermediate risk	HIV infected	Consider PEP
High risk	HIV infected	Recommend PEP

* PEP is not recommended if the exposure occurred >72 hours ago, the exposed person refuses PEP, or if the exposed person is unwilling or unable to commit to 28 days of therapy and appropriate follow-up (Table 7). When considering PEP, the approach is suggested on the basis of type and severity of exposure, fluid involved, and HIV infection status of the exposure source, as outlined in Tables 1 through 6. Characteristics of the exposed patient are also considered, as described here and in the text. Given the absence of compelling data on effectiveness of PEP, clinicians may make different, reasonable decisions in similar clinical circumstances.
† See Table 6.
‡ See Table 5.

Furthermore, PEP is not without risk and often is associated with significant adverse effects. Therefore, PEP is not routinely recommended in this situation. However, if the needle and/or syringe are found to have visible blood and the source is known to be HIV infected, some experts recommend that PEP be considered. Testing the syringe for HIV is not practical or reliable and is not recommended.

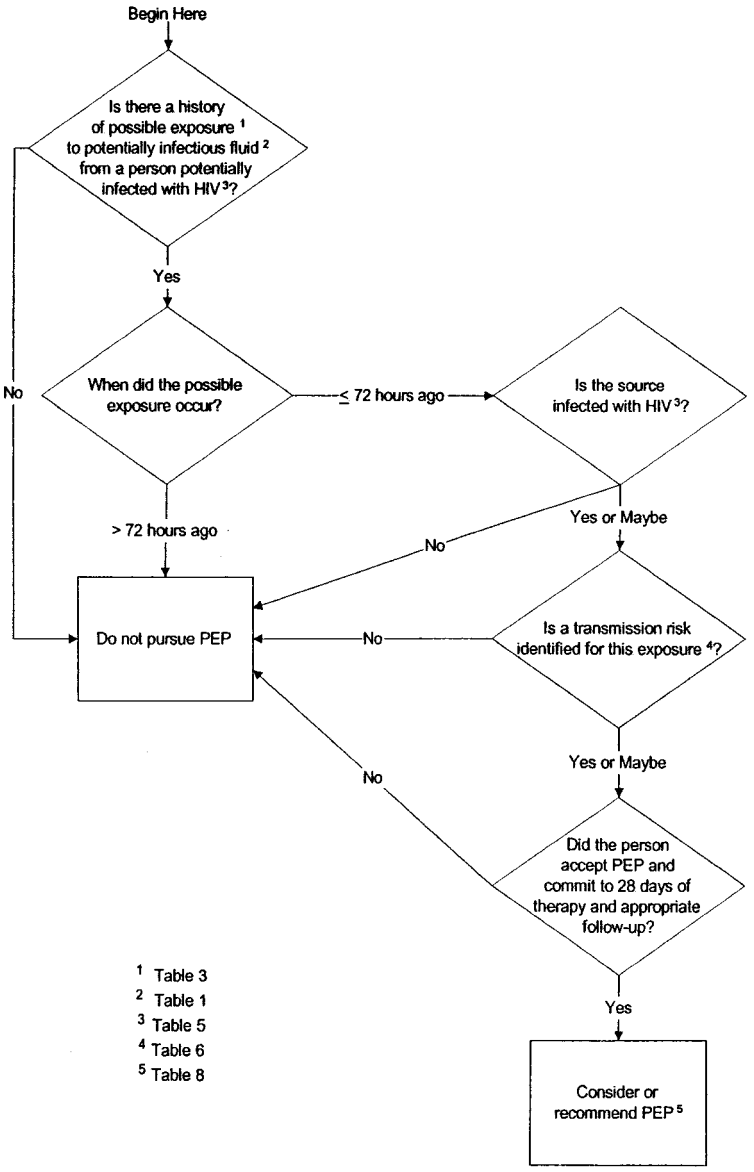

Fig 1. Possible exposure to HIV in children and adolescents: algorithm for decision-making for use of PEP.

TABLE 9. Management of Patients With Possible Exposure to HIV

Exposure Management Issue	Implementation Comment
Treat exposure site	—Wash wounds with soap and water; flush mucous membranes with water. Give tetanus booster if appropriate.
Evaluate exposure source if possible	—Determine the HIV infection status of the exposure source. If unknown, testing with appropriate consent should be offered if possible.
Evaluate exposed person	—Perform HIV serologic testing to identify current HIV infection and hepatitis B and hepatitis C serologic testing as appropriate[122] —Provide or refer for counseling to address stress and anxiety —Discuss prevention of potential secondary HIV transmission —Discuss prevention of repeat exposure, if appropriate —Report incident to legal or administrative authorities as appropriate to the setting of the exposure and the severity of the incident
Consider PEP	—Explain potential benefits and risks —Discuss issues of drug toxicity and medication compliance —Measure complete blood cell count, creatinine, and alanine transaminase concentration as baseline for possible drug toxicity —Begin prophylaxis as soon as possible after exposure, preferably within 1 to 4 h; prophylaxis begun more than 72 h after exposure is unlikely to be effective —Arrange for follow-up with HIV specialist and psychologist, if appropriate —Educate about prevention of secondary transmission (sexually active adolescent should avoid sex, or use condoms, until all follow-up test results are negative) —Report to PEP registry at CDC
Choose therapy	—Consider drug potency and toxicity, regimen complexity and effects on compliance, and possibility of drug resistance in the exposure source —Supply 3–5 d of medication immediately, instructing patients to obtain remainder of medication at follow-up visit
Follow-up	—Perform initial follow-up within 2–3 d to review drug regimen and adherence, evaluate for symptoms of drug toxicity, assess psychosocial status, and arrange appropriate referrals, if needed —Continue therapy for 28 d —Monitor for drug adverse effects at 4 wk with complete blood cell count and alanine transaminase concentration —Evaluate for psychologic stress and medication compliance with weekly office visits or telephone calls —Consider referral for counseling if needed —Repeat HIV serologic testing at 6 wk, 12 wk, and 6 mo after exposure

Bite wounds are another percutaneous body fluid exposure that may occur in children, but the risk of HIV transmission after exposure to saliva is very low. In the absence of blood in saliva and blood in the bite wound, PEP is not indicated. However, if there is blood exchange from a bite, both the person bitten and the person biting should be considered at risk of transmission of HIV and considered for PEP. Use in this setting would be extremely unusual and is potentially indicated only when there is significant exposure to deep, bloody wounds in persons with HIV infection.

Adolescents may be percutaneously exposed to potentially infectious fluids by needle sharing for injection drug use (including anabolic steroids) or for body piercing. The per-contact probabilities of HIV transmission in Table 3 apply in this setting, and for a single percutaneous exposure to blood of a person at risk for or known to have HIV infection, PEP can be considered. For adolescents with ongoing needle sharing and potential exposure to HIV, PEP is not routinely recommended, and behavioral interventions to decrease repeated exposures are more appropriate than is postexposure drug therapy after a single episode.[110,111]

Human Milk Exposures

Because HIV can be transmitted via human milk, even a single exposure to human milk should be considered to confer a potential (albeit very low) risk of HIV transmission (Table 3). Such exposure is possible in a hospital if stored, unpasteurized human milk is given to the wrong infant or if an infant is accidentally breastfed by a woman with HIV infection who is not the child's mother. Exposure also could occur if a mother developed HIV infection while breastfeeding or if a breastfeeding mother with established HIV infection was not tested for HIV in the prenatal period. However, in most areas of the United States, the prevalence of HIV infection in pregnant women is less than 2 per 1000.[112] Most breastfeeding women will have been tested for HIV during pregnancy,[113,114] and women known to be HIV infected will have been counseled not to breastfeed.[115] Therefore, the actual likelihood that exposure to HIV would occur by this route is extremely low.

For women with known HIV infection, the best approach to preventing transmission is to avoid breastfeeding. For a woman who continues to breastfeed, potent antiretroviral therapy for herself may decrease viral load and decrease risk of transmission, but prolonged therapy for the mother or the infant so exposed is of unknown benefit. For an infant with a single exposure to human milk from a woman with HIV infection, the magnitude of risk is estimated to be approximately 100 times lower than that for other mucous membrane exposures (Table 3), and PEP is likely not warranted (Tables 6–8).

TABLE 10. Dosage and Administration of Selected Antiretroviral Drugs That Might Be Used for Prophylaxis After Exposure to HIV in Children or Adolescents[121]

Drug Generic Name (Abbreviation), Trade Name	Recommended Dosage*	How Supplied
NRTIs		
ZDV, Retrovir	Preterm infants (investigational) 0–2 wk of age: 1.5 mg/kg/dose, twice daily, orally (1.0 mg/kg/dose, every 12 h, IV) >2 wk of age: 2.0 mg/kg/dose, 3 times/day, orally (1.5 mg/kg/dose, every 8 h, IV) Term infants 0–6 wk of age: 4 mg/kg/dose, twice daily, orally (3.0 mg/kg/dose, every 12 h, IV) 4 wk–12 y of age: 160 mg/m^2/dose, 3 times/day, orally, or 180–240 mg/m^2/dose, twice daily, orally (maximum 200 mg/dose, 3 times/day or 300 mg/dose, twice daily) ≥13 years of age: 200 mg/dose, 3 times/day, orally or 300 mg/dose, twice daily, orally	Syrup: 10 mg/mL Capsules: 100 mg Tablets: 300 mg Combination (Combivir): ZDV, 300 mg, plus lamivudine, 150 mg, in a single tablet Injection: 10 mg/mL in 20-mL vials
ddI, Videx	<3 mo of age: 50 mg/m^2/dose, twice daily, orally (investigational) 3 mo–12 y of age: 90–135 mg/m^2/dose, twice daily, orally or 240 mg/m^2/dose once daily, orally (investigational) ≥13 y of age: <60 kg in body weight: Tablets, 125 mg, twice daily, orally Powder, 167 mg, twice daily, orally ≥60 kg in body weight: Tablets, 200 mg, twice daily, orally, or 400 mg, once daily, orally Powder, 250 mg, twice daily, orally, or 500 mg, once daily, orally	Chewable tablets*: 25 mg, 50 mg, 100 mg, 150 mg (2 tablets/dose) Buffered powder packets: mix with water: 100 mg, 167 mg, 250 mg Coated tablets (Videx EC): 125 mg, 200 mg, 250 mg, 400 mg Pediatric powder for oral solution mixed to final concentration of 20 mg/mL or 10 mg/mL
d4T, Zerit	<30 kg in body weight: 1 mg/kg/dose, twice daily, orally 30–60 kg: 30 mg, twice daily, orally >60 kg: 40 mg, twice daily, orally	Solution: 1 mg/mL Capsules: 15, 20, 30, 40 mg. Mix with applesauce.
3TC, Epivir	<1 mo of age: 2 mg/kg/dose, twice daily, orally <37.5 kg in body weight: 4 mg/kg/dose, twice daily, orally ≥37.5 kg in body weight: 150 mg/dose, twice daily, orally	Oral solution: 10 mg/mL Tablets: 150 mg Combination (Combivir): ZDV, 300 mg, plus 3TC, 150 mg, in a single tablet.
PIs		
RTV, Norvir	3 mo–12 y of age: 400–450 mg/m^2/dose, twice daily, orally ≥13 y of age: 600 mg/dose, twice daily, orally	Oral solution: 80 mg/mL Gelcaps: 100 mg
IDV, Crixivan	3–12 y of age: 450 to 500 mg/m^2/dose, 3 times/day, orally ≥13 y of age: 800 mg, 3 times/day, orally	Capsules: 200 and 400 mg. Must be stored in original bottle.
NFV, Viracept	1 mo–12 y of age: 30–50 mg/kg/dose, 3 times/day, orally, or 55 mg/kg/dose, twice daily, orally (maximum 2000 mg/dose) ≥13 y of age: 750 to 1250 mg/dose, 3 times/day, orally, or 1250 mg/dose, twice daily, orally	Powder for oral suspension: 50 mg/"level scoop" Tablet: 250 mg
LPV/r, Kaletra	Children: LPV, 300 mg/m^2/dose, plus RTV, 75 mg/m^2/dose, twice daily, orally Adults: LPV, 400 mg/dose, plus RTV, 100 mg/dose, twice daily, orally, or LPV, 533 mg/dose, plus RTV, 133 mg/dose, twice daily, orally if given with nevirapine	Oral solution: 400 mg of LPV/100 mg of RTV per 5 mL (80 mg of LPV/20 mg of RTV per mL). Can store at room temperature for 2 mo. Capsules: 133.3 mg of LPV/33.3 mg of RTV per capsule.

IV indicates intravenous. ddI, didanosine; d4T, stavudine; 3TC, lamivudine; RTV, ritonavir; IDV, indinavir sulfate; NFV, nelfinavir mesylate; LPV/r, lopinavir/ritonavir.

* Although the doses listed for adults are usually the Food and Drug Administration-licensed doses, the doses listed for children may be higher than the Food and Drug Administration-licensed doses. Before prescribing, see package insert for complete prescribing information, including drug toxicities, potential drug interactions, and contraindications for use.

Choice of Antiretroviral Medications for PEP

No clinical studies are available to determine the best antiretroviral regimen for PEP. The most extensive data in terms of potential efficacy and safety are for ZDV monotherapy.[4,81] A clinician with experience in treatment of persons with HIV infection should be consulted before starting PEP.

Many clinicians would use the 3-drug combination of ZDV, lamivudine, and nelfinavir for PEP in children and adolescents (doses in Table 10).[116] If the efficacy of PEP is in aborting early mucosal, submucosal, subcutaneous, or lymphatic HIV infection, then potent suppressive therapies, such as 2 NRTIs plus a PI, should be chosen, because such regimens have been shown to be more likely to suppress HIV replication than have monotherapy or dual therapy.

Taking the multiple medications required for PEP is a daunting task, and problems with drug toxicity (Table 11), patient adherence, and other factors severely limit the proportion of patients who finish PEP once they have started it.[107,117–119] Completing 28 days of a 2-drug regimen is easier than completing

TABLE 11. Major Toxicities of Selected Antiretroviral Drugs for Use as Prophylaxis After Exposure to HIV in Children or Adolescents[121]

Drug Generic Name (Abbreviation), Trade Name	Major Adverse Effects
Zidovudine (ZDV), Retrovir	Anemia, neutropenia, nausea, headache, insomnia, muscle pain, weakness, lactic acidosis, hepatic steatosis
Didanosine (ddI), Videx	Pancreatitis, neuropathy, diarrhea, abdominal pain, nausea, lactic acidosis, hepatic steatosis
Stavudine (d4T), Zerit	Peripheral neuropathy, headache, diarrhea, nausea, insomnia, anorexia, pancreatitis, hepatitis, anemia, neutropenia, lactic acidosis, hepatic steatosis
Lamivudine (3TC), Epivir	Abdominal pain, nausea, diarrhea, rash, pancreatitis, lactic acidosis, hepatic steatosis
Ritonavir (RTV), Norvir	Abdominal pain, nausea, diarrhea, circumoral paresthesias, taste alteration, increased cholesterol and triglyceride concentrations
Indinavir sulfate (IDV), Crixivan	Nephrolithiasis, hyperbilirubinemia, nausea, abdominal pain, increased cholesterol and triglyceride concentrations
Nelfinavir mesylate (NFV), Viracept	Diarrhea, nausea, abdominal pain, weakness, rash, increased cholesterol and triglyceride concentrations
Lopinavir/ritonavir (LPV/r), Kaletra	Abdominal pain, nausea, diarrhea, circumoral paresthesias, taste alteration, increased cholesterol and triglyceride concentrations

a 3-drug regimen and may be associated with fewer medication adverse effects. Although the burden and toxicity of a 3-drug regimen may be warranted for treatment of persons with established HIV infection, the risk-benefit ratio for PEP may favor a 2-drug regimen for some patients. Therefore, some clinicians recommend 2-drug combinations of ZDV and lamivudine for PEP, hoping that the improved ease of use and potential decrease in toxicity will balance out the theoretic decrease in efficacy. It may be reasonable to consider a 2-drug regimen for treatment of some patients. The effectiveness of a drug regimen in practice will be related to the efficacy of the drugs and the probability of completion of the course of therapy.

ZDV and lamivudine are each available as syrups and are available together in a single tablet (Combivir [GlaxoSmithKline, London, United Kingdom]), enhancing ease of use for adolescents (doses in Table 10). If current and/or previous therapy used by the source patient is known and drug resistance is a concern, alternatives to the standard regimen might be considered in consultation with a specialist in HIV care in children and adolescents. Stavudine or didanosine are reasonable alternative NRTIs for use if resistance to ZDV or lamivudine is suspected. ZDV and stavudine should never be used in combination with one another because of intracellular antagonism. Because of the potential for a severe hypersensitivity reaction, the NRTI abacavir sulfate should be avoided in PEP regimens.

Nelfinavir is available as a powder for children who are unable to take pills, although some children prefer the crushed tablets to the powder. Indinavir is only available in capsule form, is associated with crystalluria and nephrolithiasis, and requires extra hydration and for these reasons is usually avoided for PEP in children and adolescents. Other PIs available in a liquid formulation appropriate for children include ritonavir, lopinavir/ritonavir (Kaletra [Abbott Laboratories, North Chicago, IL]), and amprenavir. However, gastrointestinal intolerance may be a problem with ritonavir and lopinavir/ritonavir. The liquid formulation of amprenavir has high levels of vitamin E, contains propylene glycol in a concentration that exceeds World Health Organization standards for use in infants, and should not be used in children under 4 years; therefore, it is not recommended for routine use in PEP regimens. PIs have multiple potential interactions with other drugs, and the package insert should always be consulted before prescribing any of these medications.

Nevirapine is a non-NRTI that has been shown to decrease mother-to-child transmission in a single-dose intrapartum and infant regimen.[78] The single-dose regimen has been shown to be safe for mothers and infants.[120] However, severe life-threatening cases of hepatotoxicity, including liver failure and death, have been reported in patients receiving nevirapine as part of a PEP regimen or as treatment of HIV infection. Therefore, nevirapine should not be used as part of a PEP regimen in children.[96,121]

All antiretroviral agents have potential adverse effects (Table 11). It is critical to review the drug regimen, assess adherence, and evaluate the child for any symptoms of drug toxicity at all follow-up visits.

Implementation and Follow-up

The HIV infection status of the exposure source should be sought. If the source person is known but HIV status unknown, then HIV testing with appropriate counseling and consent should be requested.

Wounds should be washed completely with soap and water. Mucous membranes should be flushed with water or saline solution. Tetanus booster and other wound care should be provided as needed (Table 9).

A discussion of risks and benefits of PEP with the family of an exposed toddler will differ from the discussion with a potentially exposed adolescent, whose family may be specifically excluded from knowledge of the whole event. Treating adolescents in this setting should follow state and local laws regarding confidentiality of medical care. Because of the need to begin prophylaxis as quickly as possible after an exposure, office or clinic staff should be instructed to act immediately on telephone calls concerning possible HIV exposure, and the clinician should not wait until the end of the clinic day to return a call. Such staff education might be incorpo-

rated into OSHA-mandated bloodborne pathogen training.

Emergency departments should have protocols concerning possible need for postexposure HIV prophylaxis, and a "starter kit" of 3 days of antiretroviral medicines should be available at all times to ensure immediate institution of PEP therapy. Careful follow-up is crucial to ensure that the rest of the medications can be obtained easily and that consultation with a specialist in pediatric and adolescent HIV care occurs, to monitor toxicity, and to provide support for medication adherence and psychologic stress.

Initial follow-up of the exposed child is recommended within 2 to 3 days to review drug regimen, assess adherence, evaluate for any symptoms of toxicity, assess psychosocial status of the child and family, and arrange appropriate referrals if needed. To support patient adherence to medications, visits to the clinician's office or clinic or patient-clinician telephone calls should occur at weekly intervals.

Laboratory testing for drug toxicity should be performed at baseline and 2 weeks (optional) and 4 weeks after starting therapy, and at a minimum should include complete blood cell count and alanine transaminase concentration. Persons treated with indinavir should be monitored for hematuria because of the risk of nephrolithiasis. Careful attention needs to be paid to complaints of abdominal pain, which might prompt evaluation for pancreatitis.

Monitoring for seroconversion to HIV includes testing for HIV by enzyme immunoassay, indicated at baseline and 6 weeks, 12 weeks, and 6 months after exposure. For patients coinfected with hepatitis C virus, HIV enzyme immunoassay should also be performed 12 months after the potential exposure. Testing for hepatitis B and hepatitis C should be performed as appropriate, following standard guidelines.[122]

In a significant exposure, the person at risk of HIV acquisition also becomes a potential source of HIV transmission to others. This needs to be discussed, and methods of preventing possible secondary transmission of HIV should be outlined, including abstinence or use of condoms for sexually active adolescents.

The potential for acquisition of HIV infection can lead to psychologic stress, which may require intensive counseling during the immediate postexposure period and until follow-up testing is negative 6 months after the exposure.

If local experts in the use of antiretroviral agents in children are unavailable for consultation, the University of California-San Francisco has a hot line (1–888-HIV-4911) that is supported by the CDC and the Health Resources and Services Administration and is staffed 24 hours a day to help clinicians through the decision pathways and to provide information on choice of therapy.

In selected instances of possible HIV exposure, legal or administrative issues may be raised, and careful documentation is important. For exposures in the hospital setting, hospital administrative policies should be consulted. For adolescents, support from family or friends might be encouraged, but the adolescent's right to privacy should be respected.

Reporting of Exposures and Therapy

Exposures that are considered for PEP should be reported to the nonoccupational HIV PEP registry, which is run by the John Snow Institute under the auspices of the CDC. The registry can be accessed online (www.hivpepregistry.org), by telephone (1–877-HIV-1PEP), or by fax (1–877-HIV-7PEP).

SUMMARY

The risk of HIV transmission from nonoccupational, nonperinatal exposure is generally low. Transmission risk is modified by factors related to the exposure source and extent. Determination of the HIV infection status of the exposure source may not be possible, and data on transmission risk by exposure type may not exist. Except in the setting of perinatal transmission, no studies have demonstrated the safety and efficacy of postexposure use of antiretroviral drugs for the prevention of HIV transmission in the nonoccupational setting. Antiretroviral therapy used for PEP is associated with significant toxicity. The decision to initiate prophylaxis needs to be made in consultation with the patient, family, and a clinician with experience in treatment of persons with HIV infection. If instituted, therapy should be started as soon as possible after an exposure—no later than 72 hours—and continued for 28 days. Many clinicians would use 3 drugs for prophylaxis regimens, although 2 drugs may be considered in certain circumstances. Instruction for avoiding secondary transmission should be given. Careful follow-up is needed for psychologic support, encouragement of medication adherence, toxicity monitoring, and serial HIV antibody testing.

abstract

This report provides a practical guide and algorithm for the screening and subsequent management of neonatal hypoglycemia. Current evidence does not support a specific concentration of glucose that can discriminate normal from abnormal or can potentially result in acute or chronic irreversible neurologic damage. Early identification of the at-risk infant and institution of prophylactic measures to prevent neonatal hypoglycemia are recommended as a pragmatic approach despite the absence of a consistent definition of hypoglycemia in the literature. *Pediatrics* 2011;127:575–579

INTRODUCTION

This clinical report provides a practical guide for the screening and subsequent management of neonatal hypoglycemia (NH) in at-risk late-preterm (34–36⅙ weeks' gestational age) and term infants. An expert panel convened by the National Institutes of Health in 2008 concluded that there has been no substantial evidence-based progress in defining what constitutes clinically important NH, particularly regarding how it relates to brain injury, and that monitoring for, preventing, and treating NH remain largely empirical.[1] In addition, the simultaneous occurrence of other medical conditions that are associated with brain injury, such as hypoxia-ischemia or infection, could alone, or in concert with NH, adversely affect the brain.[2–5] For these reasons, this report does not identify any specific value or range of plasma glucose concentrations that potentially could result in brain injury. Instead, it is a pragmatic approach to a controversial issue for which evidence is lacking but guidance is needed.

BACKGROUND

Blood glucose concentrations as low as 30 mg/dL are common in healthy neonates by 1 to 2 hours after birth; these low concentrations, seen in all mammalian newborns, usually are transient, asymptomatic, and considered to be part of normal adaptation to postnatal life.[6–8] Most neonates compensate for "physiologic" hypoglycemia by producing alternative fuels including ketone bodies, which are released from fat.

Clinically significant NH reflects an imbalance between supply and use of glucose and alternative fuels and may result from a multitude of disturbed regulatory mechanisms. A rational definition of NH must account for the fact that acute symptoms and long-term neurologic sequelae occur within a continuum of low plasma glucose values of varied duration and severity.

The authors of several literature reviews have concluded that there is not a specific plasma glucose concentration or duration of hypoglycemia that can predict permanent neurologic injury in high-risk infants.[3,9,10] Data that have linked plasma glucose concentration with adverse long-term neurologic outcomes are confounded by variable definitions of hypoglycemia and its duration (seldom reported), the omission of control groups, the possible inclusion of infants with confounding conditions, and the small number of asymptomatic infants who were followed.[3,11,12] In addition, there is no single concentration or range of plasma glucose concentrations that is associated with clinical signs. Therefore, there is no consensus regarding when screening should be performed and which concentration of glucose requires therapeutic intervention in the asymptomatic infant. The generally adopted plasma glucose concentration that defines NH for all infants (<47 mg/dL) is without rigorous scientific justification.[1,3,4,9,12]

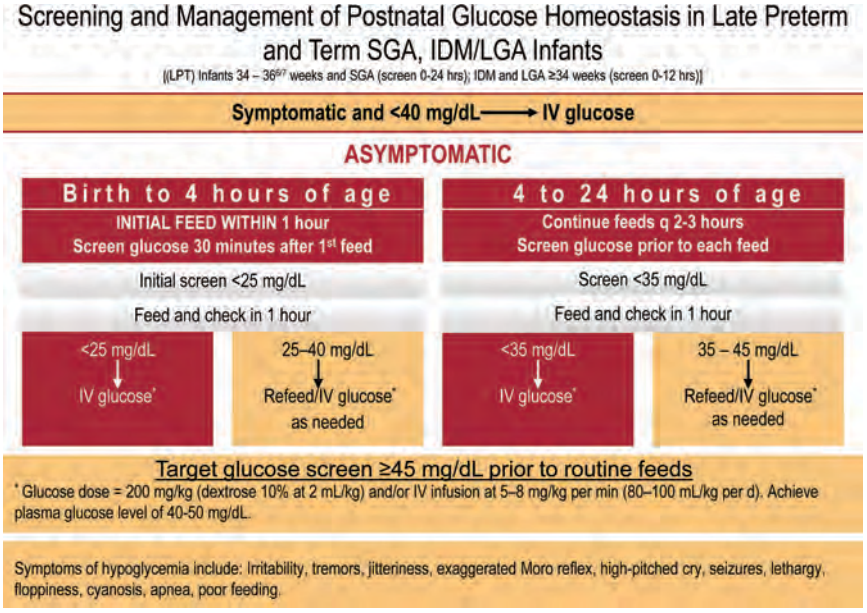

FIGURE 1
Screening for and management of postnatal glucose homeostasis in late-preterm (LPT 34–36⁶/₇ weeks) and term small-for-gestational age (SGA) infants and infants who were born to mothers with diabetes (IDM)/large-for-gestational age (LGA) infants. LPT and SGA (screen 0–24 hours), IDM and LGA ≥34 weeks (screen 0–12 hours). IV indicates intravenous.

WHICH INFANTS TO SCREEN

Because plasma glucose homeostasis requires glucogenesis and ketogenesis to maintain normal rates of fuel use,[13] NH most commonly occurs in infants with impaired glucogenesis and/or ketogenesis,[14,15] which may occur with excessive insulin production, altered counterregulatory hormone production, an inadequate substrate supply,[14–16] or a disorder of fatty acid oxidation.[15] NH occurs most commonly in infants who are small for gestational age, infants born to mothers who have diabetes, and late-preterm infants. It remains controversial whether otherwise normal infants who are large for gestational age are at risk of NH, largely because it is difficult to exclude maternal diabetes or maternal hyperglycemia (prediabetes) with standard glucose-tolerance tests.

A large number of additional maternal and fetal conditions may also place infants at risk of NH. Clinical signs are common with these conditions, and it is likely that patients with such a condition are already being monitored and that plasma glucose analyses are being performed.[13,17] Therefore, for practicality, "at risk" in the management approach outlined in Fig 1 includes only infants who are small for gestational age, infants who are large for gestational age, infants who were born to mothers who have diabetes, and late-preterm infants. Routine screening and monitoring of blood glucose concentration is not needed in healthy term newborn infants after an entirely normal pregnancy and delivery. Blood glucose concentration should only be measured in term infants who have clinical manifestations or who are known to be at risk. Plasma or blood glucose concentration should be measured as soon as possible (minutes, not hours) in any infant who manifests clinical signs (see "Clinical Signs") compatible with a low blood glucose concentration (ie, the symptomatic infant).

Breastfed term infants have lower concentrations of plasma glucose but higher concentrations of ketone bodies than do formula-fed infants.[13,17] It is postulated that breastfed infants tolerate lower plasma glucose concentrations without any clinical manifestations or sequelae of NH because of the increased ketone concentrations.[8,12–14]

WHEN TO SCREEN

Neonatal glucose concentrations decrease after birth, to as low as 30 mg/dL during the first 1 to 2 hours after birth, and then increase to higher and relatively more stable concentrations, generally above 45 mg/dL by 12 hours after birth.[6,7] Data on the optimal timing and intervals for glucose screening are limited. It is controversial whether to screen the asymptomatic at-risk infant for NH during this

normal physiologic nadir. No studies have demonstrated harm from a few hours of asymptomatic hypoglycemia during this normal postnatal period of establishing "physiologic glucose homeostasis."[9]

Infants born to mothers with diabetes may develop asymptomatic NH as early as 1 hour after birth[18] and usually by 12 hours of age.[18] In contrast, infants who are large for gestational age or small for gestational age may develop low plasma glucose concentrations at as early as 3 hours of age,[19] and these infants may be at risk of NH for up to 10 days after birth.[20] Therefore, at-risk infants should be screened for NH with a frequency and duration related to risk factors specific to the individual infant.[5] Screening the asymptomatic at-risk infant can be performed within the first hours of birth and continued through multiple feed-fast cycles. Late-preterm infants and infants who are small for gestational age should be fed every 2 to 3 hours and screened before each feeding for at least the first 24 hours. After 24 hours, repeated screening before feedings should be continued if plasma glucose concentrations remain lower than 45 mg/dL.

LABORATORY DATA

When NH is suspected, the plasma or blood glucose concentration must be determined immediately by using one of the laboratory enzymatic methods (eg, glucose oxidase, hexokinase, or dehydrogenase method). Plasma blood glucose values tend to be approximately 10% to 18% higher than whole-blood values because of the higher water content of plasma.[21,22]

Although a laboratory determination is the most accurate method of measuring the glucose concentration, the results may not be available quickly enough for rapid diagnosis of NH, which thereby delays the initiation of treatment.[23] Bedside reagent test-strip glucose analyzers can be used if the test is performed carefully and the clinician is aware of the limited accuracy of these devices. Rapid measurement methods available at the bedside include the handheld reflectance colorimeter and electrode methods. The blood sample is usually obtained from a warmed heel.

Test-strip results demonstrate a reasonable correlation with actual plasma glucose concentrations, but the variation from the actual level may be as much as 10 to 20 mg/dL.[24–27] Unfortunately, this variation is greatest at low glucose concentrations. There is no point-of-care method that is sufficiently reliable and accurate in the low range of blood glucose to allow it to be used as the sole method for screening for NH.

Because of limitations with "rapid" bedside methods, the blood or plasma glucose concentration must be confirmed by laboratory testing ordered stat. A long delay in processing the specimen can result in a falsely low concentration as erythrocytes in the sample metabolize the glucose in the plasma. This problem can be avoided by transporting the blood in tubes that contain a glycolytic inhibitor such as fluoride.

Screening of the at-risk infant for NH and institution of prophylactic measures to prevent prolonged or symptomatic NH is a reasonable goal. Treatment of suspected NH should not be postponed while waiting for laboratory confirmation. However, there is no evidence to show that such rapid treatment will mitigate neurologic sequelae.

CLINICAL SIGNS

The clinical signs of NH are not specific and include a wide range of local or generalized manifestations that are common in sick neonates.[12,13,17] These signs include jitteriness, cyanosis, seizures, apneic episodes, tachypnea, weak or high-pitched cry, floppiness or lethargy, poor feeding, and eye-rolling. It is important to screen for other possible underlying disorders (eg, infection) as well as hypoglycemia. Such signs usually subside quickly with normalization of glucose supply and plasma concentration.[9,13] Coma and seizures may occur with prolonged NH (plasma or blood glucose concentrations lower than 10 mg/dL range) and repetitive hypoglycemia. The more serious signs (eg, seizure activity) usually occur late in severe and protracted cases of hypoglycemia and are not easily or rapidly reversed with glucose replacement and normalization of plasma glucose concentrations.[28–30] Development of clinical signs may be ameliorated by the presence of alternative substrates.[31]

Because avoidance and treatment of cerebral energy deficiency is the principal concern, greatest attention should be paid to neurologic signs. To attribute signs and symptoms to NH, Cornblath et al[12] have suggested that the Whipple triad be fulfilled: (1) a low blood glucose concentration; (2) signs consistent with NH; and (3) resolution of signs and symptoms after restoring blood glucose concentrations to normal values.[12]

MANAGEMENT

Any approach to management needs to account for the overall metabolic and physiologic status of the infant and should not unnecessarily disrupt the mother-infant relationship and breastfeeding. The definition of a plasma glucose concentration at which intervention is indicated needs to be tailored to the clinical situation and the particular characteristics of a given infant. For example, further investigation and immediate intravenous glucose treatment might be instituted for an infant with clinical signs and a plasma glucose concentration of less than 40 mg/

dL, whereas an at-risk but asymptomatic term formula-fed infant may only require an increased frequency of feeding and would receive intravenous glucose only if the glucose values decreased to less than 25 mg/dL (birth to 4 hours of age) or 35 mg/dL (4–24 hours of age).[32] Follow-up glucose concentrations and clinical evaluation must always be obtained to ensure that postnatal glucose homeostasis is achieved and maintained.

Because severe, prolonged, symptomatic hypoglycemia may result in neuronal injury,[27,28,32] prompt intervention is necessary for infants who manifest clinical signs and symptoms. A reasonable (although arbitrary) cutoff for treating symptomatic infants is 40 mg/dL. This value is higher than the physiologic nadir and higher than concentrations usually associated with clinical signs. A plasma sample for a laboratory glucose determination needs to be obtained just before giving an intravenous "minibolus" of glucose (200 mg of glucose per kg, 2 mL/kg dextrose 10% in water [$D_{10}W$], intravenously) and/or starting a continuous infusion of glucose ($D_{10}W$ at 80–100 mL/kg per day). A reasonable goal is to maintain plasma glucose concentrations in symptomatic infants between 40 and 50 mg/dL.

Figure 1 is a guideline for the screening and management of NH in late-preterm infants and term infants who were born to mothers with diabetes, small for gestational age, or large for gestational age. In developing a pragmatic approach to the asymptomatic at-risk infant during the first 24 hours after birth, mode of feeding, risk factors, and hours of age were considered. This strategy is based on the following observations from Cornblath and Ichord[13]: (1) almost all infants with proven symptomatic NH during the first hours of life have plasma glucose concentrations lower than 20 to 25 mg/dL; (2) persistent or recurrent NH syndromes present with equally low plasma glucose concentrations; and (3) little or no evidence exists to indicate that asymptomatic NH at any concentration of plasma glucose in the first days of life results in any adverse sequelae in growth or neurologic development.[13]

Figure 1 is divided into 2 time periods (birth to 4 hours and 4–12 hours) and accounts for the changing values of glucose that occur over the first 12 hours after birth. The recommended values for intervention are intended to provide a margin of safety over concentrations of glucose associated with clinical signs. The intervention recommendations also provide a range of values over which the clinician can decide to refeed or provide intravenous glucose. The target glucose concentration is greater than 45 mg/dL before each feeding. At-risk infants should be fed by 1 hour of age and screened 30 minutes after the feeding. This recommendation is consistent with that of the World Health Organization. Gavage feeding may be considered in infants who are not nippling well. Glucose screening should continue until 12 hours of age for infants born to mothers with diabetes and those who are large for gestational age and maintain plasma glucose concentrations of greater than 40 mg/dL. Late-preterm infants and infants who are small for gestational age require glucose monitoring for at least 24 hours after birth, because they may be more vulnerable to low glucose concentrations, especially if regular feedings or intravenous fluids are not yet established.[20] If inadequate postnatal glucose homeostasis is documented, the clinician must be certain that the infant can maintain normal plasma glucose concentrations on a routine diet for a reasonably extended period (through at least 3 feed-fast periods) before discharge. It is recommended that the at-risk asymptomatic infant who has glucose concentrations of less than 25 mg/dL (birth to 4 hours of age) or less than 35 mg/dL (4–24 hours of age) be refed and that the glucose value be rechecked 1 hour after refeeding. Subsequent concentrations lower than 25 mg/dL, or lower than 35 mg/dL, respectively, after attempts to refeed, necessitate treatment with intravenous glucose. Persistent hypoglycemia can be treated with a minibolus (200 mg/kg [2 mL/kg] $D_{10}W$) and/or intravenous infusion of $D_{10}W$ at 5 to 8 mg/kg per minute, 80 to 100 mL/kg per day; the goal is to achieve a plasma glucose concentration of 40 to 50 mg/dL (higher concentrations will only stimulate further insulin secretion). If it is not possible to maintain blood glucose concentrations of greater than 45 mg/dL after 24 hours of using this rate of glucose infusion, consideration should be given to the possibility of hyperinsulinemic hypoglycemia, which is the most common cause of severe persistent hypoglycemia in the newborn period. A blood sample should be sent for measurement of insulin along with a glucose concentration at the time when a bedside blood glucose concentration is less than 40 mg/dL, and an endocrinologist should be consulted.

SUMMARY

Current evidence does not support a specific concentration of glucose that can discriminate euglycemia from hypoglycemia or can predict that acute or chronic irreversible neurologic damage will result. Therefore, similar to the Canadian Paediatric Society guidelines, a significantly low concentration of glucose in plasma should be reliably established and treated to restore glucose values to a normal physiologic range.[5] Recognizing infants at risk of disturbances in postnatal glucose homeostasis and providing a margin of safety by early measures to

prevent (feeding) and treat (feeding and intravenous glucose infusion) low concentrations are primary goals. Follow-up glucose measurements are always indicated to be sure an infant can maintain normal glucose concentrations over several feed-fast cycles. This will also permit recognition of infants with persistent hyperinsulinemic hypoglycemia and infants with fatty acid oxidation disorders.

Precertification Process

ABSTRACT. Precertification is a process still used by health insurance companies to control health care costs. Although we believe precertification is unnecessary and not cost-effective, in those instances where precertification is still being utilized, we suggest that the following procedures be adopted. This statement suggests guidelines that should help achieve this goal while allowing optimal access to care for children.

The precertification process is a utilization management tool used to control hospital admissions, utilization of services, and medical facility expense. This "tool" must be used uniformly with care, concern, and compassion and with a clear objective that its use does not prevent care needed by pediatric patients.

Children respond to illness and injuries differently from adults. Critical symptoms may develop more rapidly, and children often cannot appropriately communicate the severity of their condition. For these reasons children frequently require early and expedient physician evaluation and in-hospital monitoring. Delay that compromises a child's care or clinical outcome is not acceptable as part of a cost-containment screening process. The timely and appropriate approval of pediatric referrals to hospitals and physicians must be of paramount consideration in any established approval process or procedure. The following guidelines are meant to help achieve the goals of utilization management and optimal care for children.

1. The precertification process must be available in writing for use by the attending physician.
2. The precertification process must be available and clearly presented in all insurance plans and health care contracts so that the parent or guardian is aware of the requirement.
3. Contact telephone approval numbers must be on the patient's insurance card and health care contract. The contracting agency's response personnel must be available 24 hours a day, 7 days a week, including holidays, and must be knowledgeable in pediatric care. Fax or electronic communication should also be available to be used in place of telephone contact as a way to save time.
4. When disagreements about recommended management occur between referring physicians and screening personnel for the health care plan, a system of immediate response by health care plan physicians knowledgeable in pediatric care needs to be in place to resolve the concerns of the referring physician, the parents, or both.
5. If the child's situation is related to an emergency, precertification should be waived as the primary consideration must be to protect the patient's life and health.
6. In the case of a nonacute precertification conflict, an immediate review process by physicians knowledgeable in pediatric care should be available to resolve the problem.
7. Unnecessary delays in treatment must be avoided—most importantly to prevent endangering the patient's life and health and also to reduce excessive nonclinical administrative time required of referring physicians. The health insurance company should compensate the physician's office for all costs involved in performing the work of precertification.

The American Academy of Pediatrics believes it is in the best interest of children for all pediatricians to assist in the monitoring and control of the rapidly rising costs of children's health care. If this includes the use of precertification mechanisms, then the precertification process should be efficient and not result in delays in the patient receiving any recommended treatment.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Clinical Report—Premedication for Nonemergency Endotracheal Intubation in the Neonate

abstract

Endotracheal intubation is a common procedure in newborn care. The purpose of this clinical report is to review currently available evidence on use of premedication for intubation, identify gaps in knowledge, and provide guidance for making decisions about the use of premedication. *Pediatrics* 2010;125:608–615

INTRODUCTION

Endotracheal intubation is a common procedure in NICUs and should be performed expeditiously in as controlled an environment as possible to reduce complications. Several studies that evaluated the success rate of neonatal endotracheal intubations have reported that successful intubations frequently require more than 1 attempt and are rarely accomplished within the currently recommended time frame.[1–3] Many failed attempts can be attributed to suboptimal intubating conditions. Excellent intubating conditions are characterized by good jaw relaxation, open and immobile vocal cords, and suppression of pharyngeal and laryngeal reflexes assessed by the absence of coughing or diaphragmatic movements in response to intubation.[4] Several trials have demonstrated that the use of premedication for intubation of the newborn significantly improves intubating conditions, decreases the time and number of attempts needed to complete the intubation procedure, and minimizes the potential for intubation-related airway trauma.[5–10]

The alleviation of pain in neonates should be the goal of all caregivers, because repeated painful experiences have the potential for deleterious consequences.[11] The experience of being intubated is unpleasant and painful and seriously disturbs physiologic homeostasis.[12,13] A consensus statement from the International Evidence-Based Group for Neonatal Pain concluded that "tracheal intubation without the use of analgesia or sedation should be performed only for resuscitation in the delivery room or for life-threatening situations associated with the unavailability of intravenous access."[14] Subsequently, in a recent policy statement the American Academy of Pediatrics also recommended that every health care facility caring for neonates implement an effective pain-prevention program and use pharmacologic and nonpharmacologic therapies for the prevention of pain associated with procedures.[11] Despite these recommendations, there remains wide variation in the frequency of use of premedication before intubation, and in the medications used for premedication.[15,16] Some of the reasons offered for not using premedications before intubation are concern for ad-

verse reactions and/or toxic effects of the medications, inadequate time for administration of medications in emergency situations, and the perception that risk/benefit ratios are worsened by using premedications.[13] This report will address some of these issues, including the choices of available medications, the circumstances for the use of medications, the risks of these medications, and the appropriate precautions to take while adopting these procedures.

PHYSIOLOGIC RESPONSES TO INTUBATION

The process of intubation may cause hypoxemia,[17] bradycardia,[18] intracranial hypertension,[19] systemic hypertension,[17] and pulmonary hypertension.[20] Hypoxemia seems to be related either to apnea at the time of intubation or possible airway obstruction associated with positioning.[17] Bradycardia is presumed to be vagal in origin, because the very rapid onset is suggestive of a reflexive etiology[17] and is not prevented by preoxygenation and the avoidance of hypoxemia.[18] The increase in intracranial pressure may be a result of coughing and struggling of the infant that can result in venous stasis with an increase in cerebral blood volume.[19,21] Systemic arterial hypertension has been investigated in adults and seems to be caused by an increase in systemic vascular resistance, which is probably caused by catecholamine release.[22] Pulmonary hypertension leading to right ventricular failure has been described in adults,[23] and although pulmonary artery pressures have not been measured in newborn infants undergoing intubation, endotracheal suctioning is known to cause an increase in pulmonary artery pressure postoperatively in infants with congenital heart disease[20] and is presumed to occur with intubation. In addition, improperly performed direct laryngoscopy can cause traumatic injuries to the face, eyes, tongue, and gums, and placement of the endotracheal tube can dislodge the arytenoids or damage other glottic structures. These injuries can be avoided by improved technique that can be enhanced by the use of premedication.[24]

CHARACTERISTICS OF AN IDEAL STRATEGY

An ideal strategy for premedication for intubation eliminates the pain, discomfort, and physiologic abnormalities of the procedure, helps to carry out intubation expeditiously, minimizes the chances for traumatic injury to the newborn, and has no adverse effects. An individual skilled in the use of bag-mask ventilation should be present to ensure adequate ventilation after the use of premedication and before the intubation. An ideal approach would be to administer supplemental oxygen, as needed, via a properly sized face mask, then a vagolytic agent, followed by analgesic and/or hypnotic medications before infusion of a muscle relaxant. The vagolytic drug prevents bradycardia, the analgesic and/or hypnotic drug can control pain and may render the infant unconscious and minimize adverse hemodynamic responses to laryngoscopy, and the muscle relaxant provides the best possible intubating conditions. Nonpharmacologic interventions, including swaddling and comfortable positioning, would contribute to the infant's comfort as well.

Analgesia

Premedication with an analgesic reduces the pain and discomfort of intubation. An ideal analgesic agent would have a rapid onset, be of short duration, have no adverse effects on respiratory mechanics, and possess predictable pharmacokinetic properties. None of the currently available agents fit this profile.

Opioids are the most commonly used medications for analgesia in the neonate. The mechanism of action of the individual opioids involves interaction at various receptor sites in both the central and peripheral nervous system to modify transmission of painful signals and diminish pain perception.[25] Morphine is the most frequently used opiate for pain control in the neonate. It has been used for acute postoperative pain control and as a continuous infusion for ventilated infants. The use of morphine for premedication for intubation was studied in a randomized, controlled trial of 34 premature infants in which infants were given either morphine alone or placebo 5 minutes before the intubation. There was no effect on the severity of physiologic disturbances during intubation including the duration of severe hypoxemia, incidence of bradycardia, and change in mean blood pressure.[26] This lack of effect is thought to be because of the delayed onset of action of morphine[27] related to the relative hydrophilic nature of the drug. Intravenous morphine has a mean onset of action at 5 minutes and peak effect at 15 minutes.[25] Another randomized, controlled trial of 20 preterm infants compared the use of morphine and midazolam versus remifentanil and midazolam for intubation.[8] No differences were noted between the groups with regard to pain control or hemodynamic variables, but the probability of having excellent intubation conditions was significantly higher with remifentanil than with morphine. All infants pretreated with remifentanil and midazolam were intubated at first attempt compared with only 60% of the infants in the morphine and midazolam group.[8] In another study, when morphine was used in combination with a vagolytic and a paralytic agent, the time needed to intubate was reduced and bradycardia was decreased.[24] However, these effects may be related to the vagolytic and paralytic agents used in the study, not to

morphine effects. Furthermore, the status of pain control was not assessed in that study. For these reasons, morphine alone would not be the most appropriate choice for premedication for intubations. Meperidine is rarely used in neonates because of its slow onset of action, variability in metabolism, and risk of toxic effects of its metabolites; as a result, it is not recommended.[27]

Fentanyl is the most frequently used synthetic opioid in the neonate. This drug may be preferable to morphine for pain control for intubation because of a more rapid onset of action related to its more lipophilic nature.[25] Fentanyl's impact on some of the physiologic disturbances during intubation has been studied. In older infants and children this drug blunts physiologic disturbances during endotracheal suctioning and, in patients after surgery, decreases pulmonary arterial pressure and systemic hypertension.[20,23] It is likely that such responses may occur during intubation too. Its impact on cerebral and systemic hemodynamics was studied with a short-term infusion in 15 preterm infants, and there were no significant changes in the systemic or cerebral perfusion or pressure.[28] Although fentanyl as a single agent in intubation has not been studied, a cohort study of 33 preterm and term infants intubated after a combination of atropine, fentanyl, and a paralytic agent showed that fentanyl had no significant adverse effects.[7] Remifentanil, another synthetic opiate, has a rapid onset of action and an ultrashort duration of action and has been shown to be a useful drug for neonatal intubation.[8,29] A primary concern with synthetic opioid use is the risk of chest wall rigidity, but this risk can be reduced by slow administration and can be treated with either naloxone or muscle relaxants.[30] However, it is important to remember that the use of naloxone, a competitive antagonist at all opioid receptors, will also reverse the analgesic effects of these drugs.

Sedation

Sedatives do not always reduce pain but can sedate or render individuals unconscious or amnestic depending on the dose and individual response. Benzodiazepines have been frequently used for sedation before elective intubations but may not be appropriate in many cases. Midazolam is the most commonly used medication in this category[31] in the United States, but it has not been shown to reduce any physiologic changes during intubation. In a randomized, double-blind trial (stopped after only 16 intubations because of adverse events and reported in a letter to the editor), preterm infants who received midazolam and atropine for intubation had more desaturations, and 29% required cardiopulmonary resuscitation compared with those in the groups that received either atropine alone or no premedication.[32] Midazolam can cause hypotension in both preterm and term infants,[33–36] decreased cardiac output in older children,[37] and decreased cerebral blood flow velocity in premature infants.[33,38] The studies that demonstrated these effects were not performed as part of premedication for intubation, and the results may not be applicable to the circumstances necessitating endotracheal intubation. However, kinetic studies in preterm and term infants have shown that the serum half-life of midazolam given as continuous infusion or by repetitive dosing can exceed 22 hours.[38,39] Further concern in the use of midazolam for preterm infants is the exposure to the preservative benzyl alcohol.[40,41] For these reasons, midazolam should not be used in preterm infants, but it can be considered for use in the term or older infant as part of the premedication sequence for elective intubation in the NICU.

Elective intubation of patients before surgery is often accomplished with a sedative-hypnotic agent such as a barbiturate and a muscle relaxant. Barbiturates have been used for induction of anesthesia for decades; however, barbiturates are poor analgesics.[42] Barbiturates such as thiopental and methohexital have a rapid onset and short duration of action. In a randomized, placebo-controlled trial in term infants, thiopental was shown to reduce changes in heart rate and blood pressure during intubation and to shorten the time to intubation.[43] In a small cohort study of term and preterm infants, methohexital facilitated intubation with rapid onset within 1 minute of sedation and recovery within 10 minutes.[44] However, more studies are necessary before methohexital can be recommended for use.

Propofol is a nonbarbiturate anesthetic that is frequently used for induction of anesthesia in older children and adults but has not been well evaluated in newborns. Propofol is lipophilic and rapidly equilibrates between plasma and brain with quick loss of consciousness and also has a short duration of action after a single-bolus dose.[25] In a randomized, controlled trial in 63 premature infants, propofol was shown to be a more effective induction agent than the morphine, atropine, and suxamethonium regimen to facilitate neonatal intubation.[9] Oxygenation during intubation was maintained better in the propofol group and was attributed to the maintenance of spontaneous respiration in infants who received propofol. Twenty-three percent of the infants in the morphine, atropine, and suxamethonium group and 6% of the infants in the propofol group sustained intubation-related trauma. No other adverse events were noted in the propofol group. Although the results of this study are encouraging, more research

confirming these initial findings is necessary before propofol can be recommended as a single premedication agent for neonatal intubation. Propofol can only be administered intravenously, and pain at the site of injection that may sometimes be moderately severe has been reported with intravenous injection of propofol in 10% to 20% of patients.[45]

Vagolytic Agents

Vagolytic agents prevent bradycardia during intubation and decrease bronchial and salivary secretions but are infrequently used for neonatal intubation.[46] One reason for their sparse use has been the concern that vagolytic agents mask hypoxia-induced bradycardia during intubation; however, most episodes of bradycardia during intubation are secondary to vagal stimulation, not hypoxia. Glycopyrrolate and atropine are both effective vagolytic agents, and although they have not been directly compared in neonates, they have been studied in infants and children. In a randomized, controlled trial in 90 older infants and children that compared the use of glycopyrrolate and atropine at anesthetic induction, none had bradycardia, but more subjects who received atropine developed sinus tachycardia than those who received glycopyrrolate.[47] Glycopyrrolate is widely used in pediatric intensive care and anesthesia; however, its pharmacokinetics in small preterm infants is not known.

Muscle Relaxants

The ideal muscle relaxant for intubation would have a rapid onset, short duration of action, and minimal or no deleterious effect on heart rate and blood pressure. None of the currently available agents meet all these criteria for neonates, but use of a muscle relaxant to facilitate intubation can eliminate or minimize the increase in intracranial pressure that occurs during awake intubation. This has been demonstrated with both succinylcholine in preterm infants[48] and pancuronium in preterm and term infants.[18]

Succinylcholine, the only depolarizing agent in clinical use, blocks neuromuscular transmission by binding to the acetylcholine receptors of the muscle membrane and depolarizing the membrane. It has both a rapid onset and a short duration of action. In a randomized, controlled trial in preterm infants, succinylcholine given with morphine and atropine was compared with awake intubation. This combination resulted in faster intubation with less bradycardia and less trauma as defined by less blood in the oral and nasal passages.[48]

The nondepolarizing muscle relaxants compete with acetylcholine for receptors on the motor endplate but do not result in depolarization of the membrane. Of these agents, pancuronium is widely used in newborns and has few adverse effects but is slower in onset of action and longer acting compared with the other available muscle relaxants. Pancuronium has a vagolytic effect that helps minimize the reflex bradycardia that often accompanies laryngoscopy. In a randomized, controlled trial, infants who received pancuronium and atropine showed less hypoxia during intubation and less increase in intracranial pressure compared with infants who received no premedication or atropine alone.[18]

Mivacurium, another nondepolarizing agent, is no longer commercially available because of its adverse effect of histamine release and associated bronchospasm. Cisatracurium has been introduced to replace mivacurium and seems to have similar physiologic effects but has not yet been tested in a neonatal population. Vecuronium and rocuronium, 2 other nondepolarizing muscle relaxants in wide use in pediatric anesthesia and PICUs, are characterized by their minimal effects on blood pressure or heart rate. Rocuronium is a metabolic derivative of vecuronium and has quicker onset to paralysis and shorter duration of action compared with vecuronium.

ADVERSE EFFECTS

Concern for adverse effects has been a barrier to implementing premedication for intubation,[49] but most reports and randomized, controlled trials have not demonstrated serious adverse effects. A large multicenter observational study showed no increase in the frequency of adverse effects when infants were premedicated.[31] When used alone, fentanyl and other synthetic opioids have been associated with acute chest wall rigidity in both preterm and term infants, which can significantly impair ventilation.[30] However, this adverse effect may be related to dose and rapid delivery and can be prevented by slow infusion of an appropriate dose and overcome with muscle relaxant[50] or reversed with naloxone.[30]

Succinylcholine has been reported to have rare serious adverse effects in children, including hyperkalemia, myoglobinemia, and cardiac arrhythmias. Atropine seems to protect against bradyarrhythmias induced by succinylcholine.[51] Hyperkalemia is also unlikely, because marked elevations have been reported only in clinical circumstances associated with significant tissue destruction.[51] Succinylcholine is a known trigger of malignant hyperthermia, a skeletal muscle disorder inherited as an autosomal dominant trait. The incidence of malignant hyperthermia is estimated to be 0.4 to 0.5 in 10 000 in the general population.[52] Diagnosis and management of malignant hyperthermia is beyond the scope of this report. Succinylcholine should not be used in the presence of hyperkalemia and/or a family history of malignant hyperthermia.[53]

CLINICAL CIRCUMSTANCES FOR INTUBATION WITHOUT PREMEDICATION

Intubation without premedication may be acceptable during resuscitation or after acute deterioration or critical illness at a later age. The risk/benefit ratio may also support intubation without premedication in infants with upper airway anomalies such as Pierre Robin sequence. Intubation of infants with severely abnormal airways can be difficult, and the infant's own respiratory effort may be essential for maintaining an open airway. If intubation attempts are unsuccessful in these infants, the use of laryngeal mask airway (LMA) or anticipatory transfer to a center with a team of personnel, including a neonatologist, pediatric otolaryngologist, and pediatric anesthesiologist, experienced in managing infants with structurally abnormal airways should be considered. It is important to note that LMA is a temporary airway device and should be used only as a last resort while preparations for a secure airway are in progress. One might also consider the use of a fiber-optic bronchoscope for intubation if personnel experienced in its use are available.[54]

GAPS IN KNOWLEDGE

Many unanswered questions remain regarding the practice of premedication for nonemergent intubation in the newborn.

- The optimal pharmaceutical agents have not been developed for use in newborns, and appropriate drug doses of currently available agents based on gestational age are currently unknown.
- The pharmacokinetic and pharmacodynamic characteristics of many drugs used in premedication have not been well studied in newborns.
- An ideal combination and/or sequence of premedications have not been established.
- Alternative routes of administration of premedications have not been systematically studied.
- Long-term benefits and adverse effects of premedications are unknown.

Further research must continue to answer these and other questions.

CLINICAL IMPLICATIONS

- Preparation should include having appropriate equipment such as an oxygen source, appropriately sized bags, face masks, endotracheal tubes, stylet, laryngoscope, and suction.
- All support staff assisting with the procedure should have clearly preassigned responsibilities during the procedure.
- Infants should have cardiorespiratory, oxygen saturation, and noninvasive blood pressure monitoring during nonemergent intubation, and an end-tidal carbon dioxide detector should be available. Intravenous access should preferably be established, and the stomach should be decompressed.
- All personnel who intubate neonates should acquire training with LMAs, because this device may prove to be an effective bridge to intubation in some cases in which bag-mask ventilation is suboptimal.[55,56] Appropriately sized LMAs should be available for all intubations, particularly when any difficulty is anticipated. LMAs have been used successfully in late-preterm and term newborns weighing more than 2500 g.
- Individuals who perform intubations should be experienced in the use of bag-mask ventilation and be knowledgeable about the effects of the procedure of laryngoscopy and intubation, as well as risks and benefits of premedications. Ascertainment of appropriate endotracheal tube position immediately after intubation should be done by auscultation and end-tidal carbon dioxide monitoring.
- Except for emergent intubation during resuscitation either in the delivery room or after acute deterioration or critical illness at a later age, premedication should be used for all endotracheal intubations in newborns. Medications with rapid onset and short duration of action are preferable (Table 1).
  - Analgesic agents or anesthetic dose of a hypnotic drug should be given.
  - Vagolytic agents and rapid-onset muscle relaxants should be considered.
  - Use of sedatives alone such as benzodiazepines without analgesic agents should be avoided.
  - A muscle relaxant without an analgesic agent should not be used.
- Each unit should develop protocols and lists of preferred medications to improve compliance and minimize medication errors and adverse effects.
- For circumstances in which intravenous access is not available, alternative routes such as intramuscular administration can be considered.

TABLE 1 Medications for Premedication for Nonemergency Intubation

Drug	Route/Dose	Onset of Action	Duration of Action	Common Adverse Effects	Comments[a]
Analgesic					
Fentanyl	IV or IM[b]/1–4 μg/kg	IV, almost immediate; IM, 7–15 min	IV, 30–60 min; IM, 1–2 h	Apnea, hypotension, CNS depression, chest wall rigidity	Preferred analgesic Effects reversible with naloxone Give slowly (preferably over 3–5 min, at least over 1–2 min) to avoid chest wall rigidity Chest wall rigidity can be treated with naloxone and muscle relaxants
Remifentanil	IV/1–3 μg/kg May repeat in 2–3 min if needed	IV, almost immediate	IV, 3–10 min	Apnea, hypotension, CNS depression, chest wall rigidity	Acceptable analgesic Short duration of action and limited experience in neonates Effects reversible with naloxone Give slowly over 1–2 min to avoid chest wall rigidity Chest wall rigidity can be treated with naloxone and muscle relaxants
Morphine	IV or IM/0.05–0.1 mg/kg	IV, 5–15 min; IM, 10–30 min	IV, 3–5 h; IM, 3–5 h	Apnea, hypotension, CNS depression	Acceptable analgesic agent Use only if other opioids are not available; if selected, must wait at least 5 min for onset of action Effects reversible with naloxone
Hypnotic/sedative					
Midazolam	IV or IM/0.05–0.1 mg/kg	IV, 1–5 min; IM, within 5–15 min	IV, 20–30 min; IM, 1–6 h	Apnea, hypotension, CNS depression	Acceptable sedative for use in term infants in combination with analgesic agents Hypotension more likely when used in combination with fentanyl Not recommended in premature infants Effects reversible with flumazenil
Thiopental	IV/3–4 mg/kg	IV, 30–60 s	IV, 5–30 min	Histamine release, apnea, hypotension, bronchospasm	Acceptable hypnotic agent Hypotension more likely when used in combination with fentanyl and/or midazolam
Propofol	IV/2.5 mg/kg	Within 30 s	3–10 min	Histamine release, apnea, hypotension, bronchospasm, bradycardia; often causes pain at injection site	Acceptable hypnotic agent Limited experience in newborns Neonatal dosing has not been well established
Muscle relaxant					
Pancuronium	IV/0.05–0.10 mg/kg	1–3 min	40–60 min	Mild histamine release, hypertension, tachycardia, bronchospasm, excessive salivation	Acceptable muscle relaxant Relatively longer duration of action Effects reversible with atropine and neostigmine
Vecuronium	IV/0.1 mg/kg	2–3 min	30–40 min	Mild histamine release, hypertension/hypotension, tachycardia, arrhythmias, bronchospasm	Preferred muscle relaxant Effects reversible with atropine and neostigmine
Rocuronium	IV/0.6–1.2 mg/kg	1–2 min	20–30 min	Mild histamine release, hypertension/hypotension, tachycardia, arrhythmias, bronchospasm	Preferred muscle relaxant Effects reversible with atropine and neostigmine
Succinylcholine	IV/1–2 mg/kg; IM[b]/2 mg/kg	IV, 30–60 s; IM, 2–3 min	IV, 4–6 min; IM, 10–30 min	Hypertension/hypotension, tachycardia, arrhythmias, bronchospasm, hyperkalemia, myoglobinemia, malignant hyperthermia	Acceptable muscle relaxant Contraindicated in presence of hyperkalemia and family history of malignant hyperthermia
Vagolytic					
Atropine	IV or IM/0.02 mg/kg	1–2 min	0.5–2 h	Tachycardia, dry hot skin	Preferred vagolytic agent
Glycopyrrolate	IV/4–10 μg/kg	1–10 min	~6 h	Tachycardia, arrhythmias, bronchospasm	Acceptable vagolytic agent Limited experience in newborns Contains benzyl alcohol as preservative

Most of these drugs have limited pharmacokinetics data from newborns and are not approved for use in the newborn, but they have been used in newborns. IV indicates intravenously; IM, intramuscularly; CNS, central nervous system.

[a] Preferred and acceptable designation of medications is based on consensus opinion after review of available evidence.

[b] Consider only if no intravenous access.

abstract

As advocates for children and their families, pediatricians can support and guide expectant parents in the prenatal period. Prenatal visits allow the pediatrician to gather basic information from expectant parents, offer them information and advice, and identify high-risk conditions that may require special care. In addition, a prenatal visit is the first step in establishing a relationship between the family and the pediatrician (the infant's medical home) and in helping the parents develop parenting skills and confidence. There are several possible formats for this first visit. The one used depends on the experience and preference of the parents, the style of the pediatrician's practice, and pragmatic issues of reimbursement. *Pediatrics* 2009;124:1227–1232

INTRODUCTION

Prenatal contact with a pediatrician generally begins with a telephone call from a prospective parent to the physician's office to ask whether the pediatrician is accepting new patients and to inquire about hours, fees, hospital affiliation, health insurance accepted, and emergency coverage. These questions may be answered by a member of the office staff or the physician and establishes an initial relationship between the pediatrician's office and the parent. During this conversation, the parent should be invited to schedule a prenatal visit with the pediatric clinician, which should include both parents if possible.

A prenatal visit with the pediatrician is recommended for all expectant families. It is especially valuable for first pregnancies; parents who are new to the practice; single parents; families with high-risk pregnancies, pregnancy complications, or multiple gestations; and for parents who previously have experienced a perinatal death. This visit can also be valuable to parents who are planning to adopt a child.

The most comprehensive prenatal visit is a full office visit, during which the expectant parent(s) can have time to air their needs, interests, and concerns and receive initial anticipatory guidance. Most pediatricians feel that the prenatal visit is helpful for them as well as for the prospective parents. Because they cannot initiate these visits, pediatricians should discuss the concept with referring obstetricians, who can, in turn, encourage their patients to contact pediatricians for a prenatal visit.

OBJECTIVES

1. Establishing a Positive Pediatrician-Family Relationship

The prenatal period is a good time to start building the health care alliance that should last throughout the child's pediatric care.[1] This is

a particularly good time to invite spouses/partners and other supportive adults, including grandparents,[2–4] to establish a relationship with the pediatrician or other health care provider for the infant and to encourage them to come to future visits and help them support the new mother. A prenatal visit can be used to introduce parents to the concept of a medical home for the child's future health and developmental needs. Parents' comfort level should increase as they become familiar with their pediatric health care provider before the birth of their infant, especially if a referral or transfer of care seems necessary because of unusual medical needs of the infant. Adolescent parents and older first-time parents also can benefit from having the opportunity to share their special concerns with a knowledgeable professional. If grandparents are available and interested in being involved, it is important that ground rules be established so that the parents can feel supported but not controlled by their parents and that all grandparents play by the same rules.

2. Information-Gathering From the Family

The most important information to collect during the prenatal visit concerns the general assets and needs of the parents and their hopes, expectations, and worries about the infant that they are expecting.[5–7] In addition to family and parent medical history, including possible problems with previous pregnancies, discreet inquiry should be made into the parents' relationship with each other and other family members, concerns regarding possible domestic violence, anxiety about the present pregnancy, fear of hereditary or congenital disorders (if this information is available), experience with infants, resources for child rearing, delivery plans, feeding choice, and concerns about changes in lifestyle. This is an appropriate time to identify cultural beliefs, values, and practices related to pregnancy and parenting[8,9] as well as attitudes toward tobacco, alcohol, and other drug use. Additional issues to consider are the nature and extent of support from family and friends, parents' work arrangements, and child care plans, especially if both parents work outside the home. If there are other children in the family, their feelings, worries, and expectations and sibling rivalry should be considered.

3. Anticipatory Guidance and Enhanced Parenting Skills

One of the pediatrician's most complex but gratifying tasks is to help mothers, fathers, and other supportive adults become more competent caregivers. This can begin with discussion of the parents' concerns and planned strategies. Advice can be offered about shared roles in parenting, such as diapering, bathing, nighttime care, and helping with feeding. Description of the routine in the hospital, including who will be in the delivery room and how new infants behave in the first hours and days, can be reassuring. This discussion might include the newborn's ability to seek and attach to the mother's breast right after delivery. The Appendix is an example of a handout that the pediatrician can offer the parents at the prenatal visit.

This is an appropriate teaching moment for describing to both parents the many advantages of exclusive breastfeeding and how it improves outcomes for both the mother and infant.[10,11] Special breastfeeding training of expectant fathers has been shown to increase their support of their wives and the duration of breastfeeding.[12] Breastfeeding should be strongly recommended if there are no contraindications, and support services should be discussed.[13–16] However, ultimately, decisions about feeding the infant are made by the parents. If bottle feeding is the parents' choice, they should be supported in their decision and given advice on formula type, preparation, and proper bottle use.

Discussion of circumcision, including benefits, risks, the surgical process, and analgesia, can be presented at this visit, with particular attention to the family's religious and cultural views.

Safety is an important topic to present to the parents, particularly advice such as "back to sleep" and proper bedding,[17,18] proper holding of the infant, bathing and water temperature, proper use of a pacifier, and handwashing and other sanitation matters. Encouraging good family diet, regular checkups with the family physician or obstetrician[19] and dentist,[20,21] and appropriate rest and exercise is important also.

During the visit, the parents' emotions and worries should be explored and information should be offered about "baby blues," postpartum depression and the usual parental frustrations and initial feelings of incompetence.[22–24] Fathers' or partners' feelings about lack of parenting skills and decreased marital intimacy can be addressed as well. Parents should be given ideas about soothing a fussy infant, such as holding, including cuddling and kangaroo care[25]; rocking; singing; talking quietly; and dimming lights and playing soft music. They should be assured that they can call the pediatrician for advice if they feel anxious or angry or are afraid that they might hurt the infant.

Although the volume of information and advice may seem overwhelming to expectant parents, they can be given appropriate handouts, CDs, or videotapes to supplement and reinforce visit information. They should also be offered the opportunity for a follow-up

visit or telephone call if they still have questions. A Web page can be a good source of information and can include parent questionnaires for subsequent visits.

4. Identification and Approaches to High-Risk Issues

Neonatal screening and immunization should be explained so that the parents understand the benefit of early diagnosis and therapy. Family history of congenital disease, if known, can be discussed and advance planning arranged if necessary. Adolescent parents often need more guidance than more experienced parents, and older-than-usual parents often feel stressed and insecure also. Single parents may not have family or other support systems and may need referral to social service agencies for help. Absence of the father, parental disagreement, chronic parental physical or mental issues, and preterm birth or birth defect in the infant may require additional medical visits and specialist involvement[26–28] and can present physical, emotional, and financial burdens for the parents.[29] During the pregnancy, maternal obesity and maternal drug use are risk factors for birth defects and/or developmental impairment.[30,31]

TYPES OF PRENATAL VISITS

1. The Full Prenatal Visit

The most comprehensive form of visit is a scheduled office visit with both parents and other significant family members present. During this visit, the 4 objectives listed previously are discussed in detail. Discussion should include office and telephone hours; fees; office staff; hospital affiliations; coverage for night, weekend, and emergency care; arrangements for delivery at a hospital where the pediatrician is not on the staff; and the pediatrician's expectations of the family. A handout containing this information should be given to the family. This type of visit is most important for a first pregnancy, for adolescent and other young parents, when pregnancy complications or newborn problems are anticipated, or when parents are unusually anxious for any reason. The establishment of a mutual commitment to a sound and rewarding family-physician relationship usually results from this visit.

As more women have high-risk pregnancies that require bed rest, there may be a need for home prenatal visits and/or telephone calls. These contacts should include the same content as the full prenatal visit and can be conducted by the pediatrician, the office nurse, or other trained office personnel. The outcome should be the same mutual commitment as from the full prenatal visit in the office.

2. The Brief Visit to Get Acquainted

An encounter at the office for 5 to 10 minutes between the physician and an expectant parent may include introduction to other members of the staff and a short tour of the office. Administrative issues may be discussed briefly and/or a handout with the information may be given to the parent. This type of visit is appropriate for parents who are still deciding on a pediatrician and not ready for a full visit. Although such a visit cannot cover all the desirable elements of a full visit, the pediatrician can offer to schedule a longer visit and include both parents and significant family members.

3. The Basic Contact or Telephone Call

The initial prenatal contact often is an expectant parent's call to the pediatrician's office. If the pediatrician is accepting new patients, the staff member can offer a brief description of the practice, as noted above. The parent can be asked for the same identifying information as in the longer visits, such as name, address, telephone number, source of referral, expected delivery date, and type of insurance and can be invited to make an appointment for a full prenatal visit. The office information handout may be mailed to the expectant parents.

4. No Prenatal Contact

If no prenatal contact has been made, the objectives and discussion of the prenatal visit can be presented to the parents in the newborn visit or first postnatal visit. Unfortunately, the new mother may be too tired or distracted to absorb much of what the pediatrician can offer at the hospital visit, so a handout containing pertinent information may be particularly useful for this type of visit. For the infant's first office visit, parents should be encouraged to have an additional family member on hand to care for the infant while the pediatrician confers with them.

5. The Group Prenatal Visit

The concept of the group well-child visit can be used for the prenatal visit as well. It encourages mutual support among the expectant parents in addition to providing the information and advice of the more traditional session with an individual family. It has the added advantage of saving the pediatrician time and expense. The pediatrician's participation in a prenatal class is another alternative. Families with children may find group visits an opportunity to discuss sibling rivalry.

REIMBURSEMENT

Reimbursement for a prenatal visit may be problematic. Payment by third-party payers for pediatric prenatal visits rarely, if ever, occurs. Networking—sharing information and ideas with community obstetricians and with health insurance medical directors—might be of benefit in establishing reimbursement methods. If the obstetrician makes a formal referral to the

pediatrician, who in turn sends a report back to the obstetrician about the prenatal discussion with the parents, the visit might be reimbursable. Even without insurance coverage, a modest fee may not dissuade the expectant parents from attending a prenatal visit.

ADVICE FOR PEDIATRICIANS

1. Pediatric practices are encouraged to establish a policy on prenatal visits. Services offered can be flexible and designed to meet the needs of expectant parents. In many cases, a full prenatal visit is ideal, but for some parents, a shorter encounter is sufficient.
2. Communication of the policy on charges for prenatal visits to third- party payers and to families is advised. State chapters of the American Academy of Pediatrics (as through pediatric councils) and pediatric practices can advocate to insurance companies, including Medicaid, the short-term and long-term benefits of prenatal visits for the health of infants and their parents.
3. Pediatricians should share their established policies on prenatal visits with local obstetricians and with expectant parents.
4. During their training, pediatric residents should learn about the content and importance of prenatal visits.
5. A comprehensive review of this topic with suggested questions and specific suggestions for expectant parents can be found in the third of edition of *Bright Futures*.[32]

APPENDIX: PARENT PAGE

Welcome to the world of parenthood. As you get closer to the time of your delivery, here is some information that can help you get ready to care for your new baby.

Hopefully, when the baby is born, you'll be able to hold him or her right away. Brand new infants like to be cuddled, and they are usually ready to nurse at the breast. Even if you don't want to breastfeed, holding the baby close to you can make you both feel good. It's good, too, if Daddy, grandparents, and siblings can be close by for the labor and delivery. They'll want to cuddle the baby also. They will be important players in the baby's life and can be a great help for the new mother. If breastfeeding is not the family's choice, your pediatrician will advise you about formula preparation and proper bottle feeding.

The first few weeks at home will be a lot different from the time before the baby was born. Both parents will be tired, sometimes not sure how to handle the infant's crying and other behaviors, and often a bit frustrated. When you don't quite know what to do next, or if you feel blue, edgy, or angry, that's a good time to contact your pediatrician for advice.

Your sleeping will be interrupted by the baby needing feedings and diaper changes; new infants may need to be fed every 2 to 4 hours in the first several weeks. Learn to take a nap when the baby does, and let the housework be done by family and friends during the first few weeks.

Your pediatrician can offer you advice or suggestions about supplies, furniture, and other baby needs, as well as safety tips. For example, it's much safer to put the baby to sleep on his or her back, not on the tummy, and the bassinet or crib should have a firm, smooth mattress. Both alcohol and tobacco use by the pregnant woman can be harmful for the developing fetus. Tobacco smoke anywhere near the baby may lead to breathing problems for the baby then or even months later.

It's amazing and exciting to see babies develop and change in the first few weeks. As you get to know your baby's routine and personality, you'll be more comfortable in handling him or her and making decisions in the baby's best interest.

Remember, there is no such thing as a stupid question. Whenever you need an answer about anything related to your baby, you should feel free to call your pediatrician.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Preparation for Emergencies in the Offices of Pediatricians and Pediatric Primary Care Providers

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Emergency Medicine

ABSTRACT

High-quality pediatric emergency care can be provided only through the collaborative efforts of many health care professionals and child advocates working together throughout a continuum of care that extends from prevention and the medical home to prehospital care, to emergency department stabilization, to critical care and rehabilitation, and finally to a return to care in the medical home. At times, the office of the pediatric primary care provider will serve as the entry site into the emergency care system, which comprises out-of-hospital emergency medical services personnel, emergency department nurses and physicians, and other emergency and critical care providers. Recognizing the important role of pediatric primary care providers in the emergency care system for children and understanding the capabilities and limitations of that system are essential if pediatric primary care providers are to offer the best chance at intact survival for every child who is brought to the office with an emergency. Optimizing pediatric primary care provider office readiness for emergencies requires consideration of the unique aspects of each office practice, the types of patients and emergencies that might be seen, the resources on site, and the resources of the larger emergency care system of which the pediatric primary care provider's office is a part. Parent education regarding prevention, recognition, and response to emergencies, patient triage, early recognition and stabilization of pediatric emergencies in the office, and timely transfer to an appropriate facility for definitive care are important responsibilities of every pediatric primary care provider. In addition, pediatric primary care providers can collaborate with out-of-hospital and hospital-based providers and advocate for the best-quality emergency care for their patients.

INTRODUCTION

Pediatricians and pediatric primary care providers (PPCPs) are vitally important members of the emergency care system for children. Children with potentially life-threatening illnesses and injuries are sometimes taken to primary care offices, which often serve as the child's medical home, by parents or caregivers seeking help from health care professionals they know and trust. The office site then serves as an entry into the emergency care system, and it is there that vital, perhaps even life-saving, care is provided.

Studies have shown that emergencies are common in primary care practices that provide care to children. In 1 study, the authors surveyed 52 pediatric offices and found that these practices saw a median of 24 emergencies per year.[1] Most of the offices (82%) reported that they encountered, on average, at least 1 emer-

Key Words
emergency readiness, office preparedness, emergency medical services for children, pediatric emergencies, emergency response plan

Abbreviations
PPCP—pediatric primary care provider
EMS—emergency medical services
APLS—advanced pediatric life support
BLS—basic life support
ALS—advanced life support
AAP—American Academy of Pediatrics
CPR—cardiopulmonary resuscitation
ED—emergency department
PALS—pediatric advanced life support
EMT—emergency medical technician

gency per month. In another study, 62% of pediatricians and family physicians in an urban setting who were asked about emergencies in their offices reported that they assessed more than 1 patient each week in their offices who required hospitalization or urgent stabilization.[2]

Despite these findings, which suggest that a significant number of children present to primary care offices with urgent or emergent problems, some health care professionals discount the need for preparation because "emergencies are not very common" or because they feel they can rely on rapid response from emergency medical services (EMS) or proximity to a hospital. Some PPCPs have interpreted risk-management guidelines to mean that having emergency equipment and medications on site will increase their liability in emergency situations; however, lack of preparation may be a true cause of increased liability. Other providers state that emergency equipment and medications are expensive, and they cannot afford to maintain these items. Indeed, studies have shown that a substantial number of practices are not prepared to manage pediatric emergencies and have documented deficiencies in equipment and training.[3,4] One study showed that physicians with training in advanced pediatric life support (APLS) were more likely to have resuscitation equipment and to have conducted a mock code in their office.[4] Other studies have supported training in basic life support (BLS) as well as advanced life support (ALS), as suggested by the American Academy of Pediatrics (AAP) policy statement published in December 2004.[5] The statement suggested that pediatricians will improve the chance of survival of children who experience cardiac arrest by advocating for cardiopulmonary resuscitation (CPR) training of parents and caregivers and participating in BLS training courses as participants and instructors.

STATEMENT OF THE PROBLEM

Although pediatric emergencies may not be common occurrences in all primary care settings, numerous studies have shown that children continue to be taken to primary care offices at the time of an emergency.[6–9] The most common types of emergencies include respiratory emergencies, seizures, infections in young infants, and dehydration.[10] Pediatricians and PPCPs may be required to provide urgent or emergent care in their offices for children with these conditions, at least until the arrival of EMS. The consequences of being unprepared are serious; therefore, appropriate stabilization of pediatric emergencies and timely transfer to an appropriate facility for definitive care are important responsibilities of every PPCP.[11]

OFFICE-BASED SELF-ASSESSMENT

Optimizing PPCP office readiness for emergencies begins with a consideration of the unique aspects of each office practice, the types of patients and emergencies that have been or might be seen, the resources on site, and the resources of the larger emergency care system of which the PPCP's office is part. Reviewing a standardized office-based self-assessment can provide PPCPs with a starting point for optimizing office readiness.[12] Sample questions include:

1. What emergencies have you experienced in the office setting? How often have office emergencies occurred in your practice?
2. What is your office setting (freestanding office, clinic based, health center based, hospital based, other)? Are there resources outside of your office that you could call on during an office emergency (eg, security, other medical or dental professionals in the same building, hospital code team)?
3. What are the high and low staffing points during the times when your office is open? (Include nights and weekends if applicable.) What is the emergency readiness training of the staff present during those times?
4. How far is your office from a site of definitive care, such as the nearest emergency department (ED) or the nearest pediatric center? How long does it take for EMS to respond to a 9-1-1 call from your office? What is the point of entry for your local 9-1-1 response team (ie, the facility to which they are required by protocol to bring a pediatric patient)?
5. Does your practice care for any children who are technology dependent or have special health care needs? Do you have need for any additional equipment or expertise should a technology-dependent child have an emergency in your office?
6. What is your risk-management company's policy regarding emergency preparedness of your office?

Answers to these and other questions (see Appendix 1) can help PPCPs examine their office practice within the context of the larger emergency care system and make informed choices to enhance the readiness of their office setting for anticipated emergencies.

PARENT AND PATIENT EDUCATION

Through effective parent and patient education and anticipatory guidance, some emergencies that present to the PPCP office could be prevented or directed more appropriately to an ED. PPCPs can improve the outcome of childhood emergencies by advocating CPR and first aid training of parents and caregivers and by educating them about how to prevent injuries, recognize an emergency, and respond appropriately in terms of first aid, CPR, accessing the private office or EMS, and choosing the appropriate facility: office, urgent care center, local ED, or pediatric specialty care center. Anticipatory guidance regarding emergencies should include when and

how to access EMS (9-1-1 or the local emergency access number), posting the national Poison Control Center number (800-222-1222), a means of obtaining after-hours advice, the need for consent for treatment of minors, any constraints to emergency care from health plan requirements for referral, and what facilities to access in a true emergency. Family teaching materials such as *The Injury Prevention Program*, the first aid chart, and EMS information card are available through the AAP.[13]

PPCPs should discuss advance directives and limitation of life-sustaining treatment with a family before any emergency develops.[14] Because some states do not allow EMS personnel to recognize and respect pediatric advance directives, it is critical that any out-of-hospital do-not-resuscitate or "accept-natural-death" orders be discussed at the time of their issue with local EMS medical directors to ensure that EMS personnel, when called and asked to perform comfort measures instead of aggressive resuscitative measures, are acting within preapproved medical direction and remain free from liability.

In addition, PPCPs who care for children with special health care needs can help improve emergency care for these children by providing a brief but comprehensive summary of important information for hospital and prehospital providers. Nationally recognized forms, such as the emergency information form,[15] and medical-alert jewelry can provide needed information during an emergency. Inquiring about the existence of a local Emergency Medical Services for Children–sponsored "child alert" program can further enhance the EMS response and care by strengthening the link with responding EMS personnel and decreasing the anxiety levels of parents, EMS personnel, and hospital staff. With the family's consent, mechanisms to identify children with special needs in an emergency can be established and shared with local EMS providers.[15]

PREPARING THE OFFICE AND OFFICE PERSONNEL

At the time of a pediatric emergency, good resuscitation knowledge and skills are essential to provide high-quality care and ensure the best chances for intact survival for the child, but the outcome does not depend solely on the pediatrician or primary care physician. Successful stabilization requires an effective team, and members of the office staff need to be prepared; they need adequate knowledge, training, and resources to respond to an emergency.[10] They also need an opportunity to practice; awareness of each member's role on the team and an opportunity to rehearse these roles will lead to a more highly functioning, effective emergency team.

The first person to assess patients who arrive in the office may be the least clinically experienced employee: the secretary or receptionist. These employees should be able to recognize emergencies and know how to summon help. They can be taught about signs and symptoms that may signal an emergency in a child, such as labored breathing, cyanosis, audible stridor or wheezing, grunting or flaring, seizures, depressed mental status, or uncontrolled bleeding.[16] Front-desk personnel or the office nurse might periodically check the waiting area, especially if the waiting time for an acute care visit is prolonged or the waiting area is not under direct visual supervision.

A clear response plan, including a plan for those times when the office is open but not fully staffed, is very helpful at the time of an emergency.[17] Each member of the office staff can have a specific role in the overall management plan, including designation of the individual who will access the emergency response system. Personnel who fulfill this role should receive training specific to accessing EMS, and they should be knowledgeable about the capabilities and level of response provided by the local EMS agency. Office staff will need to provide information to the EMS dispatcher, including office address and location of the office within the building; the child's age, condition, and vital signs; the transport destination; and need for an ALS unit if available.[11] Office staff cue cards can be posted by the telephone to assist in accessing emergency help and providing appropriate information[12] (Appendices 2A–2D).

The PPCP can preassign roles for the "resuscitation team," and the team can then practice these roles by participating in office mock codes or simulated exercises on a regular basis. The PPCP can "run the code" and provide medical direction, but a contingency plan should be developed to guide staff if no physician is in the office at the time of the emergency. Pediatric care protocols adapted from EMS providers might help provide a basis for the development of individualized office-based protocols and scenarios for the top 5 to 10 emergency conditions. Tasks of the office team during an emergency include assisting and performing resuscitative measures, such as chest compressions, and recording or documenting the events of the resuscitation process and drawing up and administering medications and fluids. It may be helpful for PPCPs to assess the skill level and knowledge of new employees and clinical care providers who will likely have different levels of experience in handling pediatric emergencies. All PPCPs in practice should have a minimum of BLS training, and a more advanced level of training is essential if the office does not have rapid access to an ALS response unit. When the office is open, there should be someone in the office who can recognize an emergency situation, provide BLS, and activate the emergency response system. PPCPs can facilitate training in BLS and ALS by providing time for employees to take training courses offered in the community or local hospital or by collaborating with local EMS personnel who can offer training courses on site at the office. By working together in nonemergency situations, EMS providers and office staff can create an opportunity to improve communication and develop teamwork skills that will

facilitate the transfer of care at the time of an emergency (see Appendix 3). EMS staff may be able to identify logistic problems, such as ease in locating the office or accessing the examination room with a gurney, and clarify treatment and destination protocols in their region. Some PPCPs have also found it very helpful to review actual cases and invite local EMS providers to participate in simulated drills and to supplement certification or training with teaching specific to the most common problems seen in their offices.

EMERGENCY EQUIPMENT AND MEDICATIONS

Trained personnel must have rapid access to appropriate equipment and medications to use at the time of an emergency. All office staff members need to know where resuscitation equipment is located so that no time is wasted in finding it during an emergency. For those who practice in an office located in or near a hospital, basic airway equipment may be all that is needed. However, for practices and offices that have prolonged emergency response times, stabilization efforts may need to be maintained for up to 30 minutes before EMS arrives with their equipment and stabilization skills. In these offices, more equipment might be required to maintain an airway and to initiate treatment of shock.

Resuscitation equipment can be kept in an examination room designated as the resuscitation room, which is prestocked in an organized way, or it can be stocked and organized in a box, to be taken to the site of the resuscitation. A list of recommended equipment for office emergencies is provided in Table 1, and a list of recommended medications is provided in Table 2. Equipment and medications should be checked on a regular basis to ensure that all essential items are present, operating properly, and not expired.

Health care professionals, patients, and families have developed an increased awareness of issues related to patient safety since the release of the Institute of Medicine report on medical errors in 1999.[18] Current safety literature suggests that pediatric patients are especially susceptible to medication error (dosing error) because of the need to calculate doses rather than using standardized dosing as in adult medicine.[19,20] Over the past few years, a number of clinical tools have been developed to help decrease medication errors. One of the most familiar is the Broselow pediatric resuscitation tape, which is now available in many EDs and offices across the country.[21] Studies have shown that the Broselow tape can help to reduce medication dosing (prescribing) error by providing precalculated doses.[22] It allows prescribers to avoid the step of mathematical calculation, a frequent source of error in the medication process.[23–25] However, some studies have described a potential increase in medical errors when using the Broselow tape because of its design and the fact that it is often used incorrectly.[26,27]

The Duke University Medical Center maintains a Web site (Duke Enhancing Pediatric Safety Web site; available at: www.dukehealth.org/deps) that was developed to provide education about the proper use of the Broselow tape. New resuscitation tools, which are currently being developed, will help pediatricians and pediatric care providers by providing suggested care protocols with recommended medications and precalculated doses.

Every office needs a system to ensure that all equipment, medications, and resuscitation fluids are restocked and readily available. Many offices have found it helpful to stock equipment in a way that facilitates retrieval according to the size of the child. Making sure that staff members are educated about the storage system used at the office and assessing its effectiveness in quickly guiding clinicians to the appropriate supplies is crucial to ensuring a working system.

TABLE 1 Recommended Equipment for Pediatric Office Emergencies

Office Emergency Equipment and Supplies	Priority[a]
Airway management	
Oxygen-delivery system	E
Bag-valve-mask (450 and 1000 mL)	E
Clear oxygen masks, breather and nonrebreather, with reservoirs (infant, child, adult)	E
Suction device, tonsil tip, bulb syringe	E
Nebulizer (or metered-dose inhaler with spacer/mask)	E
Oropharyngeal airways (sizes 00–5)	E
Pulse oximeter	E
Nasopharyngeal airways (sizes 12–30F)	S
Magill forceps (pediatric, adult)	S
Suction catheters (sizes 5–16F) and Yankauer suction tip	S
Nasogastric tubes (sizes 6–14F)	S
Laryngoscope handle (pediatric, adult) with extra batteries, bulbs	S
Laryngoscope blades (0–2 straight and 2–3 curved)	S
Endotracheal tubes (uncuffed 2.5–5.5; cuffed 6.0–8.0)	S
Stylets (pediatric, adult)	S
Esophageal intubation detector or end-tidal carbon dioxide detector	S
Vascular access and fluid management	
Butterfly needles (19–25 gauge)	S
Catheter-over-needle device (14–24 gauge)	S
Arm boards, tape, tourniquet	S
Intraosseous needles (16 and 18 gauge)	S
Intravenous tubing, microdrip	S
Miscellaneous equipment and supplies	
Color-coded tape or preprinted drug doses	E
Cardiac arrest board/backboard	E
Sphygmomanometer (infant, child, adult, thigh cuffs)	E
Splints, sterile dressings	E
Automated external defibrillator with pediatric capabilities	S
Spot glucose test	S
Stiff neck collars (small/large)	S
Heating source (overhead warmer/infrared lamp)	S

Note that some offices are located at a distance from EMS services. Providers in offices that are located more than 10 minutes away from the nearest EMS service need equipment that may not be required in the initial minutes of a resuscitation but will be required as the resuscitation effort extends past 10 minutes.

[a] E indicates essential; S, strongly suggested (essential if EMS response time is >10 minutes).

TABLE 2 **Office Emergency Drugs**

	Priority[a]
Drugs	
Oxygen	E
Albuterol for inhalation[b]	E
Epinephrine (1:1000)	E
Activated charcoal	S
Antibiotics	S
Anticonvulsant agents (diazepam, lorazepam)	S
Corticosteroids (parenteral/oral)	S
Dextrose (25%)	S
Diphenhydramine (parenteral, 50 mg/mL)	S
Epinephrine (1:10 000)	S
Atropine sulfate (0.1 mg/mL)	S
Naloxone (0.4 mg/mL)	S
Sodium bicarbonate (4.2%)	S
Fluids	
Normal saline solution or lactated Ringer's solution (500-mL bags)	S
5% Dextrose, 0.45 normal saline (500-mL bags)	S

[a] E indicates essential; S strongly suggested (essential if EMS response time is more than 10 minutes).

[b] Metered-dose inhaler with spacer or mask may be substituted.

Adapted from: American Academy of Pediatrics, Committee on Pediatric Emergency Medicine. *Emergency Medical Services for Children: The Role of the Primary Care Provider*. Singer J, Ludwig S, eds. Elk Grove Village, IL: American Academy of Pediatrics; 1992.

HEALTH CARE PROFESSIONAL SKILLS

In the setting of a pediatric emergency, PPCPs must be able to provide basic airway management and initiate treatment of shock. The skills required to perform these tasks successfully are usually acquired in training, but many PPCPs do not use them frequently, because the incidence of office emergencies is not high. Nonetheless, when an emergency occurs, the best chance for intact survival of the child is determined by adequate airway management. Therefore, providers need to keep their resuscitation skills and knowledge up to date. Pediatric advanced life support (PALS)[28] and APLS[29] courses provide an excellent opportunity to renew knowledge and skills. The Emergency Nurse Pediatric Course, developed by the Emergency Nurses Association, provides training in basic assessment, triage skills, critical care, and pediatric emergent situations. The course includes small group sessions for skills training and evaluation.

Although maintaining knowledge and skills of clinicians is important, more is involved to ensure that the best care is provided to every child who is brought to the office with an emergency. The best way to ensure readiness for an emergency is to practice regularly in the office setting, with as many office staff members as possible participating. Simulated exercises, or mock codes, provide a good opportunity for staff members to practice the steps of an emergency.[16] A mannequin, doll, or even "volunteer child" can be used to make the practice session more realistic, and participants can be asked to "act out" each step of the resuscitation. For example, direct an individual to act as a parent and "present" to the reception area of the office, holding an "infant" (mannequin) and complaining that the infant will not wake up. The receptionist would then need to activate the emergency response system designed for the office. In some offices, this may mean calling aloud for help; in other offices, the receptionist may ring a bell or overhead-page someone for help. The nurse can be instructed to respond as he or she would in a real emergency, perhaps by taking the infant to a treatment room if one exists in the office or by calling for help and locating the emergency equipment box to bring to the examination room where the infant is taken. Clinical staff can then be asked to locate specific pieces of equipment they may need for the resuscitation. For example, they might be asked to locate the oxygen tank with appropriate tubing and demonstrate how to turn it on or locate the bag-valve-mask device (eg, Ambu bag) and demonstrate proper bagging technique. The physical act of locating and handling equipment such as the bag-valve-mask device is important for staff members to practice to be better prepared to perform these tasks when a true emergency occurs. Team members can then offer observations of their own and others' performances, and specific action plans for improvement and problem solving can be developed. Action plans might address such topics as additional training needs, skills practice, equipment needs, and organizational issues. A sample of a mock-code evaluation form is shown in Appendices 4A and 4B, and sample scenarios for use in a mock code are shown in Appendix 5.

When planning a mock code for office personnel, designate a recorder for each simulated exercise. After completing the exercise, critique not only the mock code itself but also the documentation of the event. In addition, keep records of mock codes held in the office with a note of "lessons learned" from each one. If there has been a recent change in office practice or equipment (ie, new forms used to document treatment), it may be helpful to include these as specific teaching points after the simulated exercise.

Another strategy used by some offices to improve "readiness" for an emergency is a scavenger hunt.[11] This may be especially helpful for new staff or employees as part of their orientation to the office setting. Staff members are given a list of items (such as emergency equipment, medications, supplies, posted protocols for accessing EMS) and asked to find them within a defined period of time.

DOCUMENTATION

The most effective tool for risk management of office emergencies is documentation of efforts taken to improve office readiness, such as purchase and maintenance of equipment and medications; training provided; and policy and practice for patient education, patient triage, and office flow. Working toward the common goal of improved outcomes for office emergencies, pedi-

atric practices can collaborate with their risk-management agent to find ways to reduce risk while improving readiness. Documentation should also be included in office training and mock codes and, most importantly, during true resuscitation attempts.

Emergency situations are the most difficult to document properly. Stress levels are high, there are often not enough trained assistants, and other patients in the waiting room cannot be ignored. However, complete and accurate information regarding resuscitative efforts is vital for ongoing care, especially at the time of transfer of care. Documentation should include the date and time of treatment, the estimated or actual weight of the child if known, medications given with dosages and response noted, fluid volumes given, information or explanations given to the family, and the condition of the child at the time of departure from the office. An example of a "resuscitation log" is shown in Appendix 6.

EMERGENCY MEDICAL SERVICES

When a child requires resuscitation in an office, the PPCP and office staff members need help from other members of the emergency care team to ensure the best possible outcome. EMS personnel can provide competent assistance to the office team.

EMS personnel who respond to pediatric emergencies may include first responders, BLS emergency medical technicians (EMTs), or ALS EMTs (eg, EMT-paramedics). First responders and BLS EMTs can offer essential BLS skills and transport. ALS EMTs, acting under medical control and advanced protocols, can perform advanced airway-management skills, including positive-pressure ventilation and placing airway adjuncts. They can also establish intravenous or intraosseous access, administer intravenous or nebulized medications, defibrillate, and perform other advanced skills, in accordance with local protocols.[16] Because only a small percentage (5%–10%) of EMS calls are for pediatric patients, many paramedics may have limited experience in working with children.[11] PPCPs can help EMS personnel gain experience with children by inviting them to observe well-child visits in the office and providing an opportunity to interact with children. In many communities, paramedics have assisted pediatricians by helping to teach PALS or CPR classes to office staff. Establishing good and close communication with local EMS providers can help inform your office of their unique skill sets and introduce them to the types of emergencies to which they might be called to respond from your office. Including the medical director of the EMS service in office-based emergency-preparedness activities can assist in helping the EMS personnel be prepared with proper training and protocols for pediatric patients.

EMS personnel are well trained in resuscitative skills and are important members of the health care team. However, they cannot assist in the care of children who are critically ill unless they are called. PPCPs should confirm the access number for EMS (usually 9-1-1, but in some areas it may still be a 7-digit number) and have the number posted for easy access by any office staff directed to call EMS when an emergency is recognized. The office staff and physician should not delay activating EMS because of a concern that they might not actually be needed. In the long run, it is much better to have a unit respond even if the call is canceled en route or the child is not transported if he or she stabilizes in the office.

ADVOCACY

PPCPs have a critical role as advocates for high-quality emergency care for their pediatric patients. In partnership with out-of-hospital and hospital-based staff, PPCPs can help ensure the readiness of all components of the emergency care system to care for children. For example, PPCPs can collaborate with local EMS to offer life-support training courses; provide office-based pediatric training for EMTs; participate in development of pediatric protocols with EMS; serve as advisors for out-of-hospital pediatric care review; and advocate for EMS to obtain appropriate pediatric training, equipment, and supplies. Finally, they can work to educate parents and lawmakers about the unique needs of children and the special and sometimes complex medical needs of children within the EMS system.

SUMMARY

Pediatricians and other PPCPs are critically important members of the pediatric emergency care team. They can be most successful when they understand their role within a larger emergency care system. Effective parent education can reduce emergencies and help ensure appropriate access to the emergency care system. Careful self-assessment of office practice and policies can optimize office readiness before an emergency. When the primary care office becomes the entry point into the EMS system for a child, that child's long-term outcome can be greatly influenced by care provided in the first minutes of the emergency. Skilled physicians who work with appropriate equipment and a well-trained team, in collaboration with the EMS system, can achieve timely resuscitation and transfer to definitive care and offer the best chance for intact survival for every child and family who seeks their care in an emergency.

RECOMMENDATIONS

1. Perform a self-assessment of office readiness for emergencies based on a review of experiences of common emergent, urgent, and acute conditions treated in the office, including events involving children with special health care needs.
2. Develop an organizational plan for emergency response in the office, which includes:
   a. recognition of an emergency;

b. staff communication, roles, and responsibilities at the time of an emergency during times of high and low staffing;

c. protocol to access EMS; and

d. maintaining readiness through practice (mock codes).

3. Maintain recommended emergency equipment.

   a. Organize emergency equipment in a way that facilitates access to appropriate type and size at the time of an emergency.

   b. Develop a system to check equipment on a regular basis to make sure that it is immediately available and functioning properly.

4. Maintain recommended emergency medications and use a resuscitation aid or tool that provides suggested protocols with precalculated medication doses.

   a. Develop a system to check medications on a regular basis to make sure that stock is always present and expired medications are disposed of properly.

5. Develop a plan to provide education and continuing medical education for all staff.

   a. Front-line staff: recognizing emergencies; activating the emergency response plan; and understanding EMS roles, capabilities, and access

   b. Clinical staff: maintaining knowledge and skills related to pediatric emergencies

   c. All staff: maintaining readiness; participating in mock codes; office checklist; office self-assessment

6. Practice mock codes in the office on a regular basis (quarterly or biannually).

   a. Involve as many staff members as possible.

   b. Include documentation as a defined role for a staff member.

   c. Critique the simulation and maintain a list of lessons learned.

   d. Include EMS when possible.

   e. Include disaster-preparedness scenarios in mock drills (see www.dukehealth.org/deps).

7. Educate families about what to do in an emergency.

   a. Encourage first aid and CPR training for parents and caregivers.

   b. Provide access number for after-hours advice, emergency response system, and poison information to families.

   c. Educate families about symptoms and situations for which they should access office advice, EMS, and poison information.

   d. Facilitate use and maintenance of emergency information forms for children with special health care needs.

8. Partner with EMS and hospital-based emergency providers to ensure optimal emergency care and emergency/disaster readiness for children.

APPENDIX 1: SELF-ASSESSMENT OF OFFICE PREPAREDNESS FOR PEDIATRIC EMERGENCIES

As you answer these questions, you may be better able to identify those areas in which your office preparedness can be enhanced.

1. What emergencies have you experienced in the office setting? How often have office emergencies occurred in your practice?

2. What is your office setting (freestanding office, clinic based, health center based, hospital based, other)? Are there resources outside your office on which you could call during an office emergency (eg, security, other medical or dental professionals in the same building, hospital code team)?

3. What are the high and low staffing points during the times when your office is open? (Include nights and weekends if applicable.)

4. What is the emergency readiness of the staff present during those times? (Include first aid, CPR, BLS, ALS, PALS, APLS, Emergency Nurse Pediatric Course, other continuing medical education, etc.)

5. Have nonclinical staff been trained to recognize a potential or actual emergency?

6. What anticipatory guidance and education do you provide parents regarding injury prevention, first aid and CPR training, recognizing and responding to emergencies, and accessing EMS?

7. Is your waiting room under direct observation or screened frequently by a clinical staff member? Is it childproofed?

8. Does your practice have a written protocol for response in an office emergency? Does that protocol cover times of low staffing?

9. Do all staff members know how to access the EMS system? Staff members should be able to give the location and directions to the office, level of clinical staff present, age and condition of child (including vital signs if appropriate), desired transport location, and the level of emergency response (ALS or BLS) required.

10. Do you have specific telephone triage protocols for nonclinical and clinical staff?

11. How far is your office from a site of definitive care, such as the nearest ED, or the nearest pediatric center?

12. How long does it take for EMS to respond to a 9-1-1 call from your office?
13. Has EMS ever been to visit your office for a nonemergency call or to receive experience in evaluating pediatric patients?
14. What level of provider comes when you call 9-1-1: first responder, BLS, or ALS? Does your local EMS have the necessary equipment and expertise to manage children?
15. What is the point of entry for your local 9-1-1 response team (ie, the facility to which they are required by field protocol to bring a pediatric patient)?
16. If EMS does not go directly to a pediatric center on a 9-1-1 call, how do you emergently transport a child to the desired pediatric center when necessary?
17. Does your office use oxygen? If so, how is it supplied? Do all clinical staff members know how to operate the oxygen canister and know where the key is kept?
18. What emergency dosage strategy do you use in the office (code card, length-based tape, dosage book, no strategy)?
19. What airway equipment do you stock? Do all staff members know how to locate, choose, and use the appropriate size of equipment for any given child?
20. What equipment and supplies do you have on site to provide you and your staff with universal precautions?
21. Does your practice care for any children who are technology dependent or have special health care needs? Do you have need for any additional equipment or expertise if a technology-dependent child should have an emergency in your office?
22. Do you have written office protocols for common office emergencies such as respiratory distress, anaphylaxis, sepsis, dehydration, and supraventricular tachycardia?
23. How do you document events during an office emergency (assigned role, tape recorder, retrospective, other)?
24. How do you and your staff maintain skills and readiness? (Examples include attending nursery deliveries, moonlighting in urgent care or pediatric ED, being a PALS or APLS instructor, holding regular mock office codes and scavenger hunts for infrequently used equipment, providing expert review of pediatric runs for your local EMS, or other.)
25. How do you document parent education, staff training, protocols, and stocking for emergencies?
26. What is your risk-management company's policy regarding emergency preparedness of your office?
27. Are there other aspects of your office practice that you think could be improved to achieve fewer office emergencies and better outcomes?

APPENDIX 2A: RECEPTION DESK EMERGENCY CARD

The following signs and symptoms may signal an emergency:

- Extremely labored breathing
- Blue or pale color (cyanosis)
- Noisy breathing (wheezing or stridor)
- Altered mental status
- Seizure
- Agitation (in the parent)
- Vomiting after a head injury
- Uncontrolled bleeding

If you feel a patient has symptoms that may signal an emergency, alert the following office staff: _____.

APPENDIX 2B: IMPORTANT TELEPHONE NUMBERS

- EMS provider (9-1-1 or your local emergency response number)
- Private ambulance service
- Specialized pediatric transport team(s)
- Office building security
- Police department
- Fire department
- Receiving hospital

Office address and directions _____

APPENDIX 2C: CALLING EMS FOR AN OFFICE EMERGENCY

Call 9-1-1 or your local EMS emergency response number: _____.

Be ready to give the emergency medical dispatcher the following information:

- Age and condition of child (with vital signs, if appropriate)
- Your office location (with directions and telephone number, if necessary)
- Level of clinical staff present
- Desired transport destination (pediatric center, local ED, other)
- Level of EMS provider required: ALS (advanced life support) or BLS (basic life support)
- If required, where security or other personnel will be meeting them to assist in guiding EMS to location of the child

APPENDIX 2D: IMPORTANT EMERGENCY TELEPHONE NUMBERS

(Fill in the blanks with your local emergency numbers)

EMS 9-1-1 or local EMS access number_____

Non-EMS Ambulance Transport Services

_____

_____

_____

Pediatric Transport Teams

_____

Security _____

Other _____

APPENDIX 3: BUILDING A PPCP-EMS PARTNERSHIP—ACTION POINTS

- Offer your office as a pediatric training and refresher site for EMTs.
- Invite local EMS to participate in regularly scheduled office mock codes.
- Sponsor a local EMT to take a PALS instructor course together with one of your staff members.
- Consult your local EMS to review office emergency procedures, access, and equipment in light of their response time, medications, equipment, and destination options.
- Offer to review pediatric run sheets as part of your local EMS agency quality assurance/quality improvement processes.

APPENDIX 4A: MOCK-CODE EVALUATION FORM

	Yes	No	Comments
Clinical primary survey			
Airway assessed initially			
Breathing then assessed			
Oxygen started for respiratory distress			
Circulation assessed			
Initial interventions			
Protocol or treatment guideline followed			
Patient reassessed frequently			
Secondary survey (head-to-toe examination)			
Organization			
All supplies requested were available			
Supplies were found quickly when requested			
"Code form" available and/or used			
Personnel knew how to use equipment properly (O_2 tanks, etc)			
Protocols available and/or used			
Communication			
Leader communicated effectively			
Events recorded accurately			
Roles were assigned			
Office staff reported to EMS			
EMS communicated needs/plans with office staff			
Other comments			

APPENDIX 4B: MOCK CODES IN THE OFFICE—OBSERVATIONS DURING A MOCK CODE

Clinical

- Were the ABCs assessed rapidly at the onset of the emergency then reassessed at frequent intervals during the resuscitation?
- If intravenous access was not established within 90 seconds, did the team move rapidly to intraosseous access?
- Once the ABCs were assessed, did the examiner complete a systematic evaluation of the patient?
- When interventions were unsuccessful, did the team move rapidly to another intervention?
- Was the patient stabilized before the transfer, or was the "scoop–and–run" principle utilized?
- Did office practitioners use services that EMS can provide, including equipment and skills?

Organizational

- Was the EMS system activated promptly?
- Was communication directed and clear between all members of the emergency team?
- Were roles clearly assigned by the team leader?
- Were all members of the emergency team free to make suggestions on the patient's behalf?
- Did anyone speak to the family during the emergency stabilization?
- Did someone record the events during the emergency stabilization?

APPENDIX 5: SCENARIO SAMPLES

Diabetic ketoacidosis: 10-year-old with new-onset diabetic ketoacidosis; polyuria and polydipsia for 1 week; today lethargic and confused; glucose >800.

Sepsis: 2-year-old with meningococcemia; well in past but found this morning with rash, moaning and minimally responsive; had upper respiratory infection yesterday and 2 episodes of vomiting; otherwise fine.

Asthma: 8-year-old with asthma; has been wheezing for 2 days with upper respiratory infection but worsened this afternoon; told mom before he was brought to the office that he had been giving himself puffs of his inhaler every half hour most of the day.

Head trauma: 6-year-old with concussion and possibly more; was playing soccer and collided with another child; she was "out" for 2 to 3 minutes, then woke up and was groggy but oriented; vomited once on the way to your office.

Seizures: 1-year-old with a complex febrile seizure; pulling at her ears and found to have a temperature of 104°F; mom gave her a bath to cool her off, and she began to have a generalized seizure several minutes later; her parents rushed her to the office while carrying her on their laps; the seizure has persisted for over 20 minutes.

Stridor: 2-year-old with possible epiglottitis; woke up early this morning with very loud breathing and a barking cough; feels very hot to touch; has been drooling for past 30 minutes; now appears anxious and tired.

Anaphylaxis: 5-year-old boy who was stung by a bee while playing outside; mom notes that his eyes and lips swelled within minutes; she brought him to the doctor when he subsequently developed wheezing.

Patient_____ Date_____Time_____
Physician_____Nurse_____Other_____
Nurse_____Nurse_____Other_____

Time	Intervention	Medication/Dose/Route	HR	RR	BP	Temp	Pox	O^2	CPR

Code start time	Transferred to
EMS Time Called	Physician referred to
EMS Time Arrived	Diagnosis
EMS Time Departed	
Paramedic Names	
IO Size/Location	
IV Size/Location	

APPENDIX 6
Code chart: consider for use at time of office emergency. HR indicates heart rate; RR, respiration rate; BP, blood pressure; Pox, pulse oximetry; IO, intraosseous needle; IV, intravenous catheter.

CLINICAL REPORT

Preparing for Pediatric Emergencies: Drugs to Consider

Guidance for the Clinician in Rendering Pediatric Care

Mary A. Hegenbarth, MD, and the Committee on Drugs

ABSTRACT

This clinical report provides current recommendations regarding the selection and use of drugs in preparation for pediatric emergencies. It is not intended to be a comprehensive list of all medications that may be used in all emergencies. When possible, dosage recommendations are consistent with those used in current emergency references such as the *Advanced Pediatric Life Support* and *Pediatric Advanced Life Support* textbooks and the recently revised American Heart Association resuscitation guidelines.

www.pediatrics.org/cgi/doi/10.1542/peds.2007-3284

doi:10.1542/peds.2007-3284

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

Key Words
pediatric emergency, drugs, resuscitation, emergency preparedness

Abbreviations
IV—intravenous
IO—intraosseous
ET—endotracheal
RSI—rapid-sequence intubation
VT—ventricular fibrillation
PE—phenytoin equivalent

INTRODUCTION

The purpose of this document is to assist health care professionals and facilities in their preparation for pediatric emergencies. This clinical report enables the practitioner to review current recommendations for the use of emergency medications in acutely ill children who require pharmacologic intervention. New agents and changing patterns of practice make it necessary to revise and update this clinical report.

This document is not intended to be an all-inclusive list of drugs used in pediatric emergencies, and it does not provide detailed drug information. Antimicrobial agents are not included in this document. Descriptions of medication indications and adverse effects are limited. Although not all-inclusive, the drug information listed in Table 1 should be helpful to practitioners and institutions when selecting which pharmacologic agents to have readily available for use in pediatric emergencies. The selection of which drugs to have available will depend on the setting; although emergency departments and hospitals will likely need the majority of the agents listed, a much more limited selection would likely be needed in a practitioner's office. This information should also be helpful for creating or editing preprinted drug-dosage charts. Table 2 contains a list of rescue, reversal, and antidote medications that may be useful in specific settings; it lists only the agents and indications and is not augmented with textual descriptions.

Dosages are generally given as milligrams per kilogram. The format for presented dosages is consistent with American Academy of Pediatrics recommendations for reducing medication errors.[1] For high-potency drugs such as prostaglandins, vasoactive amines, nitroprusside, and fentanyl, dosages are given as micrograms per kilograms. Historically, the weight-based "rule of 6" was recommended for preparation of vasoactive drip medications.[2] However, the Joint Commission and other organizations have recommended that standardized drip concentrations should replace rule-of-6 calculations to reduce the possibility of medication errors.[3] The selection of drugs for use in pediatric emergencies is only one part in a large system or program that needs to be designed effectively to manage pediatric patients in an emergency situation. It is the creation, monitoring, and evaluation of these systems that will result in an improved outcome for pediatric patients.[4]

Rates and routes of administration are drug specific, and proper infusion systems should be used. Both adverse events and therapeutic effectiveness are dose and rate dependent, especially when highly potent vasoactive medications are administered. In general, most drugs should be administered over several minutes to avoid transient excessive blood concentrations. However, exceptions exist. One example is adenosine, for which rapid infusion is needed for efficacy. Another example of the importance of administration rate is phenytoin/fosphenytoin, for which slow infusion is necessary to minimize adverse events. Please refer to the text below. Unless otherwise indicated, the intravenous (IV) route is preferred. In an emergency, intraosseous (IO) administration is an acceptable alternative when IV access cannot be promptly obtained. Although certain drugs (lidocaine, epinephrine, atropine, naloxone [memory aid: LEAN]) can be administered endotracheally if no

TABLE 1 Potentially Useful Drugs in Pediatric Emergencies

Adenosine	Diphenhydramine	Glucagon	Lorazepam	Phenytoin
Albuterol	Dobutamine	Glucose	Magnesium sulfate	Prednisone/Prednisolone
Alprostadil	Dopamine	Haloperidol	Mannitol	Procainamide
(see Prostaglandin E_1)	Epinephrine	Hydrocortisone	Methylprednisolone	Propranolol
Amiodarone	Epinephrine, racemic	Insulin	Midazolam	Prostaglandin E_1
Atropine	Etomidate	Ipratropium	Milrinone	Rocuronium
Bicarbonate, sodium	Fentanyl	Kayexalate™ (see sodium	Morphine	Sodium polystyrene
Calcium chloride	Flumazenil	polystyrene	Nalmefene	sulfonate
Charcoal, activated	Fosphenytoin	sulfonate)	Naloxone	Succinlycholine
Dexamethasone	Furosemide	Ketamine	Nitroprusside	Thiopental
Diazepam		Levalbuterol	Norepinephrine	Vecuronium
		(see albuterol)	Phenobarbital	
		Lidocaine		

Adenosine	
Indication	Supraventricular tachycardia
Dosage	Initial dose: 0.1 mg/kg IV (maximum: 6 mg for first dose) as rapidly as possible, followed by immediate rapid flush of the IV catheter with 5–10 mL of normal saline. A 2-syringe technique is preferred; a larger flush of up to 20 mL may be helpful in older children. The most proximal IV site possible should be used. Adenosine may be given intraosseously if IV access has not been achieved.
Subsequent doses	If no AV block occurs and there is no response within 30 s, give double the initial dose (0.2 mg/kg, up to 12 mg maximum for second/subsequent doses) followed by immediate rapid saline flush as described above.
Note	Continuous electrocardiographic monitoring should be employed during use. A defibrillator must be immediately available.
Warning	Contraindicated in patients who have had a heart transplant; contraindicated in second- and third-degree AV block or sick-sinus syndrome unless a pacemaker has been placed.
Albuterol	
Indication	Asthma exacerbation, bronchospasm
Dosage	Intermittent treatment with 0.5% nebulizer solution (5 mg/mL): minimum dose 2.5 mg (0.5 mL) every 20 min for 3 doses, then 0.15–0.30 mg/kg up to 10 mg every 1–4 h as needed. Dilute in a minimum of 2–3 mL of saline solution for adequate nebulization. Continuous/prolonged nebulization: 0.5 mg/kg per h up to 10–15 mg/h diluted in a larger amount of saline by prolonged nebulization (total amount of fluid is determined by particular type of nebulizer delivery device, usually 25–30 mL for 1 h of nebulization). Metered-dose inhaler: 4–8 puffs (90 μg per puff) every 15–20 min for 3 doses. Repeat every 1–4 h as needed. A spacer/holding chamber must be used when administering metered-dose inhaler treatments. Administration can be repeated and dose can be adjusted until desired clinical effect unless patient develops symptomatic tachycardia.
Notes	Oxygen is the preferred gas source for nebulization. Supplemental oxygen may be needed when compressed air–driven nebulizers are used or when the oxygen flow rate dictated by the nebulizer device is inadequate to maintain adequate oxygen saturation. Levalbuterol may also be used; the dose is half of the (racemic) albuterol dose listed above.
Alprostadil—see prostaglandin E_1	
Amiodarone	
Indication	Pulseless ventricular fibrillation (VT)
Dosage	IV/IO: 5 mg/kg rapid bolus (maximum: 300 mg); may be repeated up to a total daily dose of 15 mg/kg.
Indication	VT/supraventricular tachycardia with a pulse.
Dosage	IV/IO: 5 mg/kg (maximum: 300 mg) over 20–60 min. Adjust administration rate to urgency. May be followed by infusion of 5 μg/kg per min, increased to maximum of 10 μg/kg per min. Concentration of continuous infusion should not exceed 2 mg/mL and should be diluted with D5W.
Note	Amiodarone is only appropriate in pulseless ventricular arrhythmias after defibrillation and epinephrine have been initiated. Because of its long half-life and potential drug interactions, cardiologist consultation is recommended when considering amiodarone treatment outside of the cardiac arrest setting.
Warning	May cause hypotension, bradycardia, heart block, prolonged QT interval, and torsades de pointes VT. Should not be used in combination with procainamide or other drugs that cause QT prolongation without expert consultation. Contraindicated in severe sinus node dysfunction, marked sinus bradycardia, and second- and third-degree AV block. Do not confuse name with amrinone; potential fatal complications if drugs or dosages are interchanged.
Atropine	
Indication	Symptomatic vagally mediated bradycardia or AV block Symptomatic bradycardia unresponsive to oxygenation, ventilation, and epinephrine
Dosage	IV/IO: 0.02 mg/kg. Minimum single dose: 0.1 mg. Maximum single dose: 0.5 mg for a child, 1.0 mg for an adolescent. May repeat dose every 5 min to maximum total dose of 1 mg for a child and 2 mg for an adolescent or adult. IM: 0.02–0.04 mg/kg.

TABLE 1 **Continued**

	ET: Neonates: 0.01–0.03 mg/kg.
	Children and adolescents: 0.03–0.06 mg/kg.
	Follow with or dilute in saline flush (1–5 mL) based on patient size.
Note	Oxygenation and ventilation are essential first maneuvers in the treatment of symptomatic bradycardia. Epinephrine is the drug of choice if oxygen and adequate ventilation are not effective in the treatment of hypoxia-induced bradycardia.
Indication	Anticholinesterase poisoning
Dosage	IV: for children, 0.05 mg/kg (up to initial adult dose: 2–5 mg).
	Repeat/adjust dose as needed for clinical effect. If response to initial dose is inadequate, may double the dose and repeat every 10–20 min as needed to dry pulmonary secretions and achieve anticholinergic effect (atropinization). Anticholinesterase or nerve gas poisonings may require large doses of atropine and the addition of pralidoxime.
Indication	Prevention of bradycardia associated with RSI
Dosage	IV/IO: 0.01–0.02 mg/kg (minimum dose: 0.1 mg; maximum dose: 1 mg) before administration of sedative/anesthetic and paralytic agents.
Warning	Atropine sulfate comes in different concentrations; calculate dosage accordingly.
Bicarbonate, sodium	
Indication	Metabolic acidosis
	Hyperkalemia
	Sodium channel blocker (eg, tricyclic antidepressant) overdose
Dosage	IV/IO: 1–2 mEq/kg given slowly; do not give by ET route.
Notes	Only the 0.5 mEq/mL concentration should be used for newborn infants; dilution of available stock solutions may be necessary. Do not mix sodium bicarbonate with vasoactive amines or calcium.
	Routine initial use of sodium bicarbonate to treat cardiac arrest is not recommended. However, sodium bicarbonate may be used in patients with documented metabolic acidosis after effective ventilation has been established (effective ventilation is needed to allow elimination of excess CO_2 produced by bicarbonate).
	For sodium channel blocker overdose, titrate bicarbonate to maintain a serum pH of 7.45–7.55, followed by infusion of 150 mEq $NaHCO_3$/L solution to maintain alkalosis.
Calcium chloride	
Indications	Hypocalcemia
	Hyperkalemia
	Hypermagnesemia
	Calcium channel blocker toxicity
Dosage	IV/IO: 20 mg/kg (0.2 mL/kg for 10% $CaCl_2$). Give by slow push for cardiac arrest; infuse over 30–60 min for other indications. Monitor heart rate; repeat dose as necessary for desired clinical effect.
Notes	Calcium chloride administration results in a more rapid increase in ionized calcium concentration than calcium gluconate and is preferred for the critically ill child. Calcium gluconate (dose: 60 mg/kg) may be substituted if calcium chloride is not available.
	Recommended for cardiac resuscitation only in cases of documented hyperkalemia, hypocalcemia, hypermagnesemia, or calcium channel blocker toxicity.
Warning	Stop injection if symptomatic bradycardia occurs. Administration through a central venous catheter is preferred; extravasation through a peripheral IV line may cause severe skin and soft tissue injury.
Charcoal, activated	
Indication	Acute ingestion of selected toxic substances
Dosage	1–2 g/kg PO or nasogastrically; adolescent/adult dose: 50–100 g.
Note	Consultation with poison center/clinical toxicologist is strongly encouraged before use (national Poison Control Center telephone number: 800-222-1222). Iron, lithium, alcohols, ethylene glycol, alkalis, fluoride, mineral acids, and potassium are not bound by activated charcoal.
Warnings	If airway protective reflexes are impaired, the risk of administering activated charcoal may outweigh the benefits.
	Commercially available preparations of activated charcoal often contain sorbitol as a cathartic. Fatal hypernatremic dehydration has been reported after repeated doses of charcoal with sorbitol. Non–sorbitol-containing products should be used for children $<$1 y old and if repeated doses of charcoal are necessary.
Dexamethasone	
Indication	Emergency treatment of elevated ICP caused by brain tumor
Dosage	IV/IO: 1–2 mg/kg.
Indication	Laryngotracheobronchitis (croup)
	Asthma exacerbation
Dosage	IV, IM, or PO: 0.6 mg/kg (maximum: 16 mg).
Note	Further dosing and route of administration determined by clinical course.
Diazepam	
Indication	Status epilepticus
Dosage	IV: 0.1–0.3 mg/kg every 5–10 min (maximum: 10 mg per dose). Administer over ~2 min to avoid pain at IV site.
	Rectal: 0.5 mg/kg up to 20 mg (this route may be useful when IV access is unavailable, but absorption may be erratic).
Note	IM route is not recommended because of tissue necrosis (other benzodiazepines, such as lorazepam and midazolam, may be given IM). Diazepam should be followed immediately by a long-acting anticonvulsant, such as phenytoin/fosphenytoin, because it is rapidly redistributed and seizures often recur within 15–20 min. Lorazepam may be preferred, because it has a prolonged duration of anticonvulsant activity.

TABLE 1 **Continued**

Warning	There is an increased incidence of apnea when diazepam is given rapidly IV or when it is used in combination with other sedative agents. Monitor oxygen saturation and respiratory effort. Be prepared to support ventilation. Flumazenil may be administered to reverse life-threatening respiratory depression caused by diazepam or other benzodiazepines; however, it also counteracts the anticonvulsant effects and may precipitate seizures.
Diphenhydramine	
Indications	Acute hypersensitivity reactions Dystonic reactions
Dosage	IV/IM: 1–2 mg/kg (maximum initial dosage: 50 mg).
Note	May cause sedation and respiratory suppression, especially if using other sedative agents. May cause hypotension. Rapid IV administration may precipitate seizures. All doses may cause paradoxical excitement or agitation.
Dobutamine	
Indication	Cardiogenic shock, congestive heart failure
Dosage	IV infusion: 2–20 μg/kg per min, titrated to desired clinical effect.
Warning	May cause tachyarrhythmias/ectopic beats, hypotension, and hypertension. Extravascular administration can result in severe skin injury. Phentolamine (dose: 0.1–0.2 mg/kg up to 10 mg diluted in 10 mL of 0.9% sodium chloride) injected intradermally at extravasation site may be helpful for counteracting dermal vasoconstriction.
Dopamine	
Indication	Cardiogenic/distributive shock
Dosage	IV infusion: 2–20 μg/kg per min, titrated to desired clinical effect.
Note	Effects are dose dependent; low-dose (1–5 μg/kg per min) infusions usually stimulate dopaminergic and β-adrenergic receptors; α-adrenergic effects predominate at higher doses.
Warning	May cause arrhythmias and hypertension. Infusion rates of >20 μg/kg per min may cause peripheral, renal, and splanchnic vasoconstriction and ischemia. Extravascular administration can result in severe skin injury. Phentolamine (dose: 0.1–0.2 mg/kg up to 10 mg diluted in 10 mL of 0.9% sodium chloride) injected intradermally at extravasation site may be helpful for counteracting dermal vasoconstriction.
Epinephrine	
Dosage/formulation	Epinephrine is available in 2 concentrations: 1:1000 (1 mg/mL) and 1:10 000 (0.1 mg/mL). Use caution to ensure selection of the appropriate concentration for the route of administration and patient age/condition. To convert mg/kg dosage to mL/kg: 0.01 mg/kg = 0.1 mL/kg of 1:10 000 solution and 0.1 mg/kg = 0.1 mL/kg of 1:1000 solution.
Indication	Cardiopulmonary resuscitation
Dosage	
IV/IO	Newborn infants: 0.01–0.03 mg/kg of 1:10 000 solution. Older infants/children: 0.01 mg/kg of 1:10 000 solution (maximum: 1 mg), repeated every 3–5 min.
ET	Newborn infants: 0.03–0.10 mg/kg of 1:10 000 solution. Older infants/children: 0.1 mg/kg of 1:1000 solution (maximum: 10 mg). Follow ET administration with saline flush or dilute in isotonic saline (1–5 mL) based on patient size.
Note	IV high-dose epinephrine (0.1 mg/kg) is no longer recommended for routine use in resuscitation. It may be considered in exceptional circumstances such as β-blocker poisoning.
Indication	Anaphylaxis
Dosage	IM/SC: 0.01 mg/kg of 1:1000 solution (maximum: 0.3–0.5 mg), repeated every 5–20 min. The IM route is preferred for anaphylaxis. Severe reactions (eg, latex allergy) may require IV epinephrine (see above); a continuous infusion of epinephrine may be necessary.
Indication	Continued shock after volume resuscitation
Dosage	IV infusion: 0.1–1.0 μg/kg per min. Start at lowest dose and titrate to desired clinical effect. Doses as high as 5 μg/kg per min are sometimes necessary.
Warning	IV infiltration can result in severe skin injury. Phentolamine (dose: 0.1–0.2 mg/kg up to 10 mg diluted in 10 mL of 0.9% sodium chloride) injected intradermally at extravasation site may be helpful for counteracting dermal vasoconstriction.
Indication	Severe asthma exacerbation
Dosage	SC: 0.01 mg/kg of 1:1000 solution (maximum: 0.3–0.5 mg); may repeat every 20 min up to 3 doses. Begin simultaneous treatment with inhaled β-agonist (albuterol) and corticosteroids.
Indication	Laryngotracheobronchitis (croup)
Dosage	0.5 mL/kg of 1:1000 solution (maximum: 5 mL = 5 mg) administered by nebulizer.
Epinephrine, racemic	
Indication	Laryngotracheobronchitis (croup) Acute airway edema
Dosage	2.25% inhalation solution: 0.05 mL/kg (maximum: 0.5 mL) in 2 mL of normal saline administered by nebulizer.
Note	Many institutions use a standard 0.5-mL dose of racemic epinephrine for all patients. If racemic epinephrine is not available, single-isomer L-epinephrine (1:1000) can be substituted in a dosage of 0.5 mL/kg up to 5 mL.
Etomidate	
Indication	Sedation for RSI
Dosage	IV/IO: 0.2–0.4 mg/kg (maximum: 20 mg).
Etomidate	
Indication	Sedation for RSI
Dosage	IV/IO: 0.2–0.4 mg/kg (maximum: 20 mg).

TABLE 1 **Continued**

Notes	Will lower ICP and does not usually lower blood pressure. Desirable agent for patients with head injury, multisystem trauma, or hypotension. Rapid onset: duration ~ 10–15 min. This agent does not have analgesic properties.
	May cause brief myoclonic activity (hiccups, cough, twitching) and may exacerbate focal seizure disorders. Causes transient adrenal suppression that is not clinically significant.
Fentanyl	
Indications	Pain
	Adjunct to intubation
Dosage	IV: 1–2 μg/kg. Repeat dose as necessary to desired clinical effect.
Notes	Rapid administration of fentanyl has been associated with both glottic and chest wall rigidity, even with dosages as low as 1 μg/kg. Therefore, fentanyl should be titrated slowly over several minutes when used for treatment of pain. More rapid administration is allowable before intubation, particularly if a muscle relaxant is also being administered.
	Higher doses (1–5 μg/kg) are often recommended for intubation.
Warning	There is an increased incidence of apnea when combined with other sedative agents, particularly benzodiazepines. Be prepared to administer naloxone or nalmefene and provide respiratory support. May cause chest wall and glottic rigidity, which may be reversed with naloxone/nalmefene or a muscle relaxant. Be prepared for the loss of the desired clinical effect (analgesia) if a reversal agent is given.
Flumazenil	
Indications	Benzodiazepine overdose
	Required or desired reversal of therapeutic benzodiazepine effect
Dosage	IV: 0.01–0.02 mg/kg (maximum: 0.2 mg); repeat at 1-min intervals to a maximum cumulative dose of 0.05 mg/kg or 1 mg, whichever is lower. When IV access is unavailable, may be given IM.
Note	Most patients with oversedation attributable to benzodiazepines may be managed with supportive care alone. The duration of action of flumazenil is shorter than for most benzodiazepines; repeat dosage may be necessary. Patients should be observed continuously for at least 2 h after the last dose of flumazenil.
Warning	May precipitate acute withdrawal in benzodiazepine-dependent patients. Use with extreme caution in children with underlying seizure disorders who are being treated with benzodiazepines; flumazenil reverses the anticonvulsant effects and may precipitate seizures. Contraindicated in tricyclic antidepressant overdose; may induce seizures or arrhythmias.
Fosphenytoin	
Indication	Status epilepticus
Dosage	Given in phenytoin equivalents (PE).
	IV: 15–20 PE/kg, infused at a rate of 1–3 PE/kg per min (maximum rate: 150 PE per min).
	IM: 15–20 PE/kg.
Notes	When given IV, itching is common and controllable by reducing the flow rate.
	Lower risk of hypotension or cardiac effects than phenytoin.
Warning	Rate of infusion should not exceed 3 PE/kg per min. Monitor heart rate via ECG, and reduce the rate of infusion if heart rate decreases by 10 beats per min.
Furosemide	
Indications	Fluid overload
	Congestive heart failure/pulmonary edema
Dosage	IV/IM: 1–2 mg/kg (usual maximum dose: 20 mg for patients not chronically on loop diuretics).
Note	May cause significant hypokalemia.
Glucagon	
Indication	Hypoglycemia caused by insulin excess (as adjunct to glucose).
Dosage	IV/IM/SC: 0.03 mg/kg up to maximum of 1 mg; repeat every 15 min up to a total of 3 doses if needed for clinical effect.
Indication	β-adrenergic blocker or calcium channel blocker overdose.
Dosage	IV: 0.03–0.15 mg/kg, followed by an infusion of 0.07 mg/kg per h (maximum: 5 mg/h).
Adolescent dosage	5–10 mg over several min, followed by infusion of 1–5 mg/h. Reconstitute doses of >2 mg in sterile water rather than the diluent supplied by the manufacturer.
Note	May cause nausea/vomiting because of delayed gastric emptying.
Glucose	
Indications	Hypoglycemia
	Hyperkalemia
Initial Dose	
Children	IV/IO: 0.5–1.0 g/kg.
Neonates	IV: 200 mg/kg as D10W only.
Maintenance dose	Constant infusion of D10W-containing IV fluids with appropriate maintenance electrolytes at a rate of 100 mL/kg per 24 h (7 mg/kg per min). Older children may require a substantially lower dose. The rate should be titrated to achieve normoglycemia, because hyperglycemia has its own adverse central nervous system effects.
Notes	For D10W: 200 mg/kg = 2 mL/kg; 0.5–1.0 g/kg = 5–10 mL/kg.
	For D25W: 0.5–1.0 g/kg = 2–4 mL/kg.
	For D50W: 0.5–1.0 g/kg = 1–2 mL/kg.
	D50W is irritating to veins; dilution to 25% dextrose is desirable.
	Glucose, sodium, and potassium levels should be monitored carefully. Depending on etiology, hypoglycemia may recur.

TABLE 1 **Continued**

Haloperidol	
Indication	Psychosis with agitation
Dosage	IM/IV: 0.05–0.15 mg/kg; may repeat hourly as necessary. Maximum single dose: 5 mg.
Notes	Hypotension and dystonic reactions may occur. Repeated doses can prolong QT interval and precipitate torsades de pointes.
Hydrocortisone	
Indication	Adrenal insufficiency
Dosage	IV/IO: 2–3 mg/kg (maximum: 100 mg) over 3–5 min, followed by 1–5 mg/kg every 6 h for infants or 12.5 mg/m^2 every 6 h for older children.
Note	Do not underdose. Strongly consider concomitant fluid bolus of 20 mL/kg of D5NS or D10NS during the first hour of treatment.
Insulin, regular	
Indication	DKA
Dosage	IV infusion: 0.05–0.10 unit/kg per h. Neonatal IV: 0.05 unit/kg per h. SC: 0.25–0.50 unit/kg per dose.
Note	IV bolus insulin is not generally recommended for children with DKA. Monitor blood glucose and potassium concentrations hourly or more closely as needed, with the goal of gradually reducing the blood glucose level by 50–100 mg/dL per h. Appropriate fluid and electrolyte therapy is also essential when treating DKA.
Indication	Hyperkalemia (although glucose alone is effective).
Dosage	IV: 0.1 unit/kg with 400 mg/kg glucose. Ratio is 1 unit of insulin for every 4 g of glucose.
Ipratropium	
Indication	Adjunct to β-agonists for status asthmaticus/bronchospasm
Preparation	Nebulized solution (0.25 mg/mL).
Dosage	Children $<$12 y old: 0.25 mg nebulized every 20 min for up to 3 doses. Children $\geq$12 y old: 0.5 mg nebulized every 20 min for up to 3 doses.
Notes	May be mixed with albuterol for nebulization. Should not be used as first-line therapy.
Kayexalate (Sanofi-Aventis, Bridgewater, NJ)—see sodium polystyrene sulfonate	
Ketamine	
Indications	Sedation/analgesia Adjunct to intubation Infundibular spasm (hypercyanotic spell with tetralogy of Fallot)
Dosage	IV: 1–2 mg/kg, titrate repeat doses to desired effect. IM: 4–5 mg/kg (onset of action within $\sim$ 5 min); may repeat half the initial dose if patient is not fully dissociated.
Notes	Doses listed above are recommended to achieve dissociative sedation/anesthesia. Lower doses may be used to provide analgesia without full dissociation. Laryngospasm may occur, most often associated with rapid infusion or concomitant upper respiratory infection. It is usually reversible with oxygen administration, repositioning of the airway, and brief positive-pressure ventilation. Rarely, treatment with a muscle relaxant may be required. Atropine or glycopyrrolate may be used to prevent increased salivation.
Warning	Be prepared to provide respiratory support. Monitor oxygen saturation. Avoid use in patients with increased ICP or increased intraocular pressure.
Levalbuterol—see albuterol	
Lidocaine	
Indication	Ventricular arrhythmias, wide complex tachycardia
Dosage	IV/IO: 1 mg/kg (maximum: 100 mg), repeat every 5–10 min to desired effect or until maximum dose of 3 mg/kg is given. IV infusion: 20–50 μg/kg per min. ET: 2–3 mg/kg, followed by or diluted in isotonic saline (1–5 mL) based on patient size.
Note	Recent data suggest that lidocaine is less effective than amiodarone but may be used if amiodarone is not available.
Warning	High concentrations may cause myocardial depression, hypotension, and seizures. Contraindicated in complete heart block and wide complex tachycardia attributable to accessory conduction pathways.
Indication	ICP protection before ET intubation or airway manipulation.
Dosage	1–2 mg/kg IV as a single dose 30 s to 5 min before airway instrumentation.
Note	Considered optional adjunct for RSI in patients with head injury/increased ICP. When a neuroprotective agent that reduces ICP (eg, etomidate, thiopental) is used, lidocaine is less likely to provide additional benefit.
Lorazepam	
Indication	Status epilepticus
Dosage	IV/IM: 0.05–0.10 mg/kg (maximum: 4 mg per dose). May repeat dose every 10–15 min if needed for continued seizures.
Warning	There is an increased incidence of apnea when combined with other sedative agents. Monitor oxygen saturation and be prepared to provide respiratory support. Flumazenil may be administered to reverse life-threatening respiratory depression caused by lorazepam; however, it will also counteract the anticonvulsant effects and may precipitate recurrence of seizures.

TABLE 1 **Continued**

Magnesium sulfate	
Indications	Hypomagnesemia
	Torsades de pointes VT
	Refractory status asthmaticus
Dosage	IV/IO: 25–50 mg/kg (maximum: 2 g).
	Given by bolus for pulseless torsades, over 10–20 min for hypomagnesemia/torsades with pulses, and over 15–30 min for status asthmaticus.
Warning	Rapid infusion may cause hypotension and bradycardia. Have calcium chloride available if needed to reverse magnesium toxicity.
Mannitol	
Indication	Increased ICP
Dosage	IV: .25–1 g/kg given over 20–30 min.
Note	Larger doses (≥0.5 g/kg given over 15 min) may be appropriate in an acute intracranial hypertensive crisis. In conjunction with mannitol, other measures to control ICP such as hyperventilation, sedation/analgesia, head-of-bed elevation, cerebrospinal fluid drainage, barbiturates, and muscle relaxation (using a neuromuscular blocking agent) should be considered. A urine-collecting catheter should be placed when using mannitol. Monitor for hyperosmolality.
Note	Administer through a filter; do not use solutions that contain crystals.
Methylprednisolone	
Indications	Asthma/allergic reaction
	Laryngotracheobronchitis (croup)
Dosage	IV/IM: 1–2 mg/kg initial dose (must use acetate salt for IM route).
Indication	Spinal cord injury
Dosage	IV: 30 mg/kg over 15 min, followed in 45 min by a continuous infusion of 5.4 mg/kg per h for 23 h.
Note	Administration within 8 h of injury is optimal.
Midazolam	
Indication	Sedation/anxiolysis
Dosage	IV: 0.05–0.10 mg/kg given over 2–3 min (maximum single dose: 5 mg).
Note	Peak effect occurs at 3–5 min. Dose/observe and redose/observe every 3–5 min to avoid oversedation. Paradoxical agitation may occur, especially in younger children.
Dosage	PO: 0.25–0.50 mg/kg (maximum: 20 mg). Children <6 y old may require up to 1 mg/kg.
Indication	Adjunct for ET intubation
Dosage	IV: 0.2 mg/kg.
Note	Lower doses of midazolam are ineffective for RSI. After preoxygenation, allow sufficient time (2–3 min) for midazolam to take effect before administration of muscle relaxant.
Indication	Seizures
Dosage	IM: 0.2 mg/kg (maximum: 6 mg per dose); may repeat every 10–15 min.
Note	Other benzodiazepines (eg, lorazepam) are typically used for initial IV treatment of status epilepticus.
Indication	Refractory status epilepticus, not controlled by standard therapies.
Dosage	IV: Loading dose 0.15–0.20 mg/kg, followed by continuous infusion of 1 μg/kg per min, increasing by increments of 1 μg/kg per min (maximum: 5 μg/kg per min) every 15 min until seizures stop.
Warning	There is an increased incidence of apnea when combined with other sedative agents. Be prepared to provide respiratory support regardless of route of administration. Monitor oxygen saturation. Flumazenil may be administered to reverse life-threatening respiratory depression caused by benzodiazepines such as midazolam; however, it will also reverse the anticonvulsant effects and may precipitate seizures.
Milrinone	
Indication	Myocardial dysfunction and increased SVR/PVR (eg, after cardiac surgery, normotensive septic shock).
Dosage	IV/IO: loading dose of 50–75 μg/kg over 10–60 min.
	Infusion: 0.50–0.75 μg/kg per min.
Warning	May cause hypotension, ventricular arrhythmias, and angina. Monitor blood pressure and ECG continuously. Intravascular volume must be maintained. Longer infusion times reduce the risk of hypotension.
Morphine	
Indications	Pain
	Infundibular spasm (hypercyanotic spell with tetralogy of Fallot)
Dosage	IV (slowly)/IM: 0.1 mg/kg.
Notes	Repeat dose as necessary for clinical effect. Burn pain often requires larger or more frequent doses.
	Higher doses may be necessary if patient is tolerant. Histamine release with flushing, itching, and hives is common. Histamine release may also cause hypotension, particularly in unstable cardiac/trauma patients; fentanyl may be preferred in these situations.
Warning	There is an increased incidence of apnea when combined with other sedative agents, particularly benzodiazepines. Be prepared to administer naloxone/nalmefene. Monitor the patient's vital signs and oxygen saturation. Be prepared to provide respiratory support.
Nalmefene	
Indication	Apnea/respiratory depression caused by opioid overdose
Dosage	IV/IM: 0.25–0.50 μg/kg every 2 min.

TABLE 1 **Continued**

Notes	Duration of action is 4–8 h (vs <1 h for naloxone).
	For reversal of respiratory depression in sedation/analgesia or patients with pain, lower doses are indicated to avoid complete reversal of analgesia.
	Do not administer nalmefene to a newborn infant whose mother is suspected of long-term opioid use because of the risk of acute withdrawal.
Warning	May induce acute withdrawal in opioid-dependent patients. Patients should be observed continuously for recurrence of respiratory depression and other narcotic effects for at least 4 h after the last dose of nalmefene. Not recommended for empiric use in coma of unknown etiology.
Naloxone	
Indication	Apnea/respiratory depression caused by opioid overdose
Dosage	
Newborn infants	IV/IM: 0.1 mg/kg (ET route not recommended for newborn infants).
Older infants/children	IV/IO/IM/SC: <5 y old or <20 kg: 0.1 mg/kg; ≥5 y old or ≥20 kg: 2 mg.
Notes	Use lower doses (1–15 μg/kg) to reverse respiratory depression associated with therapeutic opioid use.
	Doses may be repeated as needed to maintain opiate reversal.
	Do not administer naloxone to a newborn infant whose mother is suspected of long-term opioid use because of the risk of seizures/acute withdrawal.
Warning	May induce acute withdrawal in opioid-dependent patients. Patients should be observed continuously for recurrence of respiratory depression and other narcotic effects for at least 2 h after the last dose of naloxone.
Nitroprusside	
Indications	Hypertensive crisis
	Cardiogenic shock (associated with high SVR)
Dosage	IV: starting dose 0.3–0.5 μg/kg per min (maximum dose: 10 μg/kg per min). Start at the lowest dosage and titrate for the desired clinical effect.
Note	Bottle, burette, or syringe pump should be covered with protective foil to avoid breakdown by light. IV tubing does not need protective foil.
Warning	Administration may result in profound hypotension. Blood pressure should be monitored continuously with an arterial line. Extreme caution should be used to avoid accidental flushing/bolus injection of the IV line. May cause cyanide/thiocyanate toxicity and metabolic acidosis, especially in patients with hepatic or renal insufficiency.
Norepinephrine	
Indication	Hypotensive (usually distributive) shock, with low SVR and unresponsive to fluid resuscitation (eg, hypotensive septic shock, neurogenic shock).
Dosage	IV/IO: 0.1–2.0 μg/kg per min, titrated to desired effect.
Warning	May cause tachycardia, bradycardia, arrhythmias, and hypertension. Extravascular administration can result in severe skin injury. Phentolamine (dose: 0.1–0.2 mg/kg up to 10 mg diluted in 10 mL of 0.9% sodium chloride) injected intradermally at extravasation site may be helpful for counteracting dermal vasoconstriction.
Phenobarbital	
Indication	Status epilepticus
Dosage	IV: 20 mg/kg (maximum dose: 1000 mg), infused over 10 min. Repeat dose once if necessary after 15 min (maximum total dose: 40 mg/kg).
Warning	There is an increased incidence of apnea when combined with other sedative agents. Be prepared to provide respiratory support. Monitor oxygen saturation.
Phenytoin	
Indication	Status epilepticus
Dosage	Neonates IV: 10 mg/kg.
	Children IV: 20 mg/kg.
Notes	Maximum initial dose: 1000 mg. Recommended infusion time is 10–20 min; drug-delivery rate not to exceed 1 mg/kg per min.
	Neonates have an increased risk of toxicity because of decreased protein binding; phenobarbital is preferred.
	Phenytoin should be diluted in normal saline to avoid precipitation. Incompatible with glucose-containing solutions.
Warning	May cause hypotension and arrhythmias, especially with rapid infusion. Heart rate should be monitored, and the rate of infusion should be reduced if the heart rate decreases by 10 beats per min. If available, fosphenytoin is preferred, because it has a lower risk of adverse cardiac effects.
Prednisone/prednisolone	
Indication	Asthma, acute exacerbation
Dosage	Initial dose: 1–2 mg/kg PO (maximum: 60 mg); subsequent dose: 1–2 mg/kg per d divided in 1–2 doses per d for 3–10 d (maximum: 60 mg per d).
Notes	No advantage of IV or IM preparations over the PO route if gastrointestinal absorption is not impaired.
	No need to taper steroid dose if used for <10 d.
Procainamide	
Indications	Wide complex tachycardia with a pulse, atrial flutter/fibrillation, supraventricular tachycardia resistant to other drugs
Dosage	IV/IO loading dose: 15 mg/kg over 30–60 min.
	Adult dose: 20 mg/min IV infusion up to total maximum dose of 17 mg/kg (maximum loading dose: 1.0–1.5 g).
Warning	May cause hypotension, negative inotropic effect, prolonged QT interval, torsades de pointes, heart block, and cardiac arrest. If ≥50% QRS widening or hypotension occurs during administration of the drug, the remainder of the dose should be held. Cardiologist consultation is strongly recommended when considering the use of this medication. Should not be used with amiodarone or other drugs that prolong QT interval without expert consultation.

TABLE 1 **Continued**

Propranolol	
Indication	Infundibular spasm (hypercyanotic spell with tetralogy of Fallot)
Dosage	IV: 0.15–0.25 mg/kg per dose infused over 10 min in D5W.
	Maximum initial dose: 1 mg. May repeat dose once.
Note	Oxygen should be administered first. Morphine is considered the first-line drug for the treatment of infundibular spasm. Use with caution in congestive heart failure.
Prostaglandin E_1 (alprostadil)	
Indication	Suspected or proven ductal-dependent cardiac malformation in the neonatal period
Dosage	IV/IO: 0.05–0.10 μg/kg per min infusion in D5W (maximum dose: 0.2 μg/kg per min).
Warning	Apnea, hyperthermia, and seizures may occur; however, none are reasons to stop infusion. Be prepared to provide respiratory support.
Rocuronium	
Indications	Paralysis to facilitate mechanical ventilation
	Emergency intubation
Dosage	IV: 1 mg/kg.
Notes	This drug does not provide sedation, analgesia, or amnesia.
	Satisfactory conditions for ET intubation (adequate relaxation) will generally occur in 60–90 s. Duration of action is ~30–45 min and is dose dependent.
Warning	Ventilatory support is necessary. Personnel with skills in airway management must be present and prepared to respond when this agent is administered. Age-appropriate equipment for suctioning, oxygenation, intubation, and ventilation should be immediately available.
Sodium polystyrene sulfonate (Kayexalate)	
Indication	Hyperkalemia
Dosage	PO: 1 g/kg up to 15 g (60 mL) every 6 h as needed.
	Rectal: 1 g/kg up to 50 g every 6 h as needed.
Warning	Avoid using the commercially available liquid preparation in neonates because of the hyperosmolar preservative (sorbitol) content. Hospital pharmacies can prepare sorbitol-free preparations. Extremely preterm neonates may develop intestinal hemorrhage (hematochezia) from rectal Kayexalate.
Succinylcholine	
Indications	Emergency intubation
	Laryngospasm
Dosage	IV: 1–2 mg/kg (2 mg/kg for infants <6 mo of age).
	IM: 4 mg/kg IM (5 mg/kg for infants <6 mo of age).
Notes	This drug does not provide sedation, analgesia, or amnesia.
	Atropine 0.02 mg/kg (minimum dose: 0.1 mg; maximum dose: 1 mg) is typically administered before succinylcholine to prevent bradycardia or asystole. If being used for patients with increased ICP, a defasciculation dose of a nondepolarizing agent (eg, 0.01 mg/kg of vecuronium) may be considered.
	Satisfactory conditions (adequate relaxation) for ET intubation generally occur 30–45 s after IV administration and 3–5 min after IM administration. Duration of action is ~5–10 min.
Warning	Causes increased serum potassium levels, which may be life-threatening in patients with a previous history of malignant hyperthermia, severe burns/crush injury, spinal cord injury, neuromuscular disease, or myopathy. When these contraindications exist, use a nondepolarizing muscle relaxant such as rocuronium. If cardiac arrest occurs immediately after administration of succinylcholine, suspect hyperkalemia (particularly in boys <9 y old).
Warning	Ventilatory support is necessary. Personnel with skills in airway management must be present and prepared to respond when this agent is administered. Age-appropriate equipment for suctioning, oxygenation, intubation, and ventilation should be immediately available.
Thiopental	
Indication	Sedation/anesthesia for RSI
Dosage	IV: 2–6 mg/kg.
Note	May need to use lower dose if other sedatives/narcotics have been administered. Flush with saline before administration of rocuronium or vecuronium to avoid precipitation and obstruction of IV tubing.
Warnings	IM administration leads to tissue necrosis.
	Be prepared to provide respiratory support. Monitor oxygen saturation. Causes vasodilation and decreased cardiac output; higher doses are associated with hypotension and apnea. If patient has cardiovascular dysfunction or volume depletion, consider etomidate as alternative.
Vecuronium	
Indications	Paralysis to facilitate mechanical ventilation
	Emergency intubation
Dosage	IV: 0.1 mg/kg for routine paralysis; 0.2 mg/kg for intubation.
Notes	This drug does not provide sedation, analgesia, or amnesia.
	Satisfactory conditions (adequate relaxation) for ET intubation generally do not occur until 2 min after administration. Duration of action is ~45–90 min (dose dependent). Rocuronium or succinylcholine is preferred for facilitating rapid intubation in emergency situations.
Warning	Ventilatory support is necessary. Personnel with skills in airway management must be present and prepared to respond when this agent is administered. Age-appropriate equipment for suctioning, oxygenation, intubation, and ventilation should be immediately available.

AV indicates atrioventricular; VT, ventricular tachycardia; D*n*W, *n*% dextrose in water; IM, intramuscular; PO, per os (oral); DKA, diabetic ketoacidosis; ICP, intracranial pressure; SC, subcutaneous; PE, phenytoin equivalents; ECG, electrocardiogram; D*n*NS, *n*% dextrose in normal saline; SVR, systemic vascular resistance; PVR, pulmonary vascular resistance.

TABLE 2 **Potentially Useful Rescue, Reversal, and/or Antidotal Agents**

Agent/Condition	Rescue, Reversal, and/or Antidote
Chemical intoxications	
Alcohol, toxic (eg, methanol)	Ethanol, thiamine, fomepizole (4 methyl-1H-pyrazole)
Iron	Deferoxamine
Carbon monoxide	Oxygen
Cyanide	Hydroxocobalamin (Cyanokit; Dey, LP, Napa, CA) is preferred antidote; cyanide kit (amyl nitrate, sodium nitrate, sodium thiosulfate) may be used if hydroxocobalamin unavailable
Lead	Dimercaprol (British anti-Lewisite [BAL]); edetate calcium disodium (Ca- EDTA); DMSA (succimer [Chemet])
Drug intoxications	
Acetaminophen	*N*-acetylcysteine
Benzodiazepines	Flumazenil
β-adrenergic blockers	Glucagon
Digoxin	Digoxin immune Fab (Digibind; GlaxoSmithKline, Research Triangle Park, NC)
Heparin	Protamine sulfate
Isoniazid	Pyridoxine
Opiates	Naloxone, nalmefene
Envenomations	
Snake bites	Snake-specific antivenoms (eg, CroFab [Protherics, Yorkshire, United Kingdom] for Crotalidae [rattlesnakes]; coral snake antivenom, etc)
Black widow spider bites	*Latrodectus* antivenom
Metabolic crises	
Methemoglobinemia	Methylene blue
Hyperkalemia	Bicarbonate, glucose and insulin, calcium, sodium polystyrene resin (Kayexalate)
Miscellaneous	
Nondepolarizing muscle relaxants	Neostigmine, pyridostigmine, edrophonium
Cholinergics (organophosphates, carbamates)	Atropine, pralidoxime
Radionuclides	
Iodine	Potassium iodide
Plutonium	Pentetate calcium disodium (Ca-DTPA) within 24 h followed by pentetate zinc trisodium (Zn-DTPA)
Americium	Zn-DTPA or Ca-DTPA
Uranium	Sodium bicarbonate and tubular diuretics
Cesium	Prussian blue
Tritium	Water
Phosphorus	Individualize treatment; consult Poison Control Center

Consultation with a toxicologist or the Poison Control Center (national telephone number: 800-222-1222) strongly advised if considering antidote administration.

vascular access has been obtained, any vascular access (IV or IO) is preferred, because tracheal drug administration results in lower, less predictable drug concentrations than intravascular administration.[5] If the endotracheal (ET) route is used, administer the drug with or diluted in 1 to 5 mL of isotonic saline solution followed by manual ventilations. ET administration of naloxone is no longer recommended for neonates.[6]

Most of the medications listed in this clinical report are used for airway management, resuscitation, sedation, analgesia, status epilepticus, or asthma. The Committee on Drugs recognizes that gaps exist in pediatric labeling and dosage information for many of these drugs. Despite these gaps, the package inserts, labels, and available medical literature should be consulted for additional information. The continued lack of clinical testing in pediatric populations before Food and Drug Administration approval of therapeutic agents makes it impossible to have the clinical data to support all pediatric dosing recommendations. Although local practice patterns and individual preferences exist for the use and dosage of many of these medications, the information provided in this document includes recommendations that are based on consensus opinion and literature review. References for individual drug indications and dosing are not provided in this report. Dosages should be individualized, taking into account the patient's age, weight, underlying illness, concurrently administered drugs, and known hypersensitivity. This committee recommends use of the current *Advanced Pediatric Life Support*[7] and *Pediatric Advanced Life Support*[8] textbooks, updated American Heart Association guidelines,[5] and additional references for more detailed information on pediatric resuscitation algorithms, rapid-sequence intubation (RSI), procedural sedation, and treatment of asthma.[9,10] For newborn infants, practitioners can consult the *Textbook of Neonatal Resuscitation*[11] and updated American Heart Association guidelines[6] for detailed information concerning management of neonatal emergencies and appropriate drugs, dosages, and routes of administration. In addition, pre-

printed medication cards and/or length-based resuscitation tapes (eg, Broselow tape) should be readily available at all sites that provide medical care for children.

ABSTRACT

This clinical report defines common terms of use and provides information on current practice, research, and limitations of assistive technology that can be used in systems for communication. The assessment process to determine the best devices for use with a particular child (ie, the best fit of a device) is also reviewed. The primary care pediatrician, as part of the medical home, plays an important role in the interdisciplinary effort to provide appropriate assistive technology and may be asked to make a referral for assessment or prescribe a particular device. This report provides resources to assist pediatricians in this role and reviews the interdisciplinary team functional evaluation using standardized assessments; the multiple funding opportunities available for obtaining devices and ways in which pediatricians can assist families with obtaining them; the training necessary to use these systems once the devices are procured; the follow-up evaluation to ensure that the systems are meeting their goals; and the leadership skills needed to advocate for this technology. The American Academy of Pediatrics acknowledges the need for key resources to be identified in the community and recognizes that these resources are a shared medical, educational, therapeutic, and family responsibility. Although this report primarily deals with assistive technology specific for communication impairments, many of the details in this report also can aid in the acquisition and use of other types of assistive technology. *Pediatrics* 2008;121:1271–1280

doi:10.1542/peds.2008-0695

Key Words
assistive technology, communication, children with disabilities, special health care needs, pediatrician, augmentative and alternative communication, communication impairments

Abbreviations
VOCA—voice-output communication aid
SGD—speech-generating device
AAC—augmentative/alternative communication
PECS—Picture Exchange Communication System
ICF—International Classification of Functioning, Disability and Health
AAP—American Academy of Pediatrics
IDEA—Individuals With Disabilities Education Act
EPSDT—Early and Periodic Screening, Diagnosis, and Treatment

BACKGROUND

Communication skills are ranked as the concern of highest priority for adults with physical disabilities and, therefore, should be of paramount importance for children with impaired communication and their families.[1] Nearly 5 million children in the United States (approximately 15%) have some type of disabling condition.[2] Among children with disabilities who are attending school, >20% have significant communication impairments that are not attributable to impaired hearing.[3] Conditions that can cause communication impairment include cerebral palsy, autism spectrum disorders, traumatic brain injury, and several genetic syndromes (eg, DiGeorge syndrome).

Many children and youth with special health care needs can improve day-to-day functioning with the aid of assistive technology, including alternative or augmentative technology. "Assistive technology," the more general term, describes systems and devices that help alleviate the effects of a disability and, thus, improve function. An example is the use of orthotics (braces) for a child who has L4 paraplegia attributable to spina bifida. "Alternative technology" substitutes for functional impairments related to a disability (eg, adapted power wheelchairs for children who have quadriplegia). Lastly, "augmentative devices" are those that augment a deficient area of functioning but for which residual abilities remain. An example of this would be an electronic voice-output communication aid (VOCA), sometimes called a speech-generating device (SGD), to be used for a child who has dysarthria attributable to cerebral palsy. In this situation, although natural speech may be somewhat understood by family members, it is augmented when communicating with people who are less familiar with the child.

The most common context for alternative and augmentative systems is in the field of speech-language pathology (eg, augmentative/alternative communication [AAC] systems). According to an analysis of data from the National Survey of Children With Special Health Care Needs, approximately 2.1% of children and youth with disabilities have a need for "communication aids or devices"—AAC systems.[4] The data also revealed that the needs for communication aids and devices were unmet for approximately 25% of these children.

TABLE 1 **Spectrum of Assistive Technology for Communication Impairments**

Type of AAC Technology	Characteristics	Examples	Advantages	Disadvantages
Low-tech	Uses paper, plastic or similar materials	Simple picture/word boards or cards; PECS; eye-gaze picture board; visual scheduler or planner; adapted pens/pencils	Usually low cost; portable; personal; training is quick; readily acceptable to listener; rugged; no need for power supply	Very limited speed; very limited vocabulary; unable to use for long-distance communication
Mid-tech	Uses batteries for voice, text, or light output	Lighted on/off devices; "wrist communicator" (eg, with 2–10 stored vocal outputs); keyboard with display or printer; scanning light board (eg, with pictures)	Low-to-moderate cost; usually portable; usually personally owned; training is moderate; usually acceptable to listener; occasionally can use for limited long-distance communication	Limited speed; limited vocabulary; limited distance communication; power supply needed
High-tech	Microcircuits and microcomputer technology	Adapted laptop computers; commercially available VOCAs (dynamic displays, touch pads, or keyboards); individualized devices that use special inputs (eg, eye blinks)	Ease of progressing in skill levels; able to carry out extensive and efficient conversations; usually portable; often can use for long-distance communication (eg, telephone); able to connect to other devices (eg, for access to computer or for environmental control)	Moderate to very high cost; sometimes is not personally owned; power supply needed; training often extensive; listeners may need to have training

See text for more details on some devices.

AAC is often erroneously thought to refer only to microcomputer-based and complex electronic devices. Although such electronic devices may be the best answer for a particular problem, they represent only the higher end of the spectrum of technology. Assistive technology, including AAC systems, can be thought of as low-tech, mid-tech, or high-tech.[5] The costs for assistive technology also vary widely depending on the level of complexity and other factors. Although many low- and mid-tech AAC solutions are available to assist children with communication disabilities, this report focuses primarily on high-tech VOCAs or SGDs, because pediatricians are often asked to prescribe or approve the use of these more expensive devices.

CURRENT PRACTICE

Many types of AAC systems are available for use by individuals who have speech and/or language impairment (Table 1). Low-tech strategies include the use of objects, line drawings, and actual photographs or pictures of objects or persons to replace or augment spoken words. This is especially helpful for the development of communication skills of children who are nonverbal, particularly those who are unable to read.

Low-tech AAC also includes systems such as lists of words, phrases, or symbols that can be understood easily by others in many environments. By pointing to a desired target, simple communication boards or "flip-books" can be quite effective for face-to-face communication. For children who have visual impairment, three-dimensional objects that can be felt may be substituted for pictures.

Simple communication boards can be accessed through both direct selection and assisted scanning. In direct selection, the child directly touches or points to the desired target (eg, word, symbol). In partner-assisted scanning, the communication partner scans through the available choices until he or she is stopped by a response from the child (such as an eye blink). For children with autism spectrum disorders, a systematic program called the Picture Exchange Communication System (PECS) has been developed and has gained increasing acceptance as a valuable tool for improving communication skills.[6] In this system, children are taught to "exchange" laminated picture cards of the items or activities they are requesting for the actual items or activities themselves.

Mid-tech devices are typically battery-operated portable voice-output storage devices or devices that produce printed text. Devices can store a few recorded or digitized messages, such as "I want to see a movie," or multiple levels of messages. These levels are typically changed by the communication partners on the basis of the activity. When the desired button is accessed, the recorded message plays. Most mid-tech devices are accessed only through direct selection. Some mid-tech devices have scanning capabilities, accessed with a single switch.

Low- and mid-tech communication systems have inherent limitations. Vocabulary is limited by what is presented, and lengthy, novel messages are not feasible. Communication is usually slow and often more scripted than spontaneous or independent, and mid-tech devices require programming of scripted messages before the activity.

High-tech electronic AAC devices often incorporate the use of pictures or symbols, which may substitute for sentences or other groups of words, and are becoming more commercially available. High-tech AAC aids primarily have digitized or synthesized voice output (ie, are VOCAs or SGDs), although the methods of producing this voice output vary. Many high-tech devices use synthesized speech, an electronic voice that simulates that of a human voice. The use of a synthesized vocabulary allows for the creation of novel messages. Most comput-

erized systems have the capability to add digitized speech to specific messages. Unlike mid-tech devices, high-tech devices usually feature a dynamic display that changes with the input so that many levels of symbols, words, or lengthy messages can be stored for quicker retrieval, which improves both the variety of potential vocabulary items and independence in communication.

High-tech devices typically have the capability to have multiple access (input) methods ranging from direct selection on a touch screen to various types of scanning, mouse/joystick controllers, or encoding systems. Some computer-based devices can be accessed via eye gaze. For children who have both communication and physical disabilities, these alternative access methods are often needed. Systems that allow direct selection (eg, with a finger) are used with children who have adequate control of movements.

Single-function AAC devices (SGDs or VOCAs) serve as communication-output devices only. Some of the newer AAC systems, including some VOCAs, can also perform functions such as controlling the environment, accessing a telephone, or serving as a computer-access method.

The advantage of high-tech VOCAs is their expandability and flexibility. For children whose communication skills are likely to improve over time, the vocabulary in the VOCA can be modified to accommodate the advancing development and changing needs of the child. Thus, the skills of the child and capability of the device increase in tandem and promote communicative proficiency into adulthood. As an example, for a young child who has an ASD but is limited in communication by using the PECS, a VOCA may be helpful, because at least 1 report has indicated that VOCAs can increase communication skills in preschool-aged children with autism spectrum disorders.[7]

People who have normal speech are so accustomed to a high rate of speed that patience and appropriate training are necessary to communicate with an individual using AAC systems. This is especially true if the child is using a low-tech communication aid such as a symbol, letter, or word board. Although these methods are extremely slow and/or inflexible, they should not be abandoned. Depending on the child, they often are just as effective, if not more so, than high-tech devices in simple face-to-face communications and with multiple caregivers.

Another important consideration is that electronic devices are sometimes limited by their need for a power source, which inhibits their usefulness in situations in which battery power gets depleted. A lower-tech solution, such as a word or picture board, should always be available as a backup for high-tech AAC system users.

CURRENT RESEARCH AND LIMITATIONS

Much research has been published to demonstrate the benefits of early intervention for speech and language disorders, including using alternative systems such as pictures or sign language. Furthermore, research has demonstrated that the use of AAC systems does not decrease the use of natural speech.[8] Currently, there is no consensus about the earliest age at which a child can successfully use a more complex AAC device (eg, a VOCA). Some recent reports, however, have demonstrated successful use of complex devices with children younger than 3 years.[9]

The use of electronic or computer-based AAC devices may promote natural language acquisition and cognitive development. For example, 1 study has shown that an AAC device will facilitate natural speech production in children who have some potential for speech.[10] In addition, the use of communication aids offers opportunities for research into the interaction of people who are nonverbal (because of a disability) with those who are able to speak. An interesting but limited study by Beukelman and Mirenda[11] demonstrated the need to study the process by which AAC devices are selected and used. Their research suggested that if a child who has a severe communication impairment is successfully using an AAC device by the time he or she reaches the first grade, that child will participate more actively in classroom settings. Children who were skilled and comfortable with their AAC devices communicated more frequently with their typically developing peers. Additional research on AAC systems and children is needed, especially to determine if earlier exposure to communication aids will promote more facility in their use or other gains.

ASSESSMENT ISSUES

The assessment of a child who has a communication disorder and the selection of any assistive device should be performed by a team of knowledgeable professionals. This team approach is needed to properly evaluate both the child and devices to ensure the best match and to ensure that the device can be used effectively across environments and communication partners. Depending on the AAC device to be prescribed and the disabilities of the child, this team might include speech and language pathologists, physical therapists, occupational therapists, rehabilitation engineers, primary care and developmental pediatricians, psychologists, neurologists, physiatrists, special educators and other school personnel, child care workers, computer specialists, and others in conjunction with the family. In all circumstances, however, the major evaluator and decision-maker will be the speech-language pathologist. The team should be interdisciplinary and function collaboratively with ongoing discussions among the team members. Decisions of the team should be made jointly. Team members should provide or receive training and monitor the ongoing use of the device.

The basics of the overall assessment process for assistive technology are shown in Fig 1. This cycle usually needs to be repeated periodically as the child develops and his or her needs change. The assessment process for AAC should include consideration of the entire spectrum of AAC. One possible approach is to consider the use of low-tech devices and, if needed, to progress to mid-tech devices and, finally, high-tech devices. If a low-tech solution solves a particular problem, then more sophisticated technology may not be needed currently (but may be in the future). For example, a child with an autism spectrum disorder or other severe language disorder may derive more benefit from the simple PECS

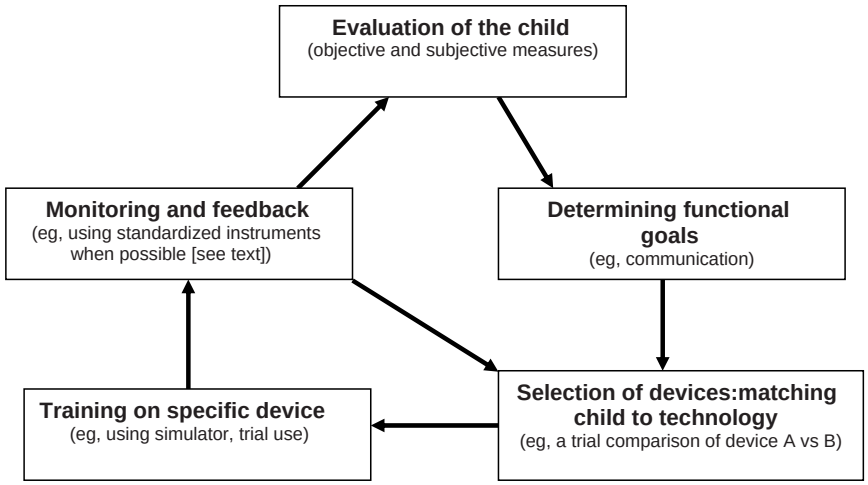

FIGURE 1
The assistive-device–assessment cycle. (Adapted from Batshaw ML, ed. *Children With Disabilities*. 6th ed. Baltimore, MD: Paul H Brookes; 2007:563.)

than a complex VOCA, but if that same child outgrows the PECS, a sophisticated VOCA may become the most appropriate means of AAC.

The ultimate goal for using any AAC device is to achieve the highest possible functional communication. The first step, therefore, is to determine the person's current functional abilities, environmental situations, and personal preferences (Fig 1). One system that may be useful in such an assessment is the International Classification of Functioning, Disability and Health (ICF), specifically that for children and youth developed by the World Health Organization.[12,13] Using this system, for example, one can classify and determine the extent of problems and strengths that a person has related to a communication disability that affects the ICF "activities and participation" domain and subcategories such as "communication" or "mobility." Using the ICF system may help to predict the effect that a specific device will have on a child in regard to each subcategory.

Standardized instruments for initial and follow-up assessments include the Functional Independence Measure, the children's version of the Functional Independence Measure (the Wee-FIM), and the Pediatric Disability Inventory.[14–16] Environmental modifications, such as the use of assistive devices, have been shown to significantly affect these types of measures.[17] Standardized language-assessment tests should also be used to determine progress in communication abilities.[18] Caution is advised when using standardized tools to evaluate children using AAC systems, because they were not developed with these devices in mind.[19] Accurate baseline measurements are crucial for evaluating functional changes over time after the introduction of any assistive technology, including AAC.[11]

Children who have moderate to severe physical and communicative limitations are in particular need of the combined knowledge and experience of an interdisciplinary team, because many barriers to the use of assistive devices exist.[20] Factors that need to be assessed include current and future language needs, motor abilities and deficits, cognitive levels of functioning, vision and hearing functioning, communication partners, and environment and mobility issues. A major task for the team is to determine which movements the child can make consistently and how these movements can be used to control some type of device. Next, the team should determine the most acceptable, useful, and feasible output method depending on the child's needs and his or her communication partners. For example, output information could be displayed on a monitor screen, output by a printer, or presented as synthesized speech. Most of the time, multiple output types are preferred. Last, the child should be observed using various devices.

Educated opinions based on the successful experiences of other children who have similar disabilities using AAC can be quite useful. Using the aforementioned steps, the skilled speech-language pathologist should be able to select the devices that are most likely to meet the child's individual needs on the basis of his or her abilities and communication environments. Ideally, the child should have a trial period with a rented or loaned unit of the intended device before it is ordered or purchased. A 1- to 2-month trial gives the child and his or her family and the educators/caregivers the opportunity to be trained and to assess the child's ability to use the device in different settings to identify both the strengths and weaknesses of the system. These steps may reduce purchases of inappropriate devices. Partnering with a reliable technology center (especially at a university or nonprofit organization) is often useful, but these centers may be quite distant or have long waiting lists.

Studies have demonstrated that assistive devices may be abandoned shortly after they are obtained in one third of cases and that up to 75% of devices are never used successfully.[21,22] Much of this can be attributed to lack of proper assessment and training. During the past 2 decades, however, methods have been developed to improve the successful matching of assistive devices to users (especially with adults [eg, "Matching Person and Technology"]).[23,24] Similar methods have been used with older children and adolescents.[25,26]

The physician or therapist who prescribes or recommends a VOCA or assistive devices in general must also accept responsibility for ensuring that the child and all

caregivers receive proper training and monitoring for the use of the device. Training is crucial for the successful use of any assistive device. Generally, the most appropriate approach to training and monitoring is to use the combined expertise of an interdisciplinary team of therapists and specialists.

A few tools and standardized measures are available to assist in the process of evaluating the efficacy and performance of assistive devices.[27,28] One promising method was reported recently by a group that developed a 10-step framework, which includes input from parents, to help professionals obtain assistive technology for young children.[29] These tools are promising but are still in their infancy and require additional work.

Despite minimal data from controlled studies, methods are available to promote evidence-based and appropriate uses of assistive devices. A useful approach for determining the effectiveness of interventions in individuals may be the implementation of what has been called a "single-subject research design."[30,31] This type of study involves the quantitative assessment of a child's baseline abilities, followed by repeat assessments after specific interventions.[32] In the best of such studies, the assessments are performed by evaluators who are unaware of the intervention ("masked"); however, this is not critical. In the single-subject research design, the individual serves as his or her own control.

Although multiple-baseline studies may be difficult to obtain with children who are in a therapeutic or school environment, 2 or more types of interventions could easily be studied across time to determine which treatment or device seems to be the most effective. Figure 1 includes a "detour" between the steps of monitoring the use of the device and selection of device to allow for multiple baselines.

ROLE OF THE PRIMARY CARE PEDIATRICIAN

Identification, Referral, and Care Coordination

As part of providing the medical home, the primary care pediatrician should recognize communication disorders in children and make appropriate referrals.[33] Knowing how to contact experienced professionals and other appropriate community resources for assistive technology (which may be primarily for adults) is crucial. Children who need AAC systems require services for evaluation, procurement, training, and monitoring for devices and therapy programs. These particular services also need to be coordinated with other therapies and programs (eg, educational) that the child is already receiving and with the family. However, this integrative process can be confusing and overwhelming for the family. The pediatrician who is providing the medical home should develop a care-coordination process that involves all available resources (internal and external) to help families through this often-complicated process.

Primary care aspects of care coordination in the context of communication disorders involves 4 components: cooperating/assisting with the diagnostic assessment process to ensure proper diagnostic and prognostic information; helping with short-term and long-term planning by appropriate professionals, especially speech-language pathologists; assisting with the implementation of any of the parts of the plan, including helping to find funding sources for the purchase of devices; and working closely with the family and a team of professionals, mainly educational and speech-language therapists, to evaluate the effectiveness of the efforts being made and to ensure appropriate follow-up.

Although the primary care pediatrician should be closely involved with all 4 of these components of care coordination, the last step is particularly important. The primary care pediatrician may be the professional who is best able to evaluate the child's progress in relationship to the family's satisfaction or dissatisfaction. For specifics about providing care coordination and care management, a recent policy statement from the American Academy of Pediatrics (AAP), "Care Coordination in the Medical Home: Integrating Health and Related Systems of Care for Children With Special Health Care Needs," provides additional information and resources.[34]

Funding Issues and Access Regulations

Funding for assistive technology for children can come from schools; third-party payers including Medicaid and private insurance companies; or philanthropic sources. Roadblocks to funding AAC still exist, and many families have found that it is much easier to obtain funding for an expensive power wheelchair than it is for a less-expensive communication device. However, it is best to assume that funding will be provided, because, in the context of communication impairments, AAC is often necessary to overcome the limitations in functional communication caused by the impairment (just as a wheelchair overcomes the limitation of not being able to walk).

Beginning in 1973, several laws were passed that affected access to assistive devices for children with disabilities. First, Section 504 of the Rehabilitation Act of 1973 (Pub L No. 93–112) prohibited discrimination of children with disabilities and mandated educational programs for children with disabilities. This law was followed by the Education for All Handicapped Children Act of 1975 (Pub L No. 94–142), which required public education systems to provide a "free and appropriate education and related services" to meet the unique needs of every child with a disability. This educational service was to be provided in the "least restrictive environment" possible, an environment in which a child with a disability may interact with nondisabled peers. Section 602 of the law provides for the "use of instructional materials, including telecommunications, sensory and other technical aids and devices," to aid the child with disabilities to function more easily in the school environment.

The Technology-Related Assistance for Individuals With Disabilities Act of 1988 (Pub L No. 100–407, later amended as Pub L No. 103–218 [1994]), although written mainly to affect adults, also has proven to be quite beneficial to children. Called the "Tech Act," this law defined assistive technology and, more importantly, provided financial assistance to states to develop projects to

improve each state's delivery of assistive-technology devices and services. By 1996, after several revisions to the law and increased funding, 56 assistive-technology centers (1 in each state and US territory) were functioning.[35]

The Education for All Handicapped Children Act was changed in 1990 to the Individuals With Disabilities Education Act (IDEA [Pub L No. 101–476]). The IDEA has increased services to children who have disabilities (birth to 21 years of age), including, by specific provisions in the law, appropriate assistive technology. This law was last reauthorized in 2004 (Pub L No. 108–446), and the sections related to assistive technology were essentially left intact.

The latest education law, the No Child Left Behind Act of 2001 (Pub L No. 107–110), does not specifically address technology but does include provisions that mandate "measurable educational improvement" for children who have disabilities.[36] In some instances, AAC technology may be needed to meet the measurable educational goals.

Recent Medicare regulations can be seen as a possible template for future mandates that may affect many more children. Medicare now authorizes that all people who receive Medicare benefits are entitled to receive "medically necessary" AAC devices, with 80% of the cost paid for by Medicare funds.[37] These new regulations, included in Part B of Medicare, cover only SGDs and provide for 4 levels of funding (up to nearly $6500 for a device). Any adapted computer, however, would not be covered, because computers are not considered "dedicated" SGDs. Since final rulings in 2001, essentially all Medicare beneficiaries are entitled to an SGD if there is any "functional need" (eg, after a stroke) and a medical necessity letter is submitted by a physician (who does not need to be a specialist). Medicare also requires an evaluation and report by a "certified speech and language pathologist," although there is, as yet, no credentialing specifically for AAC by the American Speech-Language-Hearing Association.

Approximately 3 years ago, these same Medicare regulations were used to develop rules that cover funding for VOCAs for adults and children who receive benefits from the US Department of Defense (ie, the TRICARE program).[38] However, neither of these sets of regulations (Medicare and TRICARE) contain a requirement that the communication impairment be permanent.

In contrast to these 2 sets of regulations, Medicaid payments for AAC systems, being dependent on state laws and rulings, are extremely variable, and some states with strict limits for Medicaid rarely pay for AAC systems for children, especially expensive devices such as VOCAs. Medicaid funding is further discussed later in this report.

Educational System Funding

Funding for assistive devices and software will remain challenging for many school districts unless funding inequities among schools are resolved. It is fortunate that, as noted before, there are provisions within the IDEA and subsequent laws (eg, the Tech Act) and various legal opinions about these laws that specifically indicate that funding should be made available for "technologic devices" (including software) to help children who have special education needs. Although these statements are in public law, difficulties in finding the funds to pay for assistive devices and for other "educationally related services" will continue, at least for the foreseeable future. Additional information about these issues can be found in a statement from the AAP.[39]

On occasion, schools have purchased VOCAs or other electronic communication aids for children with functional impairments. Unfortunately, these devices are sometimes kept at the school and are not allowed to be used at home. The Tech Act has tried to alleviate this problem partially by allowing Medicaid funding to be used by the school to purchase the assistive device. The Tech Act requires that such devices be allowed to be taken home with the child for "educationally related" purposes. In other words, for any device even partially funded by Medicaid, the school cannot prevent the child from using the device at home.

Debate continues whether AAC devices are "medically" or "educationally" necessary. If they could be shown to be medically necessary, it may be possible to obtain funding for these devices from health insurance companies or other third parties. In this regard, the use of AAC systems should lead to more efficient and accurate medical encounters (eg, improved describing of symptoms). If they are truly educationally necessary, perhaps school systems should be required to purchase the needed devices. Appropriate learning certainly depends on the exchange of information and efficient communication. This dichotomous debate is short sighted. Clearly, if one takes the view that health is about overall well-being and functioning, not just absence of disease, AAC is often medically necessary in many ways.

The complicated nature of education law terminology can sometimes cause knowledgeable parents to have unrealistic expectations that assistive devices, including AAC systems, must be immediately provided. Cooperative efforts between philanthropic agencies, school systems, and parents in some localities may be the best solution to finding appropriate funding. Parent groups and their allies may be able to lobby effectively for other sources of funding and convince schools of the need for appropriate assistive devices. The last resort, although laborious and slow, is to work with lawyers and the court systems if educational funding of AAC systems is not forthcoming for an identified educational need.

Third-Party Funding (Insurance and Medicaid)

As with wheelchairs, some AAC devices are increasingly being recognized as medically necessary forms of "durable medical equipment." For years, most private and governmental medical coverage programs have been willing to pay for the purchase of wheelchairs and gradually are beginning to fund other assistive devices, including AAC systems, primarily under their durable medical equipment benefit rules. In addition to requiring a doctor's prescription (and possibly a letter of medical necessity), most third-party payers also require a written evaluation report by a speech-language pathologist. It is unfortunate that some insurance companies

will not pay for any follow-up assessments or follow-up therapy critical to learning how to use the device (even when the school provides the funding for the device).

Although in all states Medicaid will pay for AAC devices, wide variation exists in state Medicaid requirements, which limit the ability to obtain funding. The Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) program, which is a required part of every state Medicaid plan, could be used for funding of AAC systems, because under EPSDT, children are entitled to an "expanded scope of benefits."[40] However, a number of recent reports have underscored continuing problems with implementation of EPSDT programs in most states.[41] Some states have put considerable restrictions on the types, severity, or permanency of disabilities for people who can receive Medicaid payment for AAC systems. For example, Medicaid regulations in 1 state indicate that AAC is not covered for any person who can "functionally communicate verbally or through use of gestures," and the person needs to have a "permanent" disorder.[42] As mentioned before, pointing and gestures are very limiting and are not efficient communication methods.

The parent or guardian of any child who receives Medicaid benefits always has the legal right to challenge any decision made by a state Medicaid program, including denial of payment for therapy services or cost of repairing an AAC device. The appeal process involves requesting an administrative hearing, a process that varies from state to state. If there is an unfavorable decision made from this hearing, an appeal can be made to state and federal courts; such appeals have been successful occasionally.

Most state Medicaid programs will not fund AAC unless it is medically necessary to treat a permanent inability to communicate through oral speech. In some children who have communication impairments (eg, posttraumatic head injury), there may not be any "proof" that they are permanently disabled. Another source of reticence from Medicaid and other funding sources can be the minimal evidence for demonstrable short-term benefits. Long-term benefits could be substantial but may also be difficult to measure and may be mainly the result of improved mental health, self-esteem, and independence.

Referrals and Prescriptions

Pediatricians are often called on to make referrals, sign prescriptions, and write letters of medical necessity to help obtain funding both for the devices and the assessments. A letter of medical necessity should be written only after conferring with members of the team who have evaluated the child (especially the speech-language pathologist). This letter should state that the physician received the evaluation reports, reviewed the recommendations, and concurs that the recommended devices are medically necessary for treatment of the child's communication impairment caused by the specific diagnosis. For some agencies, information about the child's current status and expected outcome after using the device must also be included (but this information is often part of the report from the speech-language pathologist). The funding agency needs more than just a report of the physical examination or diagnoses. Government agencies, private insurance companies, and charitable organizations all have limited funds, and requests that include the most complete and clear information are the most likely to be funded. Medicaid payers in many states and some insurance companies have set up specific requirements for a detailed evaluation report by a licensed speech-language therapist to accompany the prescription or medical-necessity letter that is signed by the physician.

Funding Overview

Obtaining funding requires perseverance. Sometimes, a request for an AAC device is denied because the funding agency has never had any experience with such a device. However, denials of funding by most agencies are subject to appeal. The appeal process in these situations should not be taken lightly. The denial letter may include reference to the specific statements made in the insurance policy. This can often be the starting point of an appeal letter by the family. Often, the speech-language pathologist, pediatrician, or other advocate can offer a supportive letter for this appeal. An appeal is most likely to be successful if it can be shown that a child can benefit significantly from using the particular device. Failure of an appeal can sometimes make funding for a particular device (or even any device) unlikely, if not impossible, for other children with similar disabilities. Therefore, a successful appeal can be used as an important precedent for future requests. AAC devices and their related professional services are relatively new and specialized, and they sometimes are not included on lists of approved products eligible for funding. Funding agencies may benefit from instruction about the potential of these devices to improve functioning and independence for children who have disabilities. Many companies that make AAC devices also have their own funding specialists on staff who can be helpful in dealing with insurance companies or other agencies.

Because funding for the purchase of devices and funding for training and monitoring in the use of AAC devices are difficult to obtain, the multidisciplinary team may need to develop insightful strategies to obtain funding for even the simplest low-tech devices. Literature is becoming available that focuses on the specifics of funding for devices and their long-term cost-effectiveness.[43–45]

Unfortunately, there is no final answer to the conundrum of who should pay, and funding often requires a good deal of patience and creativity. In some cases, the final possible source of funding, when other options have been exhausted, may be local philanthropic organizations (eg, United Cerebral Palsy, Easter Seals, various social organizations). It is possible that additional improvements in regulations or expansions of state Medicaid-based programs (such as enforcing EPSDT rules) will also lead to more availability of AAC devices for children who need them. In addition, particularly if grass-roots efforts succeed, Medicaid rules may also be expanded to more closely parallel the rules now being implemented within Medicare (because of the recent regulations made in Medicare mentioned previously). However, this might lead, once again, to the apparently common situation in which Medicaid rules may some-

times be more permissive in funding AAC and other devices for children and youth with special health care needs than are insurance programs, which sometimes contractually consider them "noncovered" benefits (eg, for children who have autism spectrum disorders).[40]

Advocacy Information

Technology advances quickly, and it is rare that a pediatrician can stay current with all new developments. Pediatricians, however, should serve as informed advocates. Families of children with disabilities may have very high expectations about AAC and other assistive technology. They may try to find answers to their concerns and questions with or without support from health care professionals. Pediatricians often have a critical role in this process, because caregivers, patients, or allied health professionals may request their opinion or prescriptions for some of these devices. To be able to provide realistic and appropriate answers, pediatricians should keep generally informed about what is being developed and marketed and, more importantly, what local resources are available to provide more information and access to a proper assessment.

Fortunately, there are readily accessible sources of information that can provide current information about assistive technology (see Appendix). An important resource for specific materials, such as examples of medical-necessity letters, is the AAP National Center for Medical Home Initiatives for Children With Special Needs. The National Assistive Technology Technical Assistance Partnership oversees the federally mandated but state-funded "Assistive Tech" projects. These state projects are excellent information hubs and can refer individuals to appropriate service providers. Various organizations that deal with children with disabilities, such as the Council for Exceptional Children and others, have also developed services that can be used to obtain references and abstracts about many facets of disability, especially with regard to school-related services. There are increasing numbers of Internet sites that offer resources for using assistive technology with children, although some of them are thinly veiled advertisements from companies or groups that may propose "alternative therapies." The Appendix contains a list of selected sources for information retrieval.

CONCLUSIONS

Children with disabilities can benefit considerably from assistive technology, perhaps sometimes more than adults with similar problems, because assistive technology can help to maximize children's developmental potential. Financial and societal barriers currently prevent the equitable distribution and application of this technology, especially for AAC systems. Many jobs are now becoming available for adults who have physical and communication disabilities. Jobs such as editing, writing, and computer applications do not depend on speed of output as much as good judgment and reasoning abilities. Children who have severe physical and communication impairments but good cognitive skills should be able to look forward to a degree of independence in adult life with the possibility of an occupation that is personally rewarding and provides financial security. Their ultimate success, however, depends on what tools they are given as children.

The future will bring many new and useful devices that can help a child who has a communication disability be more functional. Appropriate use of the entire spectrum of AAC systems and devices for children who have communication disabilities is needed, is supported by several federal and state laws, and is ethically proper.

GOALS AND GUIDANCE

1. As part of the medical home, pediatricians should identify all children who have communication problems and refer them for appropriate evaluations.
2. As a part of providing the medical home, primary care pediatricians should recognize their roles in advocacy and care coordination for children who have communication disabilities.
3. Pediatricians should ensure that all children with communication disabilities have access to appropriate AAC systems, including complete evaluations, training, and monitoring by professionals (eg, speech-language pathologists and occupational therapists) and acquisition of appropriate devices.
4. Pediatricians should advocate for the appropriate funding of AAC and related services for children with communication impairments at local, state, and federal levels. Barriers to funding must be addressed. There is a critical need for Medicaid funding of AAC and AAC evaluations to be based on a more uniform policy and funding stream, such as what has recently occurred with Medicare Part B, rather than extremely variable state-by-state decisions.
5. Care-coordination efforts by pediatricians and other health care professionals, a crucial part of the provision of a medical home, should be paid for by third-party payers.
6. All pediatricians, including subspecialists, who are vital to the child's medical home, university and tertiary care centers, state Title V agencies, school districts, state agencies, and insurers should work cooperatively and collaboratively to improve appropriate access to AAC devices and programs.
7. Pediatricians should provide guidance, information, and support for families of children with communication impairments to act as advocates and care coordinators for their children.
8. Pediatricians caring for children with communication disabilities should assist parents in discussions with school personnel and child care personnel to ensure that any communication system or device that is being used in educational settings can also be used in the home and other family-oriented settings.
9. Pediatricians should advocate for research to be directed toward new approaches to the assessment of children who have communication disabilities and evaluation of the effects of using AAC devices (especially VOCAs).

10. Pediatric residents should receive appropriate training in the assessment of children who have communication disabilities so that they are properly prepared to diagnose, manage, and coordinate care for children with communication disabilities and advocate for these children and their families.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT

Guidance for the Clinician in Rendering Pediatric Care

Linda J. Michaud, MD, and the Committee on Children With Disabilities

Prescribing Therapy Services for Children With Motor Disabilities

ABSTRACT. Pediatricians often are called on to prescribe physical, occupational, and speech-language therapy services for children with motor disabilities. This report defines the context in which rehabilitation therapies should be prescribed, emphasizing the evaluation and enhancement of the child's function and abilities and participation in age-appropriate life roles. The report encourages pediatricians to work with teams including the parents, child, teachers, therapists, and other physicians to ensure that their patients receive appropriate therapy services. ***Pediatrics*** **2004;113:1836–1838;** ***children with motor disabilities, physical therapy, occupational therapy, speech-language therapy.***

BACKGROUND

Pediatricians commonly are asked to evaluate children with motor disabilities and to write prescriptions for physical, occupational, and speech-language therapy services. Although many states require a physician's prescription for such services, many physicians have limited formal education about these therapeutic interventions.[1]

The spectrum of motor impairments affecting function in children and adolescents is wide and comprises many congenital and acquired conditions, primarily involving the neurologic and musculoskeletal systems, including but not limited to cerebral palsy, traumatic brain injury, myelomeningocele, spinal cord injury, neuromuscular disease, juvenile rheumatoid arthritis, arthrogryposis, and limb deficiencies. These conditions are associated with motor impairments including muscle weakness, abnormal muscle tone, decreased joint range of motion, and decreased balance and coordination. There are variations in severity within each of these conditions. Many children with impairments attributable to these conditions will have some degree of disability that may limit their participation in age-appropriate activities at home, in school, and in the community and should benefit from physical, occupational, and/or speech-language therapy services.

The pediatrician needs to understand the role of physical, occupational, and speech-language therapists in the overall treatment of children with motor disabilities and the therapeutic interventions that may improve function and participation.[2,3] If the child has motor problems severe enough to interfere with mobility, self-care, or communication, therapists may provide a program to help the child ameliorate, compensate for, or adapt to the impairment or disability. Physical, occupational, and speech-language therapists, working with the family, child, physician, and teacher, promote a positive functional adaptation to impairment or disability in the context of the child's developmental progress.

Physical therapists focus on gross motor skills and functional mobility, including positioning; sitting; transitional movement such as sitting to standing; walking with or without assistive devices (eg, walkers, crutches) and orthoses (braces) or prostheses (artificial limbs); wheelchair propulsion; transfers between the wheelchair and other surfaces such as a desk chair, toilet, or bath; negotiation of stairs, ramps, curbs, and elevators; and problem-solving skills for accessibility of public buildings. Physical therapists often have responsibilities for procuring adaptive equipment related to ambulation, positioning, and mobility.[4–6]

Occupational therapists focus on fine motor, visual-motor, and sensory processing skills needed for basic activities of daily living such as eating, dressing, grooming, toileting, bathing, and written communication (handwriting, keyboard skills).[7] Occupational therapy services may include training in school-related skills and strategies to help children compensate for specific deficits.[7]

Speech-language pathologists address speech, language, cognitive-communication, and swallowing skills in children with disabilities.[8] Speech therapy is the therapy most commonly prescribed by pediatricians.

The services that can be provided by physical and occupational therapists and speech-language pathologists overlap. For example, a physical or occupational therapist can address motor delay or dysfunction in the very young child. Depending on the community, occupational therapists or speech-language pathologists may address deficits in oral motor skills associated with feeding dysfunction related to motor disability. Occupational therapists and/or speech-language pathologists provide expert consultation related to adaptive equipment, environmental modifications, and assistive technology devices such as environmental control units, augmentative communication systems, adapted computers, and adaptive toys.[6]

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

EVALUATING THE EVIDENCE

The therapeutic methods, frequency and duration of service, setting in which the service is delivered, and service delivery system vary.[9] Evaluating the efficacy and effectiveness of therapy for motor disability is difficult, because treatment is not a standardized, readily quantifiable process that can be prescribed in discrete, consistent units. Individualized therapy programs vary in many parameters and incorporate subjective as well as objective elements. Clear documentation of efficacy related to the variable parameters of therapy continues to be elusive. This problem may in part reflect difficult methodologic issues including the measurement of treatment-related change on a background of developmental maturation, the establishment of appropriate outcome criteria, heterogeneity of the populations involved, and the complex nature of the interventions.[10,11]

A recent review of the evidence to support the effectiveness of neurodevelopmental treatment for children with cerebral palsy indicates that this popular method of intervention does not confer an advantage over the alternatives with which it has been compared in altering abnormal motor responses, slowing or preventing contractures, or facilitating more normal motor development or functional motor activities, nor does more intensive neurodevelopmental treatment result in greater benefit.[12] Physical therapy alone was found in 1 well-designed study to be less effective in improving motor development after 1 year than the therapy incorporating developmentally appropriate play and learning skills for children younger than 3 years with motor impairment.[13]

Improvement in motor function is more likely to occur when the goals of therapy are specific and measurable[14] and established in partnership with the child's parents and other caregivers. Intensive amounts of physical therapy may confer no advantage over routine amounts of therapy,[15] and long-term therapy may confer no advantage over short-term therapy. Provision of a home exercise program, with instruction of family members and caregivers in therapeutic exercises and age-appropriate activities to meet the child's goals, is generally indicated. This program can include recommendation of participation in sports to increase endurance, strength, and self-esteem in a natural setting with peers.[16] Aquatic therapy, hippotherapy (horseback-riding therapy), and participation in karate, gymnastics, and dance classes in integrated or special classes also can be considered to meet the child's therapeutic goals. Parent and caregiver education by all therapists is critical in effective partnerships with families for implementation of therapy programs.

Some programs such as patterning have little effect on functional skills and are inappropriate for children with motor disabilities.[17] Scientific legitimacy has also not been established for sensory integration intervention for children with motor disabilities.[18]

Prescribing therapy services for children with motor disabilities clearly cannot be based entirely on sound scientific evidence. As the knowledge base is expanded related to the effectiveness of therapy interventions, evidence-based practice described as using the best available evidence, along with clinical judgment, and taking into consideration the priorities and values of the individual patient and family in a shared decision-making process, as outlined by the Institute of Medicine, is advised.[19]

SERVICE DELIVERY

Therapies for a child with motor impairment are required to be provided by the school if the disability interferes with the educational process.[20] Recently, managed health care has made it more difficult for children with special needs to receive therapy services outside of school, with insurance companies denying services for children who attend school, maintaining that therapy is mandated at school and is partially funded with education and third-party monies.[9] Therapy services at school for students who are eligible for Medicaid and whose disabilities are medically based can be reimbursed by Medicaid if the disability has an adverse effect on the child's ability to benefit from the educational program.[9] Services also may be provided in environments other than the hospital or school, as appropriate for the child's individual circumstances; such other environments include child care, home, or job settings.

THE PEDIATRICIAN'S ROLE

The pediatrician's responsibility in writing a prescription for therapy includes providing an accurate diagnosis when possible. When the exact cause of the disability is not apparent, the physician must provide an accurate description of the medical condition and note whether the child has a transient, static, or progressive impairment. In addition to the primary motor disorder, all potential associated problems such as learning disabilities, mental retardation, sensory impairment, speech disorders, emotional difficulties, and seizure disorders must be identified, and a care plan must be recommended. There are some children with special needs whose medical conditions may be affected adversely by movement or other specific therapeutic activities; therapists and caregivers should be advised to take appropriate precautions with these children.

The physician's prescription for therapy should contain, in addition to the child's diagnosis: age; precautions; type, frequency, and duration of therapy; and designated goals. Goals for physical, occupational, and speech-language therapy do not depend solely on the diagnosis or age of the child, and they are most appropriate when they address the functional capabilities of the individual child and are relevant to the child's age-appropriate life roles (school, play, work).[9] The pediatrician should work with the family, child, therapists, school personnel, developmental diagnostic or rehabilitation team, and other physicians to establish realistic functional goals.[20] The pediatrician can assist families in identifying the short- and long-term goals of treatment, establishing realistic expectations of therapy out-

comes, and understanding that therapy will usually help the child adapt to the condition but not change the underlying neuromuscular problem. Pediatricians should be encouraged to seek and use expert consultation as in any other area of medicine. Helpful resources may include local and regional diagnostic and intervention teams, early intervention and developmental evaluation programs, developmental pediatricians, pediatric physiatrists, pediatric neurologists, pediatric orthopedists, and orthotists.

Regular communication among parents and other caregivers, therapists, educators, and prescribing physicians should be ongoing, with periodic reevaluations to assess the achievement of identified goals, to direct therapy toward new objectives, and to determine when therapy is no longer warranted.[21] Changes in the child's status (eg, surgical intervention, school-to-work transition warranting assistive technology intervention) may indicate resumption of specific short-term, goal-directed services.

SUMMARY

Successful therapy programs are individually tailored to meet the child's functional needs and should be comprehensive, coordinated, and integrated with educational and medical treatment plans, with consideration of the needs of parents and siblings. This can be facilitated by primary care pediatricians and tertiary care centers working cooperatively to provide care coordination in the context of a medical home.[22,23]

TECHNICAL REPORT

Preservation of Fertility in Pediatric and Adolescent Patients With Cancer

Mary E. Fallat, MD, John Hutter, MD, the Committee on Bioethics, Section on Hematology/Oncology, and Section on Surgery

ABSTRACT

Many cancers that present in children and adolescents are curable with surgery, chemotherapy, and/or radiation therapy. Potential adverse consequences of treatment include sterility, infertility, or subfertility as a result of either gonad removal or damage to germ cells from adjuvant therapy. In recent years, treatment of solid tumors and hematologic malignancies has been modified in an attempt to reduce damage to the gonads. Simultaneously, advances in assisted reproductive techniques have led to new possibilities for the prevention and treatment of infertility. This technical report reviews the topic of fertility preservation in pediatric and adolescent patients with cancer, including ethical considerations.

INTRODUCTION

During the past 40 years, survival rates from many childhood cancers have increased dramatically.[1] Approximately half of childhood cancers are hematologic malignancies (leukemia and lymphoma), and the anticipated long-term survival for children with these disorders is now greater than 75%. Improvements in prognosis and survival have also been observed for many other childhood malignancies, including Wilms' tumor, malignant bone tumors, and rhabdomyosarcomas. The relative 5-year survival rate for all childhood cancers combined is 78%.[2] It has been estimated that approximately 200 000 people who reside in the United States are survivors of childhood cancer.[3]

Past and contemporary treatments for childhood cancer can affect future fertility. For purposes of this discussion, sterility is defined as the inability to conceive a pregnancy naturally in the absence of clinical interventions.[4] Clinical infertility is recognized as the inability to conceive after 1 year or more of unprotected intercourse during the fertile phase of the menstrual cycle.[5,6] The baseline incidence of sterility is estimated at 1% of the general population, and this percentage does not change with age during the window of reproductive potential. Fertility begins to decline when women reach their late 20s and when men reach their late 30s.[4] The prevalence of infertility is estimated at 8% for women aged 19 to 26 years and gradually increases to 18% for women aged 35 to 39 years. This compares with an increase from 18% if the male partner is 35 years old to 28% if the male partner is 40 years old. The risks of infertility after cancer treatment variably affect these numbers depending on the type of malignancy and its specific treatment.[7]

NORMAL PHYSIOLOGY AND POTENTIAL FOR FERTILITY

The differences in the male and female reproductive systems influence available options for fertility after cancer treatment.[2,8] Spermatogenesis begins in the prepubertal male, although spermatogenesis and steroidogenesis are functions of the adult male testes.[9] Meiosis is a relatively early event that is completed by the time of maturation to spermatids. Spermatogenesis depends on the capacity of the totipotential stem cells to undergo self-renewal and provide progeny that mature into viable spermatocytes. Postmeiotic spermatocytes occasionally may be seen in children as young as 4 years. Prepubertal boys have not yet developed gametes. Spermarche (the release of spermatozoa) is an early- to midpubertal event that precedes the ability to produce an ejaculate and is associated with age-appropriate gonadotropin production.[10,11] There is a large variation in the stage of maturity among 13- to 18-year-old boys with respect to seminal plasma. Once sperm are present, sperm quality does not seem to be affected by patient age. In at least 1 study, sperm concentration, motility, and morphology showed the same pattern in 12 pubertal boys with cancer who were 14 to 17 years of age as in 210 men with malignancies who were older than 20 years.[12,13] Spermaturia is present in 1% to 2% of boys at 11 years of age, 15% to 37% at 12 to 13 years of age, and 24% to 69% at 14 years of age.[14]

It is generally accepted that in females, oocyte production ceases during fetal development, with a finite number of oocytes present at birth.[15] A few oocytes will be released during reproductive life as a consequence of ovulation, and most will be lost as a result of atresia.[16] Although recent animal studies have suggested that primordial germ cells in vitro are capable of forming oogonia and follicle-like structures[17] and that ovarian regeneration may occur from stem cells or arise from stem cells in the bone marrow,[18] these studies are problematic. They have been performed in rodents (interspecies differences can be profound), and evidence that fertility can be modified through these techniques is limited or lacking (even in rodents).[19]

RISK OF INFERTILITY AFTER TREATMENT

Most children treated for cancer now can be expected to be cured and remain fertile,[20] although many contemporary treatment modalities for childhood cancer can affect fertility. Several large studies have evaluated the fertility outcome of childhood cancer survivors. During the 1970s, a multicenter study of 5-year survivors of solid tumor cancers and Hodgkin's disease who were diagnosed before they were 20 years of age demonstrated a 15% incidence of impaired fertility, with problems more prevalent in boys than in girls.[21] Subsequent follow-up studies of childhood, adolescent, and young adult cancer and bone marrow transplant survivors have further defined variables associated with decreased fertility after cancer treatment.[22] These variables include (1) older age and/or developmental maturity of the patient at the time of therapy,[23] (2) the type of therapy,[24] (3) the site of therapy, and (4) gender. For example, the administration of alkylating agents seems to involve more of a risk of infertility in boys compared with the same therapy administered to girls,[21] although the alkylating agents destroy the primordial ovarian follicles in a dose-dependent manner.[25]

The dose of chemotherapy that will render a patient sterile will vary with his or her age and developmental maturity at the time of therapy.[26–28] Older children are more likely to be left infertile. In addition, gonadal toxic effects of chemotherapy during therapy will vary with the type of chemotherapeutic agent, dose, and schedule of administration.[1] Agents that are more likely to pose a risk to gametes include alkylating agents, cytarabine, vinblastine, cisplatin, and procarbazine, among others. Participation in therapeutic clinical trials allows concurrent assessment of efficacy and risk, with the ultimate goal of reconsidering and adjusting regimens so that efficacy is preserved and risks are reduced.

Follow-up studies of sperm production and gonadal function performed on adolescent and young adult male survivors of Hodgkin's disease have shown that both the chemotherapeutic regimen and dose intensity are important variables that affect reproductive potential. Adolescent boys and young men treated for Hodgkin's disease with 6 cycles of chemotherapy, including nitrogen mustard, vincristine, prednisone, and procarbazine, had a greater than 90% risk of infertility, primarily attributable to azoospermia.[29,30] In contrast, azoospermia occurred in only 50% of patients receiving 3 cycles or fewer[29] and in 33% of patients treated with an alternative regimen of adriamycin, bleomycin, vinblastine, and dacarbazine.[1]

The effect of chemotherapy on ovarian function and subsequent recovery is often unknown. In addition to infertility, female survivors of childhood cancer may be at risk of premature ovarian failure or early menopause.[31] Risk factors include institution of therapy after the onset of puberty, administration of alkylating agents such as procarbazine and cyclophosphamide, and the delivery of radiation therapy at doses of 1000 cGy and higher to the region of the ovaries.[25,32] The relative risk of early menopause is also significantly greater for women who have received a combination of alkylating therapy and radiation therapy below the diaphragm, compared with either modality alone.[23,31]

For radiation therapy, variables for infertility risk also include the (1) age and developmental maturity of the patient, (2) dose and fractionation of therapy, and (3) site of radiation therapy. The oocyte median lethal dose for radiation therapy is less than 2 Gy,[33] and sperm production is susceptible to damage at doses of more than 1.2 Gy.[28,34] Testicular Leydig cell function seems to be present at radiation doses up to 20 Gy.[2]

Recognizing the risks associated with both radiation and chemotherapy, the American Society of Clinical Oncology[35] has recommended that oncologists address the possibility of infertility with patients treated during their reproductive years and be prepared to discuss fertility-preservation options or refer patients to reproductive specialists as indicated. However, there is not consensus or direction on when the age of reproductive potential actually occurs or at what age patients should be referred, making it unclear how these recommendations should apply to patients with cancer who are younger than 18 years.

The issues related to considering preservation of fertility in patients younger than 18 years include whether the gonads or gametes have achieved reproductive potential and limitations of the patient and/or partner to understand or consent to necessary procedures. Before considering the unique circumstances of pediatric patients with respect to these issues, it is important to understand what options for fertility preservation are available.

PRESERVATION OF NATIVE GONADAL TISSUE DURING TREATMENT

Males

Before puberty, the only theoretical methods available for gonadal and gamete preservation involve hormonal and other manipulations to protect the testes from injury during cancer treatment. Primordial sperm cells are susceptible to toxicity at all stages of life. Gonad shielding can be used during radiation therapy but is only possible with selected radiation fields and anatomy.[35] The gonad(s) can also be temporarily relocated outside of the radiation field to either the thigh or the anterior abdominal wall.[36,37] In all studies to date, no effective interven-

tion has been identified. Gonadal protection through hormone manipulation has been evaluated only in small studies of patients with cancer and is uniformly ineffective in either preserving fertility or speeding recovery of spermatogenesis.[35] Animal studies suggest that testicular cryopreservation, autotransplantation, xenotransplantation, and in vitro maturation may be successful methods of fertility preservation, but most of these methods have yet to be tested in humans.[2] Human spermatocytes have been matured in vitro to mature spermatids, resulting in at least 1 pregnancy.[38] Testicular-tissue cryopreservation has been reported in 2 boys, with only spermatogonia (ie, cells that are the progenitors of spermatocytes) detected in 1 specimen.[39] The options for this specimen in the future include in vitro maturation or germ-cell transplantation.

Females

Gonad shielding during radiation therapy and oophoropexy to divert the ovaries from the radiation field are potential strategies for preserving ovarian function during treatment.[25,40] Although ovarian transposition is relatively effective at preserving the endocrine function of the ovary (in approximately 60% of cases), only approximately 15% of patients who wish to become pregnant ever achieve this goal.[25] There are also potential means of preserving ovarian function in selected cases of reproductive tract malignancy, including more conservative surgery for certain early-stage tumors and choosing chemotherapeutic agents that have less gonadal toxicity.[41] Germinal and stromal tumors of the ovary are more common in young women and children. Stage Ia dysgerminoma may be managed with unilateral adnexectomy and preservation of the uterus and contralateral adnexa. Early-stage epithelial ovarian cancer (stage Ia), which is less common in children and adolescents, may be managed with unilateral ovariectomy,[25,42] which preserves the chance of natural pregnancy. The overall prognosis for stage I borderline tumors of the ovary is good, and most authors have concluded that conservative treatment increases the risk of recurrence but does not increase the mortality rate.[41,42]

Uterine choriocarcinoma is seen in young people. Tumors with a good prognosis are managed with single-agent chemotherapy by using agents such as actinomycin D or methotrexate, and subsequent fertility rates are reported to be good.[25]

Recently, there has been speculation that concomitant treatment with gonadotropin-releasing hormone analogs may be a promising approach for preventing ovarian failure induced by cancer therapy. The gonadotropin-releasing hormone analog may protect against chemotherapy-induced follicular depletion, thus preserving primordial follicles. Although some studies have been performed in adult patients with cancer, these studies have not yet been extended to children.[43] However, a recent review on this topic in adults concluded that the effectiveness of the intervention is controversial.[44]

FERTILITY PRESERVATION BEFORE TREATMENT

The options for fertility preservation before treatment are different depending on gender. Boys have more available options that are less invasive, less expensive, and more effective and do not require their choosing a partner at the time that they avail themselves of fertility preservation.

Males

Sperm cryopreservation after masturbation is the most established and effective method of fertility preservation in males.[35,45] Sperm should be collected before initiation of cancer therapy because of the risk that sperm DNA integrity or sample quality will be compromised. Underlying sperm quality may be poor for patients with certain cancer types, including testicular cancer, leukemia, and Hodgkin's disease.[46] Nevertheless, recent progress in andrology laboratories and with assisted reproductive techniques allows successful freezing and future use of a very limited amount of sperm, even in cases such as these.[47] Collection of semen through masturbation in adolescents may be compromised by embarrassment and issues of informed consent.[48] Alternative methods of obtaining sperm besides masturbation include testicular aspiration or extraction, electroejaculation under sedation or anesthesia,[49] or from a postmasturbation urine sample.[48] Testicular aspirates do not freeze well and cannot be used as a method of preserving sperm. Published success in creating a viable embryo that results in a living child with any of these methods is limited to case reports.

Females

The collection of mature oocytes requires ovarian stimulation, has been used only in adult patients to date, and may be contraindicated if a cancer is estrogen sensitive.[45,50,51] Because of their large size, water content, and chromosomal architecture, mature female oocytes are extremely fragile. The spindle apparatus of the chromosome is easily damaged by intracellular ice formation during the freezing or thawing process.[52] Therefore, the number of pregnancies resulting in successful deliveries after using cryopreserved oocytes has been small. In addition, because the number of infants born from frozen oocytes is small, information on the health outcomes of children born as a result of this technique versus other techniques of advanced reproductive technologies is lacking.

Ovarian-tissue cryopreservation is a process in which normal, functioning ovarian tissue is excised from the ovary and stored cryogenically.[53–57] Currently, this technique is available only in certain parts of the United States as an experimental protocol until more can be learned about its safety and efficacy.[45] Within this context, it is the only method that can be offered to prepubertal girls.[50] There are a large number of immature oocytes in the ovarian cortex at this age, when the primordial follicles contain prophase I oocytes. This technique has been accomplished in children as young as 2.7 years of age, and the chance of later restoring fertility should be higher, theoretically, because the ovarian cor-

tex contains an increased number of primordial and primary follicles in younger children.[50] Ideally, the stored ovarian tissue is thawed and autotransplanted into the donor once treatment has been completed.[58] However, although the efficiency of ovarian-tissue autografting and/or in vitro maturation has been demonstrated in animals, studies in humans are still in their infancy.[59,60] Recently, successful pregnancies have occurred in cancer survivors after autotransplantation of cryopreserved ovarian tissue.[61,62]

Embryo cryopreservation is an established technique with acceptable pregnancy rates, but its use is limited to females who are either involved in a stable relationship or willing to identify a known or anonymous donor because of the need for sperm.[54] The need for ovarian stimulation theoretically precludes this option for women with estrogen-sensitive tumors, although the use of aromatase inhibitors during stimulation has been proposed as a way of mitigating this concern.[57]

EXPERIMENTAL ANIMAL STUDIES WITH ONCOFERTILITY POTENTIAL

Investigators have developed in vitro three-dimensional follicle-culture systems that mimic the stromal microenvironment of the ovary to produce meiotically competent oocytes that are capable of being fertilized and resulting in live birth of viable murine offspring.[63] Other investigators have shown that bone-marrow transplantation restores oocyte production in wild-type mice sterilized by chemotherapy,[18] although these studies have yet to be duplicated. Daley[64] recently reviewed the prospects of gametogenesis from embryonic stem cells and noted that clinical use of embryonic stem cell–derived gametes seems temporally remote. However, this technology would theoretically eliminate the need to worry about gamete or gonadal preservation before therapy. Although experimental, these techniques have potential in oncofertility.

COSTS OF FERTILITY PRESERVATION

The costs of fertility preservation are unlikely to be covered by insurance,[65] although the psychological distress and effects of infertility are well documented.[66,67] Therefore, patients and their families become responsible for all of the costs. Although some techniques are considered experimental and are, therefore, of unproven benefit, sperm preservation is a technique that has been used for many years and has associated benefits and a record of success that would allow for a change in coverage for this option.

The cost of sperm cryopreservation after masturbation was estimated in 2006 at approximately $1500 for 3 samples stored for 3 years, with additional costs incurred if alternative methods were needed to obtain sperm or for prolonged storage.[35]

The costs of ovarian-tissue preservation can be separated into 3 parts: (1) the procedure to retrieve the tissue, generally laparoscopy and attendant anesthesia[68]; (2) ovarian-tissue pathologic evaluation and freezing; and (3) the annual cost of ovarian-tissue storage. This cost estimate does not include the initial screening and evaluation costs performed before in vitro fertilization or the costs of estradiol testing during therapy (typically 5 blood tests at approximately $200 per sample). Egg retrieval, anesthesia, egg cryopreservation, and the first year of frozen-egg storage costs can be estimated at $5538 (Thomas Toth, MD [Vincent Reproductive Endocrinology Service, Massachusetts General Hospital, Boston, MA] written communication, March 17, 2006). Laparoscopic procedures, even in children, often can be performed on an outpatient basis, precluding any inpatient hospitalization cost.[58] The cost of ovarian-tissue freezing alone might be similar to that of freezing of testicular sperm after testicular dissection (see previous discussion), and the annual cost of ovarian-tissue storage is similar to that of embryo cryopreservation,[50] which costs approximately $350 to $500 per year.[35] Assuming recovery of the patient after treatment, the costs will then include tissue thawing and the procedure for autotransplantation, subsequent medications/hormones, and laboratory testing. The cost of subsequent thawing, culture, fertilization, and embryo transfer followed by 1 pregnancy blood test can be estimated at $3162. Separate costs would include the medication costs necessary for cycling at $2000 to $4000 per cycle, and $330 per ultrasonographic examination. The need for more sophisticated assisted reproduction techniques, such as intracytoplasmic sperm injection, would add additional costs. Use of ovarian suppression with gonadotropin-releasing hormone analogs or antagonists to ovarian tissue during chemotherapy or radiation therapy costs approximately $500 per month.[35]

ETHICAL ISSUES

Fertility preservation raises several ethical issues, including disclosure of the reproductive consequences of therapy, evidence regarding the options for fertility preservation in the setting of available techniques, cultural issues, the consent process,[20,69] and the dilemma of counseling someone who has not yet reached adulthood to make decisions concerning his or her reproductive health while facing the treatment of a life-altering disease.[70] Recognizing that fertility preservation may create both burdens and opportunities for patients with cancer, discussions regarding reproductive potential should take place in the context of maximizing the child's future options and well-being.

Recent surveys of adult male and female cancer survivors of reproductive age and studies evaluating oncology practice patterns for discussing infertility suggest that a conversation with patients with cancer on the infertility consequences of their treatment is lacking in more than half of cases.[35] Some physicians do not recognize the importance of this issue, assume that patients cannot afford fertility-preservation procedures, feel emotionally uncomfortable discussing the topic, or choose not to refer the patient because of the poor prognosis of the tumor.[50]

Most men who completed a survey given by Schover et al[71] felt that having experienced cancer increased the value they placed on family closeness and would make

them better parents. For men who desire children in the future, lack of timely information is the most common reason for not banking sperm. Making an appointment with the andrology laboratory usually is the responsibility of the patient and family. Chemotherapy induction may need to proceed expeditiously and may not allow the luxury of time for needed consultations and decision-making or may preclude the ability of the patient to provide more than 1 or 2 samples.[46] Facilitating the andrology laboratory visit and delaying the induction of chemotherapy, if possible, are 2 approaches that might be used in appropriate cases to increase the fertility options of cancer survivors. Some situations, however, are true medical emergencies (eg, respiratory compromise from a mediastinal lymphoma) or are significantly urgent to preclude even the short delay required for an andrology laboratory visit.

At the present time, ovarian-tissue preservation is limited to centers that perform research by using this technology, and it is considered experimental.[45,72] Offering the technique might provide some degree of comfort in light of a life-threatening diagnosis, because it offers an optimistic perspective for the future that may conform to a patient-centered philosophy of care. An alternative view is that the technique is not essential to the health and well-being of the child, provides unrealistic expectations because of the hope of survival and subsequent procreation, is ethically problematic, and may pose a significant financial or moral burden on the family. In addition, even offering the option to a vulnerable patient may create an additional burden, especially because refusal might be difficult in light of perceived expectations of the physician or family member. Another concern is that children might not be ready to use stored tissue for several years, and deterioration of the germ cells may occur over time.

With the exception of a heritable cancer syndrome, a history of cancer does not seem to increase the rate of congenital abnormalities or cancer in a man's offspring,[73] although some types of cancer pose a greater relative risk of ovarian or testicular metastasis, including leukemia and lymphoma. The safety of sperm preservation in boys with either of the latter disorders (ie, future risk to any offspring) has not been specifically studied. It has been suggested that patients with leukemia may have decreased sperm motility/function related to their illness.[47] Small studies have suggested a transiently higher rate of aneuploidy after chemotherapy and radiation therapy. The sperm of men before treatment may have poor DNA integrity, although in 1 reported cohort of pediatric cancer survivors, DNA integrity of sperm seemed similar to age-matched controls.[74] Ovarian metastatic involvement has been seen in childhood tumors, such as neuroblastoma, Wilms' tumor, lymphoma, osteosarcoma, Ewing sarcoma, and extragenital rhabdomyosarcoma,[75] and in adult women with breast cancer. In a child or adolescent with 1 of these tumors, there is not a specific contraindication to ovarian-tissue cryopreservation if it is available, but the potential risk of development of a metastatic tumor in the reproductive tract must be considered and fully disclosed to the patient and family before proceeding.[76]

Other issues that should be considered include the special circumstances that might be posed by specific religious beliefs or cultural values that preclude either discussing or allowing assisted reproductive techniques or that condemn masturbation.[65] The parent or guardian will most likely be transferring their beliefs to the clinical situation, and these beliefs may or may not represent the child's current or future interests. Individuals who will later be a partner in a marriage (whether arranged or not) may be adversely affected by decisions that are made for them by the patient's parents or guardians. In some cultures, a person's status in the afterlife may be culturally dependent on their ability to reproduce, which makes discussion of future reproductive options much more important. The condition of shyness may be perceived inappropriately as reticence and, thus, a full discussion of the options may be avoided. One study suggested that adolescent boys may be more successful at masturbation if a parent does not accompany them to the sperm bank.[48] Gay adolescents may decline to be involved because of reluctance to disclose their sexual preferences, although the desire to have children is not limited to heterosexual people.

There are fundamental differences between storing a gamete or ovarian tissue and storing an embryo. Embryo cryopreservation is a technique currently offered only to adults. The use of embryo cryopreservation is much different from ovarian preservation in terms of the product that it creates and the issues that it presents. Its use in children would not only be morally problematic from a procedural viewpoint (ie, is it morally acceptable under any circumstances to subject a minor to oocyte retrieval and in vitro fertilization?), but it also would introduce the ethical dilemma of divergent views about the moral status of a preimplantation embryo. Although not technically precluded, exercising this option would force the adolescent to make a mature decision not only about creating an embryo and choosing a partner or anonymous donor but also about future disposition, including the options of disposal, donation for research, or implantation of the embryo in a surrogate mother in the event of death. These are difficult and deeply unstable decisions for healthy adults with infertility and are likely to pose more difficulties for children with cancer. Other ethical issues include the future role of the partner in the decision-making process about the embryo(s) created in this process and what (if any) role the parent(s) or surrogate of the patient should have, both at the time of consent and for the future of the embryo(s). For the parent of the child, the act of preserving a child's life must take precedence over preservation of the possibility of that child's ability to have children, although the goals of each are intertwined.

Finally, consideration must be given to disposition of the sperm, oocytes, or ovarian tissue (in applicable cases) regardless of whether the child lives or dies.[51,65,77] Any procedure performed should be for the benefit of the child's reproductive future, and this must be addressed in the consent process. If the child lives, a decision must

be made relative to when he or she will have the necessary maturity and moral development to make a personal decision about what to do with the cryopreserved biological material. If the child dies, the parents should not have discretion over the biological material, and it should be destroyed.[78] The role that the child plays in this decision should be clearly defined, and questions must be posed and answered before acquisition of any biological specimen. These issues are not unique, have precedent in case law, and need to be addressed by any person who agrees to the preservation of tissue or gametes.[51]

ROLE OF THE PHYSICIAN

A physician's encouragement is a strong predictor of whether an optional intervention will be considered or conducted by a patient. The gesture of fertility preservation may be of great comfort for patients and their families and may assist them in managing the emotional trauma of the cancer diagnosis,[25] although the offer may also raise expectations.[69] Most younger patients with cancer have historically been left with significant anxieties and insufficient information about reproductive issues.[79] Oncologists have a responsibility to inform parents and age-appropriate patients about the likelihood that cancer treatment will permanently affect their fertility.[35] Ideally, the decision about candidacy for fertility preservation will be guided by an institutional policy and shaped by a medical team, including a pediatric oncologist, fertility specialist, ethicist, and mental health professional. Parents of minors and age-appropriate children should be informed of their prognosis in realistic terms. The option of adoption should be discussed. The success rates, costs, and experimental nature of specific assisted reproduction techniques and the acceptability of the option to decline the intervention should also be discussed.[69,80] The fertility specialist should lead an open and detailed discussion about ownership of reproductive tissue and/or a biological specimen in the event of the patient's death or incapacity.

There is no evidence that fertility-preservation options used today directly compromise the success of cancer therapy or adversely affect a survivor's health.[35] Other than hereditary genetic syndromes, large registry studies have also failed to demonstrate an increased risk of genetic abnormalities, birth defects, or cancers in the children of cancer survivors.[73,81] Disclosing this information to patients and families will provide reassurance of the potential value of fertility preservation. For families with hereditary conditions that are risk factors for developing malignancies, the development of preimplantation genetic diagnosis of embryos and prenatal diagnostic techniques may offer a way of minimizing the risk of transmitting cancer genes to offspring. The technique of preimplantation genetic diagnosis is controversial insofar as inherited disorders may be early or late in onset and, thus, may be ethically distinct. Although the onset of disease may be later in life, the American Society of Reproductive Medicine Ethics Committee has stated that it is ethical for couples to choose to screen embryos to avoid having children with high-risk cancers.[82]

GUIDANCE FOR COUNSELING OF PARENTS AND PATIENTS ABOUT PRESERVATION OF FERTILITY OPTIONS IN CHILDREN AND ADOLESCENTS WITH CANCER

Evaluation of candidacy for fertility preservation should involve a team of specialists, including a pediatric oncologist and/or radiation oncologist, a fertility specialist, an ethicist, and a mental health professional.

1. Cryopreservation of sperm should be offered whenever possible to male patients or families of male adolescents.
2. Current fertility-preservation options for female children and adolescents should be considered experimental and are offered only in selected institutions in the setting of a research protocol.
3. In considering actions to preserve a child's fertility, parents should consider a child's assent, the details of the procedure involved, and whether such procedures are of proven utility or experimental in nature. In some cases, after such consideration, acting to preserve a child's fertility may be appropriate.
4. Instructions concerning disposition of stored gametes, embryos, or gonadal tissue in the event of the patient's death, unavailability, or other contingency should be legally outlined and understood by all parties, including the patient if possible.
5. Concerns about the welfare of a resultant offspring with respect to future cancer risk should not be a cause for denying reproductive assistance to a patient.

CLINICAL REPORT

Preventing and Treating Homesickness

Guidance for the Clinician in Rendering Pediatric Care

Christopher A. Thurber, PhD, Edward Walton, MD, and the Council on School Health

ABSTRACT

Homesickness is the distress and functional impairment caused by an actual or anticipated separation from home and attachment objects such as parents. It is characterized by acute longing and preoccupying thoughts of home. Almost all children, adolescents, and adults experience some degree of homesickness when they are apart from familiar people and environments. Pediatricians and other health care professionals are in a unique position to assist families in understanding the etiology, prevention, and treatment of homesickness. In the case of planned separations, such as summer camp, techniques are provided that may aid in prevention. In the case of unanticipated or traumatic separations, such as hospitalization, effective treatment strategies are available.

INTRODUCTION

Leaving home is a universal developmental milestone. The homesickness associated with this event is usually mild, but the distress and level of impairment among some homesick persons can become extreme. It is an ancient phenomenon, mentioned in both the Old Testament book of Exodus and Homer's *Odyssey*. The Greek physician Hippocrates (circa 460–377 bc) believed that homesickness was caused by a surfeit of black bile in the blood.[1] Seventeenth-century Swiss physician Johannes Hofer (1688) held that homesickness resulted from exposure to foreign environments. This exposure caused "vital spirits [to] constantly surge back and forth through the nerve fibers in which the impressions of the native land are stored."[2]

Today, there is a clearer sense of what causes homesickness and how it can be prevented and treated. Comprehensive historical[1,3,4] and contemporary[5,6] reviews of the literature are available.

DEFINITIONS, EPIDEMIOLOGY, AND DIAGNOSIS

Homesickness is defined as distress and functional impairment caused by an actual or anticipated separation from home and attachment objects such as parents. According to the taxonomy of the American Psychiatric Association, severe homesickness may be best classified as adjustment disorder with mixed anxiety and depressed mood (diagnostic code 309.28).[7,8] The defining feature of homesickness is recurrent cognitions that are focused on home (eg, house, loved ones, homeland, home cooking, returning home), and the precipitating stressor is always an anticipated or actual separation from home. Therefore, it is possible to distinguish homesickness from all other kinds of anxiety disorders, mood disorders, or adjustment disorders as well as from separation distress that young people may feel

when caregivers leave home (eg, for work, military service, divorce, incarceration).[9,10] Homesickness may also be comorbid with other behavioral, emotional, cognitive, and physical problems that warrant clinical attention.

As noted, homesickness occurs to some degree in nearly everyone leaving familiar surroundings and entering a new environment. Recent research has confirmed that homesickness is a significant source of distress and impairment for young people at summer camps, boarding-school students, and hospitalized children.[6,11,12] Other populations frequently affected include immigrants, foreign students, foreign employees, displaced persons, refugees, and military personnel.[13–20]

Prevalence estimates of homesickness vary widely depending on how homesickness is defined, the population under study, the circumstances of the separation, and the type of measurement. For example, prevalence of homesickness among adolescent boarding-school students is estimated to range from 16% to 91%.[12] Because nearly all homesickness researchers have relied on retrospective self-reports, these wide-ranging prevalence estimates also reflect variation in people's recollection of bouts of homesickness. In studies in which researchers measured homesickness at the time the individual was in the new environment, a prevalence of 83% to 95% has been reported.[21,22] Prevalence rates measured while the subject was in the new environment were similar for children at summer camp[5] and hospitalized children,[11] with younger children being at greater risk. There seem to be no gender differences in the prevalence or intensity of homesickness,[9,22] nor are there cultural differences in the way individuals and researchers define the term "homesickness."[21,23]

Another way to examine the severity of homesickness is to look at the percentage of children who rate the average intensity of their homesickness at or above the midpoint of the research rating scale used. This measurement technique consistently categorizes approximately 20% of boys and girls away from home as moderately to severely homesick.[5,9,21,22] A much smaller percentage of children—between 6% and 9%—report intense homesickness that is associated with severe symptoms of depression and/or anxiety.[9,11,21,22]

Longitudinal changes in intensity of homesickness in children and adolescents also have been studied.[9,11,21,22] In summer camps as well as in hospitals, young people seem to fall into 1 of 2 groups. For the least homesick 80% of children, they begin their stay away from home with a low level of homesickness and maintain that low level throughout their time away. For the most homesick 20% of children, they begin their stay with an elevated level of homesickness, and the intensity increases over the course of several weeks, decreasing a bit just before reuniting with their caregivers. With preventive interventions, this trajectory can be altered significantly.[11] The longitudinal course of homesickness intensity for young people in other environments, such as refugee camps and foster homes, is unknown.

Children with homesickness usually present as being tearful and withdrawn. Other children might present atypically with externalizing behaviors such as fighting, swearing, or destroying property.[9,21,22] Therefore, the best diagnostic tool at anyone's disposal is the simple question, "How homesick have you been feeling?" Contrary to some conventional wisdom, research has shown that asking this question as part of a broader assessment of positive and negative moods, even on a daily basis, does not worsen symptoms of homesickness.[9] Quite the opposite: it puts adult caregivers in a better, more educated position to help. Also contrary to conventional wisdom, severe homesickness does not remit spontaneously after a few days. Although this may be true for mild cases of homesickness, severe homesickness typically worsens over time if left undiagnosed and untreated.[9,21,22]

Although some homesick children have somatic complaints, it is more likely for them to have withdrawn or depressed behaviors.[9,21,24] Of the children who somaticize their distress, only a small percentage are evaluated by a health care professional. In a study of 1412 consecutive visits to a summer camp health center by boys and girls 6 to 15 years of age, only 1.6% of visits were classified as "psychiatric."[25] Although somatization is possible in homesick children, the careful clinician will work to diagnose any contemporaneous but distinct physical ailments such as menstrual pain, viral illness, or otitis media. It should be noted that genuine physical injuries or illnesses that occur during a separation may exacerbate or even induce a bout of homesickness. The converse may also be true, at least in adults; poor self-reported physical health has been linked to homesickness.[26]

Severe homesickness in children is associated with social problems, behavior problems, significant symptoms of depression and anxiety, coping deficits, and feelings of helplessness.[9,22,27–29] In academic settings, homesickness among adolescents and young adults can be associated with nontraumatic ailments,[30–32] academic difficulties,[33–35] absentmindedness,[30,31,33,34] low self-esteem,[34,36] and/or obsessive thoughts and behaviors.[30,31]

Unfortunately, data do not exist on the incidence and severity of homesickness in children with cognitive or developmental delay. However, it can be inferred that these children would respond to these situations in a manner consistent with their developmental age, separation attitudes, attachment style, and previous experiences away from home.

Some data do exist for hospitalized children that suggest homesickness is more severe and less predictable than in comparable samples of children in less stressful environments. Across a variety of presenting problems,

approximately 50% of hospitalized children 8 to 18 years of age reported moderate-to-severe levels of homesickness.[11] The best predictors of homesickness were negative hospitalization attitudes and previous separations from home, such as foster placements. Contrary to the experience of children in other settings, homesickness for hospitalized children was not predicted by insecure attachment or low perceived control.[11]

RISK FACTORS

The risk factors for homesickness fall into 4 categories: experience, personality, family, and attitude. More is known about some of these factors in adults—especially personality factors—because more homesickness research has been performed with older populations.[23] However, a growing body of research is elucidating the etiology of homesickness in younger populations.

Experience Factors

In studies of children at summer camps and boarding schools, the experience factors most predictive of homesickness are little previous experience away from home, little or no previous experience at the camp or school, and young age.[5,37] Age, of course, is often a proxy for experience, which is the more powerful predictor. For example, an 8-year-old with lots of experience away from home has less chance of becoming homesick at summer camp than a 12-year-old with very little experience away from home. Experience is probably most valuable when it refines coping strategies.

Not surprisingly, previous experience away from home did not function as a protective factor in a study of hospitalized children.[21] This finding suggests that the types of previous separation experiences shape expectations of future separations.[38] If early separations are negative experiences, as may be the case with foster placements and traumatic hospitalizations, then expectations of future separations may be negative. This, in turn, causes homesickness, as discussed in the next paragraph.

Attitude Factors

The belief that homesickness will be strong, coupled with negative first impressions and low expectations for a new environment, is a powerful predictor of homesickness.[5] In some ways, expectations of intense homesickness and negative experiences become self-fulfilling prophecies. In a study of college freshmen, perceived absence of social support was a strong predictor of homesickness.[39] As noted above, a child's history of time spent away from home largely shapes his or her attitudes. In a study of boys 8 to 16 years of age spending 2 weeks at camp, a combination of little previous experience away from home, low perceived control, negative attitudes about the separation, and high expectations of homesickness accounted for nearly 70% of the variance in the actual intensity of the boys' homesickness.[5]

Personality Factors

An insecure attachment relationship with primary caregivers is the most common risk factor associated with homesickness.[5] In particular, children and adolescents with an "anxious-ambivalent" attachment style are likely to experience significant distress on separation from home. These young people are unsure about how reliably or positively primary caregivers will respond to their displays of distress and may have mixed feelings about how worthy they are of other people's love and attention. This uncertainty can engender great distress in new social settings with surrogate caregivers. Secure attachment, on the other hand, is associated with independence, a proclivity to explore, and solid social skills, all of which help young people adjust to a novel environment.

Two other personality factors that increase the risk of homesickness are low perceived control (over life in general or the separation itself) and anxious or depressed feelings in the months before a separation.[5] In adults, low self-directedness, high harm avoidance, rigidity, and a wishful-thinking coping style all predict homesickness,[20,23] although it is unclear whether these traits can be extrapolated downward to children and adolescents.

Family Factors

The family factor most predictive of homesickness is low "decision control."[5] In other words, when parents force a young person to spend time away, that child or adolescent feels very little decision control. Consequently, he or she is more likely to feel homesick on separation. Other family factors that are weaker predictors of homesickness include caregivers who express anxiety or ambivalence about the separation (eg, "Have a great time at camp. I don't know what I'll do without you.") and the presence of an unresolved negative life event.[5] Although conventional wisdom once held that a recent move, divorce, or similarly disruptive event might predispose a child to homesickness, research has not supported that assumption.[21] It is plausible that if children have had a chance to process the thoughts and emotions associated with a recent negative life event, they are not at increased risk of homesickness.

PREVENTION

Prevention programs for homesickness involve a combination of environmental information, psychoeducation, social support, explicit coping instruction, caregiver education, practice time away from home, and surrogate caregiver training. The result of these interventions is less severe homesickness, fewer feelings of depression and anxiety, and greater satisfaction with the new environment.[11,40,41] In advance of planned separations, such as camp, boarding school, or college, parents should be advised to:

- Involve children (to the extent possible) in the decision to spend time away from home. This is easier for a stay at summer camp than it is for a hospitalization, but even the latter can include children in the planning stages. Taking part in even the smallest decisions will increase perceptions of control.[28,42,43] By contrast, feeling forced to leave home without input into the decision often increases homesickness intensity.[5]
- Educate children. Young people should be told, "Almost everyone misses something about home when they are away. Homesickness is normal. It means there are lots of things about home you love. And the good news is that there are lots of things you can think and do to help make things better if homesickness bothers you."
- Provide explicit coping instruction (see the next section for details). Using some of these strategies during a practice time away from home will boost a child's confidence about the separation.
- Arrange for practice time away from home, such as a weekend at a friend's or relative's house. Ideally, these 2 or 3 days do not include telephone calls but do include opportunities for writing a letter or postcard home. After the practice time away, parents can discuss how things went and which coping strategies worked best.
- Practice basic correspondence. Ensuring that children know how to write letters increases the likelihood that they will maintain some contact with home. Better yet, parents can provide children with prestamped, preaddressed envelopes and notebook paper.
- Work together with children to learn about the new environment, be it a hospital, school, new neighborhood, or summer camp. Web sites, orientation booklets, and current students, alumni, or staff members are excellent resources. They increase familiarity and, thereby, reduce anxiety.[40]
- Get to know people in the new environment. Having at least 1 familiar face—be it an adult or a peer—in a new place can diminish feelings of homesickness by augmenting social support and connections.[39]
- Encourage children to make new friends and seek the support of trusted adults. Both kinds of connections ease the adjustment to a novel environment. Research suggests that college students who are socially anxious are less likely to seek social support and more likely to feel homesick.[39]
- Refrain from expressing anxious or ambivalent feelings about time away from home. Well-intentioned parents have often exacerbated homesickness with comments such as, "I sure hope the food there is decent," "I hope you'll be okay," or "Have a wonderful time. I hope I remember to feed your dog." Giving children something to worry about will increase the likelihood of their having preoccupying thoughts of home. Ideally, parents should express enthusiasm and optimism about the separation and the novel environment. They should be counseled to share their own separation anxiety with other parents, not with their children.
- Maintain predictability and perspective about the time away. Use a wall calendar to show children the time between today and the day of the separation. Highlight which days or weeks the child will be away, so he or she can see that it is a discrete period, not an eternity. During the separation, calendars are also useful tools for helping children keep a perspective on duration.

Surrogate caregivers (eg, camp counselors, nurses, teachers, child life specialists, resident advisors) should be educated about the symptoms of homesickness and the most effective treatments. Staff at an increasing number of camps, schools, and hospitals receive training on how to coach homesick children. If such training is not provided, parents or health care professionals who believe a child is at risk of severe homesickness should inform the caregivers in the new environment and provide them with the following list of treatment techniques.

TREATMENT

Treating homesickness involves normalizing homesickness, coaching young people on effective ways to cope, working on building new social connections, helping them keep some perspective on the duration of the separation, and involving them with the new environment in meaningful ways that enhance their commitment to it.[11,40]

Research with boys and girls 8 to 16 years of age who spent 2 weeks at overnight summer camp suggested that the following strategies are the most effective for coping with homesickness.[27] Some are "doing" strategies (ie, observable, behavioral ways of coping); others are "thinking" strategies (ie, unobservable, cognitive ways of coping). It is worth noting that boys and girls report using these strategies with nearly equal frequency, except for social support, which girls report doing more often than boys.[27] Boys, on the other hand, engage in a bit more aggressive and delinquent behavior than girls, but the baseline frequency of this response to homesickness is quite low.[27,28]

- Do something fun, such as play with friends, to forget about homesick feelings (distraction and social connection).
- Do something (write a letter, look at a family picture) to feel closer to home (contact with home).

- Go see someone who can talk with you to help you feel better (social support).
- Think about the good side of things (activities, friends) to feel better (optimism).
- Think that time away is actually pretty short to make time go by faster (perspective).
- Try not to think about home and loved ones to forget about homesickness (cognitive avoidance).
- Think about loved ones to figure out what they would say to help (vicarious social support).

Research also suggests that the following strategies do not help.[27,28,44] Few children respond to the stressor of separation from home with these approaches, but some may try. They deserve mention so that caregivers can steer children away from these strategies and toward something helpful.

- Doing nothing because of a belief that nothing would help make things better (relinquished control).
- Wishful thinking, such as wishing that camp or school would end tomorrow (fantasy).
- Doing something angry or mean to get sent home (aggressive or delinquent behavior).
- Trying to get home (escape).

On the subject of telephone calls and e-mail, professional opinions are mixed and research is scant. Ultimately, the kind and frequency of child-caregiver contact should be dictated by the goals of the separation.

At summer camps, for example, anecdotal evidence suggests that telephone calls, and to a lesser extent instant messaging, exacerbate homesickness during relatively short stays away from home (eg, 4 weeks or less). Such real-time correspondence also erodes the burgeoning independence that camps and trips are designed to nurture.[45] Therefore, parents should be strongly discouraged from insisting they talk with their homesick child during a short stay away. Chances are great that such contact will only increase the distress for both parties. Old-fashioned letters may be the best way to maintain contact with home. They lack the emotionally evocative quality of a telephone call, and they require narrative reflection, which promotes understanding of one's experience.[46] Such reflection may even serve a therapeutic function, as does keeping a journal.

During longer separations (eg, camp stays greater than 4 weeks, boarding school, college), scheduled telephone calls and 1-way e-mails (from parent to child) seem not to interfere with boys' and girls' enjoyment of the experience, although they still may be evocative.[14] For college students, such contact is actually associated with less homesickness.[40] Although no studies have been conducted on the topic, it is reasonable to assume that the same conclusion applies to adolescents in boarding school.

Research examining the association between contact with home and adjustment in hospitalized children is scarce. A review of these studies suggested that the quality, rather than the quantity, of child-caregiver contact is associated with adjustment.[47] Because the goal of hospitalization is good heath, rather than increased self-reliance, a different approach to child-caregiver contact is warranted. Whereas minimal contact is encouraged during a stay at camp, maximal contact—both in person and electronic—is appropriate for medically hospitalized children. For psychiatric hospitalizations, health care professionals can advise parents on the appropriate quality and quantity of child-caregiver contact. Indeed, this contact may be an integral part of treatment.

NO DEAL

Under no circumstances of planned, recreational separations from home should parents ever make a "pick-up deal" with their son or daughter.[48] Promising that "if you don't like it, I'll come pick you up" reduces the child's likelihood of success for several reasons. First, the subtext of such deals is "I have so little confidence in your ability to cope with this normal response to separation that I believe the only solution is for me to rescue you." Such expressions of anxiety and doubt contradict the recommended expressions of optimism and confidence outlined above. Second, such deals plant the seeds of homesickness by giving young people the expectation that they will not like the new place. Negative separation attitudes are powerful predictors of homesickness.[5] Third, such deals prevent the development of effective coping by pointing young people toward an escape route. Fourth, such deals paralyze surrogate caregivers who, after enthusiastic support and coaching, may be faced with a child who says, "My parents said that if I didn't like it here, they would come to get me." Parents are then faced with 2 equally unsatisfactory choices: (1) fulfill their promise, pick the child up, and deprive him or her of a wonderful opportunity to grow and develop; or (2) renege on their promise and suffer an erosion of trust in their relationship with the child.

If a conversation with a parent or child suggests great anxiety about a planned separation, invite the family to reconsider the timing of the separation. Postponing a trip, a session at camp, or a year at boarding school until parents and children are more comfortable with the separation may be indicated. Knowing when the time is right for a planned separation is the cornerstone of homesickness prevention.[49]

THE PEDIATRICIAN'S ROLE

Pediatricians have a unique role to play in the prevention and treatment of homesickness. Whether the patient is coming to the office for a camp or boarding-

school physical, establishing care because of a recent move or refugee status, or being evaluated before a hospitalization, education about homesickness should be included as a part of the anticipatory guidance associated with these encounters.

For prospective boarding-school students or overnight campers, help families assess their child's readiness to spend time away from home. Ask about previous separations, encourage practice time away from home, and assess the child's coping skills. Strongly dissuade parents from making pick-up deals (see previous section). Encourage families to activate all of the homesickness-prevention strategies listed above. Help families select a school or camp that is well matched to their child's interests, abilities, and developmental needs.[50] Be sure they have a plan for keeping in touch and that they understand the school's or camp's policies regarding telephone calls, e-mails, and visits. For children with special mental, physical, or emotional needs, be sure the school or camp has the appropriate resources in place to support and care for the child. For all children, normalize feelings of missing home and frame the separation as a positive developmental experience.

Elective interruptions in long-term medication regimens for behavioral or psychiatric diagnoses ("drug holidays") should be avoided when there are plans for a child to enter a new environment.[50] If the medications are helpful in one setting, they are likely to be helpful at school or camp. Only after 1 month or more of positive adjustment in a novel environment should changes to helpful medications be considered.

For displaced families, take time to understand the circumstances of the recent move. Was the family, or part of the family, forced to relocate? How traumatic was that for the family members? Homesickness, as noted above, is idiosyncratic, so ask, "What do you miss most about where you used to live?" In addition to the treatment strategies listed above, homesickness in displaced families is also ameliorated by settling into and connecting with the new community.[14] Parents and children alike benefit from social support, a sense of purpose (eg, work, school, or sports), and feelings of security.[29,51] As knowledgeable, native authority figures, pediatricians can be instrumental in assisting newly displaced families connect with the social, educational, and vocational opportunities in the community. Connecting a newly displaced family with an established family of the same ethnicity or country of origin can be particularly helpful.

For hospitalized children, the pediatrician's approach will depend on timing. For unplanned hospitalizations, the best approach may be to educate parents about the normalcy of adjustment difficulties encountered during hospitalizations, including homesickness.[47] Then, coach the parents and hospital staff on some of the best ways to bolster children's coping skills. Frequent, predictable contact between children and their primary caregivers is of paramount importance. For planned hospitalizations, the best anticipatory guidance will focus on creating positive attitudes about the hospitalization. Because negative separation attitudes are such strong predictors of homesickness,[5] it is essential that parents and pediatricians partner to convey positive expectations about the helpful outcomes of the hospitalization. Anecdotal evidence also suggests that orienting children to the hospital unit, to various medical procedures, and to the staff members who will be caring for them reduces anxiety and minimizes homesickness.

With children in all these circumstances, pediatricians can debunk certain myths[21,52] about homesickness:

- Homesickness is not just something that young children get. It is normal for all people to experience some degree of distress or impairment when they are away from home.
- Severe homesickness does not remit spontaneously but does get better with positive coping efforts. Therefore, encourage children to seek support from surrogate caregivers in the new environment.
- Talking about homesickness does not cause homesickness. Instead, it provides a way to educate and encourage a homesick person.
- Young people are not all homesick for their parents. Some children most miss home cooking or the family pet. Instead of assuming, always ask, "What do you (will you) miss most about home?"
- Homesickness does not always feel like sadness or nervousness. Sometimes, homesick persons feel angry, irritable, or disoriented. Therefore, homesick children are sometimes hard to identify.

APPENDIX 1: HOMESICKNESS-PREVENTION STRATEGIES FOR HOSPITAL STAFF MEMBERS WORKING WITH CHILDREN

1. Coach parents before admission to not deceive their child about the purpose and timing of hospitalization. Although the honest truth may be upsetting or startling to some children, coping with the reality of their situation now prevents uncomfortable surprises later. Children who feel "tricked" into hospitalization lose confidence in the reliability of their caregivers and therapists, and this both increases homesickness and lessens trust.
2. Orientation to the unit is one key to good adjustment. When children feel as if they have some control over the novel hospital environment, they may be less fearful and homesick. Depending on the child's condition, a tour of the unit, labeled photographs of staff members, big calendars, daily schedules, and introductions to the other kids on the unit can all help children feel comfortable and oriented in their new environment.

3. When possible, staff members should convey a consistent message about length of stay. Conflicting messages from adults in charge reduces children's global confidence in caregivers. Unpredictability leads to anxiety. If one staff member says "you'll be here about 2 weeks" and another says "you'll be here about 3 weeks," children are likely to feel distressed and homesick.
4. When hospitalization follows a traumatic event in which multiple family members were involved, family members may be in different parts of the hospital or even different hospitals. This can induce homesickness and separation anxiety. When possible, staff members should help children make contact, by telephone or in person, with dispersed family members.
5. A child's mental status during hospitalization can change dramatically, even in the course of a day. Often, these changes involve a distorted sense of time and a fluctuating awareness of the caregivers' presence. These factors can cause homesickness. Continue efforts to orient the child. Pictures of the family, large clocks and calendars, lights on in rooms during the day, and frequent reminders often help reorient homesick children.
6. Changes and uncertainties in caregiver visitations can cause homesickness. Caregivers should be apprised of the importance of frequent, reliable contact with their children. Staff members should encourage caregivers to call and give ample warning if they are unable to make a scheduled visit.
7. Sometimes hospitalized children feel left alone, and this can cause homesickness. Especially early in a hospital stay, before the child knows the staff and routine, even 5 minutes alone can be frightening. Try to keep children apprised of the day's schedule, and give ample warning if there are going to be times when the child is left alone, however briefly.
8. To ease parental separation anxiety, staff members should forewarn parents when their child will be moved to a different room. Parents are unsettled to come to visiting hours and enter their child's room, only to find it empty or occupied by a stranger. For the same reasons that children need to feel prepared for upcoming events, so do parents.
9. When possible, minimize discharge uncertainty. Children have an easier time coping with homesickness when they have a fixed-length hospital stay to manage. By the same token, avoid changing a child's discharge date if at all possible. Once staff members state an exact date out loud, children (and parents) have a tendency to fixate on that date. Changing the promised date can provoke homesickness. It may be best to tell children and families that discharge dates are hard to predict and give them a range of plausible dates.

APPENDIX 2: HOMESICKNESS-PREVENTION STRATEGIES FOR PARENTS OF HOSPITALIZED CHILDREN

1. Homesickness is normal. Almost all children feel a bit sad and nervous when they are separated from home and loved ones. No matter how turbulent your child's life has been lately, he or she is likely to miss many things about home during this hospitalization. One way that parents can help children deal with this distress is to reassure them that missing home is normal.
2. Talk with your child honestly about when and why he or she is being hospitalized. Although the honest truth may be upsetting or surprising to some children, coping with the reality of their situation now prevents uncomfortable surprises later. Children who feel "tricked" into hospitalization lose confidence in the reliability of their caregivers and therapists, which increases homesickness.
3. To help your child feel "at home" in the hospital, the staff may give your child a tour of the unit. Staff members can explain the daily routine on the unit and answer any questions that you or your child might have. This orientation, along with photographs, calendars, schedules, and introductions to other children, will help your child feel more comfortable.
4. Although you may have some mixed feelings about your child's hospitalization, try not to convey those feelings to your child. If you talk about your mixed feelings, you may increase your child's own doubts about the value of hospitalization. Instead, give your child a consistent, positive message about why he or she is here. Help your child understand the value of this hospital stay.
5. Often, it is impossible for staff to predict your child's exact discharge date. This date depends on many factors, some of which are constantly changing. Although this uncertainty is hard for families, it is even harder when an exact date does not work out as planned. The disappointment of a postponed discharge date can make children quite homesick. Therefore, instead of focusing on a particular date, ask the staff to estimate a range of dates, and be honest with your child that no one knows the exact discharge date yet.
6. Sometimes, children in the hospital get confused about time. Your child might even forget when you visited the last time or when you said you would come back for a visit. This confusion can make homesickness worse. To help your child keep track of your

visits, draw or buy a simple calendar and write your plans down. Try your best to be on time for the visits and telephone calls that you plan.

7. Frequent visits and telephone calls help ease children's homesickness. Of course, you have other commitments, but try to visit as often as possible. Avoid canceling visits at the last moment, which is particularly upsetting to children. If you cannot visit, be sure to call and talk with your child on the telephone.
8. Despite all of your efforts and all of the staff's efforts to make children feel comfortable, many of them still feel homesick in the hospital. Fortunately, many children can help themselves feel better by doing one of the things below. You and the hospital staff should share these techniques with your child:
   a. Do a fun activity to forget about missing home. Play a game with a friend, watch television, listen to music, or read a book.
   b. Do something to feel closer to home. Write a letter, talk on the telephone, or look at a family picture.
   c. Think about the good side of being in the hospital. There are kids to play with and staff to help you. Being in the hospital will help you get better.
   d. Keep a positive attitude. Staff members can answer your questions and teach you a lot about dealing with your problems.
   e. Remind yourself that you will be home soon. Hospitalizations do not last forever.
   f. Talk with someone who can make you feel better, such as your doctor or one of the other staff members.

APPENDIX 3: HOMESICKNESS-PREVENTION STRATEGIES FOR PARENTS TO USE WITH CHILDREN AROUND PLANNED SEPARATIONS

1. Discuss the upcoming separation with your child. Young people should be told, "Almost everyone misses something about home when they are away. Homesickness is normal. And the good news is that there are lots of things you can think and do to help make things better if homesickness bothers you."
2. Involve your child in the decision to spend time away from home. Prepare and pack as a family. Taking part in even the smallest decisions will increase perceptions of control. By contrast, feeling forced to leave home often increases the severity of homesickness.
3. Discuss coping strategies with your child. Using some of these strategies during practice time away from home will boost your child's confidence about the separation.
   a. Do something fun, like play with friends, to forget about homesick feelings.
   b. Do something (write a letter, look at a family picture) to feel closer to home.
   c. Go see someone who can talk with you to help you feel better.
   d. Think about the good side of things (activities, friends) to feel better.
   e. Think that time away is actually pretty short to make time go by faster.
   f. Try not to think about home and loved ones to forget about homesickness.
   g. Think about loved ones to figure out what they would say to help.
4. Arrange for practice time away from home, such as a weekend at a friend's or relative's house. Ideally, these 2 or 3 days do not include telephone calls but do include opportunities for writing a letter or postcard home. After the practice time away, discuss with your child how things went and which coping strategies worked best.
5. Practice correspondence. Ensuring that children know how to write traditional letters increases the likelihood that they will maintain some contact with home. Give children prestamped, preaddressed envelopes and notebook paper.
6. Work together with your child to learn about their new environment, be it a hospital, school, new neighborhood, or summer camp. The more young people know about the new place to which they are going, the more at home they will feel when they arrive. Web sites, orientation booklets, and current participants, alumni, or staff members are excellent resources.
7. Help your child get to know some of the people in the new environment. Having at least 1 familiar face—be it an adult or a peer—in a new place can diminish feelings of homesickness by increasing feelings of social support and connection.
8. Encourage your child to make new friends and seek the support of trusted adults. Both kinds of connections ease the transition to a new environment.
9. Avoid expressing anxious or ambivalent feelings about time away from home to your child. Instead, express enthusiasm and optimism about the fun your child is going to have in the new environment.
10. Use a wall calendar to show your child the time between today and the day of the separation. Highlight which days or weeks they will be away so that

he or she can see that it is a discrete period, not an eternity. During the separation, a calendar might be a way for your child to keep perspective on the separation.

11. Do not make a "pick-up deal" with your son or daughter. Promising that "if you don't like it, I'll come pick you up" decreases your child's likelihood of success in the new environment; this will give the impression to your child that you have so little confidence in his or her ability to cope with the separation that the only solution is to be rescued. Also, such deals create difficulties for staff members, who after enthusiastic support and coaching may be faced with a child who says, "My parents said that if I didn't like it here, they would come to get me." It also puts you in the position of either (1) fulfilling your promise to pick up your child, robbing him or her of a wonderful opportunity to grow and develop, or (2) reneging on your promise, causing an erosion of trust in your relationship with your child. Respond to the query, "What if I feel homesick?" with a statement such as, "You probably will feel a little homesick, but your practice time away has taught you what to think or do in case any homesickness bothers you. Plus, staff members will be there to talk with you and help you make it through. You'll have a great time."

AMERICAN ACADEMY OF PEDIATRICS

Committee on Injury and Poison Prevention and Committee on Community Health Services

Prevention of Agricultural Injuries Among Children and Adolescents

ABSTRACT. Although the annual number of farm deaths to children and adolescents has decreased since publication of the 1988 American Academy of Pediatrics statement, "Rural Injuries," the rate of nonfatal farm injuries has increased. Approximately 100 unintentional injury deaths occur annually to children and adolescents on US farms, and an additional 22 000 injuries to children younger than 20 years occur on farms. Relatively few adolescents are employed on farms compared with other types of industry, yet the proportion of fatalities in agriculture is higher than that for any other type of adolescent employment. The high mortality and severe morbidity associated with farm injuries require continuing and improved injury-control strategies. This statement provides recommendations for pediatricians regarding patient and community education as well as public advocacy related to agricultural injury prevention in childhood and adolescence.

ABBREVIATIONS. ED, emergency department; AAP, American Academy of Pediatrics; ATV, all-terrain vehicle; ROPS, rollover protective structures; NIOSH, National Institute for Occupational Safety and Health.

INTRODUCTION

Although "agriculture," "farm," and "rural" are not interchangeable terms, many of the risk factors are similar for injuries in each of these settings. Present data collection systems do not always allow clear distinctions among these injury categories; therefore, for purposes of this statement, only unintentional agricultural injuries will be considered. Migrant farmworker children are also not well represented in available data. Although this statement includes much that is generally applicable to any farm child, it emphasizes family farms and does not deal in full with patterns of exposure and injury specific to migrant farmworker children. Not all rural people live on farms, but most farms are in rural areas. In 1991, 923 000 children younger than 15 years and 346 000 adolescents 15 through 19 years of age resided on US farms and ranches.[1] There are no good estimates of the population of migrant farmworker children, but it is known that at least 600 000 school-aged children are enrolled in migrant education programs.[2] Thus, it is estimated that almost 2 million children live on, work on, or visit farms annually.

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

FARM FATALITIES

From 1991 to 1993, an annual average of 104 deaths of children younger than 20 years occurred on US farms and ranches.[3] Based on the estimated 1 298 000 children and adolescents younger than 20 years living on farms in 1991, the overall annual farm death rate was 8.0 per 100 000 child and adolescent farm residents. This is a 39% reduction compared with the 1979 to 1981 rate in the same data set.[4] However, the actual number of farm-related deaths is probably underestimated, because these data do not include deaths on public roadways, even if a farm vehicle was involved (motor vehicle crashes are the leading cause of death for farm children younger than 18 years, as they are for all other children younger than 18 years).[5] Also, surveillance using only death certificates at the state level has been found to miss 18% of actual agricultural fatalities.[6] The lack of a national agricultural injury surveillance system does not permit better estimates than these.

Death rates from unintentional agricultural injuries increase with age,[7] with a slight dip in the 5- to 9-year age group.[3] Death rates for boys and girls have declined equally since the 1979 to 1981 study[4]; however, fatality rates among males were 5.6 times higher when compared with those for females overall and nearly 10 times higher than rates for females among those 15 to 19 years of age. Head injuries occurred in 64% of the fatalities.[3,4]

Each year, farming ranks among the most dangerous occupations in the country for adult and adolescent workers.[8] When using estimates of actual hours worked, the rate of adolescent injury exceeds the rate for adult workers.[9] A study of 670 occupationally related deaths from 1980 to 1989 among 16- and 17-year-olds found that one third of the 354 victims with known industry of employment worked in agriculture (for the other 316 victims, industry was unknown).[9] Machinery accounted for 105 of the 670 deaths, and 68% of deaths caused by machinery were related to agriculture. Tractor-related injuries, often rollovers, account for 30% to 50% of fatal injuries.[10–13]

In a study of pediatric farm fatalities, almost 72% of victims died before ever reaching a hospital[4]; however, more recent data show a decrease to 52%.[3] This decrease may be related to expanded emergency medical services in rural areas and to increased pediatric training of prehospital providers through the Emergency Medical Services for Children program.

NONFATAL FARM INJURIES

On average, an additional 22 288 children younger than 20 years who live on farms and ranches are

injured severely enough to be seen in an emergency department (ED) each year.[3] The total childhood farm injury toll has been estimated at greater than 100 000 annually (Fig 1).[14]

Although fatality rates and the number of farm injuries have decreased since publication of the previous American Academy of Pediatrics (AAP) statement,[15] in light of a shrinking farm population, the rate of nonfatal farm injuries has risen 10.7%.[3,4] Significant long-term disability occurred in 41% of 88 people with farm-related injuries who were brought to a Minnesota ED, and 13% required reconstructive surgical procedures.[16] In New York State, permanent disability rates exceeded temporary disability (1.17:1) in agriculture, to a greater degree than in any other industry.[17]

Many studies have examined the most common causes of agricultural injury.[3,4,6,7,9–11,16–26] Tractor-related injuries and other farm machinery are a major source of morbidity.[3,4,6,7,10–13,17–23,26] Livestock, other farm machinery (including power take-offs), falls from structures, chemical burns and poisonings, and wound infections accounted for most of the remaining morbidity.[3,4,6,7,11–13,16,18,20,24–26] High school students with active involvement in farm work have been found to have audiometric evidence of early noise-induced hearing loss. As in adults, this loss was most marked in the ear turned closest to the tractor engine while driving.[27] A 4-year intervention program designed to protect hearing by promoting use of hearing protection devices was found to be successful.[28] Other environmental or health hazards experienced by adult workers, such as exposure to pesticides, fuel, toxic gases, infections, and stress, also affect children.

Among 1- to 16-year-old children brought to the ED for a farm injury, 84% were boys and 16% were girls.[16] Several studies suggest a bimodal age distribution for agricultural injuries, the first peak occurring at 3 to 4 years of age and the second at 13 to 14 years of age.[16,18] The first age peak is attributable to increased mobility, exploration, and the need for both supervision and separation of play areas from the rest of the farm. Poisonings from pesticides and alkali agents in the toddler age group can result from storage in containers that are not childproof and those that resemble drink containers.[24,25]

The second age peak at 13 to 14 years of age appears to be attributable to involvement of adolescents in farm work. Multiple factors may contribute to this peak, including the hazardous nature of the work and use of large machinery, coupled with inexperience and, in some cases, risk-taking behaviors. Among adolescents working on farms, nearly three fourths reported being injured during work.[19] In a review of workers' compensation awards to New York State youth from 1980 to 1987, only 3% of employed youth worked in agriculture, yet agriculture was the second most hazardous industry employing youth overall, and with the highest injury rates, was the most hazardous for 16- and 17-year-old workers.[17] Most of these injured adolescents were employed as farm workers (64%), gardeners and groundskeepers (14%), and animal caretakers (5%). Seasonal variation in pediatric agricultural injury has been observed, with several studies noting increases during the summer in addition to peaks occurring at planting and harvest time.[11,16,18]

RECOMMENDATIONS

The lethality of farm injuries, the implications for long-term disability of those injured, and the impact on families warrant continuing injury-control efforts on the part of pediatricians. The entire injury-control spectrum, including prevention, timely acute medical care delivered by professionals trained in the care of children, and age-appropriate rehabilitation, should be addressed by pediatricians with the support of the AAP. Several articles and publications have stressed the need for injury prevention education to farm families as well as the very important role of physicians in both prevention and treatment.[29–33] In 1996, the National Committee for Childhood Agriculture Injury Prevention, a multidisciplinary consensus group, recommended action steps to reduce unintentional agricultural injuries to children younger than 18 years.[29] The AAP supports these recommendations and makes the following recommendations to pediatricians who care for children living on or visiting farms:

1. Parents and patients should be asked about farm residence, farm work involving children, and visits to relatives on farms and should be informed about the risks of agricultural injury and effective preventive measures. Strategies for prevention might include the following:
   - Separating young children from farm hazards by fencing in a play area
   - Providing child care to assist farm families and farm workers or pooling family child care, especially at planting and harvesting times
   - Prohibiting extra riders on tractors, mowers, and all-terrain vehicles (ATVs)[34]
   - Ensuring that there are rollover protective structures (ROPS) and seat belts on tractors and other farm equipment and that these are used at all times
   - Limiting young children's access to large animals
   - Properly storing farm chemicals and cleaning agents
   - Providing children who work on farms with

personal hearing-protection equipment and training them on how to use it properly.

2. Parents should be educated about normal growth and development in adolescence and should be encouraged to consider the physical and emotional readiness of the child for work. Parents need to recognize that small adolescents on adult-sized machinery and large adolescents with immature cognitive and judgment skills are at high risk for farm injury. Consensus guidelines have been developed by the North American Guidelines for Children's Agricultural Tasks project.[35] These guidelines discuss skill sets for discrete tasks and skill acquisition necessary before advancing to a new task. They are available on the Internet[35] to physicians, parents, and youth and may be helpful for counseling about developmentally and age-appropriate agricultural work for children 7 to 16 years old.
3. For any farm machinery work, parental supervision, task-specific education, and initial experiences in good weather on level terrain with visual contact by parents or other adults should be supported. Children should be taught to get help from adults if any difficulties are encountered. These behaviors should be supported not only for individual families but also in the schools and as community norms.
4. Pediatric training programs should increase teaching about the importance of childhood and adolescent agricultural health and safety issues, including regional epidemiology and effective prevention strategies. Pediatricians should then ensure that this information is shared with the community and schools. Community farm safety organizations such as 4-H, National FFA, and Farm Safety 4 Just Kids, as well as county extension agents taking leadership roles in agricultural health and safety, should be supported. Also, community-based pediatric injury prevention organizations, such as SAFE KIDS coalitions and Safe Communities, should be encouraged to include education about prevention of agricultural injury in their rural-related activities. Especially where none of these efforts exist, rural pediatricians should themselves consider leading farm injury prevention efforts with local support and resources.
5. The emergency medical services system should be improved to provide the best possible emergency care, medical assessment, and access to tertiary care for children and adolescents residing in rural areas.
6. A national data system for childhood agricultural injury epidemiology and prevention should be maintained. The National Institute for Occupational Safety and Health (NIOSH) has been designated the lead agency in this effort. The purpose of this national system is to collect and analyze data, establish policy, promote and evaluate research, and link agencies with related purposes. Mandatory coding to identify external cause-of-injury for nonfatal agricultural injuries would greatly assist in providing an epidemiologic profile of these injuries as the first step in prevention.[36]
7. Voluntary or legislated safety standards should be promoted, including the following:
   - Improved safety standards for farm equipment. All tractors should be equipped with seat belts and ROPS, and individuals younger than 18 years should be restricted from operating any tractor not so equipped.
   - Children younger than 16 years should not operate any farm vehicles, including ATVs.[34] Individuals between 16 and 18 years of age should have a valid motor vehicle license and should also be a certified graduate of a state-approved tractor and farm vehicle safety training program, if available, to operate a farm vehicle on a public road. Such courses need to be developed, standardized, and evaluated.
   - Children and adolescents should be restricted from riding on or in areas of machinery or motorized vehicles not approved for passengers (including the racks of ATVs, fenders of tractors, and cargo areas of pickup trucks[37]).
   - Safety and environmental guidelines to protect bystander children from agricultural hazards should be established.
   - Child labor laws, including hazard orders, should be amended to apply uniformly to machinery and exposures in other settings and on farms to provide equal protection for all children.[38]
8. Manufacturers of farm equipment and farm chemicals should be encouraged to apply existing technologies and invest research funds in the development of new technologies to decrease the number of agricultural injuries and poisonings.

abstract

Choking is a leading cause of morbidity and mortality among children, especially those aged 3 years or younger. Food, coins, and toys are the primary causes of choking-related injury and death. Certain characteristics, including shape, size, and consistency, of certain toys and foods increase their potential to cause choking among children. Childhood choking hazards should be addressed through comprehensive and coordinated prevention activities. The US Consumer Product Safety Commission (CPSC) should increase efforts to ensure that toys that are sold in retail store bins, vending machines, or on the Internet have appropriate choking-hazard warnings; work with manufacturers to improve the effectiveness of recalls of products that pose a choking risk to children; and increase efforts to prevent the resale of these recalled products via online auction sites. Current gaps in choking-prevention standards for children's toys should be reevaluated and addressed, as appropriate, via revisions to the standards established under the Child Safety Protection Act, the Consumer Product Safety Improvement Act, or regulation by the CPSC. Prevention of food-related choking among children in the United States has been inadequately addressed at the federal level. The US Food and Drug Administration should establish a systematic, institutionalized process for examining and addressing the hazards of food-related choking. This process should include the establishment of the necessary surveillance, hazard evaluation, enforcement, and public education activities to prevent food-related choking among children. While maintaining its highly cooperative arrangements with the CPSC and the US Department of Agriculture, the Food and Drug Administration should have the authority to address choking-related risks of all food products, including meat products that fall under the jurisdiction of the US Department of Agriculture. The existing National Electronic Injury Surveillance System–All Injury Program of the CPSC should be modified to conduct more-detailed surveillance of choking on food among children. Food manufacturers should design new foods and redesign existing foods to avoid shapes, sizes, textures, and other characteristics that increase choking risk to children, to the extent possible. Pediatricians, dentists, and other infant and child health care providers should provide choking-prevention counseling to parents as an integral part of anticipatory guidance activities. *Pediatrics* 2010;125:601–607

INTRODUCTION

Choking is the blockage or hindrance of respiration by a foreign-body obstruction in the internal airway, including the pharynx, hypopharynx, and trachea. Airway obstruction can be fatal if it leads to serious impair-

ment of oxygenation and ventilation. Choking is a leading cause of morbidity and mortality among children, especially those who are 3 years of age or younger. This is largely because of the developmental vulnerabilities of a young child's airway and the underdeveloped ability to chew and swallow food. Young children also commonly put objects in their mouths as they explore their environments.[1] The most common objects on which children choke are food, coins, balloons, and other toys.

FACTORS ASSOCIATED WITH THE ANATOMY AND FUNCTION OF THE AIRWAY

An infant is developmentally able to suck and swallow and is equipped with involuntary reflexes (gag, cough, and glottic closure) that help to protect against aspiration during swallowing. Dentition initially develops at approximately 6 months with eruption of the incisors. Molars are required for chewing and grinding food and do not erupt until approximately 1.5 years of age. However, mature mastication abilities take longer to develop and remain relatively incomplete throughout early childhood.[2,3] Young children and children with developmental and neurologic impairment also do not have the overall cognitive skills, behavioral control, or experience to chew well and eat slowly.

Despite a strong gag reflex, a young child's airway is more vulnerable to obstruction than that of an adult in several ways. The smaller diameter is more likely to experience significant blockage by small foreign bodies. Resistance to air flow is inversely related to the radius of the airway to the fourth power, so even small changes in the cross-section of the airway of a young child can lead to dramatic changes in airway resistance and air flow. Mucus and secretions around a foreign body in the airway will reduce the radius of the airway even further and may also form a seal around the foreign body, making it more difficult to dislodge by forced air, such as with a cough or Heimlich maneuver. The force of air generated by a cough in an infant or young child is less than that in an adult; therefore, a cough may be less effective in dislodging a complete or partial airway obstruction during early childhood.[4]

EPIDEMIOLOGY

Nonfatal Choking Episodes

A complete description of nonfatal choking events among children is limited, because many of these events are transient, do not result in aspiration, and consequently do not result in visits to health professionals. Many episodes, therefore, are not reported. Choking events that result in emergency medical treatment or bronchoscopy are the most serious of episodes and have been well described.[5–8] Data are lacking regarding the long-term consequences of brain hypoxia caused by nonfatal choking; however, the morbidity in these cases can be severe.

The Centers for Disease Control and Prevention conducted an analysis of nonfatal choking episodes among children aged 14 years or younger treated in US hospital emergency departments during 2001 on the basis of data reported through the National Electronic Injury Surveillance System–All Injury Program (NEISS-AIP).[9] Of an estimated 17 537 children aged 14 years or younger who were treated for nonfatal choking, more than half (59.5%) were treated for food-related choking, approximately one third (31.4%) were treated for choking on nonfood items, and the cause of choking for the remaining 9.1% was unknown. Almost 13% of all these choking episodes were associated with coins, and 19% were caused by candy or gum. These findings are similar to those reported in a comparative retrospective analysis of foreign-body–related injuries to children from 1920–1932 and 1988–2000, confirming that food and coins are the most common foreign bodies.[10] Coin-related choking episodes among children are usually transient, with the coin typically being swallowed. The coin usually passes through the gastrointestinal tract without problems but may lodge in the esophagus.

A Centers for Disease Control and Prevention report[9] indicated that choking rates were highest among infants (140.4 per 100 000 population) and decreased consistently with increasing age, with an overall rate of 29.9 per 100 000 population among children aged 14 years and younger. Almost one third (30.5%) of choking episodes occurred among infants, and more than three fourths (77.1%) occurred among children aged 3 years or younger. Male and female children were treated for choking at similar rates: 32.1 and 27.3 per 100 000 population, respectively. An estimated 10.5% of children receiving emergency medical treatment were admitted to the hospital or transferred to a facility with advanced care available.[9]

Fatal Choking Episodes

From 1972 to 1992, 449 deaths from aspirated nonfood foreign bodies among children aged 14 years or younger were recorded by the US Consumer Product Safety Commission (CPSC). Nearly two thirds (65%) of these fatalities were among children younger than 3 years. Latex balloons were associated with 29% of deaths overall.[11] Choking on food causes the death of approximately 1 child every 5 days in the United States. Hot dogs accounted for 17% of food-related asphyxiations among children younger than 10 years of age in a 41-state study by Harris et al.[12]

NONFOOD-RELATED CHOKING

Coins and toys account for most nonfood-related choking events among children. Purchasing toys for children

with younger siblings poses a challenge to parents. They may find it difficult to meet the developmental play needs of the older child while addressing the safety needs of a younger sibling. Toys that are acceptable for older children sometimes have small or removable parts that can pose a choking risk to the younger brother or sister.

High-Risk Shapes, Sizes, and Consistencies

Of all children's products, latex balloons are the leading cause of choking death, and most of these fatalities are among children younger than 6 years.[13,14] At least 68 children died from choking on latex balloons from 1990 through 2004 in the United States.[15] Uninflated and pieces of broken latex balloons pose a particular hazard because of their ability to conform to the child's airway and form an airtight seal.

In addition to conforming objects, round, ovoid, or cylindrical objects such as balls, marbles, and spherical toys or toy parts pose the greatest risk of choking death.[11,15] When these objects are approximately the same diameter as a child's upper airway, they can completely occlude the airway with a snug fit and are difficult to dislodge with rescue maneuvers.

Monitoring and Enforcement by the CPSC

The Federal Hazardous Substance Act (FHSA) (Pub L No. 86–613 [1960]) was amended in 1994 by the Child Safety Protection Act (CSPA) (Pub L No. 109–248). The CSPA requires choking-hazard warning labels on packaging for small balls, balloons, marbles, and certain toys and games that contain small parts when these items are intended for use by children in defined age groups. This act also bans any toy intended for use by children younger than 3 years that may pose a choking, aspiration, or ingestion hazard. The CPSC created a CSPA fact sheet[16] (www.cpsc.gov/cpscpub/pubs/282.html) that lists the required warning statement for each item when intended for use by defined age groups. Section 1501 of the FHSA defines a test of object size using the small-parts test fixture (SPTF). The SPTF is a truncated cylinder with a diameter of 3.17 cm (1.25 in), simulating the mouth, and a depth between 2.54 and 5.71 cm (1.00 and 2.25 in), simulating the pharynx (Fig 1). An object is considered a small part if it fits completely within the SPTF. The SPTF was developed, in part, on the basis of data regarding the dimensions of airway foreign bodies recovered by bronchoscopy by Chevalier Jackson in the early 1900s.[8] Because of their high-risk shape, small balls are held to a stricter criterion to prevent choking. The CSPA requires that balls be at least 1.75 inches in diameter if they are intended for use by children younger than 3 years. The CSPA defines a ball as a spheroid, ovoid, or elliptical object that is designed or intended to be thrown, hit, kicked, rolled, bounced, or dropped.

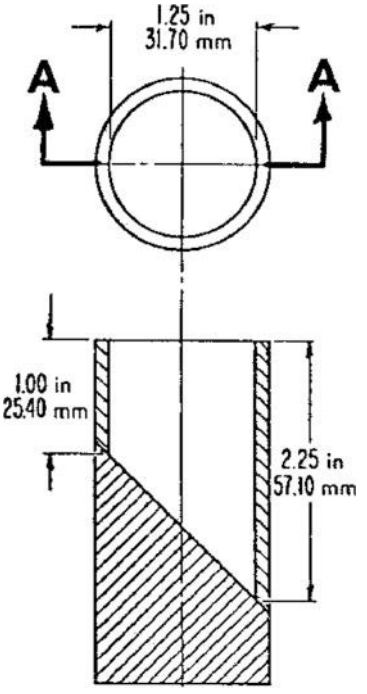

FIGURE 1
The SPTF.

In addition, the Consumer Product Safety Improvement Act of 2008 (Pub L No. 110–314) amended the FHSA to require choking-hazard warnings to be displayed on or adjacent to product advertisements on Web sites or in catalogs or other printed materials that provide a direct means for purchase or order of a product for which a warning is required under the FHSA.

High-Risk Settings and Circumstances

In a study that predated the CSPA, Rimell et al[11] examined 101 foreign bodies that had caused a choking death and found that 14 passed requirements for use by children younger than 3 years. In another study on airway foreign bodies, Reilly et al concluded that greater child protection would be achieved if the diameter of the SPTF was increased from 1.25 to 1.75 in.[10] Milkovich et al[17] examined approximately 7000 foreign-body injuries from 15 countries and recommended the use of a 1.50-in-diameter test device for nonspherical objects and a 1.75-in-diameter test device for spherical objects. The ball test fixture defined in the CSPA has a 1.75-in diameter; however, there are spheroid, ovoid, or elliptical toys or toy parts that do not meet the definition of a ball but present the same cross-sectional profile to a child's airway. Although these spheroid, ovoid, or elliptical nonball objects present an increased risk of fatal choking to young children, similar to the increased risk of fatal choking associated with balls, they currently are not held to the stricter choking-prevention standard applied to balls. Therefore, these gaps in choking-prevention standards for children's toys should be reevaluated and addressed, as appropriate, via revi-

sions to the CSPA or regulation by the CPSC.

Because the CPSC does not conduct premarket testing of toys, consumers need to be aware that just because a toy is on the market does not guarantee its safety. Consumers should be proactive in evaluating toy features that may pose a danger to a child before the toy is purchased and given to a child. Toys sold in retail store bins, vending machines, and on the Internet may not be consistently marked with appropriate warning labels and, thus, present a challenge to consumers who wish to make informed safe purchases. Toys resold in yard sales, at secondhand stores, and via online auction Web sites commonly lack appropriate cautionary labeling and information.[18] Choking risk to children younger than 3 years is the most common reason for the CPSC to issue a recall notice for a children's product; however, the effectiveness of children's product recalls is very low. For example, consumers generally return only 10% to 30% of sold infant products after they have been recalled.[19] Recalled children's products are commonly resold on online auction Web sites.[18]

FOOD-RELATED CHOKING

Choking on food poses an important and relatively underaddressed problem for US children. Approximately 66 to 77 children younger than 10 years of age die from choking on food each year in the United States,[12] and >10 000 emergency department visits annually can be attributed to choking on food among children aged 14 years and younger.[9]

High-Risk Foods and Food Characteristics

Hot dogs are the food most commonly associated with fatal choking among children.[12] A hot dog shares the physical characteristics described above for high-risk toys. It is cylindrical, airway sized, and compressible, which allows it to wedge tightly into a child's hypopharynx and completely occlude the airway. Other high-risk foods include hard candy, peanuts/nuts, seeds, whole grapes, raw carrots, apples, popcorn, chunks of peanut butter, marshmallows, chewing gum, and sausages.[12] Many of these foods, such as round candy, grapes, marshmallows, and meat sticks/sausages, share the same high-risk physical characteristics that create effective plugs for the pediatric airway. Similar to latex balloons, peanut butter can conform to the airway and form a tenacious seal that is difficult to dislodge or extract. It is noteworthy that many foods with high-risk characteristics associated with choking are man-made. The characteristics of these foods are engineered and, therefore, amenable to change, unlike naturally occurring food products such as certain fruits and vegetables. Manufacturers of foods that are frequently consumed by children should, to the extent possible, design these products to minimize choking risk to those in that age group.

Child Risk Factors

The American Academy of Pediatrics (AAP) Section on Breastfeeding and many other health organizations recommend exclusive breastfeeding for the first 6 months of life.[20] The AAP Committee on Nutrition recommends that complementary foods be introduced between 4 and 6 months of age.[21] Children younger than 4 years and children with chewing and swallowing disorders are at greater risk of food-related choking. Before the molars erupt, children are able to bite off a piece of food with their incisors but are unable to grind it adequately in preparation for swallowing. Children 3 to 4 years old have molars but are still learning to chew effectively.[2,3] Children at this age also may be easily distracted when they need to pay full attention to the task of eating. Children with swallowing disorders are at increased risk of choking. Neuromuscular disorders, developmental delay, traumatic brain injury, and other primary and secondary medical conditions may adversely affect the complex neuromuscular coordination involved in the swallowing process.[22] Therefore, caregivers should pay special attention to choking prevention among children with such neurologic impairments regardless of the age of the child.

Behavioral factors may also affect a child's risk for choking. High activity levels while eating, such as walking or running, talking, laughing, and eating quickly, may increase a child's risk of choking.[12] Child games that involve throwing food in the air and catching it in the mouth or stuffing large numbers of marshmallows or other food in the mouth also may increase the risk of choking.

Prevention of Food-Related Choking

Increased federal action to prevent choking on food by young children should include surveillance, cautionary food labeling, recalls when necessary, and public education. These actions will encourage food manufacturers to give greater attention to child safety and modify their products to prevent choking-related injury. Current systems for conducting injury surveillance (such as the NEISS-AIP) and strategies for prevention of choking associated with toys have direct application to the problem of food-related choking in the same high-risk group of young children.

Need for Increased Federal Regulation of Choking Hazards

Although the CPSC has well-established surveillance systems and an array of

legislation and regulations to protect children against choking and injury on toys and other consumer products, there are currently no counterpart surveillance systems, laws, regulations, or dedicated resources to protect children against choking on food, yet food is more likely to go into a child's mouth than a toy. A mandatory system is needed to label foods with appropriate warnings according to their choking risk, to conduct detailed surveillance and investigate food-related choking incidents, and to warn the public about emerging food-related choking hazards. As has been proposed through federal legislation, the US Food and Drug Administration (FDA) should be responsible for these measures and should work closely with the CPSC to integrate food-related hazards into product recalls and public notices. This collaborative effort would build on the support currently being provided by the CPSC to the FDA to identify food-related choking hazards. The NEISS-AIP currently collects information on food-related choking requiring an emergency department visit; however, more detail about the types of food and the choking events needs to be incorporated into the surveillance system. Enabling federal legislation with appropriate additional funding for implementing these changes should be enacted as needed.

Although some food manufacturers voluntarily label foods with choking warnings, all companies should provide appropriate warning labels, either voluntarily or through mandatory measures. Other countries are ahead of the United States in this regard. For example, Sweden has had age labeling on foods for infants and young children since 1979 and warning labels on prepackaged shelled peanuts since 1981 to prevent choking among young children.[12,23,24] The FDA should collaborate with the US Department of Agriculture (USDA), which has jurisdiction over the safety of meat products such as hot dogs. There is a precedent for such collaboration; the FDA and USDA worked together on a National Task Force on Foods and Choking in Children convened by the AAP in 1983.

An example of the involvement of the FDA in ensuring children's safety from food-related choking is its response to the hazard of gel candy. During a relatively short period, there were at least 6 choking deaths and a series of aspirations and near-deaths among children associated with gel candies containing the ingredient konjac.[25] The dimensions (which approximated the diameter of a child's upper airway), rounded shape, consistency, and slipperiness of the product contributed to a serious choking risk. Indeed, these characteristics are very similar to those of the rounded end of a hot dog, a known high-risk food for young children. These candies were packaged in rounded cups as individual mouth-size servings designed to be sucked out of the cups by the consumer. Unlike most gel products, these candies did not dissolve when in the mouth. The consumption method also contributed to the choking risk, because the candy was intended to be sucked out of its packaging.

In 2002, the FDA seized the candies at 1 manufacturer's facility in California and issued general warnings against consuming products containing konjac. The FDA also issued an import alert to prevent this product from entering the country and declared the candy as "unfit for food" under the Federal Food Drug and Cosmetic Act.[26] The action of the FDA likely prevented additional choking episodes; however, other children might have been saved had a coordinated surveillance system and mechanism for determining choking hazards associated with food already been in place. In addition, the similar characteristics of the gel candy and a hot dog (and also small balls and other high-risk toys) should have alerted public health officials to the inherent choking risk for children posed by this gel candy product.

Legislation to Prevent Food-Related Choking

Legislation focused on reducing the risk of choking on food by children was introduced, but never enacted, in each session of Congress from 2002 through 2006. The Food Choking Prevention Act went through 3 iterations and proposed various measures on food-choking prevention and education.[27–29] In different drafts of the bill, the proposals ranged from simple educational efforts and research to the establishment of an FDA Office of Choking Hazard Evaluation. State legislation addressing food-choking hazards to children has been enacted, including a law passed in 2007 in New York[30] that gave authority to the New York State Department of Health to establish age-differentiated criteria for defining foods that pose a significant and unacceptable choking hazard, produce and distribute educational materials, conduct a public education program, and establish a statewide database of food-choking incidents.

CONCLUSIONS

Choking is an important public health problem for young children. Choking hazards are primarily associated with food, coins, and toys. A comprehensive choking-prevention effort will rely on education of parents, teachers, child care workers, and other child caregivers to supervise and create safer environments for children; enactment and enforcement of safety legislation that will lead to surveillance and reduction of the availability of hazardous products on the market; and product-design changes that will reduce the inherent choking risk of consumer products, especially food and toys.

RECOMMENDATIONS

1. The FDA should establish a systematic, institutionalized process for examining and addressing the hazards of food-related choking, which should include the establishment of the necessary surveillance, hazard-evaluation, enforcement, and public-education activities to prevent food-related choking among children. Specifically, the authority and activities of the FDA should be enhanced to permit the agency to:
   - Evaluate foods and require warning labels on foods that pose a high choking risk to children. The FDA should collaborate with the USDA to ensure that meat products also undergo similar evaluation and labeling.
   - Recall food products that pose a significant and unacceptable choking hazard to the public. The FDA should collaborate with the USDA to ensure that a similar recall process exists for meat products.
   - Establish a national food-related choking-incident surveillance and reporting system to warn the public of existing and emerging hazards. The NEISS-AIP of the CPSC should be modified to provide the surveillance function of this system.
   - Conduct, in consultation with the USDA, CPSC, AAP, and other organizations, a widely publicized food-related choking-prevention campaign that is focused on children.
   - Focus resources and prevention program efforts on high-risk groups, circumstances, and products that are identified through the surveillance system.
   - Maintain highly cooperative arrangements with the CPSC and USDA, and information should be openly shared among these agencies.
2. Pediatricians, dentists, and other infant and child health care professionals should intensify choking-prevention counseling as an integral part of anticipatory guidance activities.
3. Pediatricians should continue to provide parents and caregivers guidance on appropriate food and toy selection with respect to choking prevention as outlined by the AAP.[31–35]
4. Food manufacturers should design new foods and redesign existing foods, including meat products, to avoid shapes, sizes, textures, and other characteristics that increase choking risk to children, to the extent possible.[12]
5. The CPSC should increase efforts to ensure that toys that are sold in retail store bins, in vending machines, or online have appropriate choking-hazard warnings; work with manufacturers to improve the effectiveness of recalls of products that pose a choking risk to children; and increase efforts to prevent the resale of these recalled products on online auction sites. Current gaps in choking-prevention standards for children's toys should be reevaluated and addressed via revisions to the standards established under the CSPA or the Consumer Product Safety Improvement Act or via regulation by the CPSC.
6. Because it is impossible to prevent all choking episodes among children, cardiopulmonary resuscitation and choking first aid for children should be taught to parents, teachers, child care providers, and others who care for children, particularly children at high risk of choking.

Policy Statement—Prevention of Drowning

abstract

Drowning is a leading cause of injury-related death in children. In 2006, fatal drowning claimed the lives of approximately 1100 US children younger than 20 years. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in the prevention of drowning. *Pediatrics* 2010;126:178–185

INTRODUCTION

Background

From 2000 to 2006, drowning was the second leading cause of unintentional injury death among US children between 1 and 19 years of age.[1] In 2006, drowning claimed the lives of approximately 1100 US children. Fortunately, childhood unintentional drowning fatality rates have decreased steadily from 2.68 per 100 000 in 1985 to 1.32 per 100 000 in 2006. Rates of drowning death vary with age, gender, and race. Age groups at greatest risk are toddlers and male adolescents. After 1 year of age, male children are at greater risk than are female children. Black and American Indian/Alaska Native children have higher drowning fatality rates than do white and Asian American children. From 2000 to 2006, the highest death rates were seen in white boys 0 to 4 years of age (3.53 per 100 000) and black male adolescents 15 to 19 years of age (4.46 per 100 000).[1] In 2008, approximately 3800 children younger than 20 years visited a hospital emergency department for a nonfatal drowning event, and more than 60% of those children were hospitalized.[1] Most victims of nonfatal drowning do well, but severe long-term neurologic deficits are seen with extended submersion times, prolonged resuscitation efforts, and lack of early bystander-initiated cardiopulmonary resuscitation (CPR).[2–4]

The American Academy of Pediatrics (AAP) has decided to revise this policy statement because of new information and research regarding (1) the World Health Organization's classification of drowning, (2) drain-entrapment and hair-entanglement injuries, (3) dangers of inflatable and portable pools, and (4) the possible benefit of swimming lessons for young children.

Classification of Drowning

The World Congress on Drowning and the World Health Organization have revised the definition of drowning to be "the process of experiencing respiratory impairment from submersion/immersion in liquid." Drowning outcomes are now to be classified as "death," "no morbidity," or "morbidity" (further categorized as "moderately disabled," "severely disabled," "vegetative state/coma," and "brain death"). The new definition and classification are more consistent with other medical

conditions and injuries and should help in drowning surveillance and collection of more reliable and comprehensive epidemiologic information.[5]

Drain Entrapment and Hair Entanglement

From 1990 to 2004, 74 cases (13 deaths) of body entrapment in a pool or spa drain were reported to the Consumer Product Safety Commission (CPSC).[6] In a separate report, 24 additional cases (2 deaths) were reported in the 3 years from 2005 to 2007.[7] The situation often involves a child playing with an open drain, inserting a hand or foot into the pipe, and then becoming trapped by increasing suction that causes tissue swelling. In the same time period (1990–2004), 43 incidents (12 deaths) of hair entanglement were reported.[6] These incidents typically involve females who are underwater with their long hair near a suction outlet. The water flow into the drain sweeps the hair into and around the drain cover, where it becomes tangled in the holes and protrusions of the cover. Entrapment and entanglement can be prevented by the use of special drain covers, safety vacuum-release systems (SVRSs), filter pumps with multiple drains, and a variety of other pressure-venting filter-construction techniques.[6] In 2007, Congress passed the Virginia Graeme Baker Pool and Spa Safety Act (effective December 2008), which requires special drain covers, unblockable drains, and SVRSs for all public pools and spas in the United States.[8]

Inflatable, Portable Pools

Recently there was an increase in sales of large, inexpensive, inflatable or portable above-ground pools, which come in various sizes, shapes, and water depths. The pools are 18 to 48 in deep and can hold less than 200 to more than 5000 gallons of water. Some models even require filtration equipment. Prices range from $50 to $750.[9] From 2004 to 2006, the CPSC reported 47 deaths of children related to inflatable pools.[10] Unfortunately, many parents do not consider fencing for an inflatable or portable pool, and such pools often fall outside of local building codes that require pool barriers. Because they contain such large amounts of water, these pools are often left filled for weeks at a time, which presents a continuous danger. The soft sides of some models allow children to lean over them and easily fall into the pool headfirst.

Swimming Lessons for Young Children

The position of the AAP has been that children are not developmentally ready for swimming lessons until after their fourth birthday.[11] This position was based on (1) lack of data needed to determine if infant and toddler aquatic programs increase or decrease the likelihood of drowning, (2) concerns that such programs would cause parents to develop a false sense of security and lead them to provide inadequate supervision around water, and (3) evidence that starting swimming lessons at a very young age does not result in earlier development of proficient swimming skills.[12,13] In addition, there was concern that swimming programs might reduce a child's fear of water and unwittingly encourage the child to enter the water without supervision.

A recently published case-control study report from the Eunice Kennedy Shriver National Institute of Child Health and Human Development concluded that swimming lessons do not increase the risk of drowning in 1- to 4-year-olds and may actually provide a reduction in drowning risk in this age group. Drowning victims were less likely than matched controls (3% vs 26%, respectively) to have had formal swimming instruction.[14] A Chinese study of swim instruction revealed similar drowning-protection statistics.[15] In light of this new research, it is reasonable for the AAP to relax its policy regarding the age at which children should start learning water-survival skills (see recommendation 6). The evidence no longer supports an advisory against early aquatic experience and swimming lessons for children of any specific age. However, the current evidence is insufficient to support a recommendation that all 1- to 4-year-old children receive swimming lessons. It must be stressed that even advanced swimming skills will not always prevent drowning and that swimming lessons must be considered only within the context of multilayered protection with effective pool barriers and constant, capable supervision. In addition, the possible benefit of early swimming instruction must be weighed against the potential risks (eg, hypothermia, hyponatremia, infectious illness, and lung damage from pool chemicals).[16–19]

In recent years, water-survival skills programs designed for infants younger than 12 months have become popular both in the United States and internationally. Many movies of tiny infants who have been taught to swim underwater, float fully clothed on their backs, and even cry out for help have emerged on the Internet. Although there are anecdotal reports of infants who have "saved themselves," no scientific study has clearly demonstrated the safety and efficacy of training programs for such young infants.

Additional details regarding childhood drowning are available in the accompanying technical report, available online.[20]

PREVENTION OF DROWNING

Supervision of young children around any water is an essential preventive

strategy, but inevitable lapses make supervision alone insufficient.[21] Installation of 4-sided fencing that completely isolates the pool from the house and yard is effective in preventing more than 50% of swimming-pool drownings of young children.[21,22] Some new, but limited, data suggest that swimming and water-survival skills training may lower drowning rates in 1- to 4-year-old children.[23] Lifeguards, personal flotation devices (PFDs), and CPR training seem to be effective[2,24–26]; however, data regarding the value of other potential preventive strategies, such as pool covers and pool alarms, are lacking. Interventions to prevent drowning are discussed in detail in the accompanying technical report, available online.[20]

As part of routine anticipatory guidance, pediatricians may use direct counseling, handouts, Web sites, and other educational methods to alert parents to the dangers that water presents at different ages and in different situations (see Appendix 1 for a list of resources). In addition to providing generic water-safety advice, pediatricians can provide specific targeted messages to children identified as having special risks of drowning.

1. Parents and caregivers need to be advised that they should never—even for a moment—leave small children alone or in the care of another young child while in bathtubs, pools, spas, or wading pools or near irrigation ditches or other open standing water. Because infant bath seats can tip over and children can slip out of them, bath seats cannot be a substitute for adult supervision.[27] Water should be emptied from containers, such as large pails and 5-gallon buckets, immediately after use. To prevent drowning in toilets, young children should not be left alone in the bathroom, and unsupervised access to the bathroom should be prevented.
2. Whenever infants and toddlers (or weak swimmers) are in or around water, be it in a pool or an open body of water, a supervising adult with swimming skills should be in the water, within an arm's length, providing "touch supervision." With older children and better swimmers, the eyes and attention of the supervising adult should be constantly focused on the child, and the adult should not be engaged in other distracting activities that can compromise this attention, such as talking on the telephone, socializing, tending chores, or drinking alcohol. Supervision needs to be close, constant, and capable. In case of an emergency, the supervising adult must know how to swim, perform a rescue, initiate CPR, and call for help. If children are in out-of-home child care, parents should inquire about exposure to water and water-related activities at the provider's site or during off-site visits. Recommendations for child-to-staff ratios while children are wading or swimming are available and vary according to the age of the child and according to jurisdiction. Some states include staffing ratios for water activities in their child care and school licensing requirements.[28] Parents should be aware of the ratios at their child's site of care. National recommendations are available from the AAP.[28]
3. Pediatricians are encouraged to identify families who have residential (home and apartment complex) swimming pools and include periodic drowning-prevention counseling during routine health visits (see Appendix 2 for an office-based quiz that can be used to initiate a discussion about pool safety). It is important to ask specifically about portable and inflatable above-ground pools, because so many of these types of pools do not have adequate protective fences and barriers.[9] Families (and extended families and others visited by children) should be advised to install an isolation fence (also referred to as a 4-sided fence) that prevents direct access to the pool from the house. The fence should be at least 4 ft high (or higher if required by local ordinance). The fence should also be climb resistant. For example, chain-link fences can be scaled easily by young children, whereas ornamental iron-bar fences are more difficult to climb.[29] The distance between the bottom of the fence and the ground should be less than 4 in (some building codes suggest a 2-in limit). To prevent small children from squeezing through, the distance between vertical members of the fence should be less than 4 in. The gate is the single most important component of the fence. It should be self-latching and self-closing, with the latch placed at least 54 in above the bottom of the gate. The gate should open away from the pool, and should be checked often to ensure that it is in good working order. Detailed guidelines for safety barriers for home pools are available online from the CPSC.[30]
4. Although data are lacking, families can also be advised to consider supplemental pool alarms and rigid pool covers as additional layers of protection; however, neither alarms nor pool covers are a substitute for adequate fencing. It is important to note that some types of pool covers, such as thin plastic solar covers, should not be

used as a means of protection, because children may try to walk on the cover, fall into the pool, and be hidden from view.

5. Body entrapment and hair entanglement in pool and spa drains were recently recognized as potential dangers to children.[31] Entrapment and entanglement injuries can be prevented by the use of special drain covers, SVRSs, filter pumps with multiple drains, and a variety of other pressure-venting filter-construction techniques.[6] Managers of public pools and owners of private pools and spas must be made aware of entrapment/entanglement risks and encouraged to install the drain covers and filter-pump equipment needed to prevent these injuries.
6. Children need to learn to swim. The AAP continues to support swimming lessons for most children 4 years old and older. Because children develop at different rates, not all children will be ready to learn to swim at exactly the same age. For example, children with motor or cognitive disabilities may not be ready for swimming lessons until a later age. The evidence no longer supports an advisory against early aquatic experience and swimming lessons for children of any specific age. However, the current evidence is insufficient to support a recommendation that all 1- to 4-year-old children receive swimming lessons. A parent's decision about starting swimming lessons or water-survival skills training at an early age must be individualized on the basis of the child's frequency of exposure to water, emotional maturity, physical limitations, and health concerns related to swimming pools (ie, hypothermia, hyponatremia, infectious illness, and lung damage from pool chemicals). Parents should be reminded that swimming lessons will not provide "drown-proofing" for children of any age. It is important that swim instructors stress this message as well as the need for constant supervision around water. Swimming skills are just one potential prevention strategy that must be considered in the context of a multifaceted approach that includes effective barriers, appropriate adult supervision, and training in CPR. Knowing how to swim well in a swimming pool does not necessarily make a child safe in natural water environments. Children need to be taught never to swim alone and not to swim without adult supervision.
7. Parents, caregivers, and pool owners should learn CPR and keep a telephone and equipment approved by the US Coast Guard (eg, life buoys, life jackets, and a reach tool such as a shepherd's crook) at poolside. Older children and adolescents should learn CPR, and pediatricians should support the inclusion of CPR training in high school health classes.
8. Parents should be cautioned not to use air-filled swimming aids (such as inflatable arm bands) in place of PFDs (life jackets). These aids can deflate and are not designed to keep swimmers safe.
9. All children should be required to wear an approved PFD whenever they are riding in watercraft. Small children and nonswimmers should use PFDs when they are at water's edge, such as along a river bank or on a dock or pier. Pediatricians should encourage all family members to wear PFDs to model safe behavior. Information about PFDs is available from the US Coast Guard Web site.[32]
10. Parents and children need to understand that jumping or diving into water can result in injury. Parents should know the depth of the water and the location of underwater hazards before permitting children to jump or dive. The first entry into any body of water should be feetfirst.
11. When selecting an open body of water in which their children will swim, parents should select sites with lifeguards. Even for the strongest of swimmers, it is important to consider weather, tides, waves, and water currents in selecting a safe location for recreational swimming. Swimmers should know what to do in case of rip currents (swim parallel to the shore until out of the current, then swim back toward the shore).
12. Parents and children need to recognize drowning risks in cold seasons. Children should refrain from walking, skating, or riding on weak or thawing ice on any body of water.
13. When swimming or taking a bath, children of any age with seizure disorders should be supervised closely by an adult at all times.[33] Showers are preferable to baths for situations in which the child cannot be supervised directly because of privacy issues.
14. Counseling parents and adolescents about water safety provides an opportunity to stress the problems related to illegal alcohol and drug use during any activity. Specifically, the discussion should include a warning about the increased drowning rates that result from impairment of a swimmer or watercraft occupant when alcohol or illicit drugs are used.

Because male adolescents are at much higher risk of water-based injuries than are female adolescents, they warrant extra counseling.

COMMUNITY INTERVENTIONS

1. Pediatricians are encouraged to work in their communities to pass legislation to mandate 4-sided isolation pool fencing for all new and existing residential pools. Pediatricians should encourage local governmental inspection of pool fencing with strict enforcement programs, because they have been shown to be effective in reducing drowning.[34]
2. Pediatricians should support efforts to ensure that community pools and other pools accessible to the public (such as pools at apartments, hotels, and motels) have certified lifeguards with current CPR certification. (Currently, most states do not require hotel pools to have lifeguards.)
3. Pediatricians are encouraged to support efforts in their states and communities to pass legislation and adopt regulations to establish basic safety requirements for natural swimming areas and public and private recreational facilities (eg, mandating the presence of certified lifeguards in designated swimming areas).
4. Pediatricians should support state and community efforts to enforce laws that prohibit alcohol and other drug consumption by boat occupants, not just operators.
5. Pediatricians should work with state and local emergency medical services personnel to encourage systematic reporting of information on the circumstances of immersion events. Consistent review of these data is critical for the development of drowning-prevention strategies appropriate for the geographic area.
6. Pediatricians should work in their communities to ensure adequate emergency medical services for childhood drowning victims. The Emergency Medical Services for Children (EMSC) program should be reauthorized and funded at levels recommended by the Institutes of Medicine.
7. Supportive counseling services should be available to relatives and friends of drowning victims.

APPENDIX 1: RESOURCES FOR PEDIATRICIANS

1. American Academy of Pediatrics (www.aap.org)—Contains educational materials for parents from The Injury Prevention Program (TIPP) about home water hazards for young children, life jackets, pool safety, and water safety for school-aged children; also has links to water-safety information from the CPSC, Centers for Disease Control and Prevention (CDC), and SafeKids.
2. Safe Kids USA (www.usa.safekids.org/water)—Contains information about pools and hot tubs, drain covers and SVRSs to prevent entrapment, and safety checklists (English and Spanish) about pools, spas, open-water swimming and boating, and home water safety; also has links to national research study about pool and spa safety; has some nice materials for children including boating safety coloring pages; has a color "Water Watcher" badge available for download.
3. Centers for Disease Control and Prevention (CDC) (www.cdc.gov)—Contains a water-related injuries fact sheet, CDC research and information on water safety and water-related illnesses and injuries, and a link to the Web-based Injury Statistics Query and Report System (WISQARS); the CDC Childhood Injury Report contains state-specific information about drowning and other injuries (available at: www.cdc.gov/safechild/images/CDC-childhoodinjury.pdf).
4. Consumer Product Safety Commission (CPSC) (www.cpsc.gov)—Contains information about the Virginia Graeme Baker Pool and Spa Safety Act and a list of manufacturers of approved drain covers and SVRSs; the publications section contains safety-barrier guidelines for home pools and a family education brochure about preventing childhood drowning.
5. US Coast Guard (www.uscgboating.org)—Contains detailed information and tip sheets about inflatable and foam-filled PFDs, vessel safety checks, approved on-line boating safety courses, and beach safety; also has links to sites with informa-

tion about safety and boating regulations, as well as statistics, research, and surveys about boating and boating crashes and injury.

APPENDIX 2: DROWNING-PREVENTION QUESTIONNAIRE (FOR OFFICE WATER-SAFETY COUNSELING)

Quiz

1. Which of the pictures in Figure 1 looks the most like your backyard pool area?
2. In Figure 2, can you find 3 things that are dangerous?
3. How would you supervise a 3-year-old child around water?
   A. Always be close enough to *see* the child.
   B. Always be close enough to *hear* the child.
   C. Always be close enough to *touch* the child.
4. At what age can you leave a child alone in the bathtub?
   A. As young as 2 years old, if you have a special bath seat or ring.
   B. 3 years old.
   C. Approximately 6 years old.
5. How many children and teenagers died from drowning in the United States in the past 3 years?
   A. 500
   B. 1000
   C. More than 3000

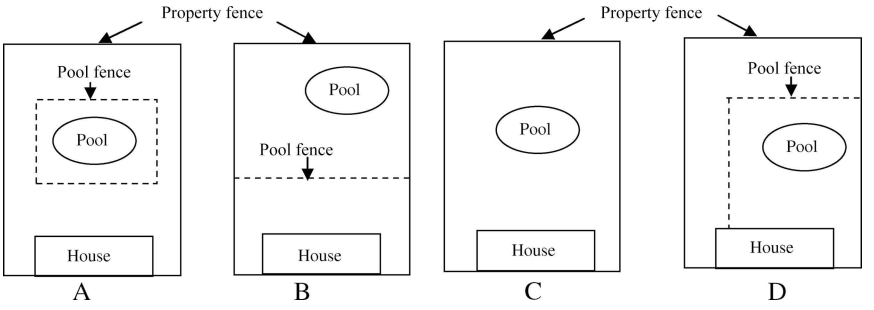

FIGURE 1

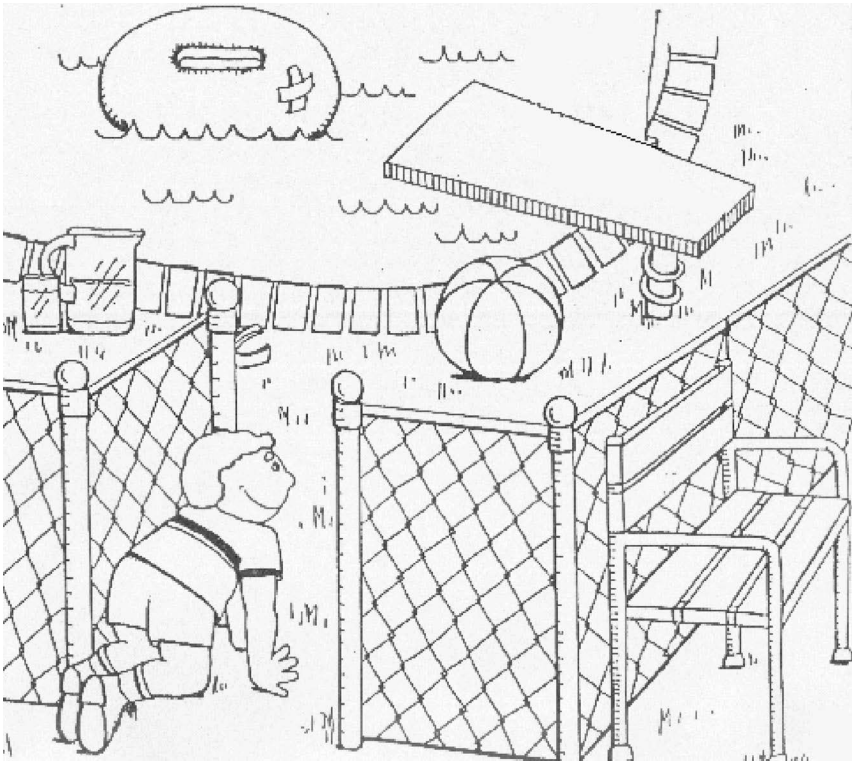

FIGURE 2

Quiz Answers

Question 1

A. *TERRIFIC!* A fence that surrounds the pool on all 4 sides is the safest. But remember, even with a good fence, children can drown if not supervised very carefully around water. The fence, gate, and latch have to be well maintained to make sure children cannot enter the pool area.

B. *GOOD!* This arrangement is good, because it will keep kids from getting out of the house and into the pool. It is important that kids playing in the pool area be well supervised—that means you can't be reading, talking on the phone, or involved in distracting conversations.

C. *DANGER!* This arrangement is not safe. Children playing in the back yard can easily get to the pool. A child could also sneak out the back door, back windows, or even through a pet door!

D. *DANGER!* Although there is a fence around the pool area, a child could enter the pool area from a door or window at the back or side of the house!

Question 2

A. The gate is open. You should never prop the gate open! Make sure that the automatic self-closing and self-locking mechanisms are working at all times.

B. The ball and pool toys will attract the child into the pool area.

C. Children can climb up on furniture to get over the fence and into the pool area. It would be better to keep the pool furniture inside the fence.

D. No glass or breakables should be in the pool area.

E. The fence design (chain-link) would allow a child to climb over it.

Question 3

C is the correct answer. You should always be close enough to *touch* your child when near the swimming pool. Pools can be as dangerous as a street, and you'd always hold your child's hand when crossing the street. It is hard, almost impossible, to watch your child all the time. It is easy to get distracted and look away. Remember that it only takes a few seconds for a child to fall into the pool. Drowning is a quick and quiet death, most kids don't thrash around and yell when they fall into the pool; they just sink to the bottom without splashing or crying out!

Question 4

C is the correct answer. Every year in the United States, several children drown in the bathtub. Bathtub seats and rings can topple over and are not safe. Some infants have died when an older brother or sister was supposed to be watching them in the tub. Only an adult or teenager should supervise bath time. And, be careful with toilets and buckets—kids have drowned in these too! We suggest that all kids under the age of 6 be watched carefully while in the bathtub.

Question 5

C is the correct answer. There have been more than 3000 children and teenagers who have died from drowning in the United States in the past 3 years. Several hundred survivors are victims of severe, permanent brain damage. These kids are from all cultural and economic backgrounds.

abstract

Drowning is a leading cause of injury-related death in children. In 2006, approximately 1100 US children younger than 20 years died from drowning. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in the prevention of drowning. *Pediatrics* 2010;126:e253–e262

INTRODUCTION

Background

From 2000 to 2006, drowning was the second leading cause of unintentional injury death among US children between 1 and 19 years of age.[1] In 2006, unintentional drowning claimed the lives of 1077 US children and adolescents, a fatality rate of 1.32 per 100 000 population. Fortunately, drowning deaths of children and adolescents have decreased dramatically since 1985 (2.68 per 100 000) and 1995 (1.96 per 100 000). In 2008, approximately 3800 children younger than 20 years visited a hospital emergency department for a nonfatal drowning event; more than 60% of those children were hospitalized.[1] Most victims of nonfatal drowning do well, but severe long-term neurologic deficits are seen with extended submersion times, prolonged resuscitation efforts, and lack of early bystander-initiated cardiopulmonary resuscitation (CPR).[2–4] Overall, 5% to 10% of drowning incidents result in severe neurologic damage,[2,4–6] but such poor outcomes are even more common when the drowning occurs in open-water settings.[3]

In 2002, the World Congress on Drowning and the World Health Organization revised the definition of drowning to be "the process of experiencing respiratory impairment from submersion/immersion in liquid."[7,8] Drowning outcomes are now to be classified as "death," "no morbidity," or "morbidity" (further categorized as "moderately disabled," "severely disabled," "vegetative state/coma," and "brain death"). The terms "wet," "dry," "active," "passive," "silent," and "secondary drowning," as well as the term "near-drowning," are no longer to be used. The new definition and classifications are more consistent with other medical conditions and injuries and should help both in drowning surveillance and collection of more reliable and comprehensive epidemiologic information.[7,8]

Sociodemographic Factors

Rates of drowning vary with age, gender, and race. The highest rate of drowning is in the 0- to 4-year age group (2.5 per 100 000), and children 12 to 36 months of age are at the highest risk (almost 4 deaths per 100 000). There is a second peak incidence in adolescence, attributable entirely to a high number of male drowning deaths.[1] After 1 year of age,

males are at greater risk of drowning than are females at all ages. Up to 12 years of age, drowning death is roughly twice as common in boys as in girls, but in adolescents, the rate is approximately 10 times higher for boys (see Table 1).[1] The higher drowning rate for males has been explained by greater exposure to aquatic environments, overestimation of swimming ability, higher risk-taking, and greater alcohol use.[9]

In the period from 2000 to 2006, 3 times more white children and adolescents died from drowning than did black children of the same age; however, the drowning-death rate was actually higher in black children than in white children (1.95 vs 1.29 per 100 000, respectively). Drowning-death rates for Native American children (1.79 per 100 000) were almost as high as those for black children, whereas rates for Asian children and adolescents (1.23 per 100 000) were similar to those for white children. Overall, the highest death rates were seen in black boys 15 to 19 years of age (4.46 per 100 000) and white boys 0 to 4 years of age (3.53 per 100 000).[1] An analysis that focused specifically on swimming-pool drowning deaths in the 5- to 24-year age group revealed that black males had higher drowning rates than either white or Hispanic males even when adjustments were made for low income. Although the majority of white children drowned in residential pools, black children were more likely to die in a public pool, often at a motel or hotel.[10] The reasons that black children and teenagers are more likely to drown are not clear, but poor parental swimming skills, lack of early training, poor swimming ability, and lack of lifeguards at motel/hotel pools may be important factors.[10,11]

TABLE 1 Unintentional Drowning Deaths: United States, 2006

Age Group, y	No. of Deaths (Rate per 100 000)		
	Male	Female	Total
<1	27 (1.26)	24 (1.18)	51 (2.64)
1–2	183 (4.36)	127 (3.17)	310 (3.78)
3–4	106 (2.57)	42 (1.07)	148 (1.83)
0–4	316 (3.02)	193 (1.93)	509 (2.49)
5–9	104 (1.03)	38 (0.40)	142 (0.72)
10–14	89 (0.85)	25 (0.25)	114 (0.55)
15–19	282 (2.59)	30 (0.29)	312 (1.47)
0–19	791 (1.89)	286 (0.72)	1077 (1.32)

The role of socioeconomic status and income on drowning rates, independent of race, is not well known. Worldwide, drowning rates are much higher in low-income, underdeveloped countries.[12] In contrast, a study of pool drownings conducted in California revealed that among children younger than 10 years, drowning rates were actually associated with higher family income and parental education. This association was attributed to increased exposure to residential swimming pools in more affluent communities.[13]

Temporal and Geographic Variation

Among all causes of unintentional injury death in the United States, drowning shows the greatest seasonal variation.[14] Among drowning victims younger than 15 years, two-thirds of deaths occur from May through August. Drowning also occurs disproportionately on Saturdays and Sundays. In a 17-year study (1990–2006) from Maricopa County, Arizona, 43% of the 865 life-threatening pool-related incidents among children 0 to 4 years of age occurred on the weekend. The peak time of day was 5:00 to 6:00 PM, and 75% of all incidents occurred between 12:00 and 8:00 PM.[15]

For the period 2000–2006, the 3 states with the highest number of drowning deaths in the 0- to 19-year age group were California (898), Texas (800), and Florida (798). For the same age group, the rates of drowning deaths per 100 000 population were highest in Alaska (3.61), Mississippi (2.77), and Florida (2.69). The lowest drowning-death rates were seen in some of the New England and Mid-Atlantic states.[1]

Location

In a large national study of 1420 drowning deaths in individuals younger than 20 years, 47% occurred in fresh bodies of water (rivers, creeks, lakes, ponds, canals, quarries), 32% occurred in artificial pools, 9% occurred in the home (bathtubs, buckets), and 4% occurred in salt water.[16] Age is an important determinant of drowning location.

Most (78%) of the approximately 60 infant drowning deaths that occur each year are in bathtubs and large buckets.[1,16] Almost all parents, even those who admitted to other risky behaviors, believe that a child should be at least 6 years old before being allowed to bathe alone.[17] Unfortunately, many caregivers confess that they do leave young children unsupervised in the bath for some period of time.[18,19] The association of unsupervised bathtub drowning deaths with the use of bathtub seats and rings was recognized more than a decade ago.[20] Three hazard scenarios have been noted: (1) seat tipping over from suction cup failure; (2) child becoming entrapped in leg openings that are too big; and (3) child climbing out of the seat.[21] In response to reports of at least 27 deaths and 29 nonfatal incidents with bath seats from 2003 to 2005, the Consumer Product Safety Commission (CPSC) has released warnings about these products but has not banned them from the market.[22]

In a national study, more than half (51%) of the drowning deaths of children 0 to 4 years of age occurred in swimming pools, but a sizable proportion (25%) occurred in ponds, rivers, and lakes.[16] Older children in the 5- to 14-year age range are slightly more

apt to drown in a natural body of water than in a swimming pool, but a high proportion (69%) of adolescents 15 to 19 years of age drowned in fresh bodies of water.[16] In a study from Washington state, open-water drowning occurred in 35% of those in the 0- to 4-year age group, 69% of those in the 5- to 14-year age group, and 95% of adolescents.[23] Regarding nonfatal drowning in children and adults, 66% occurred in pools, 22% occurred in natural water, and 12% were unspecified.[24]

Above-Ground Inflatable and Portable Pools

Recently there was an increase in sales of large, inexpensive, inflatable or portable above-ground pools that come in various sizes, shapes, and water depths. The pools are 18 to 48 in deep and can hold less than 200 to more than 5000 gallons of water. Some models even require filtration equipment. Prices range from $50 to $750.[25] From 2004 to 2006, the CPSC reported 47 deaths of children related to inflatable pools.[26] Unfortunately, many parents do not consider fencing for an inflatable or portable pool, and such pools often fall outside of local building codes that require pool barriers. Because they contain such large amounts of water, these pools are often left filled for weeks at a time, which presents a continuous danger. The soft sides of some models allow children to lean over and easily fall into the pool headfirst. In a study of above-ground pools, children between 42 and 54 months of age were shown to be able to climb into a pool with a 48-in wall, even if the ladder was removed.[27] The American Society for Testing and Materials (ASTM) has published a standard (F 2666-07) for above-ground pools for residential use that addresses structural integrity, sanitation, electrical safety, and safety-message labeling.[28]

Drain Entrapment

From 1990 to 2004, 74 cases (13 deaths) of body entrapment in a pool or spa drain were reported to the CPSC.[29] In a separate report, 24 additional cases (2 deaths) were reported in just the 3 years from 2005 to 2007.[30] The situation often involves a child playing with an open drain, inserting a hand or foot into the pipe, and then becoming trapped by increasing suction and resulting tissue swelling. The deaths were from drowning. The majority (77%) of the victims were younger than 15 years. In the same time period (1990–2004), 43 incidents (12 deaths) of hair entanglement were reported.[29] These incidents typically involve females with long hair who are underwater near a suction outlet. The water flow into the drain sweeps the hair into and around the drain cover, where it becomes tangled in the holes and protrusions of the cover. Almost all (92%) of these cases were also in children younger than 15 years. In addition, there have been 2 incidents of evisceration and disembowelment that have occurred when a young child sat on and was sucked into a drain with a missing cover.[29]

Entrapment and entanglement can be prevented by the use of special drain covers, safety vacuum-release systems (SVRSs), filter pumps with multiple drains, and a variety of other pressure-venting filter-construction techniques.[29] Unfortunately, many parents and pool and spa owners are not aware of entrapment/entanglement risk, and only 15% have installed antivortex drain covers, only 14% have multiple drain systems, and only 12% have an SVRS on their pool or spa.[31] In 2007, Congress passed the Virginia Graeme Baker Pool and Spa Safety Act, which requires drain covers, unblockable drains, and SVRSs for all public pools and spas in the United States.[32] Although the sct does not apply to private pools, all pool owners should implement the recommendations reflected in the act.

Lapses in Adult Supervision

Drowning is not generally associated with a complete lack of adult supervision but, rather, with a momentary lapse in supervision. In fact, in a study of 496 drowning deaths in children younger than 14 years that were reviewed by state child-death review teams, only 10% were completely unsupervised at the time of the drowning. Most of the children (68%) were expected to be in or near the water just before the drowning incident.[33] In a questionnaire portion of the same study, parents of children younger than 14 years admitted that they talk to others (38%), read (18%), eat (17%), and talk on the telephone (11%) while supervising their child near water. Attempts to attribute cause to 538 swimming-pool submersion incidents of children younger than 5 years in Maricopa County revealed seasonal differences (warm versus cold months) and differences related to outcome (fatal versus nonfatal). In winter months, both with fatal and nonfatal cases, lack of a barrier and broken fences and gates were responsible for most (76%) cases, and poor supervision was blamed in only 16% of the cases. During warm months, lapses in supervision were responsible for 62% of nonfatal cases; however, lack of a barrier and broken fences and gates were responsible for most (70%) of the deaths.[15] Fencing is clearly important all year round. Overall, nonfunctioning gates were the cause of 17% of all pool drowning incidents in this study.

Alcohol

A recent meta-analysis revealed that 30% to 70% of swimming and boating fatal drowning victims had a measurable blood alcohol concentration (BAC)

and that 10% to 30% of those deaths could be attributed specifically to alcohol use.[34] In boating, there is evidence that the relative risk of drowning death is directly related to BAC, with a 16-fold greater risk when the victim's BAC was more than 0.10 (100 mg/dL).[35] Alcohol intake may increase the risk of drowning not only by impairing judgment and performance but also through physiologic effects (ie, impaired orientation, hypothermia) that affect survival once submersion occurs.[35] Little information is available regarding the association of drug use and drowning. One 10-year retrospective study from Ohio revealed that only 3% of 141 accidental drowning deaths were associated with illicit drugs.[36]

Swimming Ability

Few studies have examined the relationship between swimming ability and the risk of drowning, and there is no clear evidence that drowning rates are higher in poor swimmers. Increased swimming proficiency might lead to an increase in drowning rates through an increased exposure to water and dangerous aquatic situations.[37,38] A CPSC study of 140 swimming-pool child-drowning deaths revealed that better swimming ability, as reported by the parents, was associated with lower drowning risk.[39] An 8- to 12-week training course for preschool-aged (24–42 months) children revealed that the subjects were able to develop the water-safety skills necessary to survive a fall into a home swimming pool.[40] With training, the young children could stand and recover when dropped into 2 ft of water, kick propulsively, and get to the side of the pool after jumping in or being released in the pool by an adult.

Two recent case-control studies revealed that swimming lessons may reduce drowning risk in small children. A study from rural China that examined drowning deaths in children 1 to 4 years of age revealed that drowning "case" children were less likely to have had swimming lessons than were controls (6.8% vs 12%, respectively).[41] Research on 61 drowning deaths in children 1 to 4 years of age (mean age: 2.62 years) from the Eunice Kennedy Shriver National Institute of Child Health and Human Development revealed that the drowning victims were reportedly less likely (3% vs 26%) to have participated in formal swimming lessons (odds ratio [OR]: 0.05 [95% confidence interval (CI): 0.01–0.34]; $P = .002$) and were less likely (5% vs 18%) to be able to float on their back for 10 seconds ($P = .01$). When adjusted for education, race, and risk-taking, formal swimming lessons remained a significant predictor of drowning risk (OR: 0.12 [95% CI: 0.01–0.97]). The authors indicated that "this can be interpreted as an 88% reduction in risk of drowning among those with swimming lessons, with 95% confidence that a protective effect between 3% and 99% includes the true value."[42] The study reports did not describe the details of the swim instruction or water-survival skills training.

Although swimming ability may or may not decrease drowning risk, it does not result in "drown-proofing." A study from the Canadian Red Cross revealed that 16% of those who fatally drowned while swimming had "strong" or "average" swimming skills.[43] In a study of children younger than 5 years from New Zealand, 6 of 36 (17%) of the drowning victims had received swimming instruction.[44]

In recent years, water-survival skills programs designed for infants younger than 12 months have become popular both in the United States and internationally. Many movies of tiny infants who have been taught to swim underwater, float fully clothed on their backs, and even cry out for help have emerged on the Internet. Although there are anecdotal reports of infants who have "saved themselves," no scientific study has clearly demonstrated the safety and efficacy of training programs for such young infants.

Underlying Medical Conditions

Seizure disorder is a known risk factor in drowning. Children with epilepsy are at greater risk of drowning in bathtubs as well as in swimming pools.[45] The relative risk of submersion events and drowning deaths in patients with epilepsy varies greatly from study to study and depends on such factors as age, severity of illness, degree of exposure to water, and level of supervision.[45–47] There is some evidence from studies with small numbers of patients that children with autism spectrum disorders are at higher risk of drowning than those in the general population.[48,49] The risk in children with autism seems to be higher with greater degrees of mental retardation.[48] For children without autism, no study has specifically studied developmental disabilities or attention-deficit/hyperactivity disorder as drowning risk factors. In individuals with long QT syndrome, exertion from swimming may trigger an arrhythmia.[50] Although such cases represent a small percentage of drownings, this syndrome should be considered as a possible cause for unexplained submersion injuries among proficient swimmers in low-risk settings.

Boating

In 2008, the US Coast Guard reported 71 boating deaths of individuals 19 years and younger, with 53 (75%) attributed to drowning. Eighty-five of the 669 injuries in this age group occurred while riding in an open motorboat or personal watercraft. Analysis of all fatal boating incidents has revealed that 79% of the operators had no boating

training, and 22% of the incidents involved alcohol.[51]

The vast majority of boating drowning deaths (90%) occur in individuals not wearing a personal flotation device (PFD).[51] For children younger than 14 years, it is reported that nearly 45% of those who died in a boating-related incident were not wearing a life jacket.[33] Federal law requires life-jacket use for children younger than 13 years on recreational boats in the United States. One observational study revealed that 90% of children younger than 5 years wore life jackets, but only 13% of those 14 years or older used a life jacket.[52]

Reasons commonly cited for not wearing a life jacket include beliefs that there is a low risk of drowning, that life jackets restrict movement, that life jackets are uncomfortable, that life jackets are unattractive, and that wearing a life jacket is a sign of fear.[53] Parents of children who do not always wear life jackets report reasons including (1) the parent is in close proximity to the child, (2) a PFD for the child is on board in case of emergency, and/or (3) the child has good swimming skills.[33]

INTERVENTIONS

In the Haddon matrix of injury prevention, safety interventions are aimed at changing the environment, the individual at risk, or the agent of injury (in this case, water). For drowning prevention, the environment and the individual are the prime targets. Experts generally recommend that multiple "layers of protection" be used to prevent drowning, because no single strategy is likely to prevent all submersion deaths and injuries. Such layers might include environmental changes such as adult supervision, pool fencing, pool covers, water-entry alarms, lifeguards, and CPR training. Additional prevention layers focused on the individual would include strategies such as swimming and survival skills training and use of PFDs.

Studies from the late 1990s revealed that pediatricians report that they were not adequately taught about drowning prevention during their residency training and that few of them counseled parents about this topic.[54,55] There have been no recent publications regarding the current status of drowning-prevention counseling by physicians and no research about whether such an intervention is effective in decreasing drowning rates.

Adult Supervision

Close supervision of young children around any body of water is an essential preventive strategy, but inevitable lapses make supervision alone insufficient.[15,33] Because young children who fall into water often make no noise and are hard to see below the water surface, proper care of a young nonswimmer requires the supervising adult to be within an arm's length and provide "touch supervision." To stress the importance of supervision, some communities have distributed "designated water watcher" badges as part of their drowning-prevention campaigns. While wearing the badge, the adult "water watcher" is responsible for pool safety and is expected not to engage in any distracting activities. The efficacy of such programs still needs evaluation.

Pool Fencing

Pool fencing is an important prevention strategy for decreasing the risk of drowning in swimming pools when children are not supposed to have access to the water. Compared with no fencing, installation of 4-sided fencing that isolates the pool from the house and yard has been shown to decrease the number of pool-immersion injuries among young children by more than 50%.[56–58] One Cochrane collaboration meta-analysis of available studies revealed the OR for drowning in a fenced versus an unfenced pool to be 0.27 (95% CI: 0.16–0.47). In this analysis, pool isolation fencing was revealed to be superior to property-perimeter fencing (OR: 0.17 [95% CI: 0.07–0.44]).[58] A study from Australia revealed that the risk of a child drowning in a pool with perimeter fencing was almost twice that seen in pools with an isolation fence (incidence rate ratio: 1.78 [95% CI: 1.40–1.79]).[59]

Unfortunately, laws and ordinances regarding pool fencing may have dangerous loopholes. Perimeter fencing with self-locking or alarming doors between the house and pool area are often considered acceptable, and in some locales, pool covers can substitute for a fence. Often, the fence law pertains only to new pool construction or to homes in which a young child is actually living at the time of the pool installation. Furthermore, in the United States, pool fences are rarely inspected, and ordinances are often not enforced. A recent study from Australia revealed that government inspections raised the rate of compliance with pool-fencing laws from approximately 50% to 97%.[60]

Children's ability to climb fences varies with the type of fence. In 1 study, chain-link fences were easily scaled by children, whereas ornamental iron-bar fences proved more difficult to climb.[61] Fences should be at least 4 ft high, and no opening under the fence should be more than 4 in (some building codes require a 5-ft fence and a maximum fence-to-ground distance of only 2 in). Vertical members of the fence should be less than 4 in apart to keep a child from squeezing through them, and there should be no footholds or handholds that could help a young child climb the fence. The fence should not prevent a clear view of the pool. Gates should be self-closing and self-

latching, and the latch should be placed at least 54 in above the bottom of the gate. The gate should open away from the pool and should be checked often to ensure that it is in good working order. Pool gate alarms may provide additional protection, but no research exists on their efficacy. Detailed guidelines for safety barriers for home pools are available online from the CPSC,[62] but homeowners must also be aware of local laws and building codes regarding pool-fence construction.

Pool Covers

Retractable pool covers and pool nets capable of holding the weight of a child have been advertised as effective barriers for drowning prevention. Because these covers must be removed and replaced each time the pool is used, they are not likely to be used appropriately and consistently. Because there has been no scientific study regarding the efficacy of pool covers, they cannot be recommended as a substitute for isolation fencing.

Some types of pool covers actually present a hazard for children. In 1980, the CPSC issued a warning about solar pool covers that are designed to keep the water warm and minimize pool chemical and water evaporation. When children try to walk on these thin sheets of plastic, they can fall into the water and drown while entangled in the cover or hidden from view.[63]

Pool Alarms

The CPSC has evaluated the performance of surface, subsurface, and wristband pool alarms.[64] Several of these alarms functioned properly and were thought to provide some protection against drowning; however, the report concluded that alarms "should not be relied on as a substitute for supervision or a barrier completely surrounding the pool." No study results have demonstrated whether pool alarms prevent drowning.

Lifeguards

Although no formal scientific study has quantified the value of lifeguards, anecdotal reports indicate that drowning rates are lower when lifeguards are present.[65] The US Lifesaving Association has reported that only 20 of the 109 beach drowning deaths occurred on guarded beaches in 2007.[66] In addition to rescue efforts, lifeguards serve to make beaches safer by monitoring the aquatic environment, enforcing rules and regulations, and educating beachgoers about safety and injury prevention. Those who choose to swim in natural bodies of water or other sites accessible to the public should swim in designated swim areas with lifeguards present.

CPR Training

Immediate resuscitation at the site of a submersion incident, even before the arrival of emergency medical services personnel, is an important means of secondary prevention and is associated with a significantly better outcome for children with submersion injury.[2,3] For this reason, all parents and caregivers should be trained in infant/child CPR. Initial resuscitative efforts for a drowning victim should include rescue breathing as well as chest compressions when signs of circulation are absent. "Hands-only" CPR is not appropriate for drowning victims. The Heimlich maneuver is not recommended to expel water from the lungs, because positive pressure ventilation by mouth or mask will accomplish adequate oxygenation.[67] Additional CPR information and courses for parents and caregivers is available through the American Heart Association and the American Red Cross. Education for health care professionals on resuscitation of pediatric patients is available through American Academy of Pediatrics programs Pediatric Advanced Life Support (PALS) and Pediatric Education for Prehospital Professionals (PEPP).

Swimming Instruction and Water-Survival Training

All children should eventually learn to swim. In the past, the position of the American Academy of Pediatrics has been that children are not "developmentally ready" for formal swimming lessons until after their fourth birthday.[68] This policy was based on (1) the lack of data needed to determine if infant and toddler aquatic programs increase or decrease the likelihood of drowning, (2) concerns that such programs would cause parents to develop a false sense of security and lead them to provide inadequate supervision around water, and (3) evidence that starting swimming lessons at a very young age does not result in earlier development of proficient swimming skills.[69,70] In addition, there was concern that swimming programs might reduce a child's fear of water and unwittingly encourage him or her to enter the water without supervision.

Concern about parents developing a false sense of security is well founded. Compared with controls, parents of small children who were enrolled in swimming lessons were more likely to endorse the statements "swimming lessons are the best way to prevent drowning," "toddlers can learn to save themselves if they fall into water," and "it is better to develop swimming ability rather than rely on adult supervision."[71] In a follow-up study, when they were given a targeted educational program to reverse misconceptions about toddler water safety, parents of children in a toddler swim program were more likely to agree that their child required more, not less, supervision. These parents were also more likely to disagree that swimming lessons were

the best way to prevent drowning.[72] The authors suggested that "swim schools can provide a valuable opportunity to address parental misconceptions about toddler water safety."

By 4 years of age, most children can learn basic aquatic locomotion, and by 5 or 6 years of age, most of them can master the front crawl.[69,70] The more important question for this report relates to when a child can learn water skills needed to prevent a drowning. Results of research from Asher et al,[40] Yang et al,[41] and Brenner et al[42] have indicated that some drowning-prevention skills can be learned between 1 and 4 years of age. It should be stressed, however, that these were relatively small studies that had outcomes with wide CIs. Although there is anecdotal evidence that even some small infants can successfully learn water-survival skills, there are currently no published scientific studies to indicate that such training results in the "drown-proofing" claimed by some advocates.

The American Red Cross Advisory Council on First Aid, Aquatics, Safety and Preparedness recently published an extensive scientific review regarding minimum age for swimming lessons. They concluded that the "limited empirical research evidence does not support prohibiting early aquatic experiences at any specific age." In their report, the council stated that "children between the ages of 2 and 4 years can optionally start swim lessons for the purpose of building aquatic readiness and water acclimation on an individual basis."[73] Although the council recognized that there may be some drowning-prevention benefit to swim lessons before 4 years of age, they indicated that "there is absolutely no published evidence to support anecdotal claims" that "rolling over and floating are sufficient to prevent drowning."

Although early instruction may be beneficial, there are some concerns about aquatic programs in this young age group. These concerns include the risk of gastrointestinal tract infections, dermatitis, and acute respiratory illness that can result from exposure to infectious agents and pool chemicals. Hyponatremia from drinking pool water and hypothermia have also been reported. Generally, medical problems from swimming are rare, treatable, and preventable events.[74,75] The World Aquatic Infants and Children Network has published guidelines for the operation of aquatic programs for children younger than 3 years. The guidelines address (1) required parental involvement, (2) a fun atmosphere with 1-on-1 teaching, (3) qualified teachers, (4) warm water to prevent hypothermia, (5) maintenance of water purity, and (6) a limited number of submersions to prevent water ingestion and hyponatremia.[76]

Recent articles have been published and suggest a link between infant exposure to chlorination byproducts in swimming pools and damage to respiratory epithelium, resulting in a predisposition to asthma and bronchitis.[77–79] In 1 of these studies, asthma was more likely in infants of atopic mothers.[79] In another study, atopic adolescents exposed to chlorinated pools were more likely to have hay fever, asthma, cough, and shortness of breath than were atopic adolescents who swam in pools disinfected by a copper-silver method.[80]

The AAP continues to support swimming lessons for children 4 years old and older without physical or developmental disabilities. In light of new research that has revealed that swim instruction for children 1 to 4 years of age may decrease drowning,[41,42] it is reasonable for the AAP to relax its policy regarding the age at which children should start learning water-survival skills. The evidence no longer supports an advisory against early aquatic experience and swim lessons for children of any specific age. However, the current evidence is insufficient to support a recommendation that all 1- to 4-year-old children receive swim lessons. Clearly, more research is needed to determine which types of swim instruction and water-survival skills training are most effective in preventing drowning in young children of various ages.

A parent's decision about the age at which to teach water-survival skills or initiate swimming lessons must be individualized on the basis of a variety of factors such as frequency of exposure to water, health concerns, emotional maturity, and physical limitations. Some parents may feel that the benefits of infant or toddler water programs outweigh any possible dangers. Once again, it must be stressed that even advanced swimming skills will not always prevent drowning and that swimming lessons must be considered only within the context of multilayered protection with effective pool barriers and constant, capable supervision.

PFDs

The use of an approved PFD, although not well evaluated, seems likely to decrease drowning morbidity and mortality.[81,82] US Coast Guard boating statistics from 2008 indicate that only 9% of 510 drowning-death victims (all ages) were wearing a PFD.[51] Successful educational and life-jacket–loaner programs designed to increase PFD use have been reported,[83,84] and in the past 10 years, the Coast Guard reported a slight improvement in PFD use in children younger than 18 years from 56% to 65% nationally.[85] It is important to recognize that air-filled swimming aids (such as inflatable arm bands) are toys that can deflate and should not be used in place of PFDs.

Information about infant and child PFDs for a variety of aquatic situations is available online from the US Coast Guard.[86]

Policy Statement

Advice pediatricians may provide to parents and recommendations for advocacy at the community level is specified in the accompanying policy statement.[87]

Prevention of Infective Endocarditis

Guidelines From the American Heart Association

A Guideline From the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council on Cardiovascular Surgery and Anesthesia, and the Quality of Care and Outcomes Research Interdisciplinary Working Group

Walter Wilson, MD, Chair; Kathryn A. Taubert, PhD, FAHA; Michael Gewitz, MD, FAHA; Peter B. Lockhart, DDS; Larry M. Baddour, MD; Matthew Levison, MD; Ann Bolger, MD, FAHA; Christopher H. Cabell, MD, MHS; Masato Takahashi, MD, FAHA; Robert S. Baltimore, MD; Jane W. Newburger, MD, MPH, FAHA; Brian L. Strom, MD; Lloyd Y. Tani, MD; Michael Gerber, MD; Robert O. Bonow, MD, FAHA; Thomas Pallasch, DDS, MS; Stanford T. Shulman, MD, FAHA; Anne H. Rowley, MD; Jane C. Burns, MD; Patricia Ferrieri, MD; Timothy Gardner, MD, FAHA; David Goff, MD, PhD, FAHA; David T. Durack, MD, PhD

The Council on Scientific Affairs of the American Dental Association has approved the guideline as it relates to dentistry. In addition, this guideline has been endorsed by the Infectious Diseases Society of America and by the Pediatric Infectious Diseases Society.

Backgroundð The purpose of this statement is to update the recommendations by the American Heart Association (AHA) for the prevention of infective endocarditis that were last published in 1997.

Methods and Resultsð A writing group was appointed by the AHA for their expertise in prevention and treatment of infective endocarditis, with liaison members representing the American Dental Association, the Infectious Diseases Society of America, and the American Academy of Pediatrics. The writing group reviewed input from national and international experts on infective endocarditis. The recommendations in this document reflect analyses of relevant literature regarding procedure-related bacteremia and infective endocarditis, in vitro susceptibility data of the most common microorganisms that cause infective endocarditis, results of prophylactic studies in animal models of experimental endocarditis, and retrospective and prospective studies of prevention of infective endocarditis. MEDLINE database searches from 1950 to 2006 were done for English-language papers using the following search terms: endocarditis, infective endocarditis, prophylaxis, prevention, antibiotic, antimicrobial, pathogens, organisms, dental, gastrointestinal, genitourinary, streptococcus, enterococcus, staphylococcus, respiratory, dental surgery, pathogenesis, vaccine, immunization, and bacteremia. The reference lists of the identified papers were also searched. We also searched the AHA online library. The American College of Cardiology/AHA classification of recommendations and levels of evidence for practice guidelines were used. The paper was subsequently reviewed by outside experts not affiliated with the writing group and by the AHA Science Advisory and Coordinating Committee.

Conclusionsð The major changes in the updated recommendations include the following: (1) The Committee concluded that only an extremely small number of cases of infective endocarditis might be prevented by antibiotic prophylaxis for

The American Heart Association makes every effort to avoid any actual or potential conflicts of interest that may arise as a result of an outside relationship or a personal, professional, or business interest of a member of the writing panel. Specifically, all members of the writing group are required to complete and submit a Disclosure Questionnaire showing all such relationships that might be perceived as real or potential conflicts of interest.

This guideline was approved by the American Heart Association Science Advisory and Coordinating Committee on March 7, 2007. A single reprint is available by calling 800-242-8721 (US only) or by writing the American Heart Association, Public Information, 7272 Greenville Ave, Dallas, TX 75231-4596. Expert peer review of AHA Scientific Statements and Guidelines is conducted at the AHA National Center. For more on AHA statements and guidelines development, visit http://www.americanheart.org/presenter.jhtml?identifier=3023366.

dental procedures even if such prophylactic therapy were 100% effective. (2) Infective endocarditis prophylaxis for dental procedures should be recommended only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from infective endocarditis. (3) For patients with these underlying cardiac conditions, prophylaxis is recommended for all dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa. (4) Prophylaxis is not recommended based solely on an increased lifetime risk of acquisition of infective endocarditis. (5) Administration of antibiotics solely to prevent endocarditis is not recommended for patients who undergo a genitourinary or gastrointestinal tract procedure. These changes are intended to define more clearly when infective endocarditis prophylaxis is or is not recommended and to provide more uniform and consistent global recommendations. **(*Circulation*. 2007;115:&NA;-.)**

Key Words: AHA Scientific Statements ■ cardiovascular diseases ■ endocarditis ■ prevention ■ antibiotic prophylaxis

Infective endocarditis (IE) is an uncommon but life-threatening infection. Despite advances in diagnosis, antimicrobial therapy, surgical techniques, and management of complications, patients with IE still have high morbidity and mortality rates related to this condition. Since the last American Heart Association (AHA) publication on prevention of IE in 1997,[1] many authorities and societies, as well as the conclusions of published studies, have questioned the efficacy of antimicrobial prophylaxis to prevent IE in patients who undergo a dental, gastrointestinal (GI), or genitourinary (GU) tract procedure and have suggested that the AHA guidelines should be revised.[2–5] Members of the Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee of the AHA Council on Cardiovascular Disease in the Young (ñthe Committeeò) and a national and international group of experts on IE extensively reviewed data published on the prevention of IE. The Committee is especially grateful to a group of international experts on IE who provided content review and input on this document (see Acknowledgments). The revised guidelines for IE prophylaxis are the subject of this report.

The writing group was charged with the task of performing an assessment of the evidence and giving a classification of recommendations and a level of evidence (LOE) to each recommendation. The American College of Cardiology (ACC)/AHA classification system was used as follows.

Classification of Recommendations:

Class I: Conditions for which there is evidence and/or general agreement that a given procedure or treatment is beneficial, useful, and effective.

Class II: Conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment.

Class IIa: Weight of evidence/opinion is in favor of usefulness/efficacy.

Class IIb: Usefulness/efficacy is less well established by evidence/opinion.

Class III: Conditions for which there is evidence and/or general agreement that a procedure/treatment is not useful/effective and in some cases may be harmful.

Level of Evidence:

Level of Evidence A: Data derived from multiple randomized clinical trials or meta-analyses.

Level of Evidence B: Data derived from a single randomized trial or nonrandomized studies.

Level of Evidence C: Only consensus opinion of experts, case studies, or standard of care.

History of AHA Statements on Prevention of IE

The AHA has made recommendations for the prevention of IE for more than 50 years. In 1955, the first AHA document on this subject was published in *Circulation*.[6] Table 1 shows a summary of the documents published from 1955 to 1997.[1,6–13] The 1960 document called attention to the possible emergence of penicillin-resistant oral microflora as a result of prolonged therapy for prevention of IE, and pediatric patients were included for the first time.[8] Chloramphenicol was recommended for patients who were allergic to penicillin. In 1965, the Committee published for the first time a document devoted solely to the prophylaxis of IE and recognized the importance of enterococci after GI or GU tract procedures.[9] The revised recommendations published in 1972 were endorsed for the first time by the American Dental Association (ADA) and emphasized the importance of maintenance of good oral hygiene.[10] This version introduced a recommendation for ampicillin in patients undergoing a GI or GU tract procedure. The 1977 revisions categorized both patients and procedures into high- and low-risk groups.[11] This resulted in complex tables with many footnotes. The 1984 recommendations attempted to simplify prophylactic regimens by providing clear lists of procedures for which prophylaxis was and was not recommended and reduced postprocedure prophylaxis for dental, GI, and GU tract procedures to only 1 oral or parenteral dose.[12] In 1990, a more complete list of cardiac conditions and dental or surgical procedures for which prophylaxis was and was not recommended was provided.[13] These previous recommendations recognized the potential medical-legal risks associated with IE prophylaxis and suggested that the recommendations were intended to serve as a guideline, not as established standard of care. The most recent AHA document on IE prophylaxis was published in 1997.[1] The 1997 document stratified cardiac conditions into high-, moderate-, and low-risk (negligible risk) categories, with prophylaxis not recommended for the low-risk group.[1] An even more detailed list of dental, respiratory, GI, and GU tract procedures for which prophylaxis was and was not recommended was provided. The 1997 document was notable for its acknowledgment that most cases of IE are not attributable to an invasive procedure but

TABLE 1. Summary of 9 Iterations of AHA-Recommended Antibiotic Regimens From 1955 to 1997 for Dental/Respiratory Tract Procedures*

Year (Reference)	Primary Regimens for Dental Procedures
1955 (6)	Aqueous penicillin 600 000 U and procaine penicillin 600 000 U in oil containing 2% aluminum monostearate administered IM 30 minutes before the operative procedure
1957 (7)	For 2 days before surgery, penicillin 200 000 to 250 000 U by mouth 4 times per day. On day of surgery, penicillin 200 000 to 250 000 U by mouth 4 times per day and aqueous penicillin 600 000 U with procaine penicillin 600 000 U IM 30 to 60 minutes before surgery. For 2 days after, 200 000 to 250 000 U by mouth 4 times per day.
1960 (8)	Step I: prophylaxis 2 days before surgery with procaine penicillin 600 000 U IM on each day
	Step II: day of surgery: procaine penicillin 600 000 U IM supplemented by crystalline penicillin 600 000 U IM 1 hour before surgical procedure
	Step III: for 2 days after surgery: procaine penicillin 600 000 U IM each day
1965 (9)	Day of procedure: procaine penicillin 600 000 U, supplemented by crystalline penicillin 600 000 U IM 1 to 2 hours before the procedure
	For 2 days after procedure: procaine penicillin 600 000 U IM each day
1972 (10)	Procaine penicillin G 600 000 U mixed with crystalline penicillin G 200 000 U IM 1 hour before procedure and once daily for the 2 days after the procedure
1977 (11)	Aqueous crystalline penicillin G (1 000 000 U IM) mixed with procaine penicillin G (600 000 U IM) 30 minutes to 1 hour before procedure and then penicillin V 500 mg orally every 6 hours for 8 doses.
1984 (12)	Penicillin V 2 g orally 1 hour before, then 1 g 6 hours after initial dose
1990 (13)	Amoxicillin 3 g orally 1 hour before procedure, then 1.5 g 6 hours after initial dose
1997 (1)	Amoxicillin 2 g orally 1 hour before procedure

IM indicates intramuscularly.

*These regimens were for adults and represented the initial regimen listed in each version of the recommendations. In some versions, >1 regimen was included.

rather are the result of randomly occurring bacteremias from routine daily activities and for its acknowledgment of possible IE prophylaxis failures.

Rationale for Revising the 1997 Document

It is clear from the above chronology that the AHA guidelines for IE prophylaxis have been in a process of evolution more than 50 years. The rationale for prophylaxis was based largely on expert opinion and what seemed to be a rational and prudent attempt to prevent a life-threatening infection. On the basis of the ACC and AHA Task Force on Practice Guidelinesô evidence-based grading system for ranking recommendations, the recommendations in the AHA documents published during the past 50 years would be Class IIb, LOE C. Accordingly, the basis for recommendations for IE prophylaxis was not well established, and the quality of evidence was limited to a few case-control studies or was based on expert opinion, clinical experience, and descriptive studies that utilized surrogate measures of risk.

Over the years, other international societies have published recommendations and guidelines for the prevention of IE.[14,15] Recently, the British Society for Antimicrobial Chemotherapy issued new IE prophylaxis recommendations.[15] This group now recommends prophylaxis before dental procedures only for patients who have a history of previous IE or who have had cardiac valve replacement or surgically constructed pulmonary shunts or conduits.

The fundamental underlying principles that drove the formulation of the AHA guidelines and the 9 previous AHA documents were that (1) IE is an uncommon but life-threatening disease, and prevention is preferable to treatment of established infection; (2) certain underlying cardiac conditions predispose to IE; (3) bacteremia with organisms known to cause IE occurs commonly in association with invasive dental, GI, or GU tract procedures; (4) antimicrobial prophylaxis was proven to be effective for prevention of experimental IE in animals; and (5) antimicrobial prophylaxis was thought to be effective in humans for prevention of IE associated with dental, GI, or GU tract procedures. The Committee believes that of these 5 underlying principles, the first 4 are valid and have not changed during the past 30 years. Numerous publications have questioned the validity of the fifth principle and suggested revision of the guidelines, primarily for reasons as shown in Table 2.

Another reason that led the Committee to revise the 1997 document was that over the past 50 years, the AHA guidelines on prevention of IE became overly complicated, making it difficult for patients and healthcare providers to interpret or remember specific details, and they contained ambiguities and some inconsistencies in the recommendations. The decision to substantially revise the 1997 document was not taken lightly. The present revised document was not based on the results of a single study but rather on the collective body of

TABLE 2. Primary Reasons for Revision of the IE Prophylaxis Guidelines

IE is much more likely to result from frequent exposure to random bacteremias associated with daily activities than from bacteremia caused by a dental, GI tract, or GU tract procedure.
Prophylaxis may prevent an exceedingly small number of cases of IE, if any, in individuals who undergo a dental, GI tract, or GU tract procedure.
The risk of antibiotic-associated adverse events exceeds the benefit, if any, from prophylactic antibiotic therapy.
Maintenance of optimal oral health and hygiene may reduce the incidence of bacteremia from daily activities and is more important than prophylactic antibiotics for a dental procedure to reduce the risk of IE.

evidence published in numerous studies over the past 2 decades. The Committee sought to construct the present recommendations such that they would be in the best interest of patients and providers, would be reasonable and prudent, and would represent the conclusions of published studies and the collective wisdom of many experts on IE and relevant national and international societies.

Potential Consequences of Substantive Changes in Recommendations

Substantive changes in recommendations could (1) violate long-standing expectations and practice patterns; (2) make fewer patients eligible for IE prophylaxis; (3) reduce malpractice claims related to IE prophylaxis; and (4) stimulate prospective studies on IE prophylaxis. The Committee and others[16] recognize that substantive changes in IE prophylaxis guidelines may violate long-standing expectations and practice patterns by patients and healthcare providers. The Committee recognizes that these new recommendations may cause concern among patients who have previously received antibiotic prophylaxis to prevent IE before dental or other procedures and are now advised that such prophylaxis is unnecessary. Table 2 includes the main talking points that may be helpful for clinicians in reeducating their patients about these changes. To recommend such changes demands due diligence and critical analysis. For 50 years, since the publication of the first AHA guidelines on the prevention of IE,[6] patients and healthcare providers assumed that antibiotics administered in association with a bacteremia-producing procedure effectively prevented IE in patients with underlying cardiac risk factors. Patients were educated about bacteremia-producing procedures and risk factors for IE, and they expected to receive antibiotic prophylaxis; healthcare providers, especially dentists, were expected to administer them. Patients with underlying cardiac conditions that carry a lifetime risk of acquisition of IE, such as mitral valve prolapse (MVP), had a sense of reassurance and comfort that antibiotics administered in association with a dental procedure were effective and usually safe to prevent IE. Healthcare providers, especially dentists, felt a sense of obligation and professional and legal responsibility to protect their patients from IE that might result from a procedure. On the basis of recommendations in this revised document, substantially fewer patients will be recommended for IE prophylaxis.

Cases of IE either temporally or remotely associated with an invasive procedure, especially a dental procedure, have frequently been the basis for malpractice claims against healthcare providers. Unlike many other infections for which there is conclusive evidence for the efficacy of preventive therapy, the prevention of IE is not a precise science. Because previously published AHA guidelines for the prevention of IE contained ambiguities and inconsistencies and were often based on minimal published data or expert opinion, they were subject to conflicting interpretations among patients, healthcare providers, and the legal system about patient eligibility for prophylaxis and whether there was strict adherence by healthcare providers to AHA recommendations for prophylaxis. This document is intended to identify which, if any, patients may possibly benefit from IE prophylaxis and to define, to the extent possible, which dental procedures should have prophylaxis in this select group of patients. Accordingly, the Committee hopes that this document will result in greater clarity for patients, healthcare providers, and consulting professionals.

The Committee believes that recommendations for IE prophylaxis must be evidence based. A placebo-controlled, multicenter, randomized, double-blinded study to evaluate the efficacy of IE prophylaxis in patients who undergo a dental, GI, or GU tract procedure has not been done. Such a study would require a large number of patients per treatment group and standardization of the specific invasive procedures and the patient populations. This type of study would be necessary to definitively answer long-standing unresolved questions regarding the efficacy of IE prophylaxis. The Committee hopes that this revised document will stimulate additional studies on the prevention of IE. Future published data will be reviewed carefully by the AHA, the Committee on Rheumatic Fever, Endocarditis, and Kawasaki Disease, and other societies, and further revisions to the present document will be based on relevant studies.

Pathogenesis of IE

The development of IE is the net result of the complex interaction between the bloodstream pathogen with matrix molecules and platelets at sites of endocardial cell damage. In addition, many of the clinical manifestations of IE emanate from the hostôs immune response to the infecting microorganism. The following sequence of events is thought to result in IE: formation of nonbacterial thrombotic endocarditis (NBTE) on the surface of a cardiac valve or elsewhere that endothelial damage occurs, bacteremia, adherence of the bacteria in the bloodstream to NBTE, and proliferation of bacteria within a vegetation.

Formation of NBTE

Turbulent blood flow produced by certain types of congenital or acquired heart disease, such as flow from a high- to a low-pressure chamber or across a narrowed orifice, traumatizes the endothelium. This creates a predisposition for deposition of platelets and fibrin on the surface of the endothelium, which results in NBTE. Invasion of the bloodstream with a microbial species that has the pathogenic potential to colonize this site can then result in IE.

Transient Bacteremia

Mucosal surfaces are populated by a dense endogenous microflora. Trauma to a mucosal surface, particularly the gingival crevice around teeth, oropharynx, GI tract, urethra, and vagina, releases many different microbial species transiently into the bloodstream. Transient bacteremia caused by viridans group streptococci and other oral microflora occurs commonly in association with dental extractions or other dental procedures or with routine daily activities. Although controversial, the frequency and intensity of the resulting bacteremias are believed to be related to the nature and magnitude of the tissue trauma, the density of the microbial flora, and the degree of inflammation or infection at the site of trauma. The microbial species entering the circulation

depends on the unique endogenous microflora that colonizes the particular traumatized site.

Bacterial Adherence

The ability of various microbial species to adhere to specific sites determines the anatomic localization of infection caused by these microorganisms. Mediators of bacterial adherence serve as virulence factors in the pathogenesis of IE. Numerous bacterial surface components present in streptococci, staphylococci, and enterococci have been shown in animal models of experimental endocarditis to function as critical adhesins. Some viridans group streptococci contain a FimA protein that is a lipoprotein receptor antigen I (LraI) that serves as a major adhesin to the fibrin platelet matrix of NBTE.[17] Staphylococcal adhesins function in at least 2 ways. In one, microbial surface components recognizing adhesive matrix molecules facilitate the attachment of staphylococci to human extracellular matrix proteins and to medical devices that become coated with matrix proteins after implantation. In the other, bacterial extracellular structures contribute to the formation of biofilm that forms on the surface of implanted medical devices. In both cases, staphylococcal adhesins are important virulence factors.

Both FimA and staphylococcal adhesins are immunogenic in experimental infections. Vaccines prepared against FimA and staphylococcal adhesins provide some protective effect in experimental endocarditis caused by viridans group streptococci and staphylococci.[18,19] The results of these experimental studies are highly intriguing, because the development of an effective vaccine for use in humans to prevent viridans group streptococcal or staphylococcal IE would be of major importance.

Proliferation of Bacteria Within a Vegetation

Microorganisms adherent to the vegetation stimulate further deposition of fibrin and platelets on their surface. Within this secluded focus, the buried microorganisms multiply as rapidly as bacteria in broth cultures to reach maximal microbial densities of 10^8 to 10^{11} colony-forming units per gram of vegetation within a short time on the left side of the heart, apparently uninhibited by host defenses in left-sided lesions. Right-sided vegetations have lower bacterial densities, which may be the consequence of host defense mechanisms active at this site, such as polymorphonuclear activity or platelet-derived antibacterial proteins. More than 90% of the microorganisms in mature left- or right-sided valvular vegetations are metabolically inactive rather than in an active growth phase and are therefore less responsive to the bactericidal effects of antibiotics.[20]

Rationale for or Against Prophylaxis of IE

Historical Background

Viridans group streptococci are part of the normal skin, oral, respiratory, and GI tract flora, and they cause at least 50% of cases of community-acquired native valve IE not associated with intravenous drug use.[21] More than a century ago, the oral cavity was recognized as a potential source of the bacteremia that caused viridans group streptococcal IE. In 1885, Osler[22] noted an association between bacteremia from surgery and IE. Okell and Elliott[23] in 1935 reported that 11% of patients with poor oral hygiene had positive blood cultures with viridans group streptococci and that 61% of patients had viridans group streptococcal bacteremia with dental extraction.

As a result of these early studies and subsequent studies, during the past 50 years, the AHA guidelines recommended antimicrobial prophylaxis to prevent IE in patients with underlying cardiac conditions who underwent bacteremia-producing procedures on the basis of the following factors: (1) bacteremia causes endocarditis; (2) viridans group streptococci are part of the normal oral flora, and enterococci are part of the normal GI and GU tract flora; (3) these microorganisms were usually susceptible to antibiotics recommended for prophylaxis; (4) antibiotic prophylaxis prevents viridans group streptococcal or enterococcal experimental endocarditis in animals; (5) a large number of poorly documented case reports implicated a dental procedure as a cause of IE; (6) in some cases, there was a temporal relationship between a dental procedure and the onset of symptoms of IE; (7) an awareness of bacteremia caused by viridans group streptococci associated with a dental procedure exists; (8) the risk of significant adverse reactions to an antibiotic is low in an individual patient; and (9) morbidity and mortality from IE are high. Most of these factors remain valid, but collectively, they do not compensate for the lack of published data that demonstrate a benefit from prophylaxis.

Bacteremia-Producing Dental Procedures

The large majority of published studies have focused on dental procedures as a cause of IE and the use of prophylactic antibiotics to prevent IE in patients at risk. Few data exist on the risk of or prevention of IE associated with a GI or GU tract procedure. Accordingly, the Committee undertook a critical analysis of published data in the context of the historical rationale for recommending antibiotic prophylaxis for IE before a dental procedure. The following factors were considered: (1) frequency, nature, magnitude, and duration of bacteremia associated with dental procedures; (2) impact of dental disease, oral hygiene, and type of dental procedure on bacteremia; (3) impact of antibiotic prophylaxis on bacteremia from a dental procedure; and (4) the exposure over time of frequently occurring bacteremia from routine daily activities compared with bacteremia from various dental procedures.

Frequency, Nature, Magnitude, and Duration of Bacteremia Associated With a Dental Procedure

Transient bacteremia is common with manipulation of the teeth and periodontal tissues, and there is a wide variation in reported frequencies of bacteremia in patients resulting from dental procedures: tooth extraction (10% to 100%), periodontal surgery (36% to 88%), scaling and root planing (8% to 80%), teeth cleaning (up to 40%), rubber dam matrix/wedge placement (9% to 32%), and endodontic procedures (up to 20%).[24–30] Transient bacteremia also occurs frequently during routine daily activities unrelated to a dental procedure, such as tooth brushing and flossing (20% to 68%), use of wooden toothpicks (20% to 40%), use of water irrigation devices (7%

to 50%), and chewing food (7% to 51%).[26–29,31–36] Considering that the average person living in the United States has fewer than 2 dental visits per year, the frequency of bacteremia from routine daily activities is far greater.

There has been a disproportionate focus on the frequency of bacteremia associated with dental procedures rather than on the species of bacteria recovered from blood cultures. Studies suggest that more than 700 species of bacteria, including aerobic and anaerobic Gram-positive and Gram-negative microorganisms, may be identified in the human mouth, particularly on the teeth and in the gingival crevices.[24,37–40] Approximately 30% of the flora of the gingival crevice is streptococci, predominantly of the viridans group. Of the more than 100 oral bacterial species recovered from blood cultures after dental procedures, the most prevalent are viridans group streptococci, the most common microbiological cause of community-acquired native valve IE in nonintravenous drug users.[21] In healthy mouths, a thin surface of mucosal epithelium prevents potentially pathogenic bacteria from entering the bloodstream and lymphatic system. Anaerobic microorganisms are commonly responsible for periodontal disease and frequently enter the bloodstream but rarely cause IE, with fewer than 120 cases reported.[41] Viridans group streptococci are antagonistic to periodontal pathogens and predominate in a clean, healthy mouth.[42]

Few published studies exist on the magnitude of bacteremia after a dental procedure or from routine daily activities, and most of the published data used older, often unreliable microbiological methodology. There are no published data that demonstrate that a greater magnitude of bacteremia, compared with a lower magnitude, is more likely to cause IE in humans. The magnitude of bacteremia resulting from a dental procedure is relatively low ($<10^4$ colony-forming units of bacteria per milliliter), similar to that resulting from routine daily activities, and is less than that used to cause experimental IE in animals (10^6 to 10^8 colony-forming units of bacteria per milliliter).[20,43,44] Although the infective dose required to cause IE in humans is unknown, the number of microorganisms present in blood after a dental procedure or associated with daily activities is low. Cases of IE caused by oral bacteria probably result from the exposures to low inocula of bacteria in the bloodstream that result from routine daily activities and not from a dental procedure. Additionally, the vast majority of patients with IE have not had a dental procedure within 2 weeks before the onset of symptoms of IE.[2–4]

The role of duration of bacteremia on the risk of acquisition of IE is uncertain.[45,46] Early studies reported that sequential blood cultures were positive for up to 10 minutes after tooth extraction and that the number of positive blood cultures dropped sharply after 10 to 30 minutes.[24,45–51] More recent studies support these data but report a small percentage of positive blood cultures from 30 to 60 minutes after tooth extraction.[43,52,53] Intuitively, it seems logical to assume that the longer the duration of bacteremia, the greater the risk of IE, but no published studies support this assumption. Given the preponderance of published data, there may not be a clinically significant difference in the frequency, nature, magnitude, and duration of bacteremia associated with a dental procedure compared with that resulting from routine daily activities. Accordingly, it is inconsistent to recommend prophylaxis of IE for dental procedures but not for these same patients during routine daily activities. Such a recommendation for prophylaxis for routine daily activities would be impractical and unwarranted.

Impact of Dental Disease, Oral Hygiene, and Type of Dental Procedure on Bacteremia

It is assumed that a relationship exists between poor oral hygiene, the extent of dental and periodontal disease, the type of dental procedure, and the frequency, nature, magnitude, and duration of bacteremia, but the presumed relationship is controversial.[23,29,30,38,45,54–61] Nevertheless, available evidence supports an emphasis on maintaining good oral hygiene and eradicating dental disease to decrease the frequency of bacteremia from routine daily activities.[45,56–58,62,63] In patients with poor oral hygiene, the frequency of positive blood cultures just before dental extraction may be similar to that after extraction.[62,63]

More than 80 years ago, it was suggested that poor oral hygiene and dental disease were more important as a cause of IE than were dental procedures.[64] Most studies since that time have focused instead on the risks of bacteremia associated with dental procedures. For example, tooth extraction is thought to be the dental procedure most likely to cause bacteremia, with an incidence ranging from 10% to 100%.* However, numerous other dental procedures have been reported to be associated with risks of bacteremia that are similar to that resulting from tooth extraction.À A precise determination of the relative risk of bacteremia that results from a specific dental procedure in patients with or without dental disease is probably not possible.[27,72,73]

Bleeding often occurs during a dental procedure in patients with or without periodontal disease. Previous AHA guidelines recommended antibiotic prophylaxis for dental procedures in which bleeding was anticipated but not for procedures for which bleeding was not anticipated.[1] However, no data show that visible bleeding during a dental procedure is a reliable predictor of bacteremia.[62] These ambiguities in the previous AHA guidelines led to further uncertainties among healthcare providers about which dental procedures should be covered by prophylaxis.

These factors complicated recommendations in previous AHA guidelines on prevention of IE that suggested antibiotic prophylaxis for some dental procedures but not for others. The collective published data suggest that the vast majority of dental office visits result in some degree of bacteremia; however, there is no evidence-based method to decide which procedures should require prophylaxis, because no data show that the incidence, magnitude, or duration of bacteremia from any dental procedure increase the risk of IE. Accordingly, it is not clear which dental procedures are more or less likely to cause a transient bacteremia or result in a greater magnitude of bacteremia than that which results from routine daily activities such as chewing food, tooth brushing, or flossing.

In patients with underlying cardiac conditions, lifelong antibiotic therapy is not recommended to prevent IE that might result from bacteremias associated with routine daily activities.[5] In patients with dental disease, the focus on the frequency of bacteremia associated with a specific dental procedure and the AHA guidelines for prevention of IE have resulted in an overemphasis on antibiotic prophylaxis and an underemphasis on maintenance of good oral hygiene and access to routine dental care, which are likely more important in reducing the lifetime risk of IE than the administration of antibiotic prophylaxis for a dental procedure. However, no observational or controlled studies support this contention.

Impact of Antibiotic Therapy on Bacteremia From a Dental Procedure

The ability of antibiotic therapy to prevent or reduce the frequency, magnitude, or duration of bacteremia associated with a dental procedure is controversial.[24,74] Some studies reported that antibiotics administered before a dental procedure reduced the frequency, nature, and/or duration of bacteremia,[53,75,76] whereas others did not.[24,66,77,78] Recent studies suggest that amoxicillin therapy has a statistically significant impact on reducing the incidence, nature, and duration of bacteremia from dental procedures, but it does not eliminate bacteremia.[52,53,76] However, no data show that such a reduction as a result of amoxicillin therapy reduces the risk of or prevents IE. Hall et al[78] reported that neither penicillin V nor amoxicillin therapy was effective in reducing the frequency of bacteremia compared with untreated control subjects. In patients who underwent a dental extraction, penicillin or ampicillin therapy compared with placebo diminished the percentage of viridans group streptococci and anaerobes in culture, but there was no significant difference in the percentage of patients with positive cultures 10 minutes after tooth extraction.[24,66] In a separate study, Hall et al[77] reported that cefaclor-treated patients did not have a reduction of postprocedure bacteremia compared with untreated control subjects. Contradictory published results from 2 studies showed reduction of postprocedure bacteremia by erythromycin in one[75] but lack of efficacy for erythromycin or clindamycin in another.[78] Finally, results are contradictory with regard to the efficacy of the use of topical antiseptics in reducing the frequency of bacteremia associated with dental procedures, but the preponderance of evidence suggests that there is no clear benefit. One study reported that chlorhexidine and povidone iodine mouth rinse were effective,[79] whereas others showed no statistically significant benefit.[52,80] Topical antiseptic rinses do not penetrate beyond 3 mm into the periodontal pocket and therefore do not reach areas of ulcerated tissue where bacteria most often gain entrance to the circulation. On the basis of these data, it is unlikely that topical antiseptics are effective to significantly reduce the frequency, magnitude, and duration of bacteremia associated with a dental procedure.

Cumulative Risk Over Time of Bacteremias From Routine Daily Activities Compared With the Bacteremia From a Dental Procedure

Guntheroth[81] estimated a cumulative exposure of 5370 minutes of bacteremia over a 1-month period in dentulous patients resulting from random bacteremia from chewing food and from oral hygiene measures, such as tooth brushing and flossing, and compared that with a duration of bacteremia lasting 6 to 30 minutes associated with a single tooth extraction. Roberts[62] estimated that tooth brushing 2 times daily for 1 year had a 154 000 times greater risk of exposure to bacteremia than that resulting from a single tooth extraction. The cumulative exposure during 1 year to bacteremia from routine daily activities may be as high as 5.6 million times greater than that resulting from a single tooth extraction, the dental procedure reported to be most likely to cause a bacteremia.[62]

Data exist for the duration of bacteremia from a single tooth extraction, and it is possible to estimate the annual cumulative exposure from dental procedures for the average individual. However, calculations for the incidence, nature, and duration of bacteremia from routine daily activities are at best rough estimates, and it is therefore not possible to compare precisely the cumulative monthly or annual duration of exposure for bacteremia from dental procedures compared with routine daily activities. Nevertheless, even if the estimates of bacteremia from routine daily activities are off by a factor of 1000, it is likely that the frequency and cumulative duration of exposure to bacteremia from routine daily events over 1 year are much higher than those that result from dental procedures.

Results of Clinical Studies of IE Prophylaxis for Dental Procedures

No prospective, randomized, placebo-controlled studies exist on the efficacy of antibiotic prophylaxis to prevent IE in patients who undergo a dental procedure. Data from published retrospective or prospective case-control studies are limited by the following factors: (1) the low incidence of IE, which requires a large number of patients per cohort for statistical significance; (2) the wide variation in the types and severity of underlying cardiac conditions, which would require a large number of patients with specific matched control subjects for each cardiac condition; and (3) the large variety of invasive dental procedures and dental disease states, which would be difficult to standardize for control groups. These and other limitations complicate the interpretation of the results of published studies of the efficacy of IE prophylaxis in patients who undergo dental procedures.

Although some retrospective studies suggested that there was a benefit from prophylaxis, these studies were small in size and reported insufficient clinical data. Furthermore, in a number of cases, the incubation period between the dental procedure and the onset of symptoms of IE was prolonged.[80,82–84]

van der Meer and colleagues[85] published a study of dental procedures in the Netherlands and the efficacy of antibiotic prophylaxis to prevent IE in patients with native or prosthetic cardiac valves. They concluded that dental or other procedures probably caused only a small fraction of cases of IE and that prophylaxis would prevent only a small number of cases even if it were 100% effective. These same authors[86] performed a 2-year case-control study. Among patients for whom prophylaxis was recommended, 5 of 20 cases of IE

occurred despite receiving antibiotic prophylaxis. The authors concluded that prophylaxis was not effective. In a separate study,[87] these authors reported poor awareness of recommendations for prophylaxis among both patients and healthcare providers.

Strom and colleagues[2] evaluated dental prophylaxis and cardiac risk factors in a multicenter case-control study. These authors reported that MVP, congenital heart disease (CHD), rheumatic heart disease (RHD), and previous cardiac valve surgery were risk factors for the development of IE. In that study, control subjects without IE were more likely to have undergone a dental procedure than were those with cases of IE ($P=0.03$). The authors concluded that dental treatment was not a risk factor for IE even in patients with valvular heart disease and that few cases of IE could be prevented with prophylaxis even if it were 100% effective.

These studies are in agreement with a recently published French study of the estimated risk of IE in adults with predisposing cardiac conditions who underwent dental procedures with or without antibiotic prophylaxis.[88] These authors concluded that a ñhuge number of prophylaxis doses would be necessary to prevent a very low number of IE cases.ò

Absolute Risk of IE Resulting From a Dental Procedure

No published data accurately determine the absolute risk of IE that results from a dental procedure. One study reported that 10% to 20% of patients with IE caused by oral flora underwent a preceding dental procedure (within 30 or 180 days of onset).[85] The evidence linking bacteremia associated with a dental procedure with IE is largely circumstantial, and the number of cases related to a dental procedure is overestimated for a number of reasons. For 60 years, noted opinion leaders in medicine suggested a link between bacteremia-causing dental procedures and IE,[23] and for 50 years, the AHA published regularly updated guidelines that emphasized the association between dental procedures and IE and recommended antibiotic prophylaxis.[1] Additionally, bacteremia-producing dental procedures are common; it is estimated that at least 50% of the population in the United States visits a dentist at least once a year. Furthermore, there are numerous poorly documented case reports that implicate dental procedures associated with the development of IE, but these reports did not prove a direct causal relationship. Even in the event of a close temporal relationship between a dental procedure and IE, it is not possible to determine with certainty whether the bacteremia that caused IE originated from a dental procedure or from a randomly occurring bacteremia as a result of routine daily activities during the same time period. Many case reports and reviews have included cases with a remote preceding dental procedure, often 3 to 6 months before the diagnosis of IE. Studies suggest that the time frame between bacteremia and the onset of symptoms of IE is usually 7 to 14 days for viridans group streptococci or enterococci. Reportedly, 78% of such cases of IE occur within 7 days of bacteremia and 85% within 14 days.[89] Although the upper time limit is not known, it is likely that many cases of IE with incubation periods longer than 2 weeks after a dental procedure were incorrectly attributed to the procedure. These and other factors have led to a heightened awareness among patients and healthcare providers of the possible association between dental procedures and IE, which likely has led to substantial overreporting of cases attributable to dental procedures.

Although the absolute risk for IE from a dental procedure is impossible to measure precisely, the best available estimates are as follows: If dental treatment causes 1% of all cases of viridans group streptococcal IE annually in the United States, the overall risk in the general population is estimated to be as low as 1 case of IE per 14 million dental procedures.[41,90,91] The estimated absolute risk rates for IE from a dental procedure in patients with underlying cardiac conditions are as follows: MVP, 1 per 1.1 million procedures; CHD, 1 per 475 000; RHD, 1 per 142 000; presence of a prosthetic cardiac valve, 1 per 114 000; and previous IE, 1 per 95 000 dental procedures.[41,91] Although these calculations of risk are estimates, it is likely that the number of cases of IE that result from a dental procedure is exceedingly small. Therefore, the number of cases that could be prevented by antibiotic prophylaxis, even if 100% effective, is similarly small. One would not expect antibiotic prophylaxis to be near 100% effective, however, because of the nature of the organisms and choice of antibiotics.

Risk of Adverse Reactions and Cost-Effectiveness of Prophylactic Therapy

Nonfatal adverse reactions, such as rash, diarrhea, and GI upset, occur commonly with the use of antimicrobials; however, only single-dose therapy is recommended for dental prophylaxis, and these common adverse reactions are usually not severe and are self-limited. Fatal anaphylactic reactions were estimated to occur in 15 to 25 individuals per 1 million patients who receive a dose of penicillin.[92,93] Among patients with a prior penicillin use, 36% of fatalities from anaphylaxis occurred in those with a known allergy to penicillin compared with 64% of fatalities among those with no history of penicillin allergy.[94] These calculations are at best rough estimates and may overestimate the true risk of death caused by fatal anaphylaxis from administration of a penicillin. They are based on retrospective reviews or surveys of patients or on healthcare providersô recall of events. A prospective study is necessary to accurately determine the risk of fatal anaphylaxis resulting from administration of a penicillin.

For 50 years, the AHA has recommended a penicillin as the preferred choice for dental prophylaxis for IE. During these 50 years, the Committee is unaware of any cases reported to the AHA of fatal anaphylaxis resulting from the administration of a penicillin recommended in the AHA guidelines for IE prophylaxis. The Committee believes that a single dose of amoxicillin or ampicillin is safe and is the preferred prophylactic agent for individuals who do not have a history of type I hypersensitivity reaction to a penicillin, such as anaphylaxis, urticaria, or angioedema. Fatal anaphylaxis from a cephalosporin is estimated to be less common than from penicillin, at approximately 1 case per 1 million patients.[95] Fatal reactions to a single dose of a macrolide or clindamycin are extremely rare.[96,97] There has been only 1 case report of

documented *Clostridium difficile* colitis after a single dose of prophylactic clindamycin.[98]

Summary

Although it has long been assumed that dental procedures may cause IE in patients with underlying cardiac risk factors and that antibiotic prophylaxis is effective, scientific proof is lacking to support these assumptions. The collective published evidence suggests that of the total number of cases of IE that occur annually, it is likely that an exceedingly small number are caused by bacteremia-producing dental procedures. Accordingly, only an extremely small number of cases of IE might be prevented by antibiotic prophylaxis even if it were 100% effective. The vast majority of cases of IE caused by oral microflora most likely result from random bacteremias caused by routine daily activities, such as chewing food, tooth brushing, flossing, use of toothpicks, use of water irrigation devices, and other activities. The presence of dental disease may increase the risk of bacteremia associated with these routine activities. There should be a shift in emphasis away from a focus on a dental procedure and antibiotic prophylaxis toward a greater emphasis on improved access to dental care and oral health in patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE and those conditions that predispose to the acquisition of IE.

Cardiac Conditions and Endocarditis

Previous AHA guidelines categorized underlying cardiac conditions associated with the risk of IE as those with high risk, moderate risk, and negligible risk and recommended prophylaxis for patients in the high- and moderate-risk categories.[1] For the present guidelines on prevention of IE, the Committee considered 3 distinct issues: (1) What underlying cardiac conditions over a lifetime have the highest predisposition to the acquisition of endocarditis? (2) What underlying cardiac conditions are associated with the highest risk of adverse outcome from endocarditis? (3) Should recommendations for IE prophylaxis be based on either or both of these 2 conditions?

Underlying Conditions Over a Lifetime That Have the Highest Predisposition to the Acquisition of Endocarditis

In Olmsted County, Minnesota, the incidence of IE in adults ranged from 5 to 7 cases per 100 000 person-years.[99] This incidence has remained stable during the past 4 decades and is similar to that reported in other studies.[100–103] Previously, RHD was the most common underlying condition predisposing to endocarditis, and RHD is still common in developing countries.[99] In developed countries, the frequency of RHD has declined, and MVP is now the most common underlying condition in patients with endocarditis.[104]

Few published data quantitate the lifetime risk of acquisition of IE associated with a specific underlying cardiac condition. Steckelberg and Wilson[90] reported the lifetime risk of acquisition of IE, which ranged from 5 per 100 000 patient-years in the general population with no known cardiac conditions to 2160 per 100 000 patient-years in patients who underwent replacement of an infected prosthetic cardiac valve. In that study,[90] the risk of IE per 100 000 patient-years was 4.6 in patients with MVP without an audible cardiac murmur and 52 in patients with MVP with an audible murmur of mitral regurgitation. Per 100 000 patient-years, the lifetime risk (380 to 440) for RHD was similar to that (308 to 383) for patients with a mechanical or bioprosthetic cardiac valve. The highest lifetime risks per 100 000 patient-years were as follows: cardiac valve replacement surgery for native valve IE, 630; previous IE, 740; and prosthetic valve replacement done in patients with prosthetic valve endocarditis, 2160. In a separate study, the risk of IE per 100 000 patient-years was 271 in patients with congenital aortic stenosis and 145 in patients with ventricular septal defect.[105] In that same study, the risk of IE before closure of a ventricular septal defect was more than twice that after closure. Although these data provide useful ranges of risk in large populations, it is difficult to utilize them to define accurately the lifetime risk of acquisition of IE in an individual patient with a specific underlying cardiac risk factor. This difficulty is based in part on the fact that each individual cardiac condition, such as RHD or MVP, represents a broad spectrum of pathology from minimal to severe, and the risk of IE would likely be influenced by the severity of valvular disease.

CHD is another underlying condition with multiple different cardiac abnormalities that range from relatively minor to severe, complex cyanotic heart disease. During the past 25 years, there has been an increasing use of various intracardiac valvular prostheses and intravascular shunts, grafts, and other devices for repair of valvular heart disease and CHD. The diversity and nature of these prostheses and procedures likely present different levels of risk for acquisition of IE. These factors complicate an accurate assessment of the true lifetime risk of acquisition of IE in patients with a specific underlying cardiac condition.

On the basis of the data from Steckelberg and Wilson[91] and others,[2] it is clear that the underlying conditions discussed above represent a lifetime increased risk of acquisition of IE compared with individuals with no known underlying cardiac condition. Accordingly, when utilizing previous AHA guidelines in the decision to recommend IE prophylaxis for a patient scheduled to undergo a dental, GI tract, or GU tract procedure, healthcare providers were required to base their decision on population-based studies of risk of acquisition of IE that may or may not be relevant to their specific patient. Furthermore, practitioners had to weigh the potential efficacy of IE prophylaxis in a patient who may neither need nor benefit from such therapy against the risk of adverse reaction to the antibiotic prescribed. Finally, healthcare providers had to consider the potential medicolegal risk of not prescribing IE prophylaxis. For dental procedures, there is a growing body of evidence that suggests that IE prophylaxis may prevent only an exceedingly small number of cases of IE, as discussed in detail above.

Cardiac Conditions Associated With the Highest Risk of Adverse Outcome From Endocarditis

Endocarditis, irrespective of the underlying cardiac condition, is a serious, life-threatening disease that was always fatal in

TABLE 3. Cardiac Conditions Associated With the Highest Risk of Adverse Outcome From Endocarditis for Which Prophylaxis With Dental Procedures Is Recommended

Prosthetic cardiac valve
Previous IE
Congenital heart disease (CHD)*
Unrepaired cyanotic CHD, including palliative shunts and conduits
Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 months after the procedure†
Repaired CHD with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialization)
Cardiac transplantation recipients who develop cardiac valvulopathy

*Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.

†Prophylaxis is recommended because endothelialization of prosthetic material occurs within 6 months after the procedure.

the preantibiotic era. Advances in antimicrobial therapy, early recognition and management of complications of IE, and improved surgical technology have reduced the morbidity and mortality of IE. Numerous comorbid factors, such as older age, diabetes mellitus, immunosuppressive conditions or therapy, and dialysis, may complicate IE. Each of these comorbid conditions independently increases the risk of adverse outcome from IE, and they often occur in combination, which further increases morbidity and mortality rates. Additionally, there may be long-term consequences of IE. Over time, the cardiac valve damaged by IE may undergo progressive functional deterioration that may result in the need for cardiac valve replacement.

In native valve viridans group streptococcal or enterococcal IE, the spectrum of disease may range from a relatively benign infection to severe valvular dysfunction, dehiscence, congestive heart failure, multiple embolic events, and death; however, the underlying conditions shown in Table 3 virtually always have an increased risk of adverse outcome. For example, patients with viridans group streptococcal prosthetic valve endocarditis have a mortality rate of ≈20% or greater,[106–109] whereas the mortality from patients with viridans group streptococcal native valve IE is 5% or less.[108,110–116] Similarly, the mortality of enterococcal prosthetic valve endocarditis is higher than that of native valve enterococcal IE.[107,108,114,117] Moreover, patients with prosthetic valve endocarditis are more likely than those with native valve endocarditis to develop heart failure, the need for cardiac valve replacement surgery, perivalvular extension of infection, and other complications.

Patients with relapsing or recurrent IE are at greater risk of congestive heart failure and increased need for cardiac valve replacement surgery, and they have a higher mortality rate than patients with a first episode of native valve IE.[118–124] Additionally, patients with multiple episodes of native or prosthetic valve IE are at greater risk of additional episodes of endocarditis, each of which is associated with the risk of more serious complications.[90]

Published series regarding endocarditis in patients with CHD are underpowered to determine the extent to which a specific form of CHD is an independent risk factor for morbidity and mortality. Nevertheless, most retrospective case series suggest that patients with complex cyanotic heart disease and those who have postoperative palliative shunts, conduits, or other prostheses have a high lifetime risk of acquiring IE, and these same groups appear at highest risk for morbidity and mortality among all patients with CHD.[125–129] In addition, multiple series and reviews reported that the presence of prosthetic material[130,131] and complex cyanotic heart disease in patients of very young age (newborns and infants <2 years of age)[132,133] are 2 factors associated with the worst prognoses from IE. Some types of CHD may be repaired completely without residual cardiac defects. As shown in Table 3, the Committee recommends prophylaxis for dental procedures for these patients during the first 6 months after the procedure. In these patients, endothelialization of prosthetic material or devices occurs within 6 months after the procedure.[134] The Committee does not recommend prophylaxis for dental procedures more than 6 months after the procedure provided that there is no residual defect from the repair. In most instances, treatment of patients who have infected prosthetic materials requires surgical removal in addition to medical therapy with associated high morbidity and mortality rates.

Should IE Prophylaxis Be Recommended for Patients With the Highest Risk of Acquisition of IE or for Patients With the Highest Risk of Adverse Outcome From IE?

In a major departure from previous AHA guidelines, the Committee no longer recommends IE prophylaxis based solely on an increased lifetime risk of acquisition of IE. It is noteworthy that patients with the conditions listed in Table 3 with a prosthetic cardiac valve, those with a previous episode of IE, and some patients with CHD are also among those patients with the highest lifetime risk of acquisition of endocarditis. No published data demonstrate convincingly that the administration of prophylactic antibiotics prevents IE associated with bacteremia from an invasive procedure. We cannot exclude the possibility that there may be an exceedingly small number of cases of IE that could be prevented by prophylactic antibiotics in patients who undergo an invasive procedure. However, if prophylaxis is effective, such therapy should be restricted to those patients with the highest risk of adverse outcome from IE who would derive the greatest benefit from prevention of IE. In patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (Table 3), IE prophylaxis for dental procedures may be reasonable, even though we acknowledge that its effectiveness is unknown **(*Class IIb, LOE B*)**.

Compared with previous AHA guidelines, under these revised guidelines, many fewer patients would be candidates to receive IE prophylaxis. We believe that these revised guidelines are in the best interest of patients and healthcare providers and are based on the best available published data and expert opinion. Additionally, the change in emphasis to recommend prophylaxis for only those patients with the highest risk of adverse outcome should reduce the uncertainties among patients and providers about who should receive

prophylaxis. MVP is the most common underlying condition that predisposes to acquisition of IE in the Western world; however, the absolute incidence of endocarditis is extremely low for the entire population with MVP, and it is not usually associated with the grave outcome associated with the conditions identified in Table 3. Thus, IE prophylaxis is no longer recommended for this group of individuals.

Finally, the administration of prophylactic antibiotics is not risk free, as discussed above. Additionally, the widespread use of antibiotic therapy promotes the emergence of resistant microorganisms most likely to cause endocarditis, such as viridans group streptococci and enterococci. The frequency of multidrug-resistant viridans group streptococci and enterococci has increased dramatically during the past 2 decades. This increased resistance has reduced the efficacy and number of antibiotics available for the treatment of IE.

Regimens Recommended

General Principles

An antibiotic for prophylaxis should be administered in a single dose before the procedure. If the dosage of antibiotic is *inadvertently* not administered before the procedure, the dosage may be administered up to 2 hours after the procedure. However, administration of the dosage after the procedure should be considered only when the patient did not receive the pre-procedure dose. Some patients who are scheduled for an invasive procedure may have a coincidental endocarditis. The presence of fever or other manifestations of systemic infection should alert the provider to the possibility of IE. In these circumstances, it is important to obtain blood cultures and other relevant tests before administration of antibiotics intended to prevent IE. Failure to do so may result in delay in diagnosis or treatment of a concomitant case of IE.

Regimens for Dental Procedures

Previous AHA guidelines on prophylaxis listed a substantial number of dental procedures and events for which antibiotic prophylaxis was recommended and those procedures for which prophylaxis was not recommended. On the basis of a critical review of the published data, it is clear that transient viridans group streptococcal bacteremia may result from any dental procedure that involves manipulation of the gingival or periapical region of teeth or perforation of the oral mucosa. It cannot be assumed that manipulation of a healthy-appearing mouth or a minimally invasive dental procedure reduces the likelihood of a bacteremia. Therefore, antibiotic prophylaxis is recommended for patients with the conditions listed in Table 3 who undergo any dental procedure that involves the gingival tissues or periapical region of a tooth and for those procedures that perforate the oral mucosa (Table 4). Although IE prophylaxis may be reasonable for these patients, its effectiveness is unknown **(*Class IIb, LOE C*)**. This includes procedures such as biopsies, suture removal, and placement of orthodontic bands, but it does not include routine anesthetic injections through noninfected tissue, the taking of dental radiographs, placement of removable prosthodontic or orthodontic appliances, placement of orthodontic brackets, or adjustment of orthodontic appliances. Finally, there are other events that are not dental procedures and for which prophylaxis is not recommended, such as shedding of deciduous teeth and trauma to the lips and oral mucosa.

TABLE 4. Dental Procedures for Which Endocarditis Prophylaxis Is Recommended for Patients in Table 3

All dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa*

*The following procedures and events do not need prophylaxis: routine anesthetic injections through noninfected tissue, taking dental radiographs, placement of removable prosthodontic or orthodontic appliances, adjustment of orthodontic appliances, placement of orthodontic brackets, shedding of deciduous teeth, and bleeding from trauma to the lips or oral mucosa.

In this limited patient population, prophylactic antimicrobial therapy should be directed against viridans group streptococci. During the past 2 decades, there has been a significant increase in the percentage of strains of viridans group streptococci resistant to antibiotics recommended in previous AHA guidelines for the prevention of IE. Prabhu et al[135] studied susceptibility patterns of viridans group streptococci recovered from patients with IE diagnosed during a period from 1971 to 1986 and compared these susceptibilities with those of viridans group streptococci from patients with IE diagnosed from 1994 to 2002. In that study, none of the strains of viridans group streptococci were penicillin resistant in the early time period compared with 13% of strains that were intermediately or fully penicillin resistant during the later time period. In that study, macrolide resistance increased from 11% to 26% and clindamycin resistance from 0% to 4%.

Among 352 blood culture isolates of viridans group streptococci, resistance rates were 13% for penicillin, 15% for amoxicillin, 17% for ceftriaxone, 38% for erythromycin, and 96% for cephalexin.[136] The rank order of decreasing level of activity of cephalosporins in that study was cefpodoxime equal to ceftriaxone, greater than cefprozil, and equal to cefuroxime, and cephalexin was the least active. In other studies, resistance of viridans group streptococci to penicillin ranged from 17% to 50%[137i,142] and resistance to ceftriaxone ranged from 22% to 42%.[131,140] Ceftriaxone was 2 to 4 times more active in vitro than cefazolin.[131,140] Similarly high rates of resistance were reported for macrolides, ranging from 22% to 58%[137,141,143,144]; resistance to clindamycin ranged from 13% to 27%.[128,129,131,137,138,140]

Most of the strains of viridans group streptococci in the above-cited studies were recovered from patients with serious underlying illnesses, including malignancies and febrile neutropenia. These patients are at increased risk of infection and colonization by multiple-drugï resistant microorganisms, including viridans group streptococci. Accordingly, these strains may not be representative of susceptibility patterns of viridans group streptococci recovered from presumably normal individuals who undergo a dental procedure. Diekema et al[137] reported that 32% of strains of viridans group streptococci were resistant to penicillin in patients without cancer. King et al[144] reported erythromycin resistance in 41% of streptococci recovered from throat cultures in otherwise healthy individuals who presented with mild respiratory tract infections. In that study, after treatment with either azithromycin or clindamycin, the percentage of resistant streptococci increased to 82% and 71%, respectively. Accordingly, the

TABLE 5. Regimens for a Dental Procedure

Situation	Agent	Regimen: Single Dose 30 to 60 min Before Procedure	
		Adults	Children
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medication	Ampicillin	2 g IM or IV	50 mg/kg IM or IV
	OR		
	Cefazolin or ceftriaxone	1 g IM or IV	50 mg/kg IM or IV
Allergic to penicillins or ampicillin—oral	Cephalexin*†	2 g	50 mg/kg
	OR		
	Clindamycin	600 mg	20 mg/kg
	OR		
	Azithromycin or clarithromycin	500 mg	15 mg/kg
Allergic to penicillins or ampicillin and unable to take oral medication	Cefazolin or ceftriaxone†	1 g IM or IV	50 mg/kg IM or IV
	OR		
	Clindamycin	600 mg IM or IV	20 mg/kg IM or IV

IM indicates intramuscular; IV, intravenous.

*Or other first- or second-generation oral cephalosporin in equivalent adult or pediatric dosage.

†Cephalosporins should not be used in an individual with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

resistance rates of viridans group streptococci are similarly high in otherwise healthy individuals and in patients with serious underlying diseases.

The impact of viridans group streptococcal resistance on antibiotic prevention of IE is unknown. If resistance in vitro is predictive of lack of clinical efficacy, the high resistance rates of viridans group streptococci provide additional support for the assertion that prophylactic therapy for a dental procedure is of little, if any, value. It is impractical to recommend prophylaxis with only those antibiotics, such as vancomycin or a fluoroquinolone, that are highly active in vitro against viridans group streptococci. There is no evidence that such therapy is effective for prophylaxis of IE, and their use might result in the development of resistance of viridans group streptococci and other microorganisms to these and other antibiotics.

In Table 5, amoxicillin is the preferred choice for oral therapy because it is well absorbed in the GI tract and provides high and sustained serum concentrations. For individuals who are allergic to penicillins or amoxicillin, the use of cephalexin or another first-generation oral cephalosporin, clindamycin, azithromycin, or clarithromycin is recommended. Even though cephalexin was less active against viridans group streptococci than other first-generation oral cephalosporins in 1 study,[136] cephalexin is included in Table 5. No data show superiority of 1 oral cephalosporin over another for prevention of IE, and generic cephalexin is widely available and relatively inexpensive. Because of possible cross-reactions, a cephalosporin should not be administered to patients with a history of anaphylaxis, angioedema, or urticaria after treatment with any form of penicillin, including ampicillin or amoxicillin. Patients who are unable to tolerate an oral antibiotic may be treated with ampicillin, ceftriaxone, or cefazolin administered intramuscularly or intravenously. For ampicillin-allergic patients who are unable to tolerate an oral agent, therapy is recommended with parenteral cefazolin, ceftriaxone, or clindamycin.

Regimens for Respiratory Tract Procedures

A variety of respiratory tract procedures reportedly cause transient bacteremia with a wide array of microorganisms[1]; however, no published data conclusively demonstrate a link between these procedures and IE. Antibiotic prophylaxis with a regimen listed in Table 5 may be considered **(*Class IIb, LOE C*)** for patients with the conditions listed in Table 3 who undergo an invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy. We do not recommend antibiotic prophylaxis for bronchoscopy unless the procedure involves incision of the respiratory tract mucosa. For patients listed in Table 3 who undergo an invasive respiratory tract procedure to treat an established infection, such as drainage of an abscess or empyema, we recommend that the antibiotic regimen administered to these patients contain an agent active against viridans group streptococci (Table 5). If the infection is known or suspected to be caused by *Staphylococcus aureus*, the regimen should contain an agent active against *S aureus*, such as an antistaphylococcal penicillin or cephalosporin, or vancomycin in patients unable to tolerate a β-lactam. Vancomycin should be administered if the infection is known or suspected to be caused by a methicillin-resistant strain of *S aureus*.

Recommendations for GI or GU Tract Procedures

Enterococci are part of the normal flora of the GI tract. These microorganisms may cause intra-abdominal infection or infection of the hepatobiliary system. Such infections are often polymicrobial, with a mix of aerobic and anaerobic Gram-negative and Gram-positive microorganisms, but among these varied bacteria, only enterococci are likely to cause IE. Enterococci may cause urinary tract infections, particularly in older males with prostatic hypertrophy and obstructive uropathy or prostatitis.

The administration of prophylactic antibiotics solely to prevent endocarditis is not recommended for patients who

undergo GU or GI tract procedures, including diagnostic esophagogastroduodenoscopy or colonoscopy **(*Class III, LOE B*)**. This is in contrast to previous AHA guidelines that listed GI or GU tract procedures for which IE prophylaxis was recommended and those for which prophylaxis was not recommended.[1] A large number of diagnostic and therapeutic procedures that involve the GI, hepatobiliary, or GU tract may cause transient enterococcal bacteremia. The possible association between GI or GU tract procedures and IE has not been studied as extensively as the possible association with dental procedures.[145] The cases of IE temporally associated with a GI or GU tract procedure are anecdotal, with either a single or very small number of cases reported.[83] No published data demonstrate a conclusive link between procedures of the GI or GU tract and the development of IE.[145] Moreover, no studies exist that demonstrate that the administration of antimicrobial prophylaxis prevents IE in association with procedures performed on the GI or GU tract.

There has been a dramatic increase in the frequency of antimicrobial-resistant strains of enterococci to penicillins, vancomycin, and aminoglycosides.[146–151] These antibiotics were recommended for IE prophylaxis in previous AHA guidelines.[1] The significance of the increased frequency of multiresistant strains of enterococci on prevention of IE in patients who undergo GI or GU tract procedures is unknown. The high prevalence of resistant strains of enterococci adds further doubt about the efficacy of prophylactic therapy for GI or GU tract procedures.

Patients with infections of the GI or GU tract may have intermittent or sustained enterococcal bacteremia. For patients with the conditions listed in Table 3 who have an established GI or GU tract infection or for those who receive antibiotic therapy to prevent wound infection or sepsis associated with a GI or GU tract procedure, it may be reasonable that the antibiotic regimen include an agent active against enterococci, such as penicillin, ampicillin, piperacillin, or vancomycin **(*Class IIb, LOE B*)**; however, no published studies demonstrate that such therapy would prevent enterococcal IE.

For patients with the conditions listed in Table 3 scheduled for an elective cystoscopy or other urinary tract manipulation who have an enterococcal urinary tract infection or colonization, antibiotic therapy to eradicate enterococci from the urine before the procedure may be reasonable **(*Class IIb, LOE B*)**. If the urinary tract procedure is not elective, it may be reasonable that the empiric or specific antimicrobial regimen administered to the patient contain an agent active against enterococci **(*Class IIb, LOE B*)**.

Amoxicillin or ampicillin is the preferred agent for enterococcal coverage for these patients. Vancomycin may be administered to patients unable to tolerate ampicillin. If infection is caused by a known or suspected strain of resistant enterococcus, consultation with an infectious diseases expert is recommended.

Recommendations for Procedures on Infected Skin, Skin Structure, or Musculoskeletal Tissue

These infections are often polymicrobial, but only staphylococci and β-hemolytic streptococci are likely to cause IE. For patients with the conditions listed in Table 3 who undergo a surgical procedure that involves infected skin, skin structure, or musculoskeletal tissue, it is reasonable that the therapeutic regimen administered for treatment of the infection contain an agent active against staphylococci and β-hemolytic streptococci, such as an antistaphylococcal penicillin or a cephalosporin (Table 5 for dosage; ***Class IIb, LOE C***). Vancomycin or clindamycin may be administered to patients unable to tolerate a β-lactam or who are known or suspected to have an infection caused by a methicillin-resistant strain of staphylococcus.

A summary of the major changes in these updated recommendations for prevention of IE compared with previous AHA recommendations is shown in Table 6.

TABLE 6. Summary of Major Changes in Updated Document

We concluded that bacteremia resulting from daily activities is much more likely to cause IE than bacteremia associated with a dental procedure.
We concluded that only an extremely small number of cases of IE might be prevented by antibiotic prophylaxis even if prophylaxis is 100% effective.
Antibiotic prophylaxis is not recommended based solely on an increased lifetime risk of acquisition of IE.
Limit recommendations for IE prophylaxis only to those conditions listed in Table 3.
Antibiotic prophylaxis is no longer recommended for any other form of CHD, except for the conditions listed in Table 3.
Antibiotic prophylaxis is recommended for all dental procedures that involve manipulation of gingival tissues or periapical region of teeth or perforation of oral mucosa only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (Table 3).
Antibiotic prophylaxis is recommended for procedures on respiratory tract or infected skin, skin structures, or musculoskeletal tissue only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (Table 3).
Antibiotic prophylaxis solely to prevent IE is not recommended for GU or GI tract procedures.
The writing group reaffirms the procedures noted in the 1997 prophylaxis guidelines for which endocarditis prophylaxis is not recommended and extends this to other common procedures, including ear and body piercing, tattooing, and vaginal delivery and hysterectomy.

Specific Situations and Circumstances

Patients Already Receiving Antibiotics

If a patient is already receiving long-term antibiotic therapy with an antibiotic that is also recommended for IE prophylaxis for a dental procedure, it is prudent to select an antibiotic from a different class rather than to increase the dosage of the current antibiotic. For example, antibiotic regimens used to prevent the recurrence of acute rheumatic fever are administered in dosages lower than those recommended for the prevention of IE. Individuals who take an oral penicillin for secondary prevention of rheumatic fever or for other purposes are likely to have viridans group streptococci in their oral cavity that are relatively resistant to penicillin or amoxicillin. In such cases, the provider should select either clindamycin, azithromycin, or clarithromycin for IE prophylaxis for a dental procedure, but only for patients shown in Table 3. Because of possible cross-resistance of viridans

group streptococci with cephalosporins, this class of antibiotics should be avoided. If possible, it would be preferable to delay a dental procedure until at least 10 days after completion of the antibiotic therapy. This may allow time for the usual oral flora to be reestablished.

Patients receiving parenteral antibiotic therapy for IE may require dental procedures during antimicrobial therapy, particularly if subsequent cardiac valve replacement surgery is anticipated. In these cases, the parenteral antibiotic therapy for IE should be continued and the timing of the dosage adjusted to be administered 30 to 60 minutes before the dental procedure. This parenteral antimicrobial therapy is administered in such high doses that the high concentration would overcome any possible low-level resistance developed among mouth flora (unlike the concentration that would occur after oral administration).

Patients Who Receive Anticoagulants

Intramuscular injections for IE prophylaxis should be avoided in patients who are receiving anticoagulant therapy **(*Class I, LOE A*)**. In these circumstances, orally administered regimens should be given whenever possible. Intravenously administered antibiotics should be used for patients who are unable to tolerate or absorb oral medications.

Patients Who Undergo Cardiac Surgery

A careful preoperative dental evaluation is recommended so that required dental treatment may be completed whenever possible before cardiac valve surgery or replacement or repair of CHD. Such measures may decrease the incidence of late prosthetic valve endocarditis caused by viridans group streptococci.

Patients who undergo surgery for placement of prosthetic heart valves or prosthetic intravascular or intracardiac materials are at risk for the development of infection.[152] Because the morbidity and mortality of infection in these patients are high, perioperative prophylactic antibiotics are recommended **(*Class I, LOE B*)**. Early-onset prosthetic valve endocarditis is most often caused by *S aureus*, coagulase-negative staphylococci, or diphtheroids. No single antibiotic regimen is effective against all these microorganisms. Prophylaxis at the time of cardiac surgery should be directed primarily against staphylococci and should be of short duration. A first-generation cephalosporin is most often used, but the choice of an antibiotic should be influenced by the antibiotic susceptibility patterns at each hospital. For example, a high prevalence of infection by methicillin-resistant *S aureus* should prompt the consideration of the use of vancomycin for perioperative prophylaxis. The majority of nosocomial coagulase-negative staphylococci are methicillin-resistant. Nonetheless, surgical prophylaxis with a first-generation cephalosporin is recommended for these patients **(*Class I, LOE A*)**.[107] In hospitals with a high prevalence of methicillin-resistant strains of *S epidermidis*, surgical prophylaxis with vancomycin is reasonable but has not been shown to be superior to prophylaxis with a cephalosporin **(*Class IIB, LOE C*)**. Prophylaxis should be initiated immediately before the operative procedure, repeated during prolonged procedures to maintain serum concentrations intraoperatively, and continued for no more than 48 hours postoperatively to minimize emergence of resistant microorganisms **(*Class IIa, LOE B*)**. The effects of cardiopulmonary bypass and compromised renal function on antibiotic concentrations in serum should be considered and dosages adjusted as necessary before and during the procedure.

Other Considerations

There is no evidence that coronary artery bypass graft surgery is associated with a long-term risk for infection. Therefore, antibiotic prophylaxis for dental procedures is not needed for individuals who have undergone this surgery. Antibiotic prophylaxis for dental procedures is not recommended for patients with coronary artery stents **(*Class III, LOE C*)**. The treatment and prevention of infection for these and other endovascular grafts and prosthetic devices are addressed in a separate AHA publication.[152] There are insufficient data to support specific recommendations for patients who have undergone heart transplantation. Such patients are at risk of acquired valvular dysfunction, especially during episodes of rejection. Endocarditis that occurs in a heart transplant patient is associated with a high risk of adverse outcome (Table 3).[153] Accordingly, the use of IE prophylaxis for dental procedures in cardiac transplant recipients who develop cardiac valvulopathy may be reasonable, but the usefulness is not well established **(*Class IIb, LOE C*;** Table 4). The use of prophylactic antibiotics to prevent infection of joint prostheses during potentially bacteremia-inducing procedures is not within the scope of this document.

Future Considerations

Prospective placebo-controlled, double-blinded studies of antibiotic prophylaxis of IE in patients who undergo a bacteremia-producing procedure would be necessary to evaluate accurately the efficacy of IE prophylaxis. Additional prospective case-control studies are needed. The AHA has made substantial revisions to previously published guidelines on IE prophylaxis. Given our current recommendations, we anticipate that significantly fewer patients will receive IE prophylaxis for a dental procedure. Studies are necessary to monitor the effects, if any, of these recommended changes in IE prophylaxis. The incidence of IE could change or stay the same. Because the incidence of IE is low, small changes in incidence may take years to detect. Accordingly, we urge that such studies be designed and instituted promptly so that any change in incidence may be detected sooner rather than later. Subsequent revisions of the AHA guidelines on the prevention of IE will be based on the results of these studies and other published data.

Acknowledgments

The writing group thanks the following international experts on infective endocarditis for their valuable comments: Drs Christa Gohlke-Bärwolf, Roger Hall, Jae-Hoon Song, Catherine Kilmartin, Catherine Leport, José M. Miró, Christoph Naber, Graham Roberts, and Jan T.M. van der Meer. The writing group also thanks Dr George Meyer for his helpful comments regarding gastroenterology. Finally, the writing group would like to thank Lori Hinrichs for her superb assistance with the preparation of this manuscript.

Correction

In the AHA Guideline by Wilson et al, ñPrevention of Infective Endocarditis: Guidelines From the American Heart Association: A Guideline From the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council on Cardiovascular Surgery and Anesthesia, and the Quality of Care and Outcomes Research Interdisciplinary Working Group,ò that published online on April 19, 2007 (DOI: 10.1161/CIRCULATIONAHA.106.183095), several changes are needed. After online publication of these guidelines, the writing group was made aware that there was confusion among the readership regarding the use of the language ñRecommendedò in the title of Tables 3 and 4 and ñmay be reasonableò or ñmay be consideredò in the text when referring to our Class IIb recommendations. The writing group has clarified this by revising the wording in the tables and changing the language in the text to ñis reasonable.ò According to existing American Heart Association policy for wording of classes of recommendations, this change in language is accompanied by a shift in the class of recommendation from IIb to IIa as detailed in the errata.

1. Since the online publication of this article, the American Academy of Pediatrics and the International Society of Chemotherapy for Infection and Cancer* have added their endorsements.
2. On page 1736, in the footnotes section, the following footnote applies to the endorsement by the International Society of Chemotherapy for Infection and Cancer: ñ*If these guidelines are applied outside of the United States of America, adaptation of the recommended antibiotic agents may be considered with respect to the regional situation.ò
3. On page 1737, in the Conclusions part of the abstract, the following items have been modified: ñ(2) Infective endocarditis prophylaxis for dental procedures is reasonable only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from infective endocarditis. (3) For patients with these underlying cardiac conditions, prophylaxis is reasonable for all dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa.ò
4. In Table 3 on page 1745, the following items have been modified:
   a. The title now reads: ñCardiac Conditions Associated With the Highest Risk of Adverse Outcome From Endocarditis for Which Prophylaxis With Dental Procedures Is Reasonableò
   b. The first entry now reads: ñProsthetic cardiac valve or prosthetic material used for cardiac valve repairò
   c. The second footnote now reads: ñÀProphylaxis is reasonable because endothelialization of prosthetic material occurs within 6 months after the procedure.ò
5. On page 1745, second column, second paragraph, the fifth sentence has been modified to read: ñAs shown in Table 3, the Committee concludes that prophylaxis is reasonable for dental procedures for these patients during the first 6 months after the procedure.ò
6. On page 1745, second column, third paragraph, the last sentence has been modified to read: ñIn patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (Table 3), IE prophylaxis for dental procedures is reasonable, even though we acknowledge that its effectiveness is unknown **(*Class IIa, LOE B*)**.
7. On page 1746, first column, first full paragraph, the third sentence has been modified to read: ñAdditionally, the change in emphasis to restrict prophylaxis for only those patients with the highest risk of adverse outcome should reduce the uncertainties among patients and providers about who should receive. . ..ò
8. On page 1746, first column, the section heading has been modified from ñRegimens Recommendedò to ñAntibiotic Regimens.ò

(*Circulation.* 2007;116:e376-e377.)

***Circulation* is available at http://circ.ahajournals.org**

9. On page 1746, first column, fourth paragraph, the fourth and fifth sentences have been modified to read: ñTherefore, antibiotic prophylaxis is reasonable for patients with the conditions listed in Table 3 who undergo any dental procedure that involves the gingival tissues or periapical region of a tooth and for those procedures that perforate the oral mucosa (Table 4). Although IE prophylaxis is reasonable for these patients, its effectiveness is unknown **(*Class IIa, LOE C*)**.ò
10. For Table 4 on page 1746, the title has been changed to: ñDental Procedures for Which Endocarditis Prophylaxis Is Reasonable for Patients in Table 3.ò
11. On page 1747, second column, under the ñRegimens for Respiratory Tract Proceduresò heading, the second sentence has been modified to read: ñAntibiotic prophylaxis with a regimen listed in Table 5 is reasonable **(*Class IIa, LOE C*)** for patients with the conditions listed in Table 3 who undergo an invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy.ò
12. In Table 6 on page 1748, the following items have been updated:
    a. The sixth entry should read: ñAntibiotic prophylaxis is reasonable for all dental procedures that involve manipulation of gingival tissues. . . .ò
    b. The seventh entry should read: ñAntibiotic prophylaxis is reasonable for procedures on respiratory tract or infected skin, skin structures, or musculoskeletal. . ..ò
    c. The last entry should read: ñAlthough these guidelines recommend changes in indications for IE prophylaxis with regard to selected dental procedures (see text), the writing group reaffirms that those medical procedures listed as not requiring IE prophylaxis in the 1997 statement remain unchanged and extends this view to vaginal delivery and hysterectomy and tattooing. Additionally, the committee advises against body piercing for patients in Table 3 because of the possibility of bacteremia, while recognizing there are minimal published data regarding the risk of bacteremia or endocarditis associated with body piercing.ò
13. On page 1748, second column, the heading at the top of the column has been modified to read: ñRegimens for Procedures on Infected Skin, Skin Structure, or Musculoskeletal Tissueò.
14. On page 1748, second column, first paragraph, the second sentence has been modified to read: ñFor patients with the conditions listed in Table 3 who undergo a surgical procedure that involves infected skin, skin structure, or musculoskeletal tissue, it may be reasonable that the therapeutic regimen administered for treatment of the infection contain an agent active against staphylococci. . . .ò
15. On page 1749, first column, last paragraph, the last sentence has been modified to read: ñIn hospitals with a high prevalence of methicillin-resistant strains of *S epidermidis*, surgical prophylaxis with vancomycin may be reasonable but has not been shown to be superior to prophylaxis. . ..ò
16. On page 1749, second column, under the heading ñOther Considerationsò, the penultimate sentence has been modified to read: ñAccordingly, the use of IE prophylaxis for dental procedures in cardiac transplant recipients who develop cardiac valvulopathy is reasonable, but the usefulness is not well established (***Class IIa, LOE C***; Table 4).ò

These changes have been made in the current print (*Circulation*. 2007;116:1736ï 1754) and online versions of the article.

POLICY STATEMENT

Prevention and Management of Pain in the Neonate: An Update

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

AMERICAN ACADEMY OF PEDIATRICS
Committee on Fetus and Newborn and Section on Surgery

CANADIAN PAEDIATRIC SOCIETY
Fetus and Newborn Committee

ABSTRACT

The prevention of pain in neonates should be the goal of all caregivers, because repeated painful exposures have the potential for deleterious consequences. Neonates at greatest risk of neurodevelopmental impairment as a result of preterm birth (ie, the smallest and sickest) are also those most likely to be exposed to the greatest number of painful stimuli in the NICU. Although there are major gaps in our knowledge regarding the most effective way to prevent and relieve pain in neonates, proven and safe therapies are currently underused for routine minor yet painful procedures. Every health care facility caring for neonates should implement an effective pain-prevention program, which includes strategies for routinely assessing pain, minimizing the number of painful procedures performed, effectively using pharmacologic and nonpharmacologic therapies for the prevention of pain associated with routine minor procedures, and eliminating pain associated with surgery and other major procedures.

INTRODUCTION

Objectives

This updated statement is intended for health care professionals who care for neonates (preterm to 1 month of age). The objectives are to:

1. emphasize that despite increased awareness of the importance of pain prevention, neonates in the NICU continue to be exposed to numerous painful minor procedures daily as part of their routine care;
2. present objective means of assessing neonatal pain by health care professionals;
3. describe effective strategies to prevent and treat pain associated with routine minor procedures; and
4. review appropriate methods to prevent and treat pain associated with surgery and other major procedures.

Background

The prevention of pain in neonates is an expectation of parents.[1] However, there are major gaps in our knowledge regarding the most effective way to accomplish this. Although it may not be possible to completely eliminate pain in neonates, much can be done to reduce the amount and intensity of pain. The prevention of

Key Words
pain, neonates

Abbreviations
IVH—intraventricular hemorrhage
PVL—periventricular leukomalacia
ROP—retinopathy of prematurity

pain is important not only because it is an ethical expectation but also because repeated painful exposures can have deleterious consequences.[2–21] These consequences include altered pain sensitivity[5,7–9] (which may last into adolescence[15]) and permanent neuroanatomic and behavioral abnormalities, as found in animal studies.[5,14] It seems that altered pain sensitivity can be ameliorated if effective pain relief is provided.[7,17] There is growing concern that the long-term consequences of repeated pain in vulnerable neonates may also include emotional, behavioral, and learning disabilities[3,4,6,10,13,16]; however, there are no definitive data in humans. During the last few years, there has been considerable interest in the diagnosis and treatment of acute pain in the neonate, but there has been little published on the related subjects of stress and chronic pain in this population. In the original statement, stress and chronic pain were briefly discussed in addition to acute pain.[2] However, neither chronic pain nor stress has been specifically defined for the neonate, and only an intuitive understanding of these concepts is possible. Therefore, this updated statement deals primarily with acute pain prevention.

Neonates at greatest risk of neurodevelopmental impairment as a result of preterm birth (ie, the smallest and sickest neonates) are also those most likely to be exposed to the greatest number of painful stimuli in the NICU,[18] creating a "double-hit" phenomenon. Although effective pain relief is now usually provided for neonates during and after a major surgical procedure,[21] pain-reducing therapies are often underused for the numerous minor procedures that are a part of routine medical and nursing care for neonates.[20,21] Because the most effective and safest ways to prevent pain in the neonate are unknown, striking a proper balance between effective pain relief and avoidance of serious adverse effects from pain medications is a major challenge for caregivers. The subject of pain in the neonate was recently the focus of the Newborn Drug Development Workshop sponsored by the National Institute of Child Health and Human Development and the US Food and Drug Administration. The reader is referred to their publications for a detailed review and their discussions.[22–24]

ASSESSMENT OF PAIN AND STRESS IN THE NEONATE

Optimal pain management requires competent pain assessment, which can be especially difficult to perform in neonates. The pain-assessment tool used should be multidimensional, including measurements for both physiologic and behavioral indicators of pain, because neonates cannot self-report.[25–29] Physiologic indicators of pain include changes in heart rate, respiratory rate, blood pressure, oxygen saturation, vagal tone, palmar sweating, and plasma cortisol or catecholamine concentrations. Behavioral indicators include changes in facial expressions, body movements, and crying, but these may be absent in some neonates who are neurologically impaired or pharmacologically paralyzed.

When pain is prolonged, striking changes occur in the infant's physiologic and behavioral indicators. During episodes of prolonged pain, neonates enter a state of passivity with few, if any, body movements; an expressionless face; decreased heart rate and respiratory variability; and decreased oxygen consumption, all suggestive of a marked conservation of energy. Prolonged or repeated pain also increases the response elicited by future painful stimuli (hyperalgesia) and even by usually nonpainful stimuli (allodynia). Therefore, pain scales that are used in postoperative neonates should be sensitive to the changes in response that can occur when pain is prolonged.[27]

The most commonly used assessment tools are listed in Table 1.[30–45] For each tool, the physiologic and behavioral indicators of pain are described, the population for which they have been validated are delineated, and unique aspects are listed. Whatever assessment tools are used, continual multidisciplinary training of staff in the recognition of neonatal pain and in the use of the chosen pain-assessment tools should be provided.[26] Although in recent years, increased interest and research in the assessment of pain and stress in the neonate has occurred, there remains a need to develop a tool to measure pain in pharmacologically paralyzed and severely neurologically impaired infants.[40]

REDUCING PAIN FROM BEDSIDE CARE PROCEDURES

Neonates in the NICU often experience painful procedures during routine care,[10,21] such as needle insertions,[46–51] suctioning,[47,52,53] gavage-tube placement,[51,52,54] and tape removal,[52] as well as stressful disruptions, including diaper changes,[54] chest physical therapy,[54] physical examinations,[51] nursing evaluations,[52] and exposure to environmental stimuli.[20] Despite increased awareness by caregivers that neonates in the NICU frequently experience pain, effective pain relief for these routine procedures is often underused.[20,21,55] As discussed more completely later, the continuous infusion of morphine in ventilated preterm neonates may not effectively prevent acute pain from minor painful procedures and may increase adverse events.[56,57] However, there are other effective methods of preventing minor procedural pain in neonates, which should be used routinely. As part of a comprehensive pain-prevention program,[19,58,59] each neonatal unit should develop strategies to minimize the number of minor painful or stressful procedures and provide effective nonpharmacologic and/or pharmacologic pain relief for all procedures.

Reduction of Painful Events

Clearly, the most effective way of reducing minor procedural pain in the neonate is to reduce the number of procedures performed.[58] There currently is a paucity of

TABLE 1 **Pain-Assessment Tools**

Assessment Tool	Physiologic Indicators	Behavioral Indicators	Gestational Age Tested	Assesses Sedation	Scoring Adjusts for Gestational Age	Nature of Pain Assessed
PIPP: Premature Infant Pain Profile	Heart rate, oxygen saturation	Brow bulge, eyes squeezed shut, nasolabial furrow	28–40 wk	No	Yes	Procedural and postoperative pain
CRIES: Crying, Requires Oxygen Saturation, Increased Vital Signs, Expression, Sleeplessness	Heart rate, oxygen saturation	Crying, facial expression, sleeplessness	32–36 wk	No	No	Postoperative pain
NIPS: Neonatal Infant Pain Scale	Respiratory patterns	Facial expression, cry, movements of arms and legs, state arousal	28–38 wk	No	No	Procedural pain
N-PASS: Neonatal Pain Agitation and Sedation Scale	Heart rate, respiratory rate, blood pressure, oxygen saturation	Crying, irritability, behavior state, extremities tone	0–100 d of age and adjusts score on the basis of gestational age	Yes	Yes	Ongoing and acute pain and sedation
NFCS: Neonatal Facing Coding System	None	Facial muscle group movement	Preterm and term neonates, infants at 4 mo of age	No	No	Procedural pain
PAT: Pain Assessment Tool	Respirations, heart rate, oxygen saturation, blood pressure	Posture, tone, sleep pattern, expression, color, cry	Neonates	No	No	Acute pain
SUN: Scale for Use in Newborns	Central nervous system state, breathing, heart rate, mean blood pressure	Movement, tone, face	Neonates	No	No	Acute pain
EDIN: Echelle de la Douleur Inconfort Nouveau-Ne' (Neonatal Pain and Discomfort Scale)	None	Facial activity, body movements, quality of sleep, quality of contact with nurses, consolability	25–36 wk (preterm infants)	No	No	Prolonged pain
BPSN: Bernese Pain Scale for Neonates	Heart rate, respiratory rate, blood pressure, oxygen saturation	Facial expression, body posture, movements, vigilance	Term and preterm neonates	No	No	Acute pain

research regarding effective ways to accomplish this, but strategies for reducing the number of procedures that neonates experience should be developed and their effectiveness should be tested.[55] Such an approach might include reducing the number of bedside disruptions in care.[55,60,61] Other strategies might include bundling interventions, eliminating unnecessary laboratory or radiographic procedures, using transcutaneous measurements when possible, and minimizing the number of repeat procedures performed after failed attempts.[58]

Nonpharmacologic Pain Prevention for Minor Procedures

A variety of nonpharmacologic pain-prevention and -relief techniques have been shown to effectively reduce pain from minor procedures in neonates. These include use of oral sucrose/glucose,[62–76] breastfeeding,[77] nonnutritive sucking,[49,78] "kangaroo care" (skin-to-skin contact),[55,58] facilitated tuck (holding the arms and legs in a flexed position),[79] swaddling,[80] and developmental care, which includes limiting environmental stimuli, lateral positioning, the use of supportive bedding, and attention to behavioral clues.[61] These measures have been shown to be useful in preterm and term neonates in reducing pain from a heel stick,[68,70–73,79,80] venipuncture,[62,64,65,67,74,77,81] and subcutaneous injections[81] and are generally more effective when used in combination than when used alone.[63,65,68,69,80,82] Concentrated oral sucrose has been widely studied. Oral sucrose eliminates the electroencephalographic changes associated with a painful procedure[83] in a neonate, but the mechanism of pain relief by sucking oral sucrose is not known for certain. In one study, endogenous endorphin concentrations did not increase with administration of oral sucrose as originally proposed.[84] Although the intraoral administration of sucrose to preterm infants without suckling is effective, intragastric administration is not.[72] Concentrated oral glucose has also been used and diminishes the pain response of venipuncture, but it does not decrease oxygen consumption or energy expenditure, suggesting there may still be a stress response.[85]

A wide range of oral sucrose doses have been used in neonates for pain relief, but an optimal dose has not been established.[75,86] The dosage range of sucrose for reducing pain in neonates is 0.012 to 0.12 g (0.05–0.5 mL of 24% solution).[75,86] Some authors have suggested that multiple doses for a procedure (2 minutes before and 1–2 minutes after) are more effective than a single dose.[73,75] The long-term safety of multiple doses of oral sucrose for painful procedures in neonates has not been established.[87] Additional research is needed to fully understand the mechanism of action, optimal dose, and safety of repeated doses of oral sucrose in neonates; nevertheless, available data suggest that this is an effective means of alleviating pain for many minor neonatal procedures. Because oral sucrose reduces but does not eliminate pain in neonates, it should be used with other nonpharmacologic measures to enhance its effectiveness.

Topical Anesthetic Pain Prevention for Minor Procedures

Topical anesthetics can effectively reduce pain from some procedures such as a venipuncture,[62,88–90] lumbar puncture,[91] and intravenous catheter insertion[91] in term and preterm neonates. These agents must be applied for a sufficient length of time before the procedure (usually 30 minutes for neonates), and they are not effective for a heel-stick blood draw,[92,93] because the pain from heel sticks is primarily from squeezing the heel and not from the lancet.[48] Other nonpharmacologic means of alleviating pain mentioned previously should be used for heel sticks. Topical anesthetics were not effective for peripheral intravenous central catheter placement in one trial.[94] There is a risk of methemoglobinemia after use of topical lidocaine-prilocaine cream in certain situations.[95,96] The risks can be minimized if used no more than once daily, on intact skin only, and not with other drugs known to cause methemoglobinemia.[97,98]

Prolonged Mechanical Ventilation

Many preterm neonates receiving intensive care undergo prolonged mechanical ventilation, and its use defines a population of patients experiencing numerous minor painful procedures as described previously. The routine use of continuous pain medication and sedatives for ventilated preterm neonates has been evaluated.[24] Two large randomized, controlled trials of the continuous use of intravenous morphine primarily as a potential means of decreasing poor neurologic outcome in preterm neonates receiving mechanical ventilation were published recently.[56,57] In both studies, additional open-label morphine was allowed if infants were considered to be in pain. In the first study,[56] continuous morphine infusion was used for 7 days or less as clinically needed. In this study, morphine had no apparent analgesic effect and did not alter the risk of a poor neurologic outcome (severe intraventricular hemorrhage [IVH], periventricular leukomalacia [PVL], or death). In the second study,[57] a continuous morphine infusion was used for up to 14 days. In this study, morphine use reduced pain scores slightly but did not alter the risk of severe IVH, cystic PVL, or a composite outcome (severe IVH, cystic PVL, or death within 28 days). In a subsequent analysis, the authors concluded that the use of morphine prolonged the duration of mechanical ventilation.[99] No large studies on the continuous infusion of fentanyl in ventilated preterm infants have been published, but the literature includes many smaller studies that have recently been reviewed.[24] In these studies, fentanyl seemed to result in increased ventilator settings.[24] Concern about adverse respiratory effects of continuous opioid infusions in chronically ventilated preterm infants and lack

of a demonstrated long-term benefit suggest that their routine use cannot be recommended at this time.

Midazolam has been evaluated as a sedative in mechanically ventilated preterm infants. A *Cochrane Database Systematic Review*[100] recently concluded that there were insufficient data to promote use of midazolam because of a lack of demonstrated benefit and concern for an increased risk of poor neurologic outcome. This conclusion was supported by another recent review.[24] Ketamine hydrochloride was evaluated in a randomized, controlled trial for relief of procedural pain associated with endotracheal suctioning in ventilated preterm neonates.[101] However, these authors concluded that ketamine was only modestly effective at reducing pain scores and did not alter physiologic responses in heart rate and systemic blood pressure.

REDUCING PAIN FROM SURGERY

Pain is an inevitable consequence of surgery at every age. Pain is of particular importance in the neonate because of the evidence of improved clinical outcomes, including decreased mortality, when adequate pain control is achieved.[19,102] Tissue injury, which occurs during all forms of surgery, elicits profound physiologic responses. The more marked these responses to surgery, the greater the morbidities and mortality.[103] Thus, minimizing the endocrine and metabolic responses to surgery by decreasing pain has been shown to significantly improve outcomes in neonatal surgery. Although it would now be considered unethical to perform surgery without anesthesia, the appropriate levels of anesthesia for various surgical procedures have not been well investigated. Improving pain management and improving outcomes in the neonate require a coordinated strategy of pain reduction, which must be multidimensional, requires a team approach, and should be a first priority in perioperative management. Despite fears that analgesics (opiates in particular) may lead to hypotension or respiratory depression and an increase in postoperative complications, such effects have never been shown in randomized, controlled trials. Indeed, postoperative inotrope requirements were decreased by high-dose opioids in neonates after cardiac surgery,[104] and postoperative respiratory compromise associated with the pain of a thoracotomy can be relieved by adequate analgesia.[105,106]

Because of the physiologic and metabolic immaturity of the neonate, doses of medications that are effective for the reduction of pain may be close to the doses that cause toxicity. Therefore, the concept of a "balanced analgesia" has arisen, whereby several approaches to pain reduction can be used simultaneously to decrease the dosage required of each medication and, thereby, reduce toxicity. Early and effective pain treatment is associated with a lower total dose of medications, although therapy should be guided by ongoing pain assessment. The developmental pharmacology of the agents used must also be kept in mind. For example, fentanyl, a drug that is metabolized rapidly in older infants, has a half-life averaging approximately 10 hours in the neonate,[107] and clearance is even lower in preterm infants.[108] The residual effects of intraoperative medications also need to be considered. Muscle relaxants completely prevent behavioral pain responses and may last for several hours postoperatively.

As far as possible, stress and preoperative pain should be relieved before surgical interventions. An infant who is stressed and disturbed, unclothed, hypothermic, overstimulated by noise and light, and already experiencing pain will have elevated basal concentrations of adrenal cortical and medullary hormones and will be susceptible to further stress and complications postoperatively. However, there has been little direct investigation of the effects of preoperative analgesia in neonates. A full discussion of intraoperative strategies to reduce pain in neonates is beyond the scope of this statement. However, anesthesia of sufficient depth to prevent intraoperative pain and stress responses must be provided to decrease postoperative analgesic requirements. For some procedures, regional anesthesia is an effective way of controlling intraoperative pain in neonates, but a detailed discussion about regional anesthesia is also beyond the scope of this statement.

Postoperatively, opioids can be given by continuous infusion or by regular bolus. Randomized trials do not show any substantial benefit of continuous infusion of opioids over intermittent dosing, probably because of the long half-life of many of these agents in the neonate.[109] More recently developed rapidly metabolized agents given by infusion hold promise for nurse-controlled anesthesia using a pump (the nurse providing additional boluses of medication as needed). This technique has not been widely investigated but holds promise for reducing the total dose of and complications from opioids.

Intravenous nonsteroidal antiinflammatory agents such as ketorolac and ketoprofen are well established as a means of reducing postoperative opioid requirements in adults. A small number of randomized, controlled trials in children have also shown effective analgesia, with a reduction in morphine requirements leading to reduced postoperative vomiting compared with an opioid-based analgesic.[110] However, bleeding time may be increased,[111] and some reports[112] show an increase in postoperative clinical bleeding, although there are no randomized, controlled trials that have included neonates. A case series of infants younger than 6 months after abdominal surgery suggested a reduction in morphine requirements when ketorolac was used.[113] Lacking any substantial evidence in the neonatal period, nonsteroidal antiinflammatory agents cannot be recommended for use as an adjunct to postoperative anesthesia outside a prospective clinical trial.

Acetaminophen administered orally postoperatively

has been shown to reduce morphine requirements after tonsillectomy.[114] It is associated with less postoperative vomiting than with an opioid-based analgesic[115] and does not affect coagulation. Studies in neonates seem to be limited to use for circumcision, in which it is ineffective for operative and immediate postoperative pain but decreases later postoperative pain scores at 6 hours.[116] Acetaminophen should not be used alone for severe pain but can be considered for use during the later postoperative period, after minor procedures, or as an adjunct to other measures. Dosing guidelines based on extensive literature review have been developed,[117] and a population kinetic study with a large sample size produced similar guidelines.[118] However, rectal acetaminophen should be used cautiously because of erratic absorption.

Although there are few data specific to the neonate, regional analgesia can provide effective postoperative pain relief in some situations.[119,120] There has been little systematic study of ancillary comfort measures in the postoperative neonate. Despite the importance of good pharmacologic treatment, the nonpharmacologic means of reducing pain in neonates discussed previously can also be used postoperatively and should be part of a coordinated effort to reduce the pain and stress experienced by infants during the postoperative period.

REDUCING PAIN FROM OTHER MAJOR PROCEDURES

Intercostal Drains

Insertion of a chest drain for pneumothorax or pleural fluid drainage is a painful procedure that is sometimes required in an emergency situation. There have been no prospective studies of analgesia for the insertion of chest tubes in the neonate. The recommendations, therefore, are based on general principles.[19] Infiltration of the skin site with a local anesthetic before incision has long-lasting effects on pain responses (see above) and should be used routinely unless there is life-threatening instability. Slow infiltration reduces pain from lidocaine infiltration.[121] Although there are no available data on the use of opioids before or after chest-tube insertion for pain prevention, this seems to be a reasonable approach. Nonpharmacologic means of reducing pain in neonates should be used also.

Chest-Drain Removal

Removal of the chest drain is also known to be very painful.[122] A prospective study of methohexital for chest-tube removal in the neonate has demonstrated good pain control without significant respiratory compromise.[123] In older children, low-dose morphine and topical lidocaine-prilocaine cream were equally effective.[122]

Intubation

The experience of being intubated is unpleasant[124,125] and painful.[21] Morphine seems not to reduce the occurrence of severe hypoxia with bradycardia during intubation, probably because of the delayed onset of action.[126] Opioids with a more rapid onset of action, such as fentanyl, are probably preferable.[127] In a randomized trial, thiopentone was shown to reduce apparent pain in neonates undergoing intubation.[128] Methohexital in an uncontrolled study was associated with smooth intubating conditions and no apparent distress during intubation.[129] Studies on medications for use during endotracheal intubation are needed to address the requirements for analgesia, prevention of adverse physiologic responses (particularly bradycardia), and pharmacologic paralysis. This complex issue will be discussed further in a forthcoming statement from the American Academy of Pediatrics and Canadian Paediatric Society on the use of medications for elective intubation of neonates.

Retinal Examination and Surgery for Retinopathy of Prematurity

Retinal examinations for retinopathy of prematurity (ROP) are painful,[130,131] and the pain is not completely relieved by use of oral sucrose.[132,133] Topical anesthetics are used often, but their effectiveness is limited.[134] Retinal surgery is also painful and leads to substantial physiologic disturbance that is not adequately treated with topical anesthesia.[130] There are limited data on the effective prevention of pain from ROP surgery. One small uncontrolled study suggested that continuous intravenous infusion of remifentanil effectively reduced pain from laser therapy for ROP.[135]

Circumcision

Pain relief for circumcision should always be provided. The American Academy of Pediatrics has published a separate statement on this subject.[136]

RECOMMENDATIONS

Assessment of Pain and Stress in the Neonate

1. Caregivers should be trained to assess neonates for pain using multidimensional tools.
2. Neonates should be assessed for pain routinely and before and after procedures.
3. The chosen pain scales should help guide caregivers in the provision of effective pain relief.

Reducing Pain From Bedside Care Procedures

1. Care protocols for neonates should incorporate a principle of minimizing the number of painful disruptions in care as much as possible.
2. Use of a combination of oral sucrose/glucose and other nonpharmacologic pain-reduction methods (nonnutritive sucking, kangaroo care, facilitated tuck,

swaddling, developmental care) should be used for minor routine procedures.

3. Topical anesthetics can be used to reduce pain associated with venipuncture, lumbar puncture, and intravenous catheter insertion when time permits but are ineffective for heel-stick blood draws, and repeated use of topical anesthetics should be limited.
4. The routine use of continuous infusions of morphine, fentanyl, or midazolam in chronically ventilated preterm neonates is not recommended because of concern about short-term adverse effects and lack of long-term outcome data.

Reducing Pain From Surgery

1. Any health care facility providing surgery for neonates should have an established protocol for pain management. Such a protocol requires a coordinated, multidimensional strategy and should be a priority in perioperative management.
2. Sufficient anesthesia should be provided to prevent intraoperative pain and stress responses to decrease postoperative analgesic requirements.
3. Pain should be routinely assessed by using a scale designed for postoperative or prolonged pain in neonates.
4. Opioids should be the basis for postoperative analgesia after major surgery in the absence of regional anesthesia.
5. Postoperative analgesia should be used as long as pain-assessment scales document that it is required.
6. Acetaminophen can be used after surgery as an adjunct to regional anesthetics or opioids, but there are inadequate data on pharmacokinetics at gestational ages less than 28 weeks to permit calculation of appropriate dosages.

Reducing Pain From Other Major Procedures

1. Analgesia for chest-drain insertion comprises all of the following:
   a. general nonpharmacologic measures;
   b. slow infiltration of the skin site with a local anesthetic before incision unless there is life-threatening instability (if there was inadequate time to infiltrate before insertion of the chest tube, local skin infiltration after achieving stability may reduce later pain responses and later analgesic requirements); and
   c. systemic analgesia with a rapidly acting opiate such as fentanyl.
2. Analgesia for chest-drain removal comprises the following:
   a. general nonpharmacologic measures and
   b. short-acting, rapid-onset systemic analgesic.
3. Although there are insufficient data to make a specific recommendation, retinal examinations are painful, and pain-relief measures should be used. A reasonable approach would be to administer local anesthetic eye drops and oral sucrose.
4. Retinal surgery should be considered major surgery, and effective opiate-based pain relief should be provided.

CLINICAL REPORT

Prevention and Management of Positional Skull Deformities in Infants

abstract

FREE

Positional skull deformities may be present at birth or may develop during the first few months of life. Since the early 1990s, US pediatricians have seen an increase in the number of children with cranial asymmetry, particularly unilateral flattening of the occiput, likely attributable to parents following the American Academy of Pediatrics "Back to Sleep" positioning recommendations aimed at decreasing the risk of sudden infant death syndrome. Positional skull deformities are generally benign, reversible head-shape anomalies that do not require surgical intervention, as opposed to craniosynostosis, which can result in neurologic damage and progressive craniofacial distortion. Although associated with some risk of positional skull deformity, healthy young infants should be placed down for sleep on their backs. The practice of putting infants to sleep on their backs has been associated with a drastic decrease in the incidence of sudden infant death syndrome. Pediatricians need to be able to properly differentiate infants with benign skull deformities from those with craniosynostosis, educate parents on methods of proactively decreasing the likelihood of the development of occipital flattening, initiate appropriate management, and make referrals when necessary. This report provides guidance for the prevention, diagnosis, and management of positional skull deformity in an otherwise normal infant without evidence of associated anomalies, syndromes, or spinal disease. *Pediatrics* 2011;128:1236–1241

INTRODUCTION

Flattening of the occiput and asymmetrical skull molding may be caused by mechanical factors that act on the head in utero or during early infancy. This common condition has been referred to by many names such as benign positional molding, posterior plagiocephaly, occipital plagiocephaly, plagiocephaly without synostosis, and deformational plagiocephaly. Ancient civilizations recognized the malleability of the rapidly growing newborn skull and intentionally deformed skulls by selective positioning and using external constraints to achieve cultural distinction. The term "plagiocephaly" is a Greek derivative that means "oblique head." Most skull deformities present at birth are the result of in utero or intrapartum molding.[1] Associated conditions involve uterine constraint, especially in cases of multiple-birth infants, and forces exerted on the skull during complex delivery associated with forceps or vacuum-assisted delivery.[2–4] Infants born prematurely also have a greater incidence of skull deformity attribut-

able to molding after birth.[5] Most of these deformities improve spontaneously during the first few months of life if the infant does not rest his or her head predominantly on the flattened area of the skull. If the infant continues to rest his or her head on the flattened side of the occiput, an initially occipital plagiocephalic deformity may be perpetuated or worsened by gravitational forces[6–8] and will be referred to in the remainder of this report as positional skull deformity as it relates to otherwise normal infants. Plagiocephaly is less commonly caused by unilateral lambdoidal or unilateral coronal craniosynostosis, which is a progressive and potentially devastating condition that requires early detection and surgical management. The clinical differentiation of benign positional skull deformity from craniosynostosis is well documented in the literature.[9–11] A long narrow head, known as dolichocephaly, can be positional from breech presentation, familial, or caused by sagittal craniosynostosis. Occipital flattening and atypical shape also may be caused by craniosynostosis, particularly bilateral lambdoid craniosynostosis. However, the incidence of isolated lambdoid craniosynostosis is quite rare, estimated to be approximately 3 in 100 000 births (0.003%).[12]

If the positional skull deformity develops postnatally, an initially typical, rounded skull shape may become flattened occipitally as a result of static supine positioning. Associated torticollis or "wryneck" may occur as a consequence of hemorrhage (within the sternocleidomastoid muscle) and/or subsequent scarring within the sternocleidomastoid muscle or muscle shortening caused by persistent, unidirectional positioning and limited neck motion resulting in plagiocephaly.[13]

The incidence of positional skull deformity has been estimated to be as low as 1 in 300 live births to as high as 48% of typical healthy infants younger than 1 year, depending on the sensitivity of the criteria used to make the diagnosis.[14] Since the American Academy of Pediatrics Task Force on Infant Positioning and Sudden Infant Death Syndrome (SIDS) in 1992 recommended that healthy infants be positioned supine for sleeping, the incidence of SIDS has decreased from 1.2 per 1000 live births in 1992 to 0.56 per 1000 live births in 2001.[3,6,15] Coincident with this decrease in SIDS has been a drastic increase in positional skull deformity, estimated at approximately 13% in healthy singleton infants,[14,15] which makes this a relatively common issue to be faced by the pediatrician caring for infants and their families.

Mild positional skull deformity may persist in some children into adolescence. Minor craniofacial asymmetry can be detected in a significant number of adults; however, there are few current cases of positional skull deformity serious enough to be acknowledged by patients.[12]

Families are often concerned that positional skull deformity may cause developmental delays. Although there have been no rigorous prospective studies to address this concern, there is currently no evidence to suggest that positional skull deformity causes developmental delays.[8,16–18] There has been some early motor skill developmental delay of all infants placed supine related to upper body strength and rolling over, which resolves over time.[19] Long-term follow-up studies have primarily been retrospective and questionnaire in nature and have not noted delays in cognitive or neurologic function.[18,20–22] As might be suspected, conditions that cause delayed or abnormal development may predispose to positional skull deformity (eg, infants with hypotonia or hypertonia).[23,24]

Concerns have been raised over vision development[25] and mandibular asymmetry,[26] but a causal link to positional skull deformity has not been established.[16] Likewise, there has been no credible medical evidence to support concerns brought up in lay literature associating positional skull deformity to otitis media, temporomandibular joint (TMJ) syndrome, scoliosis, or hip dislocation.

PREVENTION

The pediatrician or other primary care clinician should educate parents as well as other health care professionals, such as those in newborn care units, on methods for decreasing the risk of development of positional skull deformity and its treatment. A certain amount of prone positioning, or "tummy time," while the infant is awake and being observed is recommended to help prevent the development of flattening of the occiput and to facilitate development of the upper shoulder girdle strength necessary for timely attainment of certain motor milestones.[27] Beginning at birth, most positional skull deformity also can be prevented by nightly alternating the supine head position (ie, left and right occiputs) during sleep and periodically changing the orientation of the infant to outside activity, such as is likely to occur at the door of the room. Avoidance of prolonged placement indoors in car safety seats and swings should be discouraged. Documentation of these educational discussions and notation of infants' positive physical findings longitudinally are important.

DIAGNOSIS

Positional skull deformity risk factors (multiple births, large for gestational age, oligohydramnios, breech or transverse position, etc) should be noted at birth, and positional skull deformity should be screened for at each health supervision visit up to 1 year of age to

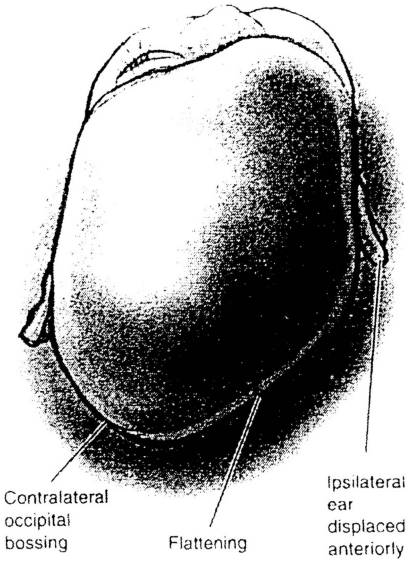

FIGURE 1

detect deformities that occur after birth as delineated in *Bright Futures*. Transient molding (caput, cephalhematoma) may be present at birth and obscure the true head shape. The diagnosis of positional skull deformity in infancy is made primarily on the basis of history and is confirmed by the physical examination. It is important for the pediatrician or other examiner to look down at the top of the head, view the position of the ears, and note the position of the cheekbones (maxilla). By doing this, the typical plagiocephalic positional skull deformity, which forms a parallelogram, will be observed. In addition to the usually unilateral flattening of the occipital area, there may be ipsilateral frontal (forehead) and parietal bossing, cheekbone prominence, and anterior ear displacement ipsilateral to the flattened occiput (Fig 1).

In contrast to deformational plagiocephaly, true craniosynostosis (either unilateral coronal or, much less commonly, lambdoid) most commonly yields a trapezoidal head shape in which there is flattening of both the occipital and frontal regions on the affected side. Uncommonly, lambdoid craniosynostosis can produce a parallelogram head shape, although the affected ear is displaced posteriorly and inferiorly in contrast to deformational plagiocephaly, with which it is displaced anteriorly. There is also tilting of the posterior skull base with prominence of the mastoid. Facial deformities are minimal if present at all. Normal and abnormal physical findings should be documented.

Examination of the face also may lead to detection of abnormalities such as head tilt and contralateral facial flattening. An assessment of neck movements also should be made to confirm or rule out the presence of torticollis. Infants with torticollis have some limitation of active rotation of their heads away from the flattened side of the occiput. The rotating-chair or stool test is a procedure that assists in the diagnosis of torticollis associated with positional skull deformity. The examiner sits on a rotating chair or stool and holds the infant facing the parent: the parent attempts to keep the infant interested in maintaining eye contact while the examiner rotates with the infant on the chair or stool and observes the infant's head movements. The difference between movement toward and away from the flattened side is helpful in making the diagnosis of torticollis associated with positional skull deformity.

SKULL RADIOGRAPHS AND CRANIAL COMPUTED TOMOGRAPHY SCANS

Because the diagnosis of positional skull deformity is made on the basis of history, findings on physical examination, and resolution over time with positional intervention, imaging studies are unnecessary in most situations. In addition, if obtained, their interpretations may be misleading to clinicians, particularly in the case of computed tomography (CT) scans. For the infant born with a normal head shape that progressively changes during the first weeks postnatally, no studies should be performed. Imaging studies should be reserved for infants born with deformities or those that do not improve over the first several weeks with repositioning. To minimize the risk of radiation exposure and the possible need for sedation, it is recommended that imaging studies be ordered by the specialist, because most craniofacial surgeons reserve radiographic imaging or CT scans for those patients who are suspected of having craniosynostosis and/or require surgical intervention.[16] Radiographs and other imaging studies are also rarely indicated for infants with torticollis unless it is progressive or associated with other clinical findings.

MANAGEMENT

Management of positional skull deformity involves preventive counseling for parents, mechanical adjustments, and exercises. Parental compliance with the management plan is pivotal in lessening the likelihood and severity of positional skull deformity. Skull-molding helmets are an option for patients with severe deformity or skull shape that is refractory to therapeutic physical adjustments and position changes.[28] Surgery is rarely necessary but may be indicated in severe refractory cases of positional skull deformity.[29] However, infants with craniosynostosis typically require surgical correction and skull reconstruction. Early surgical intervention results in less invasive procedures because an infant's normal brain growth assists in remodeling the skull postoperatively. Minimally invasive surgery is now available to some infants identified with craniosynostosis in the first months of life.

Preventive Counseling

To prevent the deformity, parents should be counseled during the new-

born period (by 2–4 weeks of age) when the skull is maximally deformable. Parents should be instructed to lay the infant down to sleep in the supine position, alternating positions (ie, left and right occiputs). When awake and being observed, the infant should spend time in the prone position for at least 30 to 60 minutes/day. The infant should spend minimal time in car seats (when not a passenger in a vehicle)[30] or other seating that maintains supine positioning. Aside from potentially preventing positional skull deformity, routine awake tummy time has been shown to enhance infant motor developmental scores during the first 15 months of life. Once positional skull deformity has developed, these same preventive strategies may be used to minimize progression. In addition, it is important to monitor head shape closely until there is confidence that improvement will continue, usually when the infant is old enough to sit, crawl, and spend less time on his or her back and until any associated torticollis is completely corrected. The prevalence of positional skull deformity generally peaks at 4 months and will begin to show significant improvement by 6 months of age.[16,31–33]

Mechanical Adjustments and Exercises

Once positional skull deformity is diagnosed, the parent should be made aware of the condition and the mechanical adjustments that can be instituted. In general, most infants improve if the appropriate measures are conducted for a 2- to 3-month period.[5] These measures include positioning the infant so that the rounded side of the head is placed dependent against the mattress. In addition, the position of the crib in the room may be changed to require the child to look away from the flattened side to see the parents and others in his or her room. The pediatrician should continue to encourage supervised tummy time on firm surfaces when the infant is awake and being observed. Torticollis perpetuates the position of the head on the flattened side and can add to a greater facial deformity. Therefore, if torticollis is present, neck-motion exercises should be taught to the parents as part of management. Neck exercises should be performed with each diaper change. There are 3 repetitions per exercise, and it is estimated to take approximately 2 additional minutes per diaper change. One hand is placed on the child's upper chest, and the other hand rotates the child's head gently so that the chin touches the shoulder. This is held for approximately 10 seconds. The head is then rotated toward the opposite side and held for the same count. This will stretch out the sternocleidomastoid muscle. Next, the head is tilted so that the infant's ear touches his or her shoulder. Again, the position is held for a count of 10 and repeated for the opposite side. This second exercise stretches the trapezius muscle. In addition, the parents may be taught the previously mentioned rotating-chair or stool technique as a therapy to enhance neck motion in the infant.

Referral

If there is progression or lack of improvement of the skull deformity after a trial of mechanical adjustments, then referral to a pediatric neurosurgeon with expertise in craniofacial malformations or to a craniofacial surgeon or craniofacial team should be considered by 4 to 6 months of age. The purpose of this referral is to obtain the expertise of the craniofacial specialist to assess the diagnosis and to direct the subsequent management, which may include molding helmets or surgery. In addition, referral to a physical therapist may be considered if torticollis does not improve with neck-stretching exercises within 2 to 3 months.

Skull-Molding Helmets

Ancient civilizations recognized the malleability of the rapidly growing newborn skull and intentionally deformed skulls by selective positioning and using external constraints to achieve a culturally desired skull form. Conversely, skull-molding helmets can be used to correct atypical skull shapes, and similar devices are now proposed for this purpose. There is currently no evidence that molding helmets work any better than positioning for infants with mild or moderate skull deformity. Because more than half of the infants will improve by 6 months of age, repositioning should be attempted as the initial treatment for infants younger than 6 months. In most situations, an improvement in response to repositioning and neck exercise is seen over a 2- to 3-month period if these measures are instituted as soon as the condition is recognized. For severe deformity, the best use of helmets occurs in the age range of 4 to 12 months[20,34] because of the greater malleability of the young infant skull bone and the normalizing effect of the rapid growth of the brain. There is less modification of the cranial configuration and more compliance problems when used after 12 months of age.[16] The use of helmets and other related devices seems to be beneficial primarily when there has been a lack of response to mechanical adjustments and exercises. Although there is some limited evidence that molding helmets may work faster for children with severe deformities, there were significant methodologic flaws associated with these studies, and there is evidence that long-term outcomes (2–3 years after treatment) may not result in a substantial benefit from helmet use.[16] In particular, a recent study of 161 children treated with po-

sitional changes only showed that 87% had achieved significant improvements, 61% achieved normal skull contours, and only 4% had severe residual deformities by the time of preschool.[35]

Although there have been few published studies, complications of helmet use seem to be low. Cost of helmets can be significant and extremely variable depending on the provider or vendor.

Surgery

Surgical correction for positional skull deformity is currently not recommended except possibly under unusual circumstances in which a child has persistent, severe deformities that have not adequately been corrected despite all other nonoperative measures.

SUMMARY

In most cases, the diagnosis and successful management of positional skull deformity can be assumed by the pediatrician or other primary health care clinician. This management includes examination for and counseling regarding positional skull deformity in the newborn period and at health supervision visits during infancy, as well as monitoring for improvement or progression. For the mild-to-moderate deformity, positioning and observation is the recommended treatment. Both positional changes and molding helmets are options for the infant with severe deformity. Cranial orthoses should be reserved for severe cases of deformity or for the infant whose deformity does not improve after 6 months of age. Referral to a pediatric neurosurgeon with expertise in craniofacial malformations, a craniofacial surgeon, or a craniofacial team should be considered if there is progression or lack of improvement after a trial of mechanical adjustments or suspicion of craniosynostosis.

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Nutrition

Prevention of Pediatric Overweight and Obesity

ABSTRACT. The dramatic increase in the prevalence of childhood overweight and its resultant comorbidities are associated with significant health and financial burdens, warranting strong and comprehensive prevention efforts. This statement proposes strategies for early identification of excessive weight gain by using body mass index, for dietary and physical activity interventions during health supervision encounters, and for advocacy and research.

ABBREVIATION. BMI, body mass index.

INTRODUCTION

Prevention is one of the hallmarks of pediatric practice and includes such diverse activities as newborn screenings, immunizations, and promotion of car safety seats and bicycle helmets. Documented trends in increasing prevalence of overweight and inactivity mean that pediatricians must focus preventive efforts on childhood obesity, with its associated comorbid conditions in childhood and likelihood of persistence into adulthood. These trends pose an unprecedented burden in terms of children's health as well as present and future health care costs. A number of statements have been published that address the scope of the problem and treatment strategies.[1–6]

The intent of this statement is to propose strategies to foster prevention and early identification of overweight and obesity in children. Evidence to support the recommendations for prevention is presented when available, but unfortunately, too few studies on prevention have been performed. The enormity of the epidemic, however, necessitates this call to action for pediatricians using the best information available.

DEFINITIONS AND DESCRIPTION OF THE PROBLEM

Body mass index (BMI) is the ratio of weight in kilograms to the square of height in meters. BMI is widely used to define overweight and obesity, because it correlates well with more accurate measures of body fatness and is derived from commonly available data—weight and height.[7] It has also been correlated with obesity-related comorbid conditions in adults and children. Clinical judgment must be used in applying these criteria to a patient, because obesity refers to excess adiposity rather than excess weight, and BMI is a surrogate for adiposity. The pediatric growth charts for the US population now include BMI for age and gender, are readily available online (http://www.cdc.gov/growthcharts), and allow longitudinal tracking of BMI.[8]

BMI between 85th and 95th percentile for age and sex is considered at risk of overweight, and BMI at or above the 95th percentile is considered overweight or obese.[9,10] The prevalence of childhood overweight and obesity is increasing at an alarming rate in the United States as well as in other developed and developing countries. Prevalence among children and adolescents has doubled in the past 2 decades in the United States. Currently, 15.3% of 6- to 11-year-olds and 15.5% of 12- to 19-year-olds are at or above the 95th percentile for BMI on standard growth charts based on reference data from the 1970s, with even higher rates among subpopulations of minority and economically disadvantaged children.[10,11] Recent data from the Centers for Disease Control and Prevention also indicate that children younger than 5 years across all ethnic groups have had significant increases in the prevalence of overweight and obesity.[12,13] American children and adolescents today are less physically active as a group than were previous generations, and less active children are more likely to be overweight and to have higher blood pressure, insulin and cholesterol concentrations and more abnormal lipid profiles.[14,15]

Obesity is associated with significant health problems in the pediatric age group and is an important early risk factor for much of adult morbidity and mortality.[15,16] Medical problems are common in obese children and adolescents and can affect cardiovascular health (hypercholesterolemia and dyslipidemia, hypertension),[14,17–19] the endocrine system (hyperinsulinism, insulin resistance, impaired glucose tolerance, type 2 diabetes mellitus, menstrual irregularity),[20–22] and mental health (depression, low self-esteem).[23,24] Because of the increasing incidence of type 2 diabetes mellitus among obese adolescents and because diabetes-related morbidities may worsen if diagnosis is delayed, the clinician should be alert to the possibility of type 2 diabetes mellitus in all obese adolescents, especially those with a fam-

ily history of early-onset (younger than 40 years) type 2 diabetes mellitus.[25] The psychologic stress of social stigmatization imposed on obese children may be just as damaging as the medical morbidities. The negative images of obesity are so strong that growth failure and pubertal delay have been reported in children practicing self-imposed caloric restriction because of fears of becoming obese.[26] Other important complications and associations include pulmonary (asthma, obstructive sleep apnea syndrome, pickwickian syndrome),[27–32] orthopedic (genu varum, slipped capital femoral epiphysis),[33,34] and gastrointestinal/hepatic (nonalcoholic steatohepatitis)[35] complications. All these disturbances are seen at an increased rate in obese individuals and have become more common in the pediatric population. The probability of childhood obesity persisting into adulthood is estimated to increase from approximately 20% at 4 years of age to approximately 80% by adolescence.[36] In addition, it is probable that comorbidities will persist into adulthood.[16,37] Thus, the potential future health care costs associated with pediatric obesity and its comorbidities are staggering, prompting the surgeon general to predict that preventable morbidity and mortality associated with obesity may exceed those associated with cigarette smoking.[10,38]

Although treatment approaches for pediatric obesity may be effective in the short term,[39–44] long-term outcome data for successful treatment approaches are limited.[45,46] The intractable nature of adult obesity is well known. Therefore, it is incumbent on the pediatric community to take a leadership role in prevention and early recognition of pediatric obesity.

RISK FACTORS

Development of effective prevention strategies mandates that physicians recognize populations and individuals at risk. Interactions between genetic, biological, psychologic, sociocultural, and environmental factors clearly are evident in childhood obesity. Elucidation of hormonal and neurochemical mechanisms that promote the energy imbalance that generates obesity has come from molecular genetics and neurochemistry. Knowledge of the genetic basis of differences in the complex of hormones and neurotransmitters (including growth hormone, leptin, ghrelin, neuropeptide Y, melanocortin, and others) that are responsible for regulating satiety, hunger, lipogenesis, and lipolysis as well as growth and reproductive development will eventually refine our understanding of risk of childhood overweight and obesity and may lead to more effective therapies.[47,48]

Genetic conditions known to be associated with propensity for obesity include Prader-Willi syndrome, Bardet-Biedl syndrome, and Cohen syndrome. In these conditions, early diagnosis allows collaboration with subspecialists, such as geneticists, endocrinologists, behavioralists, and nutritionists, to optimize growth and development while promoting healthy eating and activity patterns from a young age. For example, data suggest that growth hormone may improve some of the signs of Prader-Willi syndrome.[49–51]

It has long been recognized that obesity "runs in families"—high birth weight, maternal diabetes, and obesity in family members all are factors—but there are likely to be multiple genes and a strong interaction between genetics and environment that influence the degree of adiposity.[47,48,52,53] For young children, if 1 parent is obese, the odds ratio is approximately 3 for obesity in adulthood, but if both parents are obese, the odds ratio increases to more than 10. Before 3 years of age, parental obesity is a stronger predictor of obesity in adulthood than the child's weight status.[54] Such observations have important implications for recognition of risk and routine anticipatory guidance that is directed toward healthy eating and activity patterns in families.

There are critical periods of development for excessive weight gain. Extent and duration of breastfeeding have been found to be inversely associated with risk of obesity in later childhood, possibly mediated by physiologic factors in human milk as well as by the feeding and parenting patterns associated with nursing.[55–58] Investigations of dietary factors in infancy, such as high protein intake or the timing of introduction of complementary foods, have not consistently revealed effects on childhood obesity. It has been known for decades that adolescence is another critical period for development of obesity.[59] The normal tendency during early puberty for insulin resistance may be a natural cofactor for excessive weight gain as well as various comorbidities of obesity.[60] Early menarche is clearly associated with degree of overweight, with a twofold increase in rate of early menarche associated with BMI greater than the 85th percentile.[61] The risk of obesity persisting into adulthood is higher among obese adolescents than among younger children.[54] The roles of leptin, adiponectin, ghrelin, fat mass, and puberty on development of adolescent obesity are being actively investigated. Data suggest that adolescents who engage in high-risk behaviors, such as smoking, ethanol use, and early sexual experimentation also may be at greater risk of poor dietary and exercise habits.[62]

Environmental risk factors for overweight and obesity, including family and parental dynamics, are numerous and complicated. Although clinical interventions cannot change these factors directly, they can influence patients' adaptations to them, and the physician can advocate for change at the community level. Food insecurity may contribute to the inverse relation of obesity prevalence with socioeconomic status, but the relationship is a complex one.[63] Other barriers low-income families may face are lack of safe places for physical activity and lack of consistent access to healthful food choices, particularly fruits and vegetables. Low cognitive stimulation in the home, low socioeconomic status, and maternal obesity all predict development of obesity.[64] In research settings, there is accumulating evidence for the detrimental effects of overcontrolling parental behavior on children's ability to self-regulate energy intake. For example, maternal-child feeding practices, maternal perception of daughter's risk of overweight,[65] maternal restraint, verbal prompting to eat at mealtime, attentiveness to noneating behavior, and close parental monitoring[66] all may promote undesired

consequences for children's eating behaviors. Parental food choices influence child food preferences,[67] and degree of parental adiposity is a marker for children's fat preferences.[68] Children and adolescents of lower socioeconomic status have been reported to be less likely to eat fruits and vegetables and to have a higher intake of total and saturated fat.[69–71] Absence of family meals is associated with lower fruit and vegetable consumption as well as consumption of more fried food and carbonated beverages. Although our understanding of the development of eating behaviors is improving, there are not yet good trials to demonstrate effective translation of this knowledge base into clinical practices to prevent obesity. At a minimum, however, pediatricians need to proactively discuss and promote healthy eating behaviors for children at an early age and empower parents to promote children's ability to self-regulate energy intake while providing appropriate structure and boundaries around eating.

Widespread and profound societal changes during the last several decades have affected child rearing, which in turn has affected childhood patterns of physical activity as well as diet. National survey data indicate that children are currently less active than they have been in previous surveys. Leisure activity is increasingly sedentary, with wide availability of entertainment such as television, videos, and computer games. In addition, with increasing urbanization, there has been a decrease in frequency and duration of physical activities of daily living for children, such as walking to school and doing household chores. Changes in availability and requirements of school physical education programs have also generally decreased children's routine physical activity, with the possible exception of children specifically enrolled in athletic programs. All these factors play a potential part in the epidemic of overweight.[72]

National survey data indicate that 20% of US children 8 to 16 years of age reported 2 or fewer bouts of vigorous physical activity per week, and more than 25% watched at least 4 hours of television per day.[73] Children who watched 4 or more hours of television per day had significantly greater BMI, compared with those watching fewer than 2 hours per day.[73] Furthermore, having a television in the bedroom has been reported to be a strong predictor of being overweight, even in preschool-aged children.[74] Some cross-sectional data have found significant correlation between obesity prevalence and television viewing,[75–77] but others have not.[78,79] The results of a randomized trial to decrease television viewing for school-aged children has provided the strongest evidence to support the role of limiting television in prevention of obesity. In this study, decreasing "media use" without specifically promoting more active behaviors in the intervention group resulted in a significantly lower increase in BMI at the 1-year follow-up, compared with the control group.[80] Additional support for the importance of decreasing television viewing comes from controlled investigations that demonstrated that obese children who were reinforced for decreasing sedentary activity (and following an energy-restricted diet) had significantly greater weight loss than those who were reinforced for increasing physical activity.[42] These findings have important implications for anticipatory guidance and provide additional support for recommendations to limit television exposure for young children.[2]

EARLY RECOGNITION

Routine assessments of eating and activity patterns in children and recognition of excessive weight gain relative to linear growth are essential throughout childhood. At any age, an excessive rate of weight gain relative to linear growth should be recognized, and underlying predisposing factors should be addressed with parents and other caregivers. The Centers for Disease Control and Prevention percentile grids for BMI are important tools for anticipatory guidance and discussion of longitudinal tracking of a child's BMI. Significant changes on growth patterns (eg, upward crossing of weight for age or BMI percentiles) can be recognized and addressed before children are severely overweight.[81] An increase in BMI percentiles should be discussed with parents, some of whom may be overly concerned and some of whom may not recognize or accept potential risk.[82]

Although data are extremely limited, it is likely that anticipatory guidance or treatment intervention before obesity has become severe will be more successful. Discussions to raise parental awareness should be conducted in a nonjudgmental, blame-free manner so that unintended negative impact on the child's self-concept is avoided.[24] Data from adult patient surveys indicate that those who were asked by their physician about diet were more likely to report positive changes.[83] Similarly, the efficacy of physicians discussing physical activity,[84] breastfeeding,[85] and smoking prevention[86] is well documented. Thus, pediatricians are strongly encouraged to incorporate assessment and anticipatory guidance about diet, weight, and physical activity into routine clinical practice, being careful to discuss habits rather than focusing on habitus to avoid stigmatizing the child, adolescent, or family.

ADVOCACY

Abundant opportunities exist for pediatricians to take a leadership role in this critical area of child health, including action in the following areas: opportunities for physical activity, the food supply, research, and third-party reimbursement. Change is desperately needed in opportunities for physical activity in child care centers, schools, after-school programs, and other community settings. As leaders in their communities, pediatricians can be effective advocates for health- and fitness-promoting programs and policies. Foods that are nutrient rich and palatable yet low in excess energy from added sugars and fat need to be readily available to parents, school and child care food services, and others responsible for feeding children. Potential affordable sources include community gardens and farmers' market projects. Advertising and promotion of energy-dense, nutrient-poor food products to children may need to be regulated or curtailed. The increase in

carbonated beverage intake has been linked to obesity[87]; therefore, the sale of such beverages should not be promoted at school. Pediatricians are encouraged to work with school administrators and others in the community on ways to decrease the availability of foods and beverages with little nutritional value and to decrease the dependence on vending machines, snack bars, and school stores for school revenue. Regarding physical activity, advocacy is sorely needed for physical education programs that emphasize and model learning of daily activities for personal fitness (as opposed to physical education limited to a few team sports).

New initiatives for pilot projects to test prevention strategies have been funded by the National Institutes of Health and other organizations, but a long-term commitment of substantial funds from many sources and to many disciplines will be needed to attack this serious, widespread, and potentially intractable problem. Support for development and testing of primary prevention strategies for the primary care setting will be critical. Likewise, investment of substantial resources will be required for development of effective treatment approaches for normalizing or improving body weight and fitness and for determining long-term effects of weight loss on comorbidities of childhood obesity. Collaboration and coalitions with nutrition, behavioral health, physical therapy, and exercise physiology professionals will be needed. Working with communities and schools to develop needed counseling services, physical activity opportunities, and strategies to reinforce the gains made in clinical management is also important.

Pediatric referral centers will need to develop specialized programs for treatment of complex and difficult cases, and for research into etiology and new methods of prevention and treatment. Efforts are needed to ensure adequate health care coverage for preventive and treatment services. Even when serious comorbidities are documented, insurance reimbursement is limited.[88] Lack of reimbursement is a disincentive for physicians to develop prevention and treatment programs and presents a significant barrier to families seeking professional care.

SUMMARY/CONCLUSIONS

1. Prevalence of overweight and its significant comorbidities in pediatric populations has rapidly increased and reached epidemic proportions.
2. Prevention of overweight is critical, because long-term outcome data for successful treatment approaches are limited.
3. Genetic, environmental, or combinations of risk factors predisposing children to obesity can and should be identified.
4. Early recognition of excessive weight gain relative to linear growth should become routine in pediatric ambulatory care settings. BMI (kg/m^2 [see http://www.cdc.gov/growthcharts]) should be calculated and plotted periodically.
5. Families should be educated and empowered through anticipatory guidance to recognize the impact they have on their children's development of lifelong habits of physical activity and nutritious eating.
6. Dietary practices should be fostered that encourage moderation rather than overconsumption, emphasizing healthful choices rather than restrictive eating patterns.
7. Regular physical activity should be consciously promoted, prioritized, and protected within families, schools, and communities.
8. Optimal approaches to prevention need to combine dietary and physical activity interventions.
9. Advocacy is needed in the areas of physical activity and food policy for children; research into pathophysiology, risk factors, and early recognition and management of overweight and obesity; and improved insurance coverage and third-party reimbursement for obesity care.

RECOMMENDATIONS

1. Health supervision
   a. Identify and track patients at risk by virtue of family history, birth weight, or socioeconomic, ethnic, cultural, or environmental factors.
   b. Calculate and plot BMI once a year in all children and adolescents.
   c. Use change in BMI to identify rate of excessive weight gain relative to linear growth.
   d. Encourage, support, and protect breastfeeding.
   e. Encourage parents and caregivers to promote healthy eating patterns by offering nutritious snacks, such as vegetables and fruits, low-fat dairy foods, and whole grains; encouraging children's autonomy in self-regulation of food intake and setting appropriate limits on choices; and modeling healthy food choices.
   f. Routinely promote physical activity, including unstructured play at home, in school, in child care settings, and throughout the community.
   g. Recommend limitation of television and video time to a maximum of 2 hours per day.
   h. Recognize and monitor changes in obesity-associated risk factors for adult chronic disease, such as hypertension, dyslipidemia, hyperinsulinemia, impaired glucose tolerance, and symptoms of obstructive sleep apnea syndrome.
2. Advocacy
   a. Help parents, teachers, coaches, and others who influence youth to discuss health habits, not body habitus, as part of their efforts to control overweight and obesity.
   b. Enlist policy makers from local, state, and national organizations and schools to support a healthful lifestyle for all children, including proper diet and adequate opportunity for regular physical activity.
   c. Encourage organizations that are responsible for health care and health care financing to provide coverage for effective obesity prevention and treatment strategies.
   d. Encourage public and private sources to direct funding toward research into effective strategies to prevent overweight and obesity and to maximize limited family and community re-

sources to achieve healthful outcomes for youth.

e. Support and advocate for social marketing intended to promote healthful food choices and increased physical activity.

POLICY STATEMENT

Prevention of Rotavirus Disease: Updated Guidelines for Use of Rotavirus Vaccine

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Infectious Diseases

ABSTRACT

This statement updates and replaces the 2007 American Academy of Pediatrics statement for prevention of rotavirus gastroenteritis. In February 2006, a live oral human-bovine reassortant rotavirus vaccine (RV5 [RotaTeq]) was licensed as a 3-dose series for use in infants in the United States. The American Academy of Pediatrics recommended routine use of RV5 in infants in the United States. In April 2008, a live, oral, human attenuated rotavirus vaccine (RV1 [Rotarix]) was licensed as a 2-dose series for use in infants in the United States. The American Academy of Pediatrics recommends routine immunization of infants in the United States with rotavirus vaccine. The American Academy of Pediatrics does not express a preference for either RV5 or RV1. RV5 is to be administered orally in a 3-dose series with doses administered at 2, 4, and 6 months of age; RV1 is to be administered orally in a 2-dose series with doses administered at 2 and 4 months of age. The first dose of rotavirus vaccine should be administered from 6 weeks through 14 weeks, 6 days of age. The minimum interval between doses of rotavirus vaccine is 4 weeks. All doses should be administered by 8 months, 0 days of age. Recommendations in this statement also address the maximum ages for doses, contraindications, precautions, and special situations for administration of rotavirus vaccine. *Pediatrics* 2009;123:1412–1420

doi:10.1542/peds.2009-0466

Key Words
rotavirus vaccine, rotavirus gastroenteritis

Abbreviations
RV1—live, oral human attenuated rotavirus vaccine
AAP—American Academy of Pediatrics
RV5—live, oral human-bovine reassortant rotavirus vaccine
RR—relative risk
CI— confidence interval
CDC—Centers for Disease Control and Prevention

SUMMARY OF CHANGES TO THE RECOMMENDATIONS FROM THE 2007 STATEMENT

1. Recommendations now include a second rotavirus vaccine, live, oral human attenuated rotavirus vaccine (RV1) (Rotarix [GlaxoSmithKline, Rixensart, Belgium]), administered in a 2-dose series at 2 and 4 months of age.
2. Maximum ages for doses:
   - Maximum age for dose 1 of rotavirus vaccine is now 14 weeks, 6 days of age (previous recommendation: 12 weeks of age).
   - Maximum age for the last dose of rotavirus vaccine is now 8 months, 0 days of age (previous recommendation: 32 weeks of age).
3. The minimum interval between doses of rotavirus vaccine is 4 weeks (previous recommendation: 4 to 10 weeks between doses).
4. The rationale to consider rotavirus immunization of HIV-exposed or HIV-infected infants is described.
5. Rotavirus vaccine may be administered at any time before, concurrent with, or after administration of any blood product, including antibody-containing blood products. The previous recommendation was to defer immunization for 42 days after receipt of an antibody-containing product, if possible.

PURPOSE OF REVISED RECOMMENDATIONS AND RATIONALE

The purpose of this statement is to update recommendations of the American Academy of Pediatrics (AAP) for routine use of rotavirus vaccine in infants, which originally were published in *Pediatrics* in January 2007.[1] Updated recommendations are needed, because a second rotavirus vaccine has been licensed, and the 2 licensed rotavirus vaccines differ in composition and US Food and Drug Administration–licensed schedule of administration (Table 1).

Rotavirus is the most common cause of severe gastroenteritis in infants and young children worldwide. Before

TABLE 1 Profiles of Rotavirus Vaccines Licensed in United States

Profile	RV5 (RotaTeq)	RV1 (Rotarix)
Type of vaccine	Live attenuated oral	Live attenuated oral
Parent rotavirus strain	Bovine strain WC3	Human strain 89–12
Composition	Five human-bovine reassortant strains	Single human strain RIX4414
G and P types	G1P[5] G2P[5] G3P[5] G4P[5] G6P[8]	G1P[8]
Labeled indication	Immunization against rotavirus gastroenteritis caused by G1, G2, G3, and G4	Immunization against rotavirus gastroenteritis caused by G1, G3, G4, and G9
Labeled age of administration, wk	6 through 32[a]	6 through 24[a]
Dosing, mo of age	2, 4, and 6	2 and 4
Formulation	Liquid requiring no reconstitution	Vial of lyophilized vaccine with a prefilled oral applicator of liquid diluent
How supplied	Single-dose squeezable plastic tube	Tip cap and rubber plunger of the oral applicator contain dry natural latex rubber; the vial stopper and transfer adapter are latex-free
Volume per dose, mL	2	1
Preservatives	None	None
Shelf life, mo	24	24
Storage	Store refrigerated at 2°–8°C (36°–46°F), protect from light, and administer as soon as possible after being removed from refrigeration	Storage before reconstitution: refrigerate vials of lyophilized vaccine at 2°–8°C (36°–46°F) and protect from light; store diluent at 20°–25°C (68°–77°F). Storage after reconstitution: administer within 24 h of reconstitution; may be stored refrigerated at 2°–8°C (36°–46°F) or at room temperature up to 25°C (77°F)

[a] The AAP recommends 8 months, 0 days as maximum age for the last dose of vaccine.

initiation of the rotavirus immunization program, it was estimated that nearly every child in the United States was infected with rotavirus by 5 years of age, and most infected children developed gastroenteritis. Each year, rotavirus causes more than 400 000 physician visits, more than 200 000 emergency department visits, 55 000 to 70 000 hospitalizations, 20 to 70 childhood deaths, and direct and indirect costs in excess of $1 billion.[2–5]

VACCINES

Pentavalent Human-Bovine Reassortant Rotavirus Vaccine

In February 2006, a live, oral human-bovine reassortant rotavirus vaccine (RV5) (RotaTeq [Merck and Co, Whitehouse Station, NJ]) was licensed for use in the United States. RV5 contains 5 live reassortant rotavirus strains. The rotavirus parent strains of the reassortant viruses were isolated from human and bovine hosts. Four reassortant rotaviruses express 1 of the outer-capsid proteins (G1, G2, G3, or G4) from the human rotavirus parent strain and the attachment protein (P7[5]) from the bovine rotavirus parent strain. The fifth reassortant virus expresses the attachment protein (P1A[8]) from the human rotavirus parent strain and the outer-capsid protein G6 from the bovine rotavirus parent strain. RV5 is given to infants as 3 oral doses.

Monovalent Human Rotavirus Vaccine

A second rotavirus vaccine (RV1) was licensed on April 3, 2008, for use in the United States. The vaccine contains the RIX4414 strain of the human rotavirus G1P[8]. The RIX4414 strain was developed further from rotavirus strain 89–12, which originally was derived from a young boy in Cincinnati, Ohio. RV1 is administered to infants as 2 oral doses.

The safety and efficacy of RV5 and RV1 for prevention of rotavirus gastroenteritis in healthy infants have been evaluated in 11 randomized, controlled trials involving more than 146 000 infants worldwide (Table 2), including 3 randomized, controlled trials for RV5[6–8] and 7 randomized, controlled trials for RV1.[9–15]

SAFETY

Reactogenicity

Both vaccines are well tolerated and have a low reactogenicity profile when given alone. They do not cause clinically significant increases in reactogenicity when coadministered with other routine childhood vaccines.[16,17]

For both vaccines, the incidence of fever, vomiting, diarrhea, and irritability were measured in the clinical trials. For RV5, no significant difference versus placebo was observed in the incidence of fever or severe fever and irritability or severe irritability. A 3% increase in the incidence of diarrhea and vomiting was observed with RV5, but these symptoms were mild and did not require treatment.[6,8,18] For RV1, no difference versus placebo was observed in the incidence of diarrhea, fever or severe fever, vomiting or severe vomiting, and irritability or severe irritability within 14 days of immunization with any dose.[9,10,13,15] There was no statistically significant increased risk for death or other serious adverse events noted with either vaccine compared with placebo.

TABLE 2 Performance of Rotavirus Vaccines Licensed in United States in Clinical Trials

Profile	RV5 (RotaTeq)	RV1 (Rotarix)
Safety profile	No increase in fever or irritability, slight increase in mild diarrhea and vomiting	No increase in fever, irritability, diarrhea, or vomiting
Intussusception	Not associated	Not associated
Shedding, %	9 (of recipients after dose 1, rarely after subsequent doses)	25 (after first dose peak excretion around day 7)
Efficacy against any rotavirus gastroenteritis, %	74	87
Efficacy against severe rotavirus gastroenteritis, %	98	85–96
Efficacy against health care encounters	Significantly reduced No. of hospitalizations, physician office visits, emergency department visits	Significantly reduced No. of hospitalizations and need for medical attention
Efficacy according to serotype against severe rotavirus gastroenteritis, %	G1 (95%), G2 (88%), G3 (93%), G4 (89%), and G9 (100%)	In Latin America: G1 (91%), G2 (41%), G3, G4, and G9 (87%) In Europe: G1 (96%), G2 (86%), G3 (94%), G4 (95%), G9 (85%)

Efficacy cannot be compared between vaccines, because 2 different severity scales were used in the clinical trials.

[a] In Latin America.

[b] In Europe.

Intussusception

Two trials were designed specifically to evaluate the risk of intussusception after vaccine administration.[8,11] The risk of intussusception was no greater for either rotavirus vaccine than that observed in placebo recipients. For RV5, during the 42 days after each dose of vaccine, 6 cases of intussusception were reported among 28 038 vaccine recipients, and 5 cases were reported in 27 965 placebo recipients (relative risk [RR]: 1.2 [95% confidence interval (CI): 0.3–5.0]). During the 12 months after each dose of RV5, 12 cases of intussusception were reported among vaccine recipients and 15 in placebo recipients (RR: 0.8 [95% CI: 0.3–1.8]).[8] For RV1, during the 31 days after each dose of vaccine, 6 cases of intussusception were reported in 31 673 vaccine recipients, and 7 cases were reported in 31 552 placebo recipients (RR: 0.9 [95% CI: 0.3–2.4]). In a subset of infants, during the 12 months after each dose of RV1, 4 cases of intussusception were reported among vaccine recipients and 14 in placebo recipients (RR: 0.3 [95% CI: 0.1–0.8]).[11]

Although neither RV5 nor RV1 has been associated with intussusception in large prelicensure trials, rigorous postlicensure monitoring for safety end points is necessary because of possible differences in the characteristics of infants receiving the vaccine in routine use compared with the clinical trials and the large numbers of infants being immunized. In addition, background cases of intussusception that are unrelated to vaccine are expected to occur in the weeks after immunization by chance alone.

With more than 14 million doses of RV5 distributed in the United States since 2006, the Centers for Disease Control and Prevention (CDC) Immunization Safety Office summary of postlicensure safety monitoring of RV5 does not indicate that immunization with RV5 is associated with intussusception.[19] Further monitoring is ongoing. Rigorous postlicensure monitoring for safety end points has also been initiated for RV1.

Shedding and Transmission

Vaccine virus shedding in stool has been documented with both rotavirus vaccines. Rotavirus shedding occurs in approximately 9% of RV5 recipients after dose 1 but rarely after subsequent doses.[18] No cases of transmission of RV5 have been documented. Shedding and transmission are not considered significant safety concerns because of the attenuated nature of the rotavirus vaccine strains. For RV1, live rotavirus shedding in stool occurs in approximately 25% of recipients, with peak excretion occurring around day 7 after dose 1. Transmission of virus has not been evaluated. There have been a few cases of documented transmission to contacts. The rate of transmission is unknown, but no known cases have developed symptoms of rotavirus gastroenteritis.[10]

EFFICACY

The efficacy of rotavirus vaccines was evaluated against the following end points in healthy infants: rotavirus gastroenteritis of any severity (RV5 and RV1); severe rotavirus gastroenteritis (RV5 and RV1); rotavirus gastroenteritis requiring an office visit (RV5) or medically attended visit (RV1); rotavirus gastroenteritis requiring hospitalization (RV5 and RV1) or an emergency department visit (RV5); and rotavirus gastroenteritis caused by different rotavirus serotypes (G1P[8], G2P[4], G3P[8], G4P[8], and G9P[8]) (RV5 and RV1).

Efficacy was demonstrated for each vaccine in prelicensure clinical trials. Vaccine efficacy studies demonstrated 85% to 98% protection against severe rotavirus disease and 74% to 87% protection against any rotavirus disease. The efficacy of RV5 after completion of a 3-dose regimen against rotavirus gastroenteritis of any severity was 74%.[8] In European infants, the efficacy of RV1 against rotavirus gastroenteritis of any severity was 87%.[14] The efficacy against rotavirus gastroenteritis of any severity was not measured in the Latin American trial of RV1.[11]

The severity of rotavirus gastroenteritis in these clinical trials was assessed by using different clinical scales

(Vesikari scale for RV1 and Clark scale for RV5). A recent study that compared the clinical scales found that they differ primarily in their definition of severe cases.[20] The authors of this study concluded that the use of different evaluation scales affects the ability to compare the effectiveness of rotavirus vaccines.

Efficacy of RV5 against severe rotavirus gastroenteritis was 98%.[8] Data indicate that efficacy of RV1 against severe rotavirus gastroenteritis over the first rotavirus season in Europe was 96%, and efficacy against severe disease in Latin America was 85%.[11,14]

Efficacy against rotavirus gastroenteritis hospitalizations for RV5 was 96%.[8] For rotavirus gastroenteritis-associated emergency department visits, efficacy after the third dose of RV5 was 94%.[8] Efficacy of RV1 against any rotavirus gastroenteritis hospitalization in Europe was 96%, and efficacy against hospitalizations in Latin America was 85%.[11,14]

Rotavirus immunization reduced the need for any medical attention attributable to rotavirus gastroenteritis. For RV5, data indicate that immunization reduced the number of office visits by 86%.[8] Data available for RV1 from Europe indicate that efficacy in prevention of acute rotavirus gastroenteritis requiring medical attention (from a visit to a doctor to hospitalization) is 84% through the end of the second season of follow-up.[14]

Efficacy has been established for both vaccines against clinically important outcomes for the most prevalent circulating serotypes (G1P[8], G3P[8], G4P[8], G9P[8], and G2P[4]).[8,11,14] Efficacy of RV5 against rotavirus gastroenteritis-associated hospitalization or emergency department visits was demonstrated against G1 (95%), G2 (88%), G3 (93%), G4 (89%), and G9 (100%) serotypes, although relatively few non-G1 rotavirus cases were reported.[8] In Latin America, efficacy of RV1 against severe rotavirus episodes caused by serotype G1 strains, homologous to the vaccine strain, was 91%, and efficacy against strains that share only the P[8] antigen (G3, G4, and G9) was 87%.[11] For serotype G2P[4] rotavirus, which does not share either the G or the P antigen with the RV1 vaccine strain, efficacy was 41%. In the European trial, efficacy of RV1 against severe rotavirus episodes caused by serotype G1 strains was 96%; efficacy was also demonstrated against G3 (94%), G4 (95%), and G9 (85%) serotype strains.[14] For serotype G2P,[4] rotavirus efficacy was 86%.

Data for efficacy of fewer than 3 doses of RV5 and fewer than 2 doses of RV1 are limited. The protective effect of RV1 against any grade of severity of rotavirus gastroenteritis observed immediately after receipt of dose 1 and before receipt of dose 2 was 90%.[14] Published data on the efficacy of fewer than 3 doses of RV5 are not available.

Interchangeability of Rotavirus Vaccines

No studies have addressed the interchangeability of the rotavirus vaccines. However, there is no theoretical reason to expect that risk of adverse events would be increased if the series included more than 1 product, compared with the risk of adverse events of a series containing only 1 product. In addition, although it is possible that effectiveness of a series that contained both products could have been reduced compared with a complete series with 1 product, the effectiveness of a series that contained both products is likely to have been greater than an incomplete series with 1 product.

Postlicensure Vaccine Effectiveness of RV5 in the United States

To summarize rotavirus activity during the 2007–2008 rotavirus season, the CDC analyzed data from the National Respiratory and Enteric Virus Surveillance System and the New Vaccine Surveillance Network.[21] Compared with the 15 previous seasons (1991–2006), rotavirus activity during the 2007–2008 rotavirus season was delayed in onset by 2 to 4 months and reduced in magnitude by more than 50%. Additional surveillance and epidemiologic studies are needed to confirm the impact of rotavirus immunization on the 2007–2008 rotavirus season and to monitor the impact of the vaccine on the disease incidence, geographical distribution, and timing of rotavirus disease during future seasons. Studies also are needed to monitor serotype distribution and possible strain replacement in future seasons.

Efficacy in Special Populations

Studies have shown that either rotavirus vaccine can be administered to infants who are being breastfed without the efficacy of the vaccines being affected.[9,11,22] An uninterrupted schedule of breastfeeding was permitted in infants participating in prelicensure clinical trials of both vaccines.

Coadministration of each rotavirus vaccine with commonly administered pediatric vaccines has been evaluated. Both RV1 and RV5 can be coadministered with diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP), *Haemophilus influenzae* type b vaccine (Hib), inactivated poliovirus vaccine (IPV), hepatitis B vaccine (HPV), and pneumococcal conjugate vaccine with no observed immune interference.[16,17]

Few data are available on the efficacy, safety, and reactogenicity of rotavirus vaccine in infants with underlying conditions. Studies of HIV-infected infants are ongoing for RV1 and are planned for RV5.

Evidence indicates that RV5 can be given safely to otherwise healthy preterm infants born at more than 32 weeks of gestation (median: 34 weeks of gestation), according to postnatal age, on the same schedule as for infants born at term.[23] Overall, 3 doses of RV5 reduced the rate of hospitalizations and emergency department visits in preterm infants attributable to rotavirus gastroenteritis by 100%. The vaccine also prevented 73% of rotavirus gastroenteritis cases of any severity. Studies examining administration of RV1 in preterm infants are ongoing.

COST/BENEFIT ANALYSIS

In a published analysis using estimates of rotavirus disease burden, vaccine efficacy, vaccine coverage rates, and health care costs in the late 1990s, investigators estimated that a national rotavirus immunization pro-

gram for the United States in which 3 doses of RV5 are administered at 2, 4, and 6 months of age to a single birth cohort of 4 million infants would result in 255 000 fewer physician visits, 137 000 fewer emergency department visits, 44 000 fewer hospitalizations, and 13 fewer deaths per year in children younger than 5 years.[5] At a manufacturer price of $62.50 (2006 dollars) per dose, a 3-dose RV5 immunization series would cost $138 per case averted, $3024 per serious case averted, and $197 190 per life-year saved. In 2008, the CDC conducted an updated analysis of a rotavirus immunization program in the United States and concluded that the cost-effectiveness of a 3-dose RV5 vaccine program and a 2-dose RV1 vaccine program would be similar (CDC, unpublished data, 2008). The cohort model used in the study by Widdowson et al[5] was used. At an estimated total immunization cost per child for 3 doses of RV5 of $218 and 2 doses of RV1 of $208, immunization cost per case averted was $139 for RV5 and $94 for RV1. The cost per life-year saved was $198 546 for RV5 and $128 400 for RV1. Although the median estimates in this model suggest small increased cost-effectiveness of 2-dose RV1 vaccine over 3-dose RV5 vaccine, the CDC concluded that these differences in median estimates might not translate into a true difference for a program because of variation in the actual cost of vaccine to providers, possible differences in the costs for administration and shipping of each product, and the field vaccine effectiveness of a product's full or partial series.[24] For example, if there is as high a vaccine efficacy after dose 1 for the 3-dose RV5 vaccine as reported after the first dose of RV1, the difference between the 2 vaccines will be much smaller.

Rotavirus vaccine may be more cost-effective than calculations to date, if immunization provides indirect protection to unimmunized children and children who failed to have an adequate immune response to vaccine.

CONTRAINDICATIONS AND PRECAUTIONS

Contraindications

- Rotavirus vaccine should not be administered to infants who have a history of a severe allergic reaction (eg, anaphylaxis) after a previous dose of rotavirus vaccine or to a vaccine component (AIII [see Appendix]).
- Latex rubber is contained in the RV1 oral applicator, so infants with a severe (anaphylactic) allergy to latex should not receive RV1 (AIII). The RV5 dosing tube is latex-free.

Precautions

- Altered immunocompetence: Practitioners should consider the potential risks and benefits of administering rotavirus vaccine to infants with known or suspected altered immunocompetence; consultation with an immunologist or infectious diseases specialist is advised (CIII). Children and adults who are immunocompromised because of congenital immunodeficiency, hematopoietic stem cell transplantation, or solid organ transplantation sometimes experience severe or prolonged rotavirus gastroenteritis. However, no published safety or efficacy data are available for administration of rotavirus vaccine to infants who are immunocompromised or potentially immunocompromised, including infants:
  - with primary and acquired immunodeficiency states, including cellular immunodeficiencies, and hypogammaglobulinemic and dysgammaglobulinemic states;
  - with blood dyscrasias, leukemia, lymphomas, or other malignant neoplasms affecting the bone marrow or lymphatic system;
  - on immunosuppressive therapy (including high-dose systemic corticosteroids [≥2 mg/kg per day of prednisone or equivalent]); or
  - who are HIV-exposed or HIV-infected. However, the decision whether to immunize HIV-exposed or HIV-infected infants should be made on the basis of the following considerations:
    - HIV infection may be presumptively excluded by 4 to 8 weeks of age, before the first rotavirus vaccine dose is given, in infants born to HIV-infected mothers in the United States who are not breastfeeding (infants in the United States born to HIV-infected mothers should not be breastfed);
    - HIV-exposed infants in the United States who are not breastfeeding can be identified as HIV-infected by 4 to 8 weeks of age;
    - Preliminary data with 1 of the licensed vaccines have shown the vaccine to be safe when given to HIV-infected infants in Africa;
    - Vaccine strains of rotavirus are considerably attenuated.
- Moderate-to-severe acute gastroenteritis: Rotavirus vaccine should not be administered to infants with acute, moderate-to-severe gastroenteritis until the condition improves. However, infants with mild acute gastroenteritis may be immunized, particularly if the delay in immunization might be substantial and might make the child ineligible to receive vaccine (eg, 15 weeks, 0 days of age or older before the vaccine series is started or older than 8 months, 0 days at the time of the last dose) (CIII).
  - Rotavirus vaccine has not been studied in infants with concurrent acute gastroenteritis. In these infants, the immunogenicity and efficacy of rotavirus vaccine theoretically can be compromised. For example, infants who receive oral poliovirus vaccine (OPV) during an episode of acute gastroenteritis, in some circumstances, have diminished poliovirus antibody responses.
- Moderate-to-severe acute illness: Immunization should not be delayed because of mild respiratory tract illness or other mild acute illness with or without fever. In contrast, as with all other vaccines, the pres-

ence of a moderate or severe acute illness with or without fever is a precaution to administration of rotavirus vaccine. Infants with a moderate-to-severe acute illness should be immunized as soon as they have recovered from the acute phase of the illness (BIII).

- This precaution avoids superimposing any potential adverse effects of the vaccine on the underlying illness or mistakenly attributing a manifestation of the underlying illness to the vaccine.

- Preexisting chronic gastrointestinal diseases: Infants with preexisting gastrointestinal tract conditions (eg, congenital malabsorption syndromes, Hirschsprung disease, short-gut syndrome) who are not undergoing immunosuppressive therapy should benefit from receiving rotavirus vaccine, and the AAP believes the benefits outweigh the theoretical risks (CIII).
  - No data are available on the safety and efficacy of rotavirus vaccine for infants with preexisting chronic gastrointestinal tract disease.
- Previous history of intussusception: Practitioners should consider the potential risks and benefits of administering rotavirus vaccine to infants with a previous history of intussusception (BIII).
  - Compared with infants who have never had intussusception, infants with a history of intussusception are at higher risk of a repeat episode of intussusception. No data are available on the administration of rotavirus vaccine to infants with a previous history of intussusception. Available data do not indicate that RV5 or RV1 are associated with intussusception. A previously licensed rotavirus vaccine that is no longer available (RotaShield [Wyeth-Lederle Vaccines, Radnor, PA]) was associated with an increased risk of intussusception.
- Infants with spina bifida or bladder exstrophy: Latex rubber is contained in the RV1 oral applicator. The RV5 dosing tube is latex-free. Some experts, therefore, prefer that infants with spina bifida or bladder exstrophy, who are at high risk of acquiring latex allergy, receive RV5 instead of RV1 to minimize latex exposure in these children (CIII). However, if RV1 is the only rotavirus vaccine available, it should be given, because the benefit of immunization is considered to be greater than the risk of sensitization.

RECOMMENDATIONS

Routine Administration

- The AAP recommends routine immunization of infants in the United States with rotavirus vaccine. The AAP does not express a preference for either of the 2 licensed rotavirus vaccines, RV5 and RV1, for use in infants in the United States (AI).
- RV5 is to be administered orally in a 3-dose series with doses administered at 2, 4, and 6 months of age. RV1 is to be administered orally in a 2-dose series with doses administered at 2 and 4 months of age (Table 3) (AI).

TABLE 3 Recommended Schedule for Administration of Rotavirus Vaccine

Recommendations	RV5 (RotaTeq)	RV1 (Rotarix)
No. of doses in series	3	2
Recommended ages for doses	2, 4, and 6 mo	2 and 4 mo
Minimum age for first dose	6 wk	6 wk
Maximum age for first dose	14 wk 6 d	14 wk 6 d
Minimum interval between doses	4 wk	4 wk
Maximum age for last dose	8 mo 0 d	8 mo 0 d

- The first dose of rotavirus vaccine should be administered from 6 weeks, 0 days of age through 14 weeks, 6 days of age. Immunization should not be initiated for infants 15 weeks, 0 days of age or older because of insufficient data on safety of the first dose of rotavirus vaccine in older infants (CIII).
- The minimum interval between doses of rotavirus vaccine is 4 weeks. All doses should be administered by 8 months, 0 days of age (RV5, AI; RV1, CIII).
- For infants to whom the first dose of rotavirus vaccine is inadvertently administered at 15 weeks, 0 days of age or older, the remainder of the rotavirus immunization series should be completed according to the schedule, because timing of the first dose should not affect the safety and efficacy of the subsequent dose(s) (BIII).
- Infants who have had rotavirus gastroenteritis before receiving the full series of rotavirus immunization should begin or complete the schedule following the age and interval recommendations, because the initial rotavirus infection provides only partial protection against subsequent rotavirus disease (AII).
- Breastfeeding before or after receipt of rotavirus vaccine is encouraged. Breastfed infants should be immunized according to the same schedule as nonbreastfed infants (AI).
- As with all other vaccines, rotavirus vaccine may be administered to infants with minor acute illness (eg, mild gastroenteritis or mild upper respiratory tract infection, with or without fever) (AIII).

Simultaneous Administration

- Rotavirus vaccine may be administered concurrently with diphtheria and tetanus toxoids and acellular pertussis vaccine, *Haemophilus influenzae* type b vaccine, inactivated poliovirus vaccine, HBV, and pneumococcal conjugate vaccine (AI).
- Rotavirus vaccine may be administered concurrently with trivalent inactivated influenza vaccine for infants older than 6 months. Live-attenuated influenza vaccine is not licensed for immunization of children younger than 2 years (BIII).

- The infant's immune response to trivalent inactivated influenza vaccine administered at the same time as rotavirus vaccine has not been studied. However, the general recommendations issued by the Advisory Committee on Immunization Practices (ACIP) of the CDC noted that an inactivated vaccine (eg, inactivated influenza vaccine) may be administered either simultaneously or at any time before or after a different inactivated vaccine or live vaccine (eg, rotavirus vaccine).

Interchangeability of Rotavirus Vaccines

- The AAP recommends that the rotavirus vaccine series be completed with the same product whenever possible (AIII).
- Rotavirus immunization should not be deferred because the product used for a previous dose(s) is unknown or is not available. In such a circumstance, the health care professional should continue or complete the series with the product available. If any dose in the series was RV5 or the vaccine product is unknown for any dose in the series, a total of 3 doses of rotavirus vaccine should be administered (CIII). All doses should be given by 8 months, 0 days of age.

Special Situations

- Preterm infants (those born at less than 37 weeks' gestation): Preterm infants should be immunized on the same schedule and with the same precautions as for term infants and under the following conditions: the infant's postnatal age meets the age requirements for rotavirus vaccine (eg, from 6 weeks through 14 weeks, 6 days of age for the first dose) and the infant is clinically stable (RV5, AI; RV1, BIII).
  - Data suggest that preterm infants are at increased risk of hospitalization from rotavirus or other viral pathogens associated with gastroenteritis during their first year of life. In clinical trials, rotavirus vaccine seemed to be generally well tolerated in a relatively small number of preterm infants. Although the lower level of maternal antibody against prevalent rotavirus serotypes in very preterm infants theoretically could increase the risk of adverse events from rotavirus vaccine, the AAP believes the benefit of immunizing infants when they are age-eligible and clinically stable outweighs the theoretical risks.
- Preterm infants in the NICU or nursery: Preterm infants who are age-eligible and clinically stable may be immunized at the time of discharge from the NICU or nursery (BIII).
  - Vaccine strains of rotavirus are shed in stools of immunized infants, so if an infant were to be immunized with a rotavirus vaccine while still needing care in the NICU or nursery, at least a theoretical risk exists for vaccine virus being transmitted to infants in the same unit who are acutely ill (moderate-to-severe illness is a precaution for immunization) and preterm infants who are not age-eligible for vaccine. The AAP believes that, in usual circumstances, the risk from shedding outweighs the benefit of immunizing infants who are age-eligible for vaccine but who will remain in the NICU or nursery after immunization.
- Readmission of an immunized preterm infant to the NICU or nursery: If an infant immunized with a rotavirus vaccine requires readmission to the NICU or nursery within 2 weeks after receipt of vaccine, contact precautions should be instituted for the readmitted infant and should be maintained for 2 to 3 weeks after vaccine administration (BIII).
- Exposure of immunocompromised people to immunized infants: Infants living in households with people who have or are suspected of having an immunodeficiency disorder or impaired immune status can be immunized (BIII).
  - Vaccine virus (attenuated rotavirus) is shed in the stool of infants after rotavirus immunization. However, no data are available on risk of transmission of vaccine virus to household contacts and the risk for any subsequent disease. Vaccine virus is shed more commonly and for longer periods after receipt of RV1 than after receipt of RV5. The majority of experts believe the protection of an immunocompromised household member afforded by immunizing the infant in the household and preventing wild-type rotavirus disease outweighs the small risk for transmitting vaccine virus to an immunocompromised household member and any subsequent risk of vaccine virus-associated disease. Vaccine virus is shed during the first weeks after administration of rotavirus vaccine; hand-washing after diaper changing is always recommended.
- Exposure of pregnant women to immunized infants: Infants living in households with pregnant women should be immunized according to the same schedule as infants in households without pregnant women (BIII).
  - The majority of women of childbearing age have preexisting immunity to rotavirus; therefore, the risk of infection and any subsequent theoretical risk of disease from potential exposure to the attenuated vaccine virus are believed to be very low.
- Regurgitation of vaccine: The practitioner should not readminister a second dose of rotavirus vaccine to an infant who regurgitates, spits out, or vomits during or after administration of vaccine (BIII).
  - No data exist on the benefits or risks associated with readministering a dose. The infant should receive the remaining recommended doses of rotavirus vaccine following the routine schedule (with a 4-week minimum interval between doses).
- Hospitalization after immunization: If a recently immunized infant is hospitalized for any reason, no pre-

cautions other than standard precautions need to be taken to prevent the spread of vaccine virus in the hospital setting (BIII).

- Infants who have recently received or will receive an antibody-containing blood product: Rotavirus vaccine may be administered at any time before, concurrent with, or after administration of any blood product, including antibody-containing products, according to the routinely recommended schedule for rotavirus vaccine among infants who are eligible for immunization (BIII).
  - In theory, infants who have recently received an antibody-containing blood product might have an attenuated immune response to a dose of rotavirus vaccine. However, 2 or 3 doses of vaccine are administered in the full rotavirus vaccine series, so adequate protection is anticipated, and no increased risk of adverse events is expected.

ACKNOWLEDGMENTS

This AAP policy statement was prepared in parallel with CDC recommendations and reports. Much of this statement is based on literature reviews, analyses of unpublished data, and deliberations of CDC staff in collaboration with the Advisory Committee on Immunization Practices Rotavirus Working Group, with liaison from the AAP.

APPENDIX 1 Infectious Diseases Society of America-US Public Health Service Grading System for Ranking Recommendations in Clinical Guidelines

Category, Grade	Definition
Strength of recommendation	
A	Good evidence to support a recommendation for use
B	Moderate evidence to support a recommendation for use
C	Poor evidence to support a recommendation
Quality of evidence	
I	Evidence from ≥1 properly randomized, controlled trial
II	Evidence from ≥1 well-designed clinical trial, without randomization; from cohort or case-controlled analytical studies (preferably from >1 center); from multiple time series; or from dramatic results from uncontrolled experiments
III	Evidence from opinions of respected authorities, based on clinical experience, descriptive studies, or reports of expert committees

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Prevention of Sexual Harassment in the Workplace and Educational Settings

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Pediatric Workforce

ABSTRACT

The American Academy of Pediatrics is committed to working to ensure that workplaces and educational settings in which pediatricians spend time are free of sexual harassment. The purpose of this statement is to heighten awareness and sensitivity to this important issue, recognizing that institutions, clinics, and office-based practices may have existing policies.

STATEMENT OF THE PROBLEM

Although this policy statement focuses on medical schools and hospitals, the same principles apply to other professional settings including publicly and privately supported clinics and office-based practices regardless of the number of employees.

More than one third of female physicians perceive that they have been sexually harassed. Research supports the significance of the problem in the medical education setting. According to a study of female physicians, sexual harassment has been found to be more common among individuals in medical school (20%) or during internship, residency, or fellowship (19%) than in practice (11%).[1] Although conventional wisdom has held that sexual harassment is perpetrated only on women, 13.5% of sexual harassment charges brought to the Equal Employment Opportunity Commission in 2001 were from men. This represented an almost twofold increase in reports by men compared with the previous decade.[2] Despite increasing awareness about sexual harassment in the workplace, a survey of hospital human resources managers in 2002 indicated that among the sexual harassment allegations lodged over 4.5 years, physicians were the reported perpetrators 15% of the time, up from 10% 7 years earlier, and 10% of sexual harassment complaints were filed by men.[3]

Gender discrimination and/or sexual harassment were reported in all academic contexts by 69% of female and 33% of male graduating medical students in a 1997 survey of 14 US medical schools, with 63% of women and 30% of men describing these problem behaviors during their core clerkships.[4] In another survey of 1001 graduating students from 8 US medical schools, 21% of the female students and 2% of the male students reported that they had experienced some form of sexual harassment in medical school.[5] In a 1991 survey of second-year residents about their working and learning environment, 63% of female respondents reported having experienced at least 1 episode of sexual harassment or discrimination.[6] A survey of full-time faculty at 24 US medical schools found that 52% of female and 5% of male faculty indicated that they had been sexually harassed by a superior or

colleague; the reported incidence of sexual harassment was almost twice as high in non–primary care compared with primary care specialties.[7]

Sexual harassment in the workplace and in educational settings creates an environment that demeans people and may have a negative impact on individual performance and effectiveness as well as organizational productivity and unit morale. Female medical residents who experienced disrespectful behavior, including sexual harassment, were shown to be 11 times more likely to score high for possible problem drinking compared with their female counterparts who experienced no harassment.[8] Female medical school faculty members who were sexually harassed scored lower on career-satisfaction scales despite equivalent academic achievement.[7] Two studies of university employees demonstrated that those who experienced sexual harassment experienced adverse alcohol-related outcomes and increased utilization of either mental health or health services.[9,10] Although these examples highlight problems in hospital and educational settings as they apply to students, residents, and other employees, there is no reason to believe that other settings such as clinics or physician offices are immune to the effects of this unwelcome behavior. Sexual harassment is certain to affect employees at all levels.

Although sensitivity to this complex issue has been heightened recently, much confusion exists, even about exactly what constitutes sexual harassment, as well as about modalities appropriate for dealing with the problem. It is incumbent on employers, organizations, and institutions to represent all their constituents, male and female, and provide education and guidance to facilitate eradication of this destructive behavior. In particular, medical schools and training programs must be aware of the prevalence of the problem and have action plans available. It is also important to recognize that most medical schools and university hospitals will have separate sexual harassment policies with disparate policies and procedures in place, so grievances from medical students, residents, or staff members may need to be handled in very different ways. The first step is a proactive approach based on fair policy development. Due process is a particularly important component, because false accusations may be made. Policy development, therefore, will also need to address those who are falsely accused. Second, dissemination of grievance and complaint procedures, followed by a prompt response to all complaints, should be the standard in all health care settings, from a small office-based practice to more formal institutional or educational settings.

BACKGROUND

Title VII of the Civil Rights Act of 1964 states that it is unlawful for an employer to discriminate against an individual because of gender[11]; sexual harassment is one form of gender discrimination. Sexual harassment is defined by the Equal Employment Opportunity Commission as follows:

> Unwelcome advances, requests for sexual favors, and other verbal and physical conduct of a sexual nature constitute sexual harassment when: 1) submission to such conduct is made explicitly or implicitly a term or condition of an individual's employment; 2) submission to or rejection of such conduct by an individual is used as a basis for employment decisions affecting such individuals; or 3) such conduct has the purpose or effect of substantially interfering with an individual's work performance or creating an intimidating, hostile or offensive work environment.[12]

Thus, there are 2 general aspects of sexual harassment.[13] The first aspect involves the "quid-pro-quo" or "this-for-that" situation, when submission to unwelcome sexual conduct becomes a condition of employment or personnel action (items 1 and 2 in the aforementioned definition). The second aspect involves the creation of a "hostile work environment" (item 3 in the definition).

Sexual harassment is not gender specific, nor is it always clear-cut. Its presence, however, is noted throughout the entire workforce, which includes all health care personnel. To determine if certain conduct constitutes harassment, various factors may be taken into consideration:

- whether the conduct was unwelcome, unsolicited, or offensive;
- whether the conduct was repeated, particularly if it was repeated despite a warning that it was unwelcome or offensive;
- whether the behavior involved a supervisor-subordinate relationship in which one individual had "power" over another;
- the substance and severity of the conduct: verbal, physical, hostile, disruptive, continuous, pervasive, or provoking;
- whether preferential treatment of individuals in the workplace, on the basis of their sexual behavior, had a negative impact on others in the working environment[14]; and
- whether a "reasonable person" would be substantially negatively affected by similar circumstances.[15]

Notwithstanding all the law, literature, and discussion on this issue, even very well-meaning people remain confused and concerned about what really constitutes sexual harassment. Until very recently, sexual harassment of men by other men was not explicitly defined by Title VII; discrimination based on sexual orientation was generally not considered sexual harassment. However, a number of court cases and surveys of undergraduate students, medical students, and physicians make us reconsider these long-held beliefs. In a landmark case

brought to the US Supreme Court in 1997, a man filed a complaint against his employer after being subjected to egregious "hazing" behaviors involving groping and physical contact by co-workers. The court held that same-sex harassment is actionable under Title VII and that men, as well as women, are entitled to protection.[16]

Although not much research has been published on sexual harassment of gays and lesbians in medicine, in a survey conducted by the US-based Gay and Lesbian Medical Association, 59% of gay and lesbian medical students and physicians reported job-related discrimination.[17] A survey of gay and lesbian Yale students and community members indicated that 65% were targets of verbal insults, 25% received threats of physical violence, and 42% were physically abused because of their sexual orientation. Of both male and female respondents, 12% indicated that they were sexually harassed or assaulted because of their sexual orientation.[18] A survey of gay and lesbian third- and fourth-year medical students applying for residency was conducted in parallel with a survey of family practice program directors to assess attitudes and biases about sexual orientation. More than 70% of the medical students indicated that their specialty choice was influenced by their own perceptions of how other physicians in a given field would accept them. Furthermore, 8% of family medicine program directors regarded disclosure about an applicant's homosexuality in a negative light, 25% demonstrated a neutral perspective, and 67% demonstrated an accepting attitude.[19]

Certain egregious behaviors clearly represent sexual harassment. Rape or indecent assault, as well as using one's position of authority by offering rewards or threatening to influence another person's career on the basis of sexual favors, are agreed on as clearly constituting sexual harassment. At the other end of the spectrum, most people agree that it is acceptable behavior for a person to respectfully compliment someone's appearance. However, repetitive unwelcome requests or leering, gesturing, or making insulting, sexually oriented comments also constitute sexual harassment. Although consensual sexual relationships with no duress generally do not fall within the rubric of sexual harassment, they nonetheless may still be ethically inappropriate (if not sexual harassment) in the workplace if, for example, a supervisor-subordinate relationship exists. The American Medical Association has taken a firm stand on this issue in their policy titled "Sexual Harassment and Exploitation Between Medical Supervisors and Trainees" and suggests that even consensual sexual relationships between supervisors and trainees are not acceptable.[20] Thus, it may be important for an institution, organization, or employer (including medical school administration, faculty members, and program directors) to address, as well, standards of conduct that are broader in scope than just those that are considered sexual harassment.

What constitutes a "hostile environment" is often unclear but may certainly include sexually oriented posters, pictures, or calendars as well as sexually explicit jokes or comments. Touching is considered to be sexual in some cases but not in others. Common sense should prevail. The best solution to the problem of sexual harassment is prevention. Individuals working in all medical education and health care delivery settings should take steps to ensure open communication, dissemination of institutional policies, and creation of an environment in which individuals can safely communicate their discomfort to those harassing them.

The American Academy of Pediatrics (AAP) concurs with the American Medical Association policy[21] that dictates that all medical training programs develop and implement a policy that specifically addresses sexual harassment and exploitation. The Accreditation Council for Graduate Medical Education's institutional requirements, which apply to all residency programs in all specialties, mandate that "[t]he Sponsoring Institution must have written policies covering sexual and other forms of harassment" and that "[t]he Sponsoring Institution retains responsibility for the quality of GME [graduate medical education] even when resident education occurs in other institutions." This and other policies must be contained in, or referenced as part of, the resident's agreement of appointment.[22] These institutional requirements direct sponsoring institutions to maintain master affiliation agreements with major participating institutions and program letters of agreement or memoranda of understanding in compliance with program requirements. Resident education, therefore, is conducted at each site where residents rotate, with the expressed understanding that some harassment policy will apply. Some locations, such as major academic affiliations, may have their own harassment policies. According to Patricia M. Surdyk, PhD (Executive Director, Accreditation Council for Graduate Medical Education Institutional Review Committee, written communication, March 2006), the master affiliation agreement and/or program letters of agreement with individual sites such as physician offices would clarify which harassment policies apply in such cases. Residents must both be protected in all situations in which they find themselves as part of the education program, and likewise are expected to adhere to policies governing behavior at all locations.

Although the vast majority of hospitals have formal written policies on sexual harassment,[3] many private medical groups and office-based practices may not have such policies in place. As medical professionals, interactions with patients, parents, and caregivers may also be subject to close scrutiny and potential accusations of impropriety. The AAP offers guidance on this through a number of resources including a policy statement, "Appropriate Boundaries in the Pediatrician-Family-Patient

Relationship."[23] The rules that apply to conduct with co-workers should also apply to behavior at the bedside and during office visits. Although it is not required by law that private medical offices have in place official policies regarding sexual harassment, having such a policy may offset many potential claims from employees in this setting as well. Resources are now available to private practitioners to guide them in establishing such office policies. One author has suggested that employers develop a simple written policy on sexual harassment, which should include a step-by-step grievance procedure.[24] The sexual harassment policy should be made available in the employee handbook and posted in the office; employees may also benefit from 1 or more sexual harassment training sessions.[25] Several sample sexual harassment policies that can be adapted for medical offices and individual physicians are available online.[26,27]

RECOMMENDATIONS

Sexual harassment has important implications for men and women and for all individuals involved in health care delivery. Reference literature provides guidance regarding the scope of protection, liabilities, and remedies for sexual harassment.[28] Irrespective of the specifics of the law, all individuals desire and deserve a workplace in which they are treated with appropriate respect in a comfortable environment conducive to effective teamwork and optimal productivity. As such, leaders and employers must set the pace in affirmatively combating sexual harassment in the workplace regardless of the number of employees.[29] Several recommendations for corporate, academic, and office-based practice settings include:

- Educate people to avoid sexually offensive behavior.
- Establish written procedures to address sexual harassment issues and achieve problem and grievance resolution.
- Ensure that the rights of both parties are considered and both are afforded due process.

The following are additional suggestions for decreasing the incidence of sexual harassment in the workplace and educational settings:

- Encourage supervisors, physicians, and administrators to set an example by serving as positive role models.
- Investigate all complaints promptly and confidentially.
- Follow-up on all complaints.
- Sensitize employees through an interactive training process.
- Consider using an outside mediator to evaluate any complaints of sexual harassment (especially for smaller health care organizations).[30]

Risk management requires communication of clear definitions of acceptable standards of behavior, treatment of all complaints as serious matters, discipline for offenders, and steps to prevent subsequent offenses. In addition, once a complaint has been adjudicated, efforts must be taken to ensure a smooth transition for the employees coming back into the workplace. Follow-up counseling and/or periodic meetings individually with the party or parties involved should be provided as warranted.

The AAP recognizes that its constituents work in a broad spectrum of settings, often moving from the office, to a hospital, and to an educational environment within a single day. The size and nature of each organization are important factors in determining the degree of formality required to accomplish the eradication of sexual harassment. It is our intent that this policy statement be used in concert with any existing procedures. The purpose of this statement is to heighten awareness and sensitivity to this important issue and encourage reassessment of existing policies in all medical practice and educational settings.

AMERICAN ACADEMY OF PEDIATRICS

CLINICAL REPORT
Guidance for the Clinician in Rendering Pediatric Care

Sheila Gahagan, MD; Janet Silverstein, MD; and the Committee on Native American Child Health and Section on Endocrinology

Prevention and Treatment of Type 2 Diabetes Mellitus in Children, With Special Emphasis on American Indian and Alaska Native Children

ABSTRACT. The emergence of type 2 diabetes mellitus in the American Indian/Alaska Native pediatric population presents a new challenge for pediatricians and other health care professionals. This chronic disease requires preventive efforts, early diagnosis, and collaborative care of the patient and family within the context of a medical home. ***Pediatrics*** **2003;112:e328–e347. URL: http://www.pediatrics.org/cgi/content/full/112/4/e328;** ***type 2 diabetes mellitus, children, American Indian, Alaska Native, Native American, pediatric population.***

ABBREVIATIONS. AI/AN, American Indian/Alaska Native; AAP, American Academy of Pediatrics; IHS, Indian Health Service; CDC, Centers for Disease Control and Prevention; ADA, American Diabetes Association; PCOS, polycystic ovarian syndrome; BMI, body mass index; HbA_{1c}, glycosylated hemoglobin; OGTT, oral glucose tolerance test; FBG, fasting blood glucose; FPG, fasting plasma glucose; SMBG, self-monitoring of blood glucose; ACE, angiotensin-converting enzyme; LDL, low-density lipoprotein; HDL, high-density lipoprotein; NDEP, National Diabetes Education Program; NPH, neutral protamine Hagedorn; TZD, thiazolidinedione.

STATEMENT OF THE PROBLEM

Type 2 diabetes mellitus* is a new morbidity in children and adolescents.[1–4] For pediatric patients, it heralds earlier onset of cardiovascular disease, retinopathy, nephropathy, and neuropathy, with risk of impaired quality of life and premature death. The emergence of type 2 diabetes mellitus in young people is believed to be associated with changes in physical activity and nutrition that are ubiquitous in modern society. Not all populations are equally affected. American Indian/Alaska Native (AI/AN) children in the United States and Canada have a higher rate of this disease than do children of other ethnicities. Mexican American and black children are at increased risk. Vulnerable populations that exhibit new disease trends may be seen as the "canary in the coal mine," warning of hazards present for the entire population. In US children, the prevalence of type 2 diabetes mellitus is expected to exceed that of type 1 diabetes mellitus within 10 years. There is a compelling need for additional research, primary and secondary prevention efforts, and evidence-based treatment for youth with type 2 diabetes mellitus.

PURPOSE

These guidelines have been developed to assist in clinical decision making by primary health care professionals and are not intended to replace existing management protocols for the medical treatment of diabetes.[5] It is assumed that clinical care will be individualized for each child and adolescent. In keeping with the spirit of community pediatrics and the *Healthy People 2010* objectives, the American Academy of Pediatrics (AAP) believes that medical care for AI/AN children, like that of all other children, should be provided within a medical home, which "ideally should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective. It should be delivered or directed by well-trained physicians who provide primary care and manage and facilitate essentially all aspects of pediatric care. The physician should be known to the child and family and should be able to develop a partnership of mutual responsibility and trust with them."[6]

METHODS

The AAP Committee on Native American Child Health, in collaboration with the Indian Health Service (IHS) Diabetes Program, the Centers for Disease Control and Prevention (CDC), and the AAP Section on Endocrinology, developed these guidelines to improve the medical care for AI/AN children with type 2 diabetes mellitus and those at risk of type 2 diabetes mellitus. This effort was greatly assisted by the 2000 American Diabetes Association (ADA) consensus statement on type 2 diabetes mellitus in children and adolescents.[2,3]

These guidelines were developed after a review of published data on type 2 diabetes mellitus in American Indian and First

The recommendations in this report do not indicate an exclusive course of treatment or serve as a standard of care. Variations, taking into account individual circumstances, may be appropriate.

*Type 1 diabetes mellitus is characterized by a lack of insulin production. Type 2 diabetes mellitus is a metabolic disorder secondary to an inability to appropriately use or make adequate insulin.

Nations† children[7–23] and are adapted from the medical literature on adults with type 2 diabetes mellitus.[5,24–29]

These guidelines were developed to support the role of the general pediatrician or other primary health care professional as the front line for care. The treatment of most AI/AN children with type 2 diabetes mellitus will be managed by primary health care professionals with specialty consultation. It is hoped that these guidelines will serve as a framework for the development of diabetes care programs and strategies aimed at decreasing the devastating impact of type 2 diabetes mellitus on AI/AN children and their families and communities. A section on primary prevention of type 2 diabetes mellitus is included and is based on existing data.

PRIMARY AND SECONDARY PREVENTION

Prevention must take highest priority and should focus on decreasing the risk, incidence, and consequences of type 2 diabetes mellitus among AI/AN children. Primary prevention efforts by primary health care professionals are recommended in 2 arenas: 1) general community health promotion and health education and 2) clinically based activities. Clinically based health promotion activities should not duplicate community-wide health promotion but instead should offer additive benefits. For example, if significant health education is offered at the community level, then motivational interviewing and collaborative problem solving can be offered in the clinical setting. When type 2 diabetes mellitus is the established diagnosis, secondary prevention efforts by primary health care professionals are important for the prevention of complications (eg, vascular, neural, renal, retinal). Early diagnosis and optimal medical care are the keys to effective secondary prevention.

To be effective, prevention efforts need a strong community base and acceptance. Current evidence suggests that modifiable risks for type 2 diabetes mellitus include obesity and lack of breastfeeding.[30] Primary prevention efforts can focus on the prevention of obesity in children and the promotion of breastfeeding. Preventing obesity in women of childbearing age is another primary prevention goal, because exposure to the environment of a diabetic pregnancy places the fetus at increased risk of future onset of diabetes.[30]

Community Activities

Community prevention activities are being developed in AI/AN communities on the basis of each tribe's unique needs and resources. Development and implementation of these activities should have the endorsement of appropriate tribal authorities. Ideally, these activities are multidisciplinary (eg, medical, nutrition, public health, nursing, health education) and include local businesses, community recreational programs, Head Start programs, and schools.[31,32] Tribal food and nutrition programs (eg, Special Supplemental Nutrition Program for Women, Infants, and Children; US Department of Agriculture's Food Distribution and Food Stamp program) have a prominent role in promoting foods that minimize the risk of obesity. Community programs and services should develop consistent messages and supply foods that assist in decreasing the prevalence of obesity. Studies to evaluate the effectiveness of community-based obesity and diabetes risk reduction efforts are in progress.[33,34]

Health care professionals can play a crucial role in their communities by raising community awareness about the importance of programs and facilities for physical activity and resources for healthy nutrition.[35] The powerful influence of physicians extends outside the clinic when they thoughtfully advocate for healthy lifestyles and good nutrition practices within the community.

Pediatricians and other health care professionals should advocate for school policy that requires daily physical activity for every child and for physical fitness programs in the school and community. They should urge stores, restaurants, and schools to offer low-caloric density foods of high nutritional value in appropriate portions. Lack of physical activity is associated with the development of obesity, type 2 diabetes mellitus, and cardiovascular morbidity and mortality. Despite information on the importance of exercise, a low proportion of high school students participate in daily physical education classes.[36,37] Increasing physical activity should include participating in at least 30 minutes of physical activity daily, limiting sedentary activity (eg, watching television, playing video games, using a computer) to no more than 1 to 2 hours per day, and participating in sports. Community recreation programs and schools should encourage youth to participate in events that require physical activity. The community leadership should receive information on and understand the importance of physical activity and the value of having programs and facilities available for youth. Recommendations and programs should respect family, culture, and community values.

Health care professionals can use their expertise to provide prevention messages to the community on healthful lifestyles and good nutrition via local media (eg, radio, television, newspapers, posters). Prevention messages need to be thoughtfully developed to resonate with community and tribal culture and beliefs. Youth involvement in community prevention efforts can be highly effective.

Community involvement in the promotion and support of healthful lifestyles reinforces recommendations made in the health care setting. The engagement and empowerment of communities is critical for overall success in decreasing the disease burden of type 2 diabetes mellitus for the AI/AN population. Schools are integral in the successful management of type 2 diabetes mellitus (and other chronic illnesses) and potentially are important resources for promoting children's diabetes self-care, including blood glucose monitoring, appropriate recognition and treatment of hypoglycemia, and treatment of acute hyperglycemia.

Clinically Based Primary and Secondary Prevention Activities

Health care professionals have influential roles in preventing type 2 diabetes mellitus among at-risk

†First Nations is the term used in Canada to identify Native or Aboriginal people. In this article, this term is used when citing research done in Canada.

youth via direct patient care contacts. Children with 1 or more risk factors (see "Case Finding") identified by the ADA consensus panel on type 2 diabetes mellitus in children should be monitored closely.[2,3] Identification of disorders associated with insulin resistance, such as acanthosis nigricans, polycystic ovarian syndrome (PCOS), and family history of diabetes, should trigger education and the initiation of prevention activities.

Children whose body mass index‡ (BMI; see also "Physical Assessment") is greater than the 85th percentile for their age§ should receive appropriate counseling on nutrition, weight control, and physical activity. This is especially important because there is evidence that type 2 diabetes mellitus can be delayed or prevented by lifestyle interventions. These children may require treatment for hypertension and hyperlipidemia and should return for follow-up evaluation and additional lifestyle intervention within 3 months.

Until results of current prevention trials with oral hypoglycemic agents in youth are available, intervention using glucose-lowering drugs for prevention of diabetes is not recommended. (These medications are, however, recommended for treatment of children with diagnosed type 2 diabetes mellitus.)

Knowledgeable health care professionals (eg, nutritionists, health educators, physicians, nurses, community outreach workers) should guide nutrition interventions in AI/AN children and their families. Any intervention needs to consider growth and development in children. The most effective approach is appropriate reduction of calories along with increased energy expenditure. Specific recommendations need to be individualized, and continued evaluation is crucial for long-term success. Individualized plans are based on collaboration with the child and the family to assess food preferences, timing and location of meals and snacks, food preparation, and desire to change behaviors. Family resources and the availability of low-calorie nutritious foods in the community must be considered. Pharmacologic therapy to decrease weight is not recommended for children until more safety and efficacy data are available. Very low-calorie diets and high-protein diets are contraindicated, except in a well-controlled research setting. Quick-fix weight loss programs are unsafe for children and rarely result in long-term weight control; furthermore, they do not promote lasting, healthful eating behaviors. Weight loss programs with the best results combine exercise and dietary components with behavior modification.[38] Accomplishing changes in the child's eating behavior and activity relies on changes made by the entire family.

‡BMI is a measure based on weight and stature (kg/m^2). A simple calculation can be made as follows: weight in pounds divided by height in inches, divided by height in inches again, and multiplied by 703.
§Growth charts developed by the CDC; see "Physical Assessment" for Web site address.

IDENTIFICATION

The prevalence of type 2 diabetes mellitus in AI/AN children as well as AI/AN adults is higher than among other ethnic groups.[2,3,18] Among Pima Indian adolescents 15 to 19 years of age, the prevalence of type 2 diabetes mellitus estimated through screening increased significantly during the past 2 decades and reached 5% in the 1992–1996 time period.[19] (Although population-based prevalence estimates are not available for children and adolescents in the United States, a retrospective review estimated an incidence of 7.2 per 100 000 for black and white children and adolescents in southwestern Ohio in 1994.[20]) In Manitoba, Canada, the prevalence of type 2 diabetes mellitus diagnosed through screening was 3.6% for First Nations girls (0% for boys) 10 to 19 years of age in 1996–1997.[15] The prevalence of diagnosed diabetes (all types) among youth 15 to 19 years of age receiving services from the IHS was 0.45% in 1996, reflecting a 54% increase since 1988.[21] In Montana and Wyoming IHS clinics, the prevalence of diagnosed diabetes (all types) was 0.23% among American Indian youth 0 to 19 years of age in the period 1997–1999.[22,23] Therefore, the high burden of diabetes on AI/AN communities and their youth deserves specific research efforts directed toward better case identification.

Population-Based Screening

Many AI/AN communities are interested in population-based screening for type 2 diabetes mellitus. The evidence that microvascular complications of diabetes are strongly associated with previous hyperglycemia raises interest in earlier diagnosis during the asymptomatic period.[39] However, population-based screening for type 2 diabetes mellitus in high-risk children is not recommended, except as part of research efforts to advance knowledge about optimal prevention, diagnosis, and treatment.[40–43] Population-based screening remains controversial, because there are no data from controlled trials showing that earlier diagnosis improves long-term outcome. It is essential that studies be performed to determine the specificity, sensitivity, and cost-benefit of screening for type 2 diabetes mellitus in high-risk populations of children and adolescents.

The World Health Organization has recommended that before embarking on population-based screening, the following criteria be met[44]:

1. The condition should be an important health problem.
2. There should be an accepted treatment for patients with recognized disease.
3. Facilities for diagnosis and treatment should be available.
4. There should be a recognizable latent or early symptomatic stage.
5. There should be a suitable test or examination.
6. The test should be acceptable to the population.
7. The natural history of the condition, including development from latent to declared disease, should be understood adequately.

8. There should be an agreed policy on whom to treat as patients.
9. The cost of case finding should be economically balanced in relation to possible expenditure on medical care as a whole.
10. Case finding should be a continuing process and not a once-and-for-all project.

Although some of these criteria can be met, a key aspect to the second criterion is that there must be evidence that earlier identification improves clinical outcomes before the costs of this endeavor can be justified under nonresearch protocol.[44] The first results from the Diabetes Prevention Program show that diet and exercise delay the onset of diabetes and normalize blood glucose in adults.[45] Therefore, it is important to identify children and adolescents who are at risk of developing diabetes, such as those with obesity and signs of insulin resistance, to begin lifestyle management programs that could prevent and delay the development of diabetes. Many of these children will have impaired glucose tolerance.

Before beginning screening programs, health care systems and institutions must identify resources for intervention for people who will be identified with type 2 diabetes mellitus or altered glucose metabolism by the screening program. Screening programs can cause harm if effective treatment is not available.

If universal screening were performed in the United States on the basis of the ADA risk criteria for type 2 diabetes mellitus in youth, then 10% of US adolescents (2.5 million) 12 to 19 years of age would be tested.[43] This screening would not yield a large number of new diagnoses because of the low prevalence of type 2 diabetes mellitus in the general adolescent population.[46]

Screening efforts have been implemented as part of research initiatives for some high-risk populations. Among the Pima Indians, screening has been performed by the National Institutes of Health since 1965 as part of a longitudinal epidemiologic study. Because of the high prevalence of type 2 diabetes mellitus among Pima Indian children identified by the epidemiologic study, current efforts focus on measuring glycosylated hemoglobin (HbA_{1c}) concentration in children who are at risk and referring them for a 2-hour oral glucose tolerance test (OGTT) if the HbA_{1c} concentration is more than 5.5%.[18] Another survey conducted in 1996–1997 in 717 First Nations school youth 4 to 19 years of age from Manitoba identified 6 new cases and 2 previously identified cases by using the fasting blood glucose (FBG) concentration.[15] A survey of 276 Navajo students 13 to 20 years of age at 2 high schools found 1 case of diabetes and 8 cases of impaired glucose tolerance or impaired FBG concentration.[8] Future studies may identify specific criteria for screening children for type 2 diabetes mellitus in AI/AN populations.

Earlier diagnosis of diabetes may prevent or slow the development of complications if active treatment is implemented early and proves efficacious. In a world of limited resources, the benefits of screening efforts need to be assessed and balanced with those of other programs that may benefit the same population.

Some IHS areas and Indian tribes are developing screening and intervention programs for obesity and hypertension in youth. These efforts will result in identifying youth who are at increased risk of type 2 diabetes mellitus and have the potential to benefit from primary prevention interventions.

Case Finding

Although population-based screening is not recommended, early case finding and early initiation of treatment may prevent some sequelae of type 2 diabetes mellitus. Overweight children who have entered puberty (or who are older than 10 years) are considered at risk by the ADA if they meet 2 of the following criteria[2,3]:

- Family history of type 2 diabetes mellitus in first- or second-degree relative
- Race or ethnicity is American Indian, Alaska Native, black, Hispanic, or Asian/Pacific Islander
- Presence of a condition associated with insulin resistance (acanthosis nigricans, hypertension, dyslipidemia, PCOS)

The following are definitions for being at risk for overweight[47]:

- BMI between the 85th and 95th percentiles for age and sex
- Weight-for-height ratio between the 85th and 95th percentiles

The following are definitions for being overweight:

- BMI greater than the 95th percentile for age and sex
- Weight-for-height ratio greater than the 95th percentile
- Weight greater than 20% of the ideal weight for height

The term "obese" is not defined for children by the CDC. Health care professionals should be knowledgeable about risk factors and make appropriate decisions to test individual patients.

Diagnosis (Clinic Based)

The diagnosis of type 2 diabetes mellitus in a child or an adolescent usually will be made by an astute health care professional in a clinical setting rather than as a result of a screening program. Knowledge of the aforementioned risk factors will assist the health care professional in considering and making the diagnosis when the patient is asymptomatic. Symptomatic and asymptomatic disease manifestations are described in "Pharmacologic Management on the Basis of Clinical Manifestations."

Specialists should be consulted for children and adolescents in whom diabetic ketoacidosis is detected. Furthermore, subspecialty consultation is indicated for children with hyperglycemia (FBG >250 mg/dL [>13.9 mmol/L]) but without the clinical features, family history, or physical characteristics

commonly associated with type 2 diabetes mellitus. In such cases, diagnostic differentiation between type 1 and type 2 diabetes mellitus may require additional studies, such as autoimmune markers (islet cell antibodies, glutamic acid decarboxylase antibodies), challenge tests with high-calorie nutritional supplements (eg, Sustacal and Boost Nutritional Energy Drink [Mead Johnson Nutritionals, Evansville, IN]) or glucagon, or assays of insulin or C peptide. Children with type 2 diabetes mellitus may have normal or high C peptide and fasting insulin concentrations. However, children with type 2 diabetes mellitus with toxic effects of glucose attributable to prolonged hyperglycemia before diagnosis may have transient low insulin concentrations and may benefit from a short course of subcutaneous insulin therapy. Specialty consultation also should be sought when youth are unable to achieve treatment goals in a reasonable time frame or when complications occur. Specialty consultation is helpful for youth with hyperlipidemia and hypertension.

The subspecialist often is a pediatric endocrinologist. However, the primary health care professional (eg, pediatrician, family physician, internist) who is responsible for the diabetes clinic in an AI/AN health care facility may be a clinically competent expert in the management of type 2 diabetes mellitus. In geographically isolated locations, telemedicine may facilitate specialty consultation.

ONGOING EVALUATION AND MONITORING FOR TYPE 2 DIABETES MELLITUS IN CHILDREN

History and Psychosocial Assessment

A complete medical history, including a review of systems, is essential at diagnosis and at regular intervals (Table 1), with special attention to emotional disorders; eating disorders; alcohol, tobacco, and drug use; and family support. Emotional and behavioral disorders, particularly depression, have been associated with diabetes.[48–57] Psychosocial assessment is recommended at diagnosis and informally at every visit. Assessment may be performed on the basis of patient history or by using a standardized screening tool.[58,59] A social worker or a psychologist on the diabetes team can assist with this evaluation. If depression or another emotional disorder is identified, then treatment and referral should be initiated promptly.

Health care professionals and dietitians should screen for eating disorders as part of the standard nutrition evaluation for all children with type 2 diabetes mellitus.[60] Binge eating and bulimia are significant concerns. Psychiatrically defined eating disorders are differentiated from culturally normal behaviors, some of which may be unhealthful.

The use of alcohol, tobacco, and drugs should be evaluated in all children and adolescents in whom diabetes is newly diagnosed, and it should be reevaluated, at least informally, at every visit. The family's attitudes toward the use of these and other substances should be evaluated as well. Alcohol use may aggravate hypoglycemia caused by sulfonylureas or insulin and increase the risk of lactic acidosis in patients who use metformin.

Family support is essential to the child or adolescent with type 2 diabetes mellitus. The family's strengths and needs should be assessed so that necessary assistance can be offered. This assessment should include positive and negative role models in the home, availability of healthful foods (eg, fresh fruits and vegetables), financial resources, parental literacy, cultural beliefs about health and illness, and the family's understanding of diabetes. The involvement of the whole family in dietary and activity changes will promote successful management of the child's diabetes. A family history of diabetes and cardiovascular disease will influence the meaning of this illness within the family. Support services for the family may include health education, financial services, social services, mental health counseling, transportation, and home visiting. Socially disorganized families need early psychologic and social work intervention.

Physical Assessment

Although a complete physical examination is recommended for all children at diagnosis, special attention should be given to the following elements (Table 2).

Weight and height should be plotted on a growth chart. The weight goal should be based on BMI (weight [kg]/height^2 [m^2]). (The Web site for growth charts[61] is: www.cdc.gov/nchs/about/major/nhanes/growthcharts/charts.htm.) Weight should be measured at each visit, but height may be measured twice a year.

The blood pressure goal is less than the 90th percentile on the basis of height and weight standards. Blood pressure is assessed at each visit. Blood pressure control is discussed in "Reducing Cardiovascular Risk"[62,63] (Table 3).

The skin, especially the back of the neck, the underarms, and the groin, should be evaluated for acanthosis nigricans, a thickened, hyperpigmented

TABLE 1. Ongoing Evaluation and Monitoring After Diagnosis: History

History Component	Frequency*	Recommendations
Interval history	Initially every 3 months	Include ROS
Psychosocial assessment	↓	May use standardized questionnaire[78,79]
Eating disorder	↓	Binge eating, bulimia
Substance abuse	↓	Alcohol, tobacco, drugs
Family assessment	↓	Strengths, needs

ROS indicates review of systems.
* Frequency of detailed history may decrease in case of metabolic control and low-risk social circumstances to every 6 to 12 months.

TABLE 2. Ongoing Evaluation and Monitoring After Diagnosis: Physical Examination

Physical Examination Component	Frequency	Recommendations
Weight	Initially every 3 mo*	
Height, BMI	Initially every 3 mo*	
Blood pressure	Initially every 3 mo*	
Skin	Every 12 mo	Acanthosis nigricans, hirsutism, tinea, acne
Foot	Every 12 mo but visual foot check every 3 mo	Pedal pulses, neurologic examination, nails

* May decrease to every 6 months if linear growth is complete and glucose is well controlled.

skin condition (Fig 1). Acanthosis nigricans often correlates with high BMI and insulin resistance. The resolution of acanthosis nigricans may be a useful marker for decreasing insulin resistance.[64] Insulin resistance may improve as weight decreases. The improvement of the skin condition as a result of better metabolic control is highly desirable to adolescents. Therefore, identification of this condition is especially useful as a motivator for adolescents. Other treatable skin conditions may occur in association with insulin resistance, including tinea capitis, tinea corporis, and tinea pedis. Hirsutism or significant acne may be markers of hyperandrogenism in girls. Hirsutism is related to hyperinsulinism and is another potential motivating factor for adolescents to accomplish nutritional and physical activity goals.[65–67]

A thorough visual inspection of the feet, including pedal pulses (posterior tibial and dorsalis pedis) and a neurologic examination are recommended shortly after diagnosis and then annually (Fig 2). The monofilament examination for foot sensation is included to assess protective sensation.[68] This examination is performed using the 5.07 (10-g) Semmes-Weinstein nylon monofilament mounted on a holder that has been standardized to deliver a 10-g force when applied properly. Because the sensory deficits appear first in the most distal portions of the foot and progress proximally in a "stocking" distribution, the toes are the first areas to lose protective sensation. The examination should include assessment for treatable nail conditions, such as paronychia and ingrown toenails. The main purpose of the foot examination in children is to teach that foot care is an important health habit.

A funduscopic examination with dilation to detect signs of diabetic retinopathy is recommended shortly after diagnosis and then annually by an experienced eye care professional.[69,70]

Yeast vaginitis and balanitis are commonly seen in children and adolescents with type 2 diabetes mellitus.[71] Inspection of the vulva and penis should be included in the physical examination to screen for these disorders. Tanner staging of children and adolescents with type 2 diabetes mellitus should be performed every 3 to 6 months until puberty is complete, because early onset of puberty is noted in overnourished children.[72,73] A gynecologic examination for girls and a genital examination for boys may provide an opportunity to obtain additional sexual history and to offer abstinence and contraceptive counseling. Menstrual irregularities may be symptoms of PCOS in postpubertal girls.

Laboratory Evaluation

The fasting plasma glucose (FPG) concentration is the standard test for diagnosis. Monitoring is based on the FPG concentration and additional blood glucose measurements throughout the day. Fasting is defined as no consumption of food or any beverage other than water for at least 8 hours before testing. Most monitoring is performed by self-monitoring of blood glucose (SMBG) concentrations. Tables 4 and 5 include diagnostic and self-monitoring values.

The 2-hour postprandial glucose test provides information about glucose metabolism that is not provided by FPG measurement. It can be used for diagnosis together with FPG testing and must be used for monitoring.

Measurement of HbA_{1c} concentration should be performed quarterly. The results should be available at the time of the patient visit and discussed with the patient. Technology is available to perform rapid HbA_{1c} testing. Many diabetes clinics have standing orders for the performance of HbA_{1c} testing before the health care professional's consultation and discussion with the patient. The HbA_{1c} result can verify SMBG data and is useful for identifying the need to adjust insulin dosage when SMBG data are unavailable. Setting realistic short- and long-term goals in consultation with a pediatric endocrinologist or other health care professional knowledgeable about childhood type 2 diabetes mellitus is recommended whenever possible. The HbA_{1c} concentration goal is less than 7.0% (or <1% above the laboratory reference range). This may not be achievable for all patients. Realistic goals should be individualized for each patient. HbA_{1c} concentration greater than 8.0% is associated with a substantial increase in complications.[74] Any sustained decrease is beneficial.

It is important to screen for proteinuria at diagnosis and annually. Testing for microalbuminuria is indicated if proteinuria is absent. Microalbuminuria is a high urinary albumin concentration that is not detected on routine dipstick testing. Microalbuminuria is defined as a urinary albumin excretion of 20 to 200 μg per minute (30–300 mg per day). Annual screening for microalbuminuria permits early identification and treatment of patients who are at risk of nephropathy. The recommended method of detection is the measurement of the albumin-creatinine ratio in a spot urine collection. An alternative method uses reagent tablets or dipsticks that detect microalbuminuria. When positive, the results of rapid tests should be confirmed by the urinary albumin-creatinine ratio in a timed urine collection. A patient is not designated as having microalbuminuria unless 2 of 3 collections performed within a 3- to 6-month period show increased concentrations. This test is not valid if the patient has a urinary tract infection or during menses. Although microalbuminuria may be encountered in patients in whom type 2

TABLE 3. Classification of Hypertension

Age (Years)	High Normal (mm Hg)*	Significant Hypertension (mm Hg)†	Severe Hypertension (mm Hg)‡
6–9	Systolic: 111–121	Systolic: 122–129	Systolic: >129 (129)§
	Diastolic: 70–77	Diastolic: 70–85	Diastolic: >85 (84)
10–12	Systolic: 117–122	Systolic: 126–133	Systolic: >133 (134)
	Diastolic: 75–81	Diastolic: 82–89	Diastolic: >89 (89)
13–15	Systolic: 124–135	Systolic: 136–143	Systolic: >143 (149)
	Diastolic: 77–85	Diastolic: 86–91	Diastolic: >91 (94)
16–18	Systolic: 127–141	Systolic: 142–149	Systolic: >149 (159)
	Diastolic: 80–91	Diastolic: 92–97	Diastolic: >97 (99)

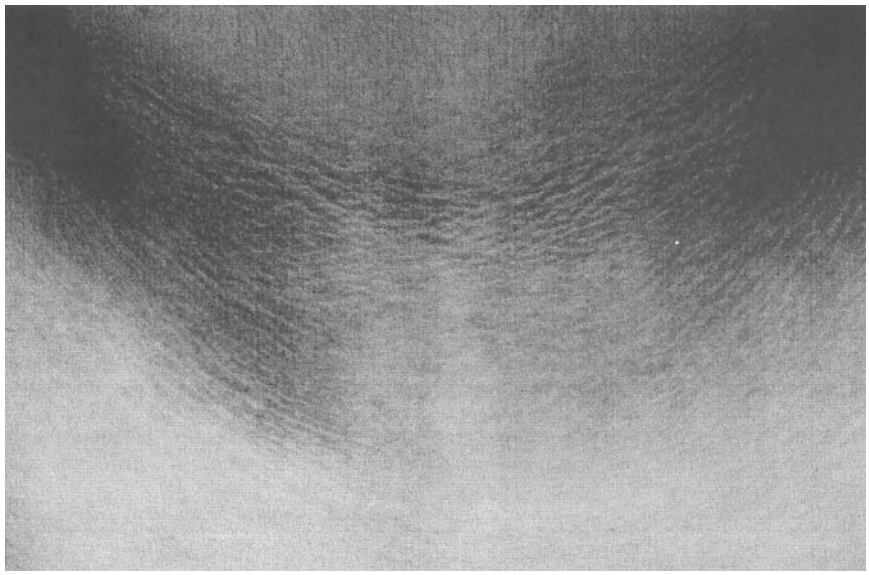

Fig 1. Acanthosis nigricans on the neck.

diabetes mellitus is newly diagnosed, proteinuria is the hallmark of diabetic nephropathy (Fig 3).[19,75,76]

The serum creatinine concentration should be determined at diagnosis and when indicated for drug therapy. Annual serum creatinine screening is indicated for patients with hypertension or microalbuminuria and for people taking angiotensin-converting enzyme (ACE) inhibitors.

A fasting lipid profile, including total cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL), and triglyceride concentrations, should be performed after diagnosis. The fasting lipid profile is best obtained after initial metabolic stabilization (1–3 months after diagnosis). The primary goal of therapy is to lower the LDL concentration,[77] which is discussed further in "Reducing Cardiovascular Risk."

Liver function tests, including aspartate transaminase and alanine transaminase, should be performed before initiation of oral hypoglycemic therapy. Additional monitoring may be required depending on the person's drug regimen.

The concentrations of C peptide and insulin should not be measured routinely.[2,3] When differentiation between type 1 and type 2 diabetes mellitus is difficult, consultation with a subspecialist with expertise in type 2 diabetes mellitus in children and adolescents is recommended. There currently is no definitive diagnostic tool to differentiate between type 1 and type 2 diabetes mellitus. The differentiation typically is made clinically on the basis of obesity, family history, ethnicity, age, pubertal status, and evidence of insulin resistance (eg, acanthosis nigricans, PCOS).

TREATMENT

Goals of Treatment

The goals of treatment are adequate metabolic control (HbA_{1c} concentration <7%) and prevention of

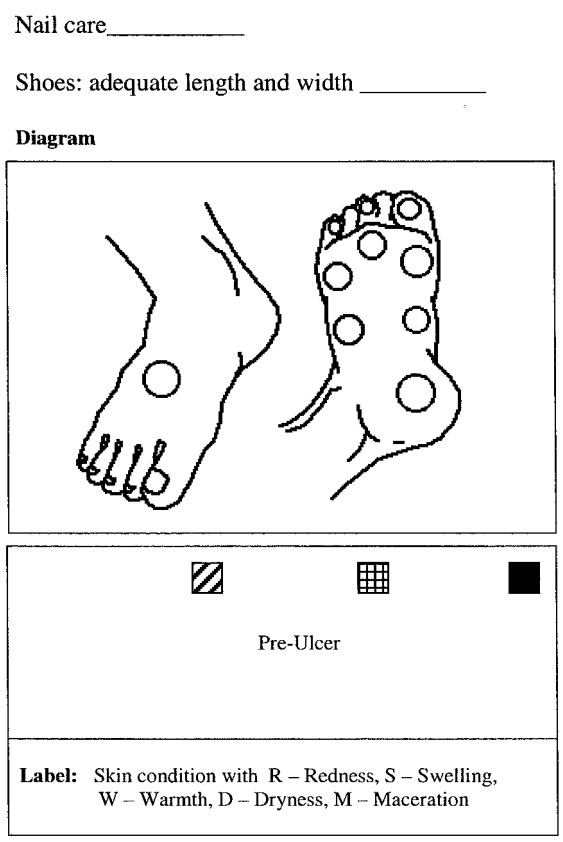

Fig 2. Foot screening for youth with diabetes.

microvascular and macrovascular complications. More specific treatment objectives include the following:

- Eliminating symptoms of hyperglycemia
- Assisting the patient in maintaining a reasonable body weight (weight stabilization)
- Decreasing cardiovascular risk factors: hypertension, hyperlipidemia, hyperglycemia, microalbuminuria, sedentary lifestyle, and use of tobacco products
- Achieving overall improvement in the child's physical and emotional well-being

Recommended treatment modalities include dietary modification, increased physical activity, decreased sedentary behaviors, and pharmacologic intervention (primarily metformin and insulin). Therapy to achieve these goals should be individualized on the basis of the child's age, other illnesses, lifestyle, self-management skills, and level of motivation. Education and other interventions that enhance self-care behaviors are essential for the successful management of type 2 diabetes mellitus. In general, weight loss is not recommended for prepubertal children. Children with morbid obesity and resultant health consequences, such as sleep apnea, may be referred to a subspecialist for weight reduction or a multidisciplinary child obesity clinic. Weight stabilization is the goal until girls are menstruating and boys have reached Tanner stage 5. After pubertal growth is complete, weight loss may be appropriate.

TABLE 4. Impaired Glucose Metabolism

Test	Impaired	Diagnostic for Diabetes
Fasting glucose	≥110 mg/dL and <126 mg/dL	≥126 mg/dL
Impaired 2-h OGTT	≥140 mg/dL and <200 mg/dL	≥200 mg/dL

Barriers to Care

A functional and supportive environment is key in the treatment of children and adolescents with type 2 diabetes mellitus. One of the most serious barriers to achieving the goals of management is a dysfunctional family situation. The medical model of focusing only on the identified patient instead of treating the entire family further decreases the effectiveness of care.

Additional barriers exist for AI/AN youth. Environmental obstacles (eg, harsh climate, lack of transportation, limited access to healthy foods) create difficulties. Specific tribal or cultural issues, including beliefs and feelings about diabetes, may interfere with optimal self-care. For example, many families have a fatalistic attitude about diabetes: "My parents died of diabetes. I have it, and my children are going to get it." Eating and mood disorders, life stresses, and low self-esteem are common obstacles. Lack of appropriate role models, particularly healthy individuals living with diabetes, creates significant hardship for AI/AN children with diabetes. A low level of reading comprehension and proficiency in English may add additional barriers for some families. Furthermore, substance abuse is particularly problematic for many AI/AN children and their families. The health care system's frequent lack of understanding and respect for cultural beliefs may be a barrier to achieving optimal self-care. Many strategies have been shown to help overcome such barriers, including the use of trained professional interpreters, cultural competence and humility training for health care professionals and staff, and inclusion of members of the community in the design of clinical services.

Team Management

Multidisciplinary team management is strongly recommended for youth with type 2 diabetes mellitus. A primary health care professional alone usually cannot provide focused diabetes education, nutrition management, and psychosocial support. The team usually is composed of a physician, a registered di-

TABLE 5. Ongoing Evaluation and Monitoring After Diagnosis: Laboratory Evaluation*

Test	Frequency	Recommendations
SMBG	Fasting and 2-h postprandial glucose daily	Individualized
FPG test	Initially and ongoing	
2-h postprandial glucose test	At diagnosis and as needed	
HbA_{1c}	Every 3 mo	
Urinalysis	Every 12 mo	
Microalbuminuria	Every 12 mo	
Creatinine	At diagnosis	And per protocol if there is hypertension, microalbuminuria, or ACE inhibitor treatment
Lipid profile	At diagnosis and every 12 mo	
LFTs	At diagnosis	Before initiating oral hypoglycemic agents

LFT indicates liver function test.
*More frequent monitoring at diagnosis, during initiation of new treatment, and during metabolic changes (illness, stress, increased activity, and growth).

etitian, a nurse clinician, a social worker, and the patient and the family. The patient and the family are integral members of the team, and participation of the child or adolescent with the diabetes team should be frequent and ongoing. The diabetes team monitors the patient's knowledge about diabetes and its acute and chronic complications. The team also assesses and monitors the patient's knowledge and attitudes toward nutrition and physical activity. In addition, the team promotes the use of medications, SMBG, and problem-solving skills. Screening for barriers to self-care is recommended at each visit. The team assists in identification of achievable self-care goals that are appropriate for age and development level.

Many AI/AN health care facilities have existing diabetes clinics with multidisciplinary teams. It is highly recommended that these clinics organize a pediatric component so that youth receive developmentally appropriate care.

Lifestyle Modifications

The cornerstones of initial treatment of type 2 diabetes mellitus are acquiring and integrating healthful behaviors in nutrition, exercise, and weight management. Frequent contact with the health care team is required to accomplish these goals. The approach to healthful living must be emphasized throughout diabetes treatment. Initially, type 2 diabetes mellitus in asymptomatic youth may be managed by lifestyle modification without adjunctive medication. Basic diabetes education, counseling, and SMBG should be included. The natural history of type 2 diabetes mellitus is one of progressive insulin insufficiency and deterioration of metabolic control.[78–84] Therefore, close monitoring and follow-up are important. Eventually, most people with type 2 diabetes mellitus require medication to achieve adequate metabolic control (Tables 4 and 5).

Resources

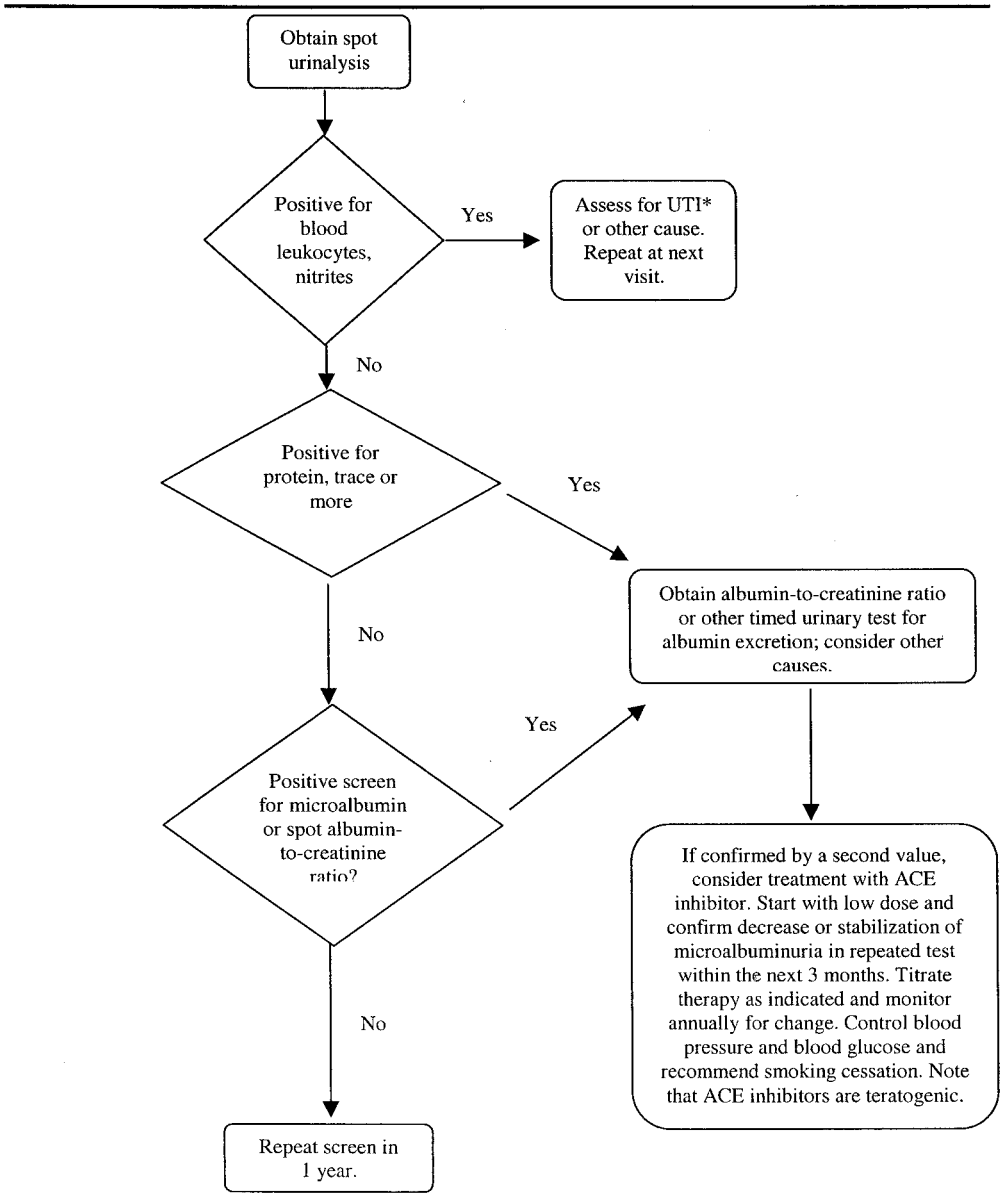
Many resources are available for health care professionals and their patients to help achieve therapeutic goals. However, there is a great need for more culturally sensitive educational materials. Information prepared for adults often is confusing to children and adolescents. Furthermore, resources for children and families with type 1 diabetes mellitus do not apply easily to families affected by type 2 diabetes mellitus.

The National Diabetes Education Program (NDEP) is a federally sponsored initiative of the National Institute of Diabetes and Digestive and Kidney Diseases of the National Institutes of Health, the CDC, and more than 200 public and private partners to improve treatment and outcomes for people with diabetes, promote early diagnosis, and, ultimately, prevent the onset of diabetes. The objectives of the NDEP are to:

- Increase public awareness of the seriousness of diabetes and its risk factors and strategies for preventing diabetes and its complications
- Improve understanding about diabetes and its control and promote better self-management behaviors among people with diabetes
- Improve health care professionals' understanding of diabetes and its control and promote an integrated approach to care
- Promote health care policies that improve the quality of and access to diabetes care

Target audiences include people with diabetes and their families (with special attention to Hispanic, black, and Asian Americans; Pacific Islanders; and the AI/AN population); the general public; health care professionals; and health care payers, purchasers, and policy makers.

The NDEP has convened a Diabetes in Children and Adolescents Work Group to address awareness and education issues related to children with diabetes, including the growing emergence of type 2 diabetes mellitus in youth. Furthermore, the NDEP American Indian/Alaska Native Work Group is focusing on youth with diabetes. The NDEP aims to assist health care professionals in increasing their knowledge about type 2 diabetes mellitus in children and adolescents; diabetes education materials for patients and health care professionals can be obtained from NDEP. For more information about the NDEP, see its Internet site at http://www.ndep.nih.gov or call 800-438-5383. Materials for educators about the management of diabetes in school settings are available.



* UTI indicates urinary tract infection.

Fig 3. Annual evaluation and treatment for microalbuminuria.

The ADA has a useful diabetes education program called WIZDOM, which includes specific patient education material in English and Spanish for youth with type 2 diabetes mellitus. Information can be found at the following Internet site: http://www.diabetes.org/wizdom/pod.asp.

MANAGEMENT TOOLS

Self-monitoring of Blood Glucose

The frequency of SMBG should be individualized. Daily fasting and 2-hour postprandial (after-dinner) glucose measurements are recommended.[5] More frequent monitoring is recommended during initiation of treatment. Furthermore, monitoring frequency should be increased during the following situations: insulin treatment, medication dosage adjustments, initiation of new therapies, increased activity, rapid growth, illness, and emotional stress. The frequency of SMBG may be negotiated with the patient and the family. For people who take insulin, the recommended frequency is before every meal and at bedtime. The recommended method is a blood glucose meter with memory. It can be instructive for patients to record their blood glucose results in a log to determine patterns. Reviewing these results with the patient at each visit is recommended. Many patients on medication will learn to make their own dosage adjustments on the basis of blood glucose patterns.

- Ideal targets: more than 50% of SMBG concentrations within target range:
  - Fasting: 80 to 120 mg/dL (4.4–6.7 mmol/L)
  - Postprandial (2 hours after start of meal): 100 to 160 mg/dL (5.6–8.9 mmol/L)
  - Bedtime: 100 to 160 mg/dL (5.6–8.9 mmol/L)

Medical Nutrition Therapy

Meal planning, nutrition education, and exercise are primary treatment strategies for type 2 diabetes mellitus. All people with diabetes should receive regular nutrition counseling and consult with a registered dietitian or nutritionist or a diabetes educator at least every 6 to 12 months. Some children may require more frequent evaluation and counseling. The success of the child in adopting healthful eating habits is much more likely when the entire family follows the dietary recommendations. Other family members may be able to serve as role models. Assisting the family and the patient in change related to eating behavior is recommended.[85] For example, some families will choose to purchase more fruits and vegetables and make them more readily available to all family members. Families may choose to discourage eating outside of mealtimes and make rules about limiting eating while watching television. Weight management must be individualized for the patient initially and in follow-up visits. Each encounter is an opportunity for nutritional education.

Diabetes Education

Patients and their families require diabetes self-care information that is culturally relevant. It is important to recognize that there are many different tribal cultures. The National Standards for Diabetes Care and Patient Education provide guidelines for education program development with criteria specific for Native American health care facilities.[86] In addition, adolescents have distinct needs related to the culture of youth.

Education alone is not enough to motivate people to adopt more healthful behaviors. Children and adolescents, in particular, are not easily motivated by long-term health consequences, which seem irrelevant to them. They are more likely to be influenced by immediate concerns, such as physical attractiveness, feelings of well-being and acceptance, and their desire to be able to do more in school or sports. The use of motivational interviewing or collaborative problem solving may be useful in helping children and adolescents make and maintain necessary behavior changes.

Physical Activity Education

Physical activity is a cornerstone of the management of type 2 diabetes mellitus. Physical goals should be stated concretely. Exercise is associated with improvement in short- and long-term metabolic control,[87,88] and physical activity improves insulin sensitivity. All patients should be assessed for level of fitness and current exercise routines. Recommendations should be based on the patient's needs and current condition. It is important to assess the opportunities available within the family and the community. Adaptive physical education classes may be helpful for children who are overweight. Youth with obesity and type 2 diabetes mellitus are not likely to participate in organized sports, so other physical activity strategies are needed. Activities of daily living can be adapted to increase physical fitness.[88–91] Sedentary activities should be limited, and positive alternatives should be emphasized. When making behavioral changes, simple, achievable goals promote efficacy. Children and adolescents are more likely to accept fitness goals when they are framed in terms of feeling better, looking better, or doing more.[31]

Preconception Counseling and Management

A sexual activity history should be obtained at diagnosis in postpubertal youth. Counseling about the necessity of metabolic control for healthful pregnancy outcomes should start at puberty. Abstinence counseling should be provided, if appropriate. Family planning options should be discussed with adolescents who are or may become sexually active. Pregnancy should be deferred until optimal glycemic control has been achieved to decrease first-trimester risks to the fetus, including congenital heart disease, caudal regression, and neural tube defects, and third-trimester risks of macrosomia, neonatal hypoglycemia, and hypocalcemia, all of which are common in preexisting type 2 diabetes mellitus and gestational diabetes. All oral hypoglycemic agents are contraindicated during pregnancy. Furthermore, treatment of diabetes may increase fertility and the likelihood of pregnancy in young women. Metformin, in particular, may improve ovarian function and ovulation.

Immunizations

Usual childhood immunizations (including hepatitis B, influenza, and pneumococcal immunizations) are recommended. Tuberculosis screening by purified protein derivative should be documented once after the diagnosis of diabetes and performed at appropriate intervals, as indicated by community-specific tuberculosis prevalence.

Dental Examinations

Dental examinations are recommended every 6 months. Periodontal disease is more common in people with diabetes than in those without and has been called the sixth complication of diabetes (the other 5 complications involve the heart, kidney, eyes, skin, and feet).[92–94]

DECREASING CARDIOVASCULAR RISK

Identification and Treatment of Hyperlipidemia

Children with type 2 diabetes mellitus are at risk of hyperlipidemia, which compounds their risk of premature cardiovascular disease. Although the American Heart Association recommends that children's total cholesterol concentration be less than 170 mg/dL (<4.40 mmol/L) and the LDL concentration be less than 110 mg/dL (<2.84 mmol/L), the ADA recommends a lower target concentration for LDL in adults with diabetes[28,87,95]: less than 100 mg/dL (<2.59 mmol/L). Because of the higher risk of cardiovascular disease in children with diabetes, the lower acceptable value recommended by the ADA is preferred. A lipoprotein analysis after a 12-hour fast is recommended to obtain triglyceride concentrations for computation of accurate LDL concentra-

tions,[95] although recent evidence indicates non-HDL cholesterol is a better predictor of atherogenesis than LDL cholesterol. If a fasting measurement is not possible, then a measurement of the HDL concentration, along with the total cholesterol concentration, will provide an alternative. Other reliable analyses of the lipid profile may become available in the future. Children with an LDL concentration more than 100 mg/dL (>2.59 mmol/L) or a total cholesterol concentration more than 170 mg/dL (>4.40 mmol/L) should receive advice about other risk factors for cardiovascular disease, such as smoking and sedentary lifestyle. High triglyceride concentrations are increasingly recognized as an additional cardiovascular risk factor for people with diabetes. In addition to studies showing the benefit of decreasing the cholesterol concentration in adults, the Bogalusa Heart Study provides evidence that risk factors, such as a low HDL concentration, high triglyceride and LDL concentrations, and smoking, have clinical significance for development of cardiovascular disease beginning in childhood.[96–98]

The American Heart Association Step-One diet should be initiated for children with high total cholesterol or LDL concentrations. The Step-One diet includes fewer than 30% of total calories from fat, fewer than 10% of total calories from saturated fat, 10% or fewer calories from polyunsaturated fat, and cholesterol of no more than 100 mg/1000 cal. If cholesterol concentrations do not normalize despite a history of adherence to the Step-One diet, then the Step-Two diet is used. The Step-Two diet is lower in total cholesterol (67 mg/1000 cal) and saturated fat (<7% of total cal). People who follow these diets should be reevaluated every 6–12 months. More information about the Step-One and the Step-Two diets can be found on the American Heart Association's Internet site at http://www.americanheart.org. The assistance of a registered dietitian or other qualified nutrition professional is necessary to ensure adequacy of nutrients, vitamins, and minerals. Glycemic control, as well as therapy with metformin, can help to lower triglyceride and LDL concentrations. Cholesterol-lowering drug therapy should be considered for children older than 10 years if an adequate trial of diet therapy is unsuccessful after 6 to 12 months. An LDL concentration of 100 mg/dL or more (≥2.59 mmol/L) and 1 of the following risk factors or physical inactivity indicate a need for cholesterol lowering medication: family history of premature cardiovascular disease (55 years or younger), cigarette smoking, high blood pressure, low HDL concentration (<35 mg/dL [<0.91 mmol/L]), and obesity (≥95th percentile weight for height).

The recommended cholesterol-lowering medications for children include cholestyramine and colestipol hydrochloride. These medications are difficult to take because of the frequency of dosing and adverse gastrointestinal effects. Although the efficacy and safety of these medications have been documented in children, long-term data on improved morbidity and mortality are lacking.[77] The 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (statins) are now approved for use in children who have familial hyperlipidemia and are 10 years of age and older. They are being used and tested in pediatric populations for other indications. Rhabdomyolysis is a known adverse effect, and safety during pregnancy has not been proved. Specialty consultation may be helpful for treating youth with hyperlipidemia.

Blood Pressure Control

In adults, tight blood pressure control has been shown to have a greater impact on cardiovascular disease risk reduction than blood glucose control.[99–102] Systemic hypertension is defined as systolic or diastolic pressure greater than or equal to the 95th percentile for age.[103] However, for children with type 2 diabetes mellitus, the blood pressure goal is less than the 90th percentile. Accurate blood pressure measurement is critical to the evaluation of suspected hypertension. The patient should be resting and comfortable. Cuff size, the position of the arm, the person's position (sitting or supine), and the speed of inflation and deflation of the cuff can affect the measurement. The cuff bladder width should be approximately 40% of the arm circumference midway between the olecranon and the acromion. The arm should be supported, and the cubital fossa should be at the level of the heart. The bell of the stethoscope should be placed over the brachial artery pulse. The cuff should be inflated to 20 mm Hg above the point at which the radial pulse disappears. The cuff is then deflated at a rate of 2 to 3 mm Hg per second. Automated devices are not as accurate for determining diastolic pressure. The diagnosis of hypertension should be confirmed in 3 separate consecutive examinations. For mild hypertension (slightly above the 95th percentile), the initial assessment should evaluate the possibility of renal disease. The evaluation of severe hypertension (≥99th percentile for age) should include an echocardiogram.

Conservative management (eg, lifestyle changes, such as weight decrease in postpubertal patients, nutrition, and exercise) is recommended as initial therapy. Sodium restriction may be difficult for adolescents. Significant reduction in blood pressure may be noted with weight loss and exercise programs. If blood pressure reduction is not achieved by lifestyle changes, then drug therapy will be necessary. ACE inhibitors are the usual first-line agents because of cardiovascular and renal benefits.[104,105] Because ACE inhibitors are teratogenic, another agent might be preferable for girls of childbearing age. Beta-blockers are an alternative unless the child is taking insulin, as symptoms of hypoglycemia may be masked.

Smoking and Alcohol Cessation and Prevention and Increasing Physical Activity

Smoking cessation and prevention of smoking initiation are essential for decreasing the risk of cardiovascular problems. Smoking is associated with an increased incidence of diabetes in adults.[106] It is important to screen for tobacco use and advise or refer for tobacco cessation if use is confirmed. Tobacco use information should be updated at each visit. Because

of the greatly increased risk of macrovascular and microvascular disease in people who have diabetes and smoke,[107] children and adolescents who do not smoke or use other tobacco products should receive positive reinforcement and information about the importance of continued abstinence.

Alcohol affects insulin production and increases insulin resistance, which also increases the risk of cardiovascular complications. The independent risk of cardiovascular complications associated with alcohol consumption by people with diabetes is a long-term hazard for youth with diabetes. A more immediate risk is hypoglycemia caused by alcohol consumption.

Alcohol use may aggravate the hypoglycemia caused by sulfonylureas or insulin treatment, and it may increase the risk of lactic acidosis for patients who use metformin. Alcohol and drug use should be assessed at every visit. Adolescents are at risk of substance abuse, which may interfere with the achievement of treatment goals. Anticipatory guidance regarding alcohol avoidance is recommended, including for children and adolescents who do not use alcohol or other drugs. The benefits of not drinking should be emphasized. The effectiveness of creative strategies should be evaluated.

Increasing physical activity is a positive way to decrease risk of cardiovascular complications.

Treatment of Microalbuminuria

Microalbuminuria is a sign of incipient diabetic nephropathy and is a risk factor for cardiovascular complications. Microalbuminuria may be encountered in people who have a new diagnosis of type 2 diabetes mellitus. Proteinuria, conversely, is the hallmark of diabetic nephropathy. ACE inhibitors are indicated for proteinuria or microalbuminuria and have been shown to slow the rate of progression of nephropathy in adults. Improved glycemic and blood pressure control slows the progression of nephropathy. ACE inhibitors are an additional important treatment modality, as shown in the evaluation and treatment algorithm (Fig 3).

PHARMACOLOGIC MANAGEMENT ON THE BASIS OF CLINICAL MANIFESTATIONS

The options for pharmacologic treatment include insulin; oral hypoglycemic agents, especially metformin; and any combination thereof. Intensive blood glucose control with insulin or sulfonylureas has been shown to decrease microvascular but not macrovascular complications.[79] The choice of medications is discussed in relation to the patient's status at diagnosis. The following sections are given in order of increasing severity and decreasing incidence.

Impaired Glucose Metabolism

Patients with impaired glucose tolerance and impaired fasting glucose have glucose concentrations too high to be considered normal but do not meet the diagnostic criteria for diabetes. They are considered to have prediabetes. Patients with impaired fasting glucose have FPG‖ concentrations of 110 mg/dL or more (≥6.1 mmol/L) but less than 126 mg/dL (<7.0 mmol/L). Patients with prediabetes have 2-hour OGTT results between 140 and 200 mg/dL (7.8 and 11.1 mmol/L [Table 5]). Compared with the FPG, the 2-hour OGTT will identify more people as having impaired glucose tolerance. Although the 2-hour OGTT is more sensitive than the FPG, it is not as reproducible. It is, therefore, important to identify which test was used for diagnosis. An increase in the postprandial glucose concentration precedes an increase in the FPG concentration in adults. The natural history of impaired glucose tolerance in children and adolescents has not been studied. The US Diabetes Prevention Program has shown that lifestyle interventions are more effective than metformin and both approaches are more promising than conventional treatment in reducing progression to diabetes in adults with impaired glucose tolerance.[108] Similarly, a study of Finnish adults was interrupted because of the success of the lifestyle intervention arm.[109] Patients with prediabetes and their families should receive nutrition and physical activity intervention and support. Their risk of diabetes should be discussed. Monitoring of weight, nutrition, physical activity, and FPG should be performed regularly (at least every 3 months). Some diabetes centers recommend SMBG for high-risk patients with impaired glucose metabolism.

Asymptomatic Diabetes

People with diabetes may be identified as part of community-based case-finding efforts or by primary health care professionals who test asymptomatic children and youth who are at risk of type 2 diabetes mellitus. Patients with an FPG concentration of 126 mg/dL or more (≥7.0 mmol/L) or a 2-hour plasma glucose concentration of 200 mg/dL or more (≥11.1 mmol/L), using a glucose load of 75 g of anhydrous glucose dissolved in water, but who do not have polyuria, polydipsia, or weight loss are considered to have asymptomatic type 2 diabetes mellitus. When diabetes is identified early, treatment with lifestyle modifications and SMBG (fasting and postprandial) may be instituted. If plasma glucose or HbA_{1c} concentrations remain increased for 3 months, then treatment with oral agents or insulin should be started. Patients who attain euglycemia through lifestyle modification should be monitored every 3 months.

People with an FPG concentration greater than 250 mg/dL (>13.9 mmol/L) should be treated as if they have symptoms, even if they report none.

Symptomatic Diabetes Without Ketoacidosis

Symptoms include polyuria and polydipsia, nocturia, sleep apnea, vaginitis, dysuria, and even weight loss. Many families do not recognize polyuria and polydipsia in adolescents. Educational ap-

‖When glucose concentration is measured in a laboratory, plasma glucose concentration is measured. When a self-monitoring system is used, blood glucose concentration is measured; in most cases, these values are similar.

proaches to raise adolescent awareness about the potential significance of the symptoms of increased thirst and urination could encourage teenagers to alert their families and primary health care professionals.

Insulin

Initial treatment with subcutaneous insulin is suggested for children with FPG concentrations greater than 250 mg/dL (>13.9 mmol/L) and for children who are symptomatic. First Nations children with type 2 diabetes mellitus have been treated with subcutaneous insulin for 2 to 6 weeks followed by abrupt discontinuation of treatment with acceptable metabolic control.[110]

The use of insulin in children and adolescents with type 2 diabetes mellitus is safe.[2,3,111–113] Preliminary data suggest that early insulin therapy may preserve beta cell function in type 1 diabetes mellitus. This may be true in type 2 diabetes mellitus as well.[114,115] Symptomatic youth often have evidence of the toxic effects of glucose or a transient deterioration of beta cell function brought on by prolonged hyperglycemia. Thus, insulin often is needed for initial metabolic control. When C peptide or insulin concentrations are obtained at diagnosis, they may be uncharacteristically low. Therefore, if C peptide concentrations are measured to determine whether a patient has type 1 or type 2 diabetes mellitus, then it is best to wait until adequate metabolic control is obtained.

The recommended starting dose of insulin is individualized from 0.5 to 1.0 U/kg body weight per day. Additional insulin may be given if blood glucose concentrations do not fall below 150 mg/dL (8.3 mmol/L) before meals. Insulin dosage must be adjusted to achieve target blood glucose concentrations. Children and adolescents with type 2 diabetes mellitus often require much higher doses of insulin because of insulin resistance. Insulin regimens must be individualized. Some patients may require only intermediate-acting insulin (isophane [neutral protamine Hagedorn (NPH)] or lente) given once or twice daily. Others may require short- or rapid-acting insulin (regular or lispro/aspart) and intermediate-acting insulin (NPH or lente) with a distribution of two thirds of the total dose before breakfast and one third of the total dose before dinner.[116] As with type 1 diabetes mellitus, an initial regimen might be to give the morning dose as one third regular or lispro/aspart and two thirds NPH or lente and the evening dose as one half regular or lispro/aspart and one half NPH or lente.[117] It may be more physiologically appropriate to give the evening intermediate-acting insulin at bedtime.[118] Lispro and aspart have certain advantages over regular insulin—its action profile provides insulin coverage for meals, and the dose can be adjusted according to the amount of food to be eaten. Other regimens that have proved successful are the use of the long-acting insulin glargine in conjunction with an oral hypoglycemic agent that increases endogenous insulin secretion to cover meals.

These dosage recommendations are to be considered a starting point, because insulin dosing must be adjusted on the basis of the blood glucose concentration. As metabolic control is achieved, insulin dosages start to decrease. It is not necessary to initiate insulin treatment with frequent dosing of rapid-acting insulin before meals. Using intermediate- and rapid-acting insulin early in treatment permits more rapid stabilization of glucose concentrations. When the health care professional judges that insulin will be required over the long-term, the person may be taught to give bolus insulin doses before meals, depending on the amount of carbohydrate to be consumed. Oral agents may be started once the glucose concentration is stabilized, and the insulin dosage gradually can be weaned. The glucose concentration usually is stable between 3 and 4 weeks after the initiation of therapy.[29]

Oral Agents

The recently completed United Kingdom Prospective Diabetes Study demonstrated that type 2 diabetes mellitus is a progressive disorder that can be treated initially with oral agent monotherapy.[79,80] Current recommendations for adults suggest beginning oral monotherapy if target glycemic goals are not achieved within 1 to 3 months of initial intervention of lifestyle modification. This period may not be practical for many AI/AN youth because of greater barriers to achieving activity and nutritional goals. A longer period may be warranted only if there is slow and steady improvement in achieving target glycemic goals.

Metformin is the only oral hypoglycemic agent approved for use in children. Data are not yet available regarding the safety, efficacy, or dosing of the other oral agents used to treat type 2 diabetes mellitus in children, although such data are available for adults. The biguanides (eg, metformin) and the sulfonylureas (eg, glyburide) have been part of the clinical experience in the treatment of type 2 diabetes mellitus in children. Sulfonylureas have been used for several years in the treatment of maturity-onset diabetes of youth, a set of rare, genetically determined diabetes. Use of metformin has increased in recent years, and clinical trials are in progress.

Metformin

The ADA consensus statement recommends that "if treatment goals with nutrition education and exercise are not met, pharmacologic therapy is indicated. The first oral agent should be metformin."[2,3,118] Metformin works by decreasing hepatic glucose production and enhancing insulin sensitivity. It is contraindicated for people with renal or hepatic disease, conditions that lead to hypoxia (eg, unstable asthma), or severe infection or those who abuse alcohol. It should be withheld before radiographic studies requiring the administration of radiocontrast dye. Metformin improves ovarian function, especially in women with PCOS, making family planning and contraception (when indicated) important. Lactic acidosis rarely has been reported.[119] Gastrointestinal adverse effects, such as

abdominal discomfort and diarrhea, occur in approximately 20% to 30% of people who take metformin. These effects can be minimized by slowly titrating the dose and beginning with 250 mg each day, increasing to 250 mg twice daily, and finally increasing to 500 mg twice daily, if necessary. In adults, 80% to 85% of the maximal glucose-lowering effect is observed with a daily dose of 1500 mg. Most children who require treatment are at or above normal adult weight. Therefore, beginning at a dose of 500 mg per day would be considered safe. In adults, a clinically significant response at a dosage of less than 1500 mg per day is unusual. Metformin is supplied as 500- and 850-mg tablets and extended-release tablets. The maximum recommended daily dosage of metformin is 2550 mg. The current cost of metformin is approximately twice that of a second-generation sulfonylurea. However, less costly generic medications should soon be available. Advantages of metformin include decreased weight gain, possible weight loss, lower insulin concentrations, and improved lipid profile.[29,120]

Sulfonylureas

The primary mechanism of action of the sulfonylureas is enhancement of insulin secretion. In adults in whom type 2 diabetes mellitus has recently been diagnosed, good results have been achieved with mild to moderate fasting hyperglycemia (220–240 mg/dL [12.2–13.3 mmol/L]), good beta cell function as reflected by a high fasting C peptide concentration, and the absence of islet-cell or glutamic acid decarboxylase antibodies. No sulfonylureas are currently approved for use in children, although studies in the pediatric population with second-generation agents are ongoing. In most studies in adults, sulfonylureas have had neutral or slightly beneficial effects on plasma lipid concentrations. Weight gain is common with use, a negative effect in patients in whom weight loss is a major goal. Most pediatric endocrinologists use sulfonylureas with other agents when monotherapy with metformin or insulin sensitizers has failed. First-generation sulfonylureas (chlorpropamide, tolazamide, acetohexamide, and tolbutamide) must be given in higher doses than second-generation sulfonylureas (glyburide, glipizide, and glimepiride). The second-generation sulfonylureas are largely free of drug interactions. The major adverse effect associated with sulfonylureas is hypoglycemia. Most of the hypoglycemic action of the sulfonylurea is observed with a daily dose that represents half of the maximally effective dose. Sulfonylureas may potentiate the hypoglycemia associated with alcohol use. Therefore, alcohol consumption is contraindicated when a person is taking a sulfonylurea. Other adverse effects are uncommon but include nausea; vomiting; and skin reactions, including rashes, purpura, and pruritus. Leukopenia, thrombocytopenia, hemolytic anemia, and cholestasis have been reported. Although a 1970 study[121] suggested that sulfonylureas may exacerbate coronary artery disease in people with type 2 diabetes mellitus, the ADA issued a statement in 1979 opposing any formal restrictions on use of the sulfonylurea agents on the basis of interpretation of that study. In addition, the United Kingdom Prospective Diabetes Study found no increased incidence of coronary artery disease for patients with type 2 diabetes mellitus who were assigned to intensive therapy with sulfonylureas, compared with patients who received dietary therapy without medications. The sulfonylureas have an additional advantage of low cost. Table 6 outlines the characteristics of select sulfonylureas.[122,123]

Repaglinide

Repaglinide is a new agent. Like the sulfonylureas, it enhances the release of insulin, but the response is quicker and of shorter duration than that of sulfonylureas. Repaglinide's glucose-lowering effect is additive to the glucose-lowering effect of metformin. Furthermore, repaglinide has no significant effect on plasma lipid concentrations. Repaglinide must be taken before each meal because of its short duration of action. Thus, its primary effect is on the postprandial blood glucose concentration.

Thiazolidinediones

Thiazolidinediones (TZDs) work primarily by increasing insulin sensitivity in muscle and adipose tissue with a lesser effect on hepatic glucose uptake. The first TZD to be marketed in the United States, troglitazone, was taken off the market because of hepatotoxic effects. However, the newer agents in this class seem to have an improved safety profile. Although not approved for children, clinical trials in the pediatric population are in progress. Because TZDs increase insulin sensitivity, they have a favor-

TABLE 6. Pharmacologic Characteristics of Sulfonylureas[123]

Characteristics	Tolbutamide	Tolazamide	Chlorpropamide	Glipizide	Glyburide

* Studies have shown that the maximum effective dose of glipizide is 10 mg/dL. Doses above this may cause decreased efficacy.
† Glyburide is available worldwide as better-absorbed micronized preparations. These preparations are available in 1.5-, 1.75-, 3-, 3.7-, and 6-mg tablets.

able effect on HDL and triglyceride concentrations. Studies in adults indicate that TZDs result in a 1% to 2% decrease in HbA_{1c} values when used as monotherapy, although monotherapy is not recommended. Adverse effects include weight gain and fluid retention. TZDs may decrease the effectiveness of oral contraceptives. Another disadvantage is the high cost of this class of drugs. Dosing with pioglitazone hydrochloride is initiated at 15 mg daily with or without food. The dose can be increased after 8 to 12 weeks if the decrease in HbA_{1c} is inadequate. The maximum daily dosage is 45 mg for monotherapy and 30 mg for combined therapy. The dosage does not need to be adjusted for patients with renal disease. Pioglitazone is available as 15-, 30-, and 45-mg tablets. Rosiglitazone maleate initially is given as a single 4-mg dose. The dose may be increased to 4 mg twice daily or 8 mg daily if the response is inadequate after 8 to 12 weeks; however, the maximum dosage is 8 mg daily. Like pioglitazone, rosiglitazone can be given with or without meals and does not need dosage adjustment for patients with renal failure. It is available in 4- and 8-mg tablets.

Acarbose

The α-glucosidase inhibitor acarbose was introduced in the United States in the late 1990s. It primarily affects postprandial glucose concentrations by delaying carbohydrate digestion.[124–126] Its major adverse effect, flatulence, has limited its acceptance in the pediatric population.

Combining Oral Agents

A maximal dose of a single oral agent (metformin or a sulfonylurea) may not maintain long-term acceptable glycemic control, according to ADA guidelines (FPG concentration <140 mg/dL [<7.8 mmol/L] or HbA_{1c} value <8.0%).¶ Because type 2 diabetes mellitus is a progressive disease with decreasing beta cell function, most people with an initial acceptable response to monotherapy will require additional agents as their disease progresses.[127–129] Randomized, placebo-controlled studies of combination therapy support the effectiveness of this strategy for decreasing FPG and HbA_{1c} concentrations.[130–132] When beta cells fail, insulin will need to be added to the therapeutic regimen.

Because metformin promotes weight loss and decreases lipid concentrations, it is preferred for use by overweight people with type 2 diabetes mellitus and dyslipidemia. The dose of metformin or sulfonylureas can be increased over a 4- to 8-week period until acceptable glucose control is achieved or the maximum dose is reached. If monotherapy fails with metformin, then a sulfonylurea should be added. It is prudent to assess whether the person is taking the medication as directed before initiating combination therapy. Patients may not take their medication for a variety of reasons, including denial of illness; fear of being labeled diabetic; fear of adverse effects, such as hypoglycemia; actual adverse symptoms; and lack of knowledge about the need for long-term treatment. If combination therapy with 2 oral agents does not achieve the desired therapeutic goal, then bedtime insulin or a third oral agent may be considered. Referral to a specialist in type 2 diabetes mellitus for children and adolescents is recommended when combination therapy has failed.

¶The ADA currently recommends intensifying treatment on the basis of HbA_{1c} concentration <8%. However, the recommended target goal for HbA_{1c} concentration is <7%.

Symptomatic Diabetes With Ketoacidosis

Diabetic ketoacidosis is defined by a bicarbonate concentration less than 15 mmol/L (<15 mEq/L) and/or pH less than 7.25. Type 2 diabetes mellitus may manifest with ketosis and, uncommonly, with ketoacidosis. Therefore, clinical presentation with ketoacidosis does not preclude the diagnosis of type 2 diabetes mellitus.

Insulin

Children with diabetic ketoacidosis require initial treatment with intravenous insulin followed by subcutaneous insulin. High doses may be required because of the insulin resistance characteristic of type 2 diabetes mellitus.[133] Health care professionals, nurses, and laboratory professionals who care for a large number of patients with diabetic ketoacidosis are more likely to have the necessary clinical competence to provide this high-acuity care. When care by such personnel is not possible, consultation with a subspecialist is recommended. Excellent treatment protocols and guidelines are available for the treatment of ketoacidosis.[134–137] Once the patient's condition is stable, the important lifestyle modifications discussed previously can be addressed. As people often are willing to consider major lifestyle changes during a crisis, this may be an optimal teachable moment.[137]

CONCLUSION

Type 2 diabetes mellitus in AI/AN youth is an alarming new morbidity that, without intervention, will lead to significant increased morbidity and mortality during adulthood. Health care professionals must address multiple medical and psychosocial concerns within the context of a medical home with the goal of coordinating comprehensive services from health care professionals and the community. Health care professionals who care for families affected by type 2 diabetes mellitus face the challenge of motivating people to adopt significant behavioral changes.

Several interventions have proved effective in preventing diabetes complications among adults, and evaluation of these interventions in children with type 2 diabetes mellitus is urgently needed. It is expected that clinical trials using behavioral and treatment interventions for children with diabetes will be developed. More knowledge about current care, gaps in care, and the natural history of the disease is forthcoming. Finally, results of research efforts in primary prevention of type 2 diabetes mellitus for adults and youth soon will be available. The increasing evidence base will challenge current treat-

ment guidelines and ultimately improve the health of children with type 2 diabetes mellitus over their lifetimes.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Native American Child Health and Committee on Injury and Poison Prevention

The Prevention of Unintentional Injury Among American Indian and Alaska Native Children: A Subject Review

ABSTRACT. Among ethnic groups in the United States, American Indian and Alaska Native (AI/AN) children experience the highest rates of injury mortality and morbidity. Injury mortality rates for AI/AN children have decreased during the past quarter century, but remain almost double the rate for all children in the United States. The Indian Health Service (IHS), the federal agency with the primary responsibility for the health care of AI/AN people, has sponsored an internationally recognized injury prevention program designed to reduce the risk of injury death by addressing community-specific risk factors. Model programs developed by the IHS and tribal governments have led to successful outcomes in motor vehicle occupant safety, drowning prevention, and fire safety. Injury prevention programs in tribal communities require special attention to the sovereignty of tribal governments and the unique cultural aspects of health care and communication. Pediatricians working with AI/AN children on reservations or in urban environments are strongly urged to collaborate with tribes and the IHS to create community-based coalitions and develop programs to address highly preventable injury-related mortality and morbidity. Strong advocacy also is needed to promote childhood injury prevention as an important priority for federal agencies and tribes.

ABBREVIATIONS. AI, American Indian; AN, Alaska Native; IHS, Indian Health Service; AAP, American Academy of Pediatrics.

More than 700 000 American Indian and Alaska Native (AI/AN) children younger than 19 years old live in the United States.[1] These AI/AN children experience higher rates of morbidity and mortality from unintentional injuries than do other US children. The 881 injury deaths to AI children between 1992 and 1994 translate to an overall rate of 52.3 deaths per 100 000 children per year. This rate is almost twice the US rate of 28.3 per 100 000 children for all races (1993).[2] Rates of injury deaths are high for rural and urban AI/AN populations.[3]

Although rates of injury death have dropped considerably during the past 25 years, they remain disproportionately high among AI/AN children for the most common causes of injury. Fatality rates for motor vehicle occupant injuries are 3 times higher for AI/AN children than for white and black children.[1] Pedestrian-motor vehicle collision deaths are almost 4 times that for all US races combined, and drowning, the second leading cause of injury death, occurs at rates almost 2 times higher than those for white and black children. Native American children also die as a result of fire and burn injury at 2.8 times the rate of white children.

Some of the recognized important risk factors for unintentional injury mortality among AI/AN children include poverty, alcohol abuse, substandard housing, limited access to emergency medical services, rural residences, and low seat belt use rates.[2,4–8] The high rates of injury-related death and disability make it especially important to emphasize and intensify injury prevention efforts within this population.

Injury prevention specialists use media campaigns, targeted education, safety technology, environmental modification, and passage of laws and regulations to achieve their aims. Each of these approaches has been used successfully by the tribes, often working in close partnership with the Indian Health Service (IHS) Injury Prevention Program. Some examples of successful injury prevention programs for AI/AN communities include a program promoting winter coats with flotation devices in Alaska to prevent drowning[9]; a livestock control program to reduce motor vehicle collisions with large animals[10]; and the Navajo Nation motor vehicle occupant safety program to boost seat belt use.[11]

The sovereignty of tribes provides special challenges to the regulatory and legislative approach to injury control in AI/AN communities. Safety laws vary considerably among the 550 federally recognized tribes. Although some tribes fall under the jurisdiction of state laws (eg, California, Oklahoma, and Alaska), many enact their own laws and tribal codes. According to a recent inventory of tribal laws relating to occupant safety, only 14% of the responding tribes had passed their own laws requiring seat belt use, 46% had adopted state laws, and the remainder had no relevant law.[12] The regulatory and legislative approach is complex and may often require working with each tribe separately, similar to the enactment of laws in states.

The AI/AN groups are culturally and linguistically diverse with more than 200 native languages still spoken. Although similarities exist among some tribes, such as the Pueblo tribes, most tribes have unique cultural practices. Intervention strategies should account for these differences. For example, the promotion of the use of child safety seats is a well-accepted form of prevention for motor vehicle

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

crash injury, but the method used to promote them may need to be tailored to the cultural beliefs of the specific tribe. In some tribes, discussions of mortality, risk, and harm are forbidden.[13] For example, health care professionals should not warn that death is a potential outcome if certain protective measures are not taken. One strategy used by the IHS Injury Prevention Program was to conduct a crash test using a cradle board to demonstrate the inadequacy of this device as a child vehicle restraint. Video footage of this test was sufficient to communicate the risk without having to predict risk of harm to the child.

Pediatricians can increase their understanding of tribal cultures in many ways. In many tribes, traditional healers, tribal elders, or community health workers can be approached respectfully and asked to provide guidance; in other tribes it may be more appropriate to work directly with the tribal health director. Many tribes have or are developing cultural centers to assist nonmembers to gain a greater understanding of the tribe.

Some general strategies also can be used to communicate with AI/AN patients. First, avoid comparisons between AI/AN people and people of other cultures. Second, providers should take extra time to convey information in a clear nonjudgmental style that is free of jargon. Common cultural attributes of the AI/AN people include cooperation and patience. They may respond quietly or ask few questions because of their beliefs about respect and consideration.

RECOMMENDATIONS

Because of concern about the high rate of childhood injury morbidity and mortality among AI/AN people, the American Academy of Pediatrics (AAP) supports the continued implementation and expansion of a broad-based injury prevention program among these populations. Pediatricians and others caring for AI/AN children should:

1. Form coalitions linking IHS and tribal injury control specialists with others interested in childhood injury control in the surrounding community and state. All should be encouraged to work within AI/AN communities to understand how best to introduce injury prevention strategies.
2. Respect tribal sovereignty and community-specific cultural factors when considering regulatory or legal approaches to injury prevention.
3. Provide assistance with advocacy for adoption of tribal seat belt and child car seat traffic safety laws or the adoption by tribes of state child motor vehicle safety laws. (The AAP and the IHS have developed model injury prevention legislation that may be helpful in some cases.)
4. Promote comprehensive seat belt and child car seat educational and media campaigns in AI/AN communities.
5. Support other targeted child safety efforts among rural and urban AI/AN populations that are known to be effective, including the promotion of bicycle helmet use, fire safety, the prevention of drowning and falls, and firearm safety. Pediatricians can facilitate injury prevention in the clinic by use of the AAP TIPP (The Injury Prevention Program) materials with patients.
6. Support efforts to improve the quality of injury-related data through the establishment of confidential comprehensive data systems to monitor the epidemiology of all medically reported injuries and the improvement of coding of health records to decrease racial misclassification.
7. Advocate for increased emphasis on and funding by tribal and federal programs (eg, the IHS, the Centers for Disease Control and Prevention, and the National Highway Traffic Safety Administration) of injury control initiatives and appropriate injury prevention research in AI/AN communities.
8. Urge the IHS, tribally operated, and urban health programs to implement injury prevention programs as a cost-effective use of health care dollars.

Pediatricians and others involved in child health care have an opportunity and a challenge to reduce injury-related morbidity and mortality among AI/AN children. If the challenge can be met, Native American children will be protected from injuries at least as well as other US children, who have seen a more favorable reduction in injury mortality in recent years.[14]

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Policy Statement—Principles of Health Care Financing

abstract

FREE

The American Academy of Pediatrics advocates that all children must have health insurance coverage that ensures them access to affordable and comprehensive quality care. Access to care depends on the design and implementation of payment systems that ensure the economic viability of the medical home; support and grow the professional pediatric workforce; promote the adoption and implementation of health information technology; enhance medical education, training, and research; and encourage and reward quality-improvement programs that advance and strengthen the medical home. Health insurance plans must be portable from state to state, with administrative procedures to eliminate breaks and gaps in coverage to ensure continuous coverage from year to year. Plans should ensure free choice of clinicians and foster coordination with public and private community-based programs for infants, children, and adolescents through the age of 26. The scope of services provided by all health plans must include preventive, acute and chronic illness, behavioral, inpatient, emergency, and home health care. These plans must be affordable and have cost-sharing policies that protect patients and families from financial strain and are without risk of loss of benefits because of plan design, current illness, or preexisting condition. *Pediatrics* 2010;126:1018–1021

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

INTRODUCTION

All children must have coverage that ensures them access to affordable and comprehensive quality care. Appropriate and adequate payment is essential to ensure the viability of the pediatric workforce to provide such care. Coverage and payment must provide access to pediatric primary care and comprehensive and coordinated medical subspecialty and surgical specialty services; developmental, behavioral, and mental health services; inpatient and emergency department care; home health care; dental care; and other specialized pediatric services within a medical home model of care. The principles outlined in this statement should be used to evaluate national and state health insurance reform proposals and to make ongoing improvements to private and public financing of health care for children and adolescents.

ACCESS TO HEALTH INSURANCE

All children and adolescents, from birth to 26 years of age, regardless of income, must have access to comprehensive health insurance. Quality health insurance should be guaranteed for every child, pregnant woman, family, and, ultimately, all individuals. Such coverage should be portable from state to state and continuous

from year to year with streamlined administrative procedures. It must ensure free choice of clinicians and foster coordination with public programs for children and adolescents. Ensuring access to health insurance must be a shared responsibility of parents, employers, and state and federal government agencies.

Recommendations

- All children up to 26 years of age in families with incomes up to 133% of the federal poverty level should have access to Medicaid or, at higher eligible incomes, the Children's Health Insurance Program (CHIP).
- Dependent children must not be denied coverage because of a preexisting condition, and their coverage should not be terminated because of illness.
- There must be no annual or lifetime limit on insurance benefits.
- For children whose families lose employer-sponsored health insurance, COBRA (Consolidated Omnibus Budget Reconciliation Act of 1985) premiums should remain at employer-sponsored rates. If the former employee is not able to afford that premium, there must be other health insurance options that will reduce the cost of coverage.
- For children ineligible for public coverage, national and state outreach efforts should be undertaken to educate their families on health insurance options and how to access care through the various public or private health care entities in their community.
- For children who remain uninsured despite access to public or private insurance, a safety-net system of care should be subsidized and offered through office-based practices in addition to community health centers and hospitals. For children whose families have access to employer or other group health insurance, financial incentives should be extended to employers to offer and maintain dependent coverage up to 26 years of age.
- Dependent premium contributions for family coverage should be a responsibility shared between the employer and employee. Employers should be encouraged to provide access to family coverage to all employees.
- When employers offer insurance coverage for dependent children, the premium rate calculations must be based on the requirements of the March 2010 Patient Protection and Affordable Care Act.

HEALTH INSURANCE COVERAGE

All children and adolescents must have a comprehensive age-appropriate benefit package. The health insurance package should cover all pediatric services including preventive and wellness services, acute, inpatient, and chronic care services, including developmental, pregnancy-related and other reproductive health, newborn care, mental and behavioral health, substance abuse disorders, emergency services, facilitative, habilitative, and rehabilitative services and devices, palliative, home health, and hospice care services, prescription drugs, vision care services, and oral health services reflecting the scope of benefits recommended by the American Academy of Pediatrics (AAP)[1] and the National Business Group on Health.[2]

Recommendations

- Preventive benefits for children and adolescents must be consistent with *Bright Futures*[3] recommendations, not the US Preventive Services Task Force recommendations.
- All benefits must be sufficient in amount, duration, and scope to achieve the best clinical outcome.
- Health insurers must work from a common definition of medical necessity so that health care services:
  - reflect the need to promote normal growth and development and prevent, diagnose, treat, ameliorate, or palliate the effects of physical, developmental, mental, behavioral, genetic, or congenital conditions, illness, injuries, or disability;
  - are in accordance with generally accepted standards of medical practice based on credible scientific evidence as would be published in peer-reviewed medical literature[4] or are evidence-informed by clinical experts in pediatric care when insufficient studies are available; and
  - reflect the appropriate type, frequency, duration, and setting for effective care for that particular condition and patient.
- Health plans must provide information about how they determine medical necessity, including how they use clinical evidence that supports coverage of interventions, how they incorporate the opinions of experts in child/adolescent medicine, how they assist families who seek to appeal a medical-necessity decision, and how and when coverage decisions will be made.
- All public and private payers should establish cost-sharing policies that ensure affordable health services. Cost-sharing policies should not shift cost to physicians, hospitals, and other health care providers and should not deter the use of medically necessary services.
- Cost-sharing must not be applied to

preventive care, including recommended immunizations, for children and adolescents.

- For children whose family income is below 133% of the federal poverty level, cost-sharing, premiums, and other fees should be prohibited. For children whose family income is between 133% and 200% of the federal poverty level, deductibles and cost-sharing should be nominal and only applied to nonessential services.
- There should be no deductibles for children whose family income is below 133% of the federal poverty level.
- Annual and lifetime out-of-pocket limits must be established to protect families from significant medical debt.
- The impact of cost-sharing, premiums, and other out-of-pocket expenses on access to care should be regularly assessed by state insurance commissioners or another appropriate state agency that governs health insurance to ensure access and affordability of coverage.

PAYMENT POLICIES TO SUPPORT FAMILY- AND PATIENT-CENTERED MEDICAL HOMES

There should be cooperation between payers, employers, physicians, and patients and their families so that medical home payment reforms are implemented in ways that ensure quality care, financial viability, and fairness for payers and providers so that children and adolescents receive all AAP-recommended services. These reforms should be based on the medical home principles adopted jointly by the AAP, American Academy of Family Physicians, American Osteopathic Association, and American College of Physicians.[5] The payment structure for comprehensive care should encompass recognition of relevant Current Procedural Terminology (CPT) and Healthcare Common Procedure Coding System (HCPCS) codes, optimal community-based care coordination, current quality-improvement activities, and up-front investments and support for medical home infrastructure, including health information technology.

Recommendations

The following should be required by all health plans:

- All private and public payers should adopt a comprehensive set of medical home payment reforms that include 3 components:
  1. Encounter-based fee component that recognizes and values evaluative/cognitive services, preventive counseling, telephone and e-mail communication, collaborative consultation, and team care as defined by CPT or HCPCS codes. These items should be paid as fee-for-service or integrated into enhanced capitation payments.
  2. A community-based care coordination fee, which recognizes the work of clinical and administrative staff who provide medical home services. Payment for these services should be as a per-member-per-month fee, with adjustments based on the complexity of the patient panel.
  3. A performance (pay-for-performance) or quality-improvement fee for evidence-based or evidence-informed process, structure, or outcome measures. Payment should be as a bonus, either on a per-member-per-month basis or as a fee-schedule increase.
- Payment for vaccine products must exceed the acquisition cost of each vaccine and the overhead expense associated with them. Any increase in a specific vaccine cost or new vaccine recommendation must be updated in a timely fashion, with retroactive compensation if there is any lag time to implement such change.
- Payment for vaccine-administration codes must cover costs of office overhead for scheduling, coordinating, educating patients and their families, pain management, staff time, supplies, and billing and should be, at minimum, 100% of the Medicare rate for each vaccine-administration CPT code.
- Payments for encounter-based visits should be closely tied to evidence-based or evidence-informed clinical decision-making. Methods used to determine payment should consider the child's age, symptom chronicity, severity of underlying health, and behavioral, social, and other problems and include a geographic adjustment.
- Payment policies should recognize and reward clinicians who provide population-based prevention and who promote continuous and coordinated care, including care coordination between generalists and specialists. Payment should be discouraged for clinics that provide episodic care for minor conditions.

SUPPORT FOR CLINICAL CARE, PAYMENT-SYSTEM REFORMS, AND TRAINING INNOVATIONS

At both national and state levels, expert pediatric advisory groups should be established to monitor progress related to health insurance access, comprehensive and affordable coverage, medical home implementation, payment reforms, and investments in innovation. There should be a federally funded pediatric-specific entity to support innovations in medical home implementation, education/training, quality im-

provement, health services research, and population-based prevention.

Recommendations

- Payment systems should be developed that reward high-quality, coordinated care.
- Care should be coordinated through collaborative practice involving primary care physicians and pediatric subspecialists.
- Access to pediatric medical subspecialists and surgical specialists should be improved. Concerted efforts should be aimed at recruitment, scholarship, loan support, and development of telemedicine technology for remote or physician-underserved locations.
- Clinical, community-based prevention programs that support population health, including but not limited to obesity and mental health, should be expanded.
- Clinical and population research should be supported with expanded efforts focusing on care coordination, self-management, preventive care, immunizations, behavioral health, children and adolescents with special health care needs, diabetes, depression, medication management, pregnancy and childbirth, and obesity.
- Transition planning from pediatric to adult health care should be promoted and implemented and should include training, consultation, and financial incentives to encourage early transition planning and the use of AAP recommendations.[6]
- Health care professionals should be trained to use advanced health information technology to support continuity of care and continuous quality improvement.
- Health literacy should be promoted for parents, children, and adolescents. A particular focus should be on low-income and non–English-speaking populations.
- Vaccine registries should be established at the local, state, and national levels with requirements that registries link providers and vaccine manufacturers so that practice-management systems, including electronic health records, contain recipient as well as vaccine product and administration details and ensure interoperability between vaccine registries and personal health records.

Policy Statement—Prevention of Varicella: Update of Recommendations for Use of Quadrivalent and Monovalent Varicella Vaccines in Children

abstract

FREE

Two varicella-containing vaccines are licensed for use in the United States: monovalent varicella vaccine (Varivax [Merck & Co, Inc, West Point, PA]) and quadrivalent measles-mumps-rubella-varicella vaccine (MMRV) (ProQuad [Merck & Co, Inc]). It is estimated from postlicensure data that after vaccination at 12 through 23 months of age, 7 to 9 febrile seizures occur per 10 000 children who receive the MMRV, and 3 to 4 febrile seizures occur per 10 000 children who receive the measles-mumps-rubella (MMR) and varicella vaccines administered concurrently but at separate sites. Thus, 1 additional febrile seizure is expected to occur per approximately 2300 to 2600 children 12 to 23 months old vaccinated with the MMRV, when compared with separate MMR and varicella vaccine administration. The period of risk for febrile seizures is from 5 through 12 days after receipt of the vaccine(s). No increased risk of febrile seizures is seen among patients 4 to 6 years of age receiving MMRV. Febrile seizures do not predispose to epilepsy or neurodevelopmental delays later in life and are not associated with long-term health impairment. The American Academy of Pediatrics recommends that either MMR and varicella vaccines separately or the MMRV be used for the first dose of measles, mumps, rubella, and varicella vaccines administered at 12 through 47 months of age. For the first dose of measles, mumps, rubella, and varicella vaccines administered at ages 48 months and older, and for dose 2 at any age (15 months to 12 years), use of MMRV generally is preferred over separate injections of MMR and varicella vaccines. *Pediatrics* 2011;128:630–632

INTRODUCTION

Since implementation of routine varicella vaccination in 1995, disease and death from varicella-zoster virus has declined significantly.[1–3] Two varicella-containing vaccines currently are licensed for use in the United States: monovalent varicella vaccine (Varivax [Merck & Co, Inc, West Point, PA], licensed in 1995) and quadrivalent measles-mumps-rubella-varicella vaccine (MMRV) (ProQuad [Merck & Co, Inc], licensed in 2005).

The American Academy of Pediatrics updated its statement on the prevention of varicella[4] in 2007 and reaffirmed that statement in 2010. The purpose of this brief vaccine policy statement is to provide additional data to update these recommendations.

BACKGROUND AND RATIONALE

Prelicensure studies of the MMRV indicated that fever was more common after MMRV (22%) than after measles-mumps-rubella (MMR) and varicella vaccines administered concurrently but at separate sites (15%) during the 0 through 42 days after receipt of the vaccine. The reasons for this are not fully understood, but the increased occurrence of fever might suggest a more vigorous immune response as a reaction to an increase in measles virus replication, as reflected in measles antibody titers. The measles, mumps, and rubella viruses in the MMRV are identical and of equal potency to those in the MMR vaccine, but the potency of the varicella-zoster virus is at least 7 times higher than the potency in the monovalent varicella vaccine. However, measles geometric mean titers (GMTs) measured 6 weeks after vaccination were higher among children who received the first dose of MMRV than among children who received the first dose of MMR vaccine and varicella vaccine administered concurrently but at separate sites; varicella GMTs were similar. Statistical modeling indicated that the level of the measles antibody titer after receipt of MMRV was associated positively with the rate of fever.

It was postulated at the time of licensure that the increased frequency of fever after the MMRV might correlate with an increased likelihood of febrile seizures. Postlicensure studies were conducted in 2008 and 2009 by the Centers for Disease Control and Prevention Vaccine Safety Datalink and Merck to evaluate this possibility.[5]

EVIDENCE TO SUPPORT POLICY/ RECOMMENDATION

Results of the Vaccine Safety Datalink and Merck studies were remarkably similar. After vaccination at 12 through 23 months of age, 7 to 9 febrile seizures occur per 10 000 children who receive the MMRV, and 3 to 4 febrile seizures occur per 10 000 children who receive the MMR and varicella vaccines administered separately. Thus, 1 additional febrile seizure is expected to occur per approximately 2300 to 2600 children 12 through 23 months old vaccinated with the MMRV compared with separate MMR and varicella vaccines. The period of increased risk for febrile seizures is from 5 through 12 days after receipt of the vaccine.

Among older children 4 through 6 years of age receiving the second dose of the MMRV, there is no evidence to suggest an increased risk of febrile seizures after MMRV vaccination compared with those who receive separate MMR and varicella vaccine injections at the same visit.

Febrile seizures do not predispose to epilepsy or neurodevelopmental delays later in life. Although they are frightening for parents, febrile seizures are not associated with long-term health impairment for the affected child.

POLICY OR RECOMMENDATION

The routinely recommended ages for measles, mumps, rubella, and varicella vaccination continue to be 12 through 15 months for dose 1 and 4 through 6 years for dose 2. The American Academy of Pediatrics recommends for the first dose at ages 12 through 47 months that either MMR and varicella vaccines administered separately or MMRV can be used. Use of separate MMR and varicella vaccines averts the slight increase in risk of fever and febrile seizures after MMRV administration but at the cost of the pain associated with an extra injection and the risk of an infant falling behind schedule if all vaccines indicated at that visit are not given. Providers who are considering administering MMRV should discuss the benefits and risks of both vaccination options with the parents or caregivers. Because parents need to be fully aware of the slight increase in risk of febrile seizures with the combination MMRV compared with separate MMR and varicella injections at the same visit, providers who face barriers to clearly communicating these benefits and risks for any reason (eg, language barriers) should administer MMR and varicella vaccines separately.

The risk of febrile seizures is not increased in older children who receive the second dose of MMRV. Therefore, when the first dose of measles, mumps, rubella, and varicella vaccines is administered at ages 48 months and older, and for dose 2 at any age (15 months through 12 years), use of the MMRV generally is preferred over separate injections of its equivalent component vaccines (ie, MMR and varicella vaccines) because of the decreased number of injections required with the MMRV.

A personal or family (such as sibling or parent) history of seizures is now a precaution for MMRV vaccination. Children with a personal or family history of seizures generally should be vaccinated with MMR and varicella vaccines, because the risks of using the MMRV in this group of children generally outweigh the benefits.

IMPLEMENTATION ISSUES

Fact sheets have been developed (www.cdc.gov/vaccines/vpd-vac/combovaccines/mmrv/vacopt-factsheet-hcp.htm), and the Vaccine Information Statement (VIS) has been updated (www.cdc.gov/vaccines/pubs/vis/downloads/vis-mmrv.pdf). Current availability of

the MMRV can be accessed at www.cdc.gov/vaccines/vac-gen/shortages/default.htm#4 (as of June 28, 2010).

POLICY STATEMENT

Preventive Oral Health Intervention for Pediatricians

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Section on Pediatric Dentistry and Oral Health

ABSTRACT

This policy is a compilation of current concepts and scientific evidence required to understand and implement practice-based preventive oral health programs designed to improve oral health outcomes for all children and especially children at significant risk of dental decay. In addition, it reviews cariology and caries risk assessment and defines, through available evidence, appropriate recommendations for preventive oral health intervention by primary care pediatric practitioners. *Pediatrics* 2008;122:1387–1394

PURPOSE/INTRODUCTION

Review of Circumstances Leading to Development of This Policy

Oral health is an integral part of the overall health of children.[1] Dental caries is a common and chronic disease process with significant consequences. As health care professionals responsible for the overall health of children, pediatricians frequently confront morbidity associated with dental caries. Because caries is a nonclassic infectious process (arising from shifts in subpopulation ratios of established normal flora), pediatricians have an opportunity to prevent, intervene, and, in collaboration with dental colleagues, manage this disease.

Justification of Policy

The prevalence of dental caries for the youngest of children has not decreased over the past decade, despite improvements for older children.[2] Data from the Medical Expenditure Panel Survey revealed that 89% of infants and 1-year-olds had office-based physician visits annually, compared with only 1.5% who had dental visits. Consequently, visits to physicians outnumbered visits to dentists at 250 to 1 for this age group.[3] Because the youngest of the pediatric patient population visit the pediatrician more than the dentist, it is critical that pediatricians be knowledgeable about dental caries, prevention of the disease, and interventions available to the pediatrician and the family.

Rationale for Format

This policy statement is an effort to assist the primary care pediatric practitioner in addressing issues of dental caries and general oral health. The statement begins by building a knowledge base regarding the caries process that can serve as a foundation for understanding prevention and intervention strategies. After explaining the science of cariology, assessment of caries risk is described to assist the pediatrician in deciding which preventive and interventional strategies need to be used. Specific prevention and intervention strategies are then described and explained.

In addition, the concept and importance of the dental home as well as strategies for improving the connection of the medical and dental homes are presented. Last, recommendations are provided to assist the pediatrician with implementation of the provided information.

BACKGROUND CONCEPTS

Cariology

The most common oral disease encountered by children is dental caries. Dental caries is a nonclassic infectious disease[4] that results from an interaction between oral flora and dietary carbohydrates on the tooth surface. To adhere to tooth structure, oral flora utilize dietary sugars to create a sticky biofilm that is referred to as dental plaque. Dietary sugar can change the biochemical and microbiologic composition of dental plaque. In the presence of a high-carbohydrate diet, cariogenic organisms constitute a greater portion of the total bacterial population.[5,6] Acids

produced by bacterial fermentation of carbohydrates reduce the pH of dental plaque to the point at which demineralization of the enamel occurs. The initial carious lesion appears as an opaque white spot on the enamel, and progressive demineralization results in cavitations of the teeth. Dental caries is a process, and loss of tooth structure (a dental cavity) is an end stage in the process.[7]

Human dental flora, generally regarded as qualitatively stable once established and site specific to human dentition, is believed to consist of more than 1000 different organisms, of which only a limited number are associated with dental caries.[8] *Streptococcus mutans* is most strongly associated with dental caries and is considered to be an indicator organism of a subpopulation of cariogenic organisms. *S mutans*, like its related cariogenic cohorts, has the ability to adhere to enamel and is uniquely equipped to produce significant amounts of acid (acidogenic) and endure within that acidic environment (aciduric).

Dental flora adheres to the teeth by creating a tenacious and highly complex biofilm referred to as dental plaque. Dental plaque is capable of concentrating dietary sugars; therefore, the chronic consumption of sugary foods and liquids will continually recharge the plaque matrix, resulting in copious supplies of sugars within the plaque matrix. *S mutans* and other cariogenic flora will then ferment available sugars, resulting in high levels of lactic acid, a decreased local pH (~5.0), and demineralization of dental enamel (at an approximate pH of ≤5.5). Because *S mutans* and its aciduric cohorts continue to thrive at low pH, the resulting environment selects against nonaciduric flora, creating a shift in the subpopulation ratio of benign to aciduric flora. As this process continues over multiple generations, aciduric organisms incur an upregulation of virulence genes that allow them to thrive at even lower pH (4.0). Diet-mediated shifts in subpopulation ratios of dental flora are instigated by significant sugar intake (environmentally selecting for carious organisms). Therefore, significant sugar intake is a driving cause of the caries process.

Preventive Strategies

An understanding of normal dental flora serves as a foundation for the development of preventive strategies, with 2 important considerations. First, dental flora exists in a symbiosis with the human species. Second, only a small number of the organisms within dental flora cause caries. Therefore, our objective is not to eliminate all dental flora but to suppress the cariogenic bacteria within the flora.

Preventive strategies can be differentiated into 2 distinct categories. Primary prevention involves optimization of maternal dental flora before and during colonization of the oral flora of the infant (during eruption of the primary dentition). This invaluable mode of prevention provides an opportunity for a reduction in the mother's constitutionally virulent, aciduric flora and downregulation of virulence genes within the aciduric flora, decreasing the child's risk of dental decay, and is the basis for first dental visit recommendations at 1 year or earlier made by various medical and dental organizations. This mode of prevention and its adjuncts are reviewed in detail in a policy statement from the American Academy of Pediatrics, "Oral Health Risk Assessment Timing and Establishment of the Dental Home."[9]

Secondary prevention is the continual and ongoing management of subpopulation ratios of benign and aciduric flora within dental plaque. This mode of prevention consists of managing the balance between causative factors and protective factors and is critical for preventing and reversing the caries process. Secondary preventive strategies are hierarchical and currently consist of dietary counseling, oral hygiene instruction, and judicious administration of fluoride modalities. Therefore, although all preventive modalities are important, modification of diet is most important, followed by oral hygiene compliance and then administration of fluorides.

By controlling risk factors before disease occurs, the probability of preventing disease, both in the immediate future and the long-term, is improved. Preventive strategies for this complex, chronic disease require a comprehensive and multifocal approach that begins with caries risk assessment.

Caries Risk Assessment

Caries risk assessment, based on developmental, biological, behavioral, and environmental factors, evaluates the probability of enamel demineralization exceeding enamel remineralization over time. The goal of risk assessment is to anticipate and prevent caries initiation before the first sign of disease. During the period of 1999–2002, 41% of US children 2 to 11 years of age had caries in primary teeth.[2] An earlier study noted that 25% of children 5 to 17 years of age had 80% of carious permanent teeth.[10] Assessing each child's risk of caries and tailoring preventive strategies to specific risk factors are necessary for improving oral health in a cost-effective manner.

Caries risk assessment is very much a work in progress. In a systematic review of literature regarding risk factors in primary teeth of children aged 6 years and younger, a paucity of studies of optimal (ie, longitudinal) design was noted.[11] A study that evaluated the reliability of multiple risk indicators determined that there is no consistent combination of risk variables that provide a good predictor of caries risk when applied to different populations across different age groups.[12] The authors concluded that the best predictor of caries in primary teeth was previous caries experience, followed by parents' education and socioeconomic status.[12] Although previous caries experience cannot be used as a risk indicator for the predentate or very young child, white-spot lesions, as precursors to cavities, can be considered analogous to previous caries experience when assessing the risk of a very young patient. An analysis of National Health and Nutrition Examination Survey (NHANES) III data revealed that children from households with low income levels are more likely to experience caries and have higher levels of untreated caries than their counterparts from higher-income households.[13] Collectively, children enrolled in Special Supplemental Nutrition Pro-

gram for Women, Infants, and Children (WIC) programs, Head Start, or Medicaid are at higher risk than are children in the general population.

Caries risk factors unique to infants and young children include perinatal considerations, establishment of oral flora and host-defense systems, susceptibility of newly erupted teeth, dietary transitioning from breast and bottle feedings to cups and solid foods, and establishment of childhood food preferences. Although preterm birth per se is not a risk factor, a child with low birth weight may require a special diet or have developmental enamel defects or disabilities that increase caries risk. Early acquisition of *S mutans* is a major risk factor for early childhood caries and future caries experience.[14] A reduction of the salivary level of *S mutans* in highly infected mothers can inhibit or delay colonization of their infants.[15] Although evidence suggests that children are most likely to develop caries if *S mutans* is acquired at an early age, this may be compensated in part by other factors such as good oral hygiene and a noncariogenic diet.[11] High-risk dietary practices seem to be established early, probably by 12 months of age, and are maintained throughout early childhood.[16] In addition to the amount of sugar consumed, frequency of intake is important.[17] Sugar consumption likely is a more significant factor for those without regular exposure to fluorides.[18] Children experiencing caries as infants and toddlers have a much greater probability of subsequent caries in both the primary and permanent dentitions.[19]

Early risk assessment targets infants and young children who traditionally have yet to establish a dental home. Unrecognized disease and delayed care can result in exacerbated problems, leading to more extensive, costly, and time-consuming care.

Risk-assessment strategies most applicable for screening purposes include those that are acceptable to patients, reliable, inexpensive, and performed easily and efficiently and require limited equipment/supplies. The American Academy of Pediatric Dentistry (AAPD) has developed a caries risk-assessment tool for use by dentists and primary care practitioners familiar with the clinical presentation of caries and factors related to caries initiation and progression (see www.aapd.org/media/Policies_Guidelines/P_CariesRiskAssess.pdf).[20] Radiographic assessment and microbiologic testing have been included in the caries risk-assessment tool but are not required. In addition, the American Academy of Pediatrics has created *Oral Health Risk Assessment Training for Pediatricians and Other Child Health Professionals*, which provides a concise overview of the elements of risk assessment and triage for infants and young children (see www.aap.org/commpeds/dochs/oralhealth/screening.cfm).[21]

The chronic, complex nature of caries requires that risk be reassessed periodically to detect changes in the child's behavioral, environmental, and general health conditions. All available data must be analyzed to determine the patient's caries risk profile. Periodic reassessment allows the practitioner to individualize preventive programs and optimize the frequency of recall and dental radiographic examinations.

SPECIFIC PREVENTIVE STRATEGIES

Dietary Counseling

Dietary counseling for optimal oral health in children should be an essential part of general health counseling. The recent policy statement from the American Academy of Pediatrics on prevention of pediatric overweight and obesity highlighted concerns about health problems in overweight children, including cardiovascular, endocrine, and mental health problems, and the importance of promoting healthy eating behaviors. Consumption of juice and sugar-sweetened beverages has been linked to childhood obesity and caries development.[22–25]

Sugars are a critical factor in caries development. Caries risk is greatest if sugars are consumed at high frequency and are in a form that remains in the mouth for longer periods.[26] Sucrose is the most cariogenic sugar, because it can form glucan, which enables bacterial adhesion to teeth and limits diffusion and buffering of acids. Although starch-rich foods pose a low caries risk, mixtures of finely ground, heat-treated starch and sucrose (eg, cereals, potato or corn chips) are also cariogenic.[27]

Human milk by itself does not promote tooth decay.[28] However, breastfed infants are at risk of caries when they receive sugary liquids or eat foods with sugars and fermentable carbohydrates.[26]

Parents and caregivers should be counseled on the importance of reducing exposure to sugars in foods and drinks. To decrease the risk of dental caries and ensure the best possible health and developmental outcomes, it is recommended that parents do the following:

- Breastfeed infants during the first year of life and beyond as is mutually desired.[29]
- After nursing, remove the breast from a sleeping infant's mouth and cleanse the gums and teeth after feedings and before bedtime.
- Discourage a child's sleeping with a bottle; any bottle taken to bed should contain only water.
- Limit sugary foods and drinks to mealtimes.
- Avoid carbonated beverages and juice drinks (juice drinks contain high-fructose corn syrup and <100% natural juice).
- Encourage children to drink only water and milk between meals.
- Encourage children to eat fruits.
- Limit the intake of 100% fruit juice to no more than 4 oz per day.
- Foster eating patterns that are consistent with MyPyramid guidelines from the US Department of Agriculture.[30]

Optimal Use of Fluorides

Fluoride, a naturally occurring element, has been instrumental in the widespread decrease in dental caries.[31,32] The mechanisms of fluoride are both topical and systemic, with evidence pointing to a greater topical effect.[33]

Fluoride reduces enamel dissolution while it encourages remineralization.[34] Antimicrobial effects of fluorides at low pH are also significant.[35]

The delivery of fluoride includes community-based, professionally applied, and self-administered modalities. Water fluoridation is a community-based intervention that optimizes the level of fluoride in drinking water, resulting in preeruptive and posteruptive protection of the teeth.[36] Water fluoridation is a cost-effective means of preventing dental caries, with the lifetime cost per person equaling less than the cost of 1 dental restoration.[37,38] In short, fluoridated water is the cheapest and most effective way to deliver anticaries benefits to communities.

Professionally applied topical fluorides (PATFs) have their greatest effect preventing caries and must be applied at regular intervals.[39] PATFs include gel, foam, in-office rinse, and varnish. PATFs are safe and efficacious, with varnishes having the advantage of adherence to the tooth surface, decreasing likelihood of ingestion, and increasing time of contact between the fluoride and tooth surface.[37,39] In the primary dentition, varnish effectiveness (measured by percent of caries reduction) ranges from 30% to 63.2%,[40,41] and an analysis of the number of fluoride-varnish applications received resulted in a dose-response effect that was enhanced when coupled with counseling.[42] Finally, self-administered fluorides, including dietary fluoride supplementation and fluoridated toothpaste, have proven effective, providing low but protracted elevation of fluoride concentrations.[35,43] Caries reduction associated with self-administered fluoride supplementation ranges from 32% to 72% in the primary dentition.[40] In children and adolescents, fluoride toothpastes, mouth rinses, and gels reduce dental caries to a similar extent.[44]

The decision to use fluoride therapies must balance the risk of caries against the risk of enamel fluorosis (hypomineralization of the developing enamel caused by excess fluoride ingestion). Patients determined to be at increased risk of dental caries are candidates for more aggressive fluoride therapy utilization. Caries susceptibility and sources of dietary fluoride (eg, water supplies, beverages, prepared food, toothpaste) should be considered before recommending fluoride therapies.[45–48] Enamel fluorosis develops before tooth maturation and emergence, typically in children younger than 8 years.[49] The risk of enamel fluorosis is an aesthetic concern, with very mild or mild forms most commonly observed in the general population.[2,50]

ANTICIPATORY GUIDANCE

Anticipatory guidance is the process of providing practical, developmentally appropriate information about children's health to prepare parents for significant physical, emotional, and psychological milestones.[51] Anticipatory guidance during well-child visits is an effective tool to educate parents about maintaining children's health. Mirroring the pediatric model, the American Academy of Pediatric Dentistry advocates oral health anticipatory guidance.[52–55] Anticipatory guidance focused on oral health disease should be an integral part of preventive pediatrics. Information concerning the impact of diet on dental health and counseling in regards to oral hygiene, nonnutritive oral habits, and dental safety should be shared with parents. Therefore, in addition to dietary counseling and optimizing fluoride exposure, anticipatory guidance for oral health includes:

1. Infant oral hygiene instruction: Teeth should be brushed at least twice daily with caregiver supervision and assistance for children. For children with elevated dental caries risk, consider using a pea-sized amount of toothpaste or an amount equivalent to the child's fifth-digit fingernail. Flossing should begin as soon as adjacent teeth are in contact and for surfaces at which 2 teeth touch and they can no longer be cleansed with a toothbrush.
2. Counseling regarding nonnutritive oral habits: Use of pacifiers in the first year of life may prevent sudden infant death syndrome.[56] Sucking habits (eg, pacifiers or digits) of sufficient frequency, duration, and intensity may be associated with dentoalveolar deformations. Some changes persist past cessation of the habit. Professional evaluation is indicated for nonnutritive sucking habits that continue beyond 3 years of age.[53]
3. Age-appropriate information regarding dental injury prevention: Parents should cover sharp corners of household furnishings at the level of walking toddlers, ensure use of car safety seats, and be aware of electrical cord risk for mouth injury. Properly fitted mouth guards are indicated for youths involved in sporting activities that carry a risk of orofacial injury.

Anticipatory guidance is valuable, because it emphasizes prevention of dental problems rather than surgical or restorative care. Anticipatory guidance and well-child visits during the first 2 years of life decrease the number of hospitalizations among poor and near-poor children irrespective of race and health status.[57] Oral health anticipatory guidance can reduce dental expenditures.[58] In light of this evidence, oral health anticipatory guidance should be integrated as a part of comprehensive counseling during well-child visits.[59]

INTERPROFESSIONAL COLLABORATION AND ESTABLISHMENT OF A DENTAL HOME

To be successful in preventing dental disease, interventions must begin within the first year of life. Pediatricians are well positioned to initiate preventive oral health care by providing early assessment of risk, anticipatory guidance, and timely referral to establish a dental home. The American Academy of Pediatric Dentistry, the American Dental Association, and the American Association of Public Health Dentistry recommend that infants be scheduled for an initial oral examination within 6 months of the eruption of the first primary tooth but by no later than 12 months of age.

The pediatric community promotes the concept of a medical home to improve families' care utilization, seeking appropriate and preventive services with optimal compliance to recommendations. The concept of the

dental home is based on this model and is intended to improve access to oral care. A dental home is the ongoing relationship between the dentist and the patient, inclusive of all aspects of oral health care delivered in a comprehensive, continuously accessible, coordinated, and family-centered way.[52,60,61] A dental home should be able to provide the following:

1. an accurate risk assessment for oral diseases and conditions;
2. an individualized preventive dental health program based on risk assessment;
3. anticipatory guidance about growth and development issues (eg, maxillofacial and dentoalveolar development);
4. a plan for emergency dental trauma management;
5. information regarding care of teeth and oral soft tissues;
6. nutrition and dietary counseling;
7. comprehensive oral health care in accordance with accepted guidelines and periodicity schedules for pediatric oral health; and
8. referrals to dental specialists such as endodontists, oral surgeons, orthodontists, and periodontists when care cannot be provided directly within the dental home.

Lack of access to dental care can be a barrier to establishment of a dental home. Because of the specialized training and expertise, the dentist provides an ideal dental home; however, when a dentist is not available, the pediatric medical provider should fulfill the dictates of preventive oral health care until a dentist can be accessed and a dental home can be established. Therefore, primary care pediatric practitioners are an integral community component in the overall effort to address oral health issues (eg, access to care, preventive intervention). With the continuing challenges of access to dentistry coupled with preschool-aged children making many more visits to medical offices than to dental offices, primary care practitioners with oral health training have reported that they have provided preventive oral health services for their pediatric patients.[51,52] North Carolina primary care practitioners were able to integrate preventive dental services into their practices, increasing preventive services for young children who receive Medicaid benefits and whose access to dentists is restricted (eg, geographically or because of nonparticipation of dentists).[62] Often, the first step of timely establishment of a dental home is a referral from the physician. Although a report from the US Preventive Services Task Force on physicians' roles in preventing dental caries in preschool-aged children found referral by a primary care practitioner only partially effective in increasing dental visits,[40] another study[63] reported that dentists were more likely to see young children referred by primary care practitioners.

Primary care practitioners are able to identify children in need of a referral to a dentist.[64] After 2 hours of training in infant oral health, primary care pediatric practitioners accurately identified children with cavities with good specificity (92%–100%) and sensitivity (87%–99%).[40,63] These results suggest that dental screening can be incorporated into a busy pediatrics practice and that primary care pediatric practitioners can contribute significantly to the overall oral health of young children by encouraging parents to enroll their children in a dental home as early as possible.

In summary, the ideal setting for administration of oral health care is the dental home. When there is no access to a dentist, the pediatric medical provider should consider administering risk-based preventive oral health measures until a dental home can be made available. With preparation, primary care practitioners are routinely able to screen accurately and provide oral health anticipatory guidance for children. Furthermore, they are ideally positioned to refer children to a dental home in a timely manner. Establishing collaborative relationships between physicians and dentists at the community level is essential for increasing access to dental care for all children and improving their oral and overall health.

RECOMMENDATIONS FOR PRIMARY CARE PEDIATRIC PRACTITIONERS

1. An oral health risk assessment should be administered periodically to all children.
2. Oral health risk-assessment training should be recommended for medical practitioners who are in training programs and those who currently administer care to children.
3. Dietary counseling for optimal oral health should be an intrinsic component of general health counseling.
4. Anticipatory guidance for oral health should be an integral part of comprehensive patient counseling.
5. Administration of all fluoride modalities should be based on an individual's caries risk. Patients who have a high risk of caries are candidates for consideration of more intensive fluoride exposure after dietary counseling and oral hygiene instruction as compared with patients with a lower risk of caries (see Figs 1 and 2).
6. Supervised use of fluoride toothpaste is recommended for all children with teeth.
7. The application of fluoride varnish by the medical practitioner is appropriate for patients with significant risk of dental caries who are unable to establish a dental home.
8. Every child should have a dental home established by 1 year of age.
9. Collaborative relationships with local dentists should be established to optimize the availability of a dental home.

CONCLUSIONS

Oral health is an integral part of the overall health and well-being of children. A pediatrician who is familiar

High caries risk protocol.

with the science of dental caries, capable of assessing caries risk, comfortable with applying various strategies of prevention and intervention, and connected to dental resources can contribute considerably to the health of his or her patients. This policy statement, in conjunction with the oral health recommendations of the American Academy of Pediatrics *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*, 3rd edition,[65] serves as a resource for pediatricians and other clinicians to be knowledgeable about addressing dental caries. With dental caries being such a common and consequential disease process in the pediatric population, it is essential that pediatricians include oral health in their daily practice of pediatrics.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

POLICY STATEMENT

Principles for the Development and Use of Quality Measures

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Steering Committee on Quality Improvement and Management and Committee on Practice and Ambulatory Medicine

ABSTRACT

The American Academy of Pediatrics and its members are committed to improving the health care system to provide the highest-quality and safest health care for infants, children, adolescents, and young adults. This statement is intended as a guide for pediatricians and pediatric leadership on the appropriate uses of quality measures and the criteria on which they should be based. The statement summarizes the current national efforts on quality measurement and provides a set of principles for the development, use, and evaluation of quality measures for improving children's health and health care. The American Academy of Pediatrics recommends that these measures address important issues for children; be appropriate for children's health and health care, scientifically valid, and feasible; and focus on what can be improved. In addition, the American Academy of Pediatrics supports reasonable principles for the oversight and implementation of pay-for-performance programs.

INTRODUCTION

The American Academy of Pediatrics (AAP) and its members are committed to improving the health care system to provide the highest-quality and safest health care for infants, children, adolescents, and young adults. This statement, based on available evidence and committee expertise, provides information on pediatric quality measurement and a set of principles for the development and appropriate use of quality measures. In addition, this information may be helpful for employer groups, health plans, and other organizations involved in the development and evaluation of child health quality measures.

OPPORTUNITIES FOR IMPROVEMENT IN CHILDREN'S HEALTH

Pediatricians and other child health clinicians strive to provide the best care for children and families. Despite excellent intentions and pockets of superb care, numerous studies, including the Commonwealth Fund's *Quality of Health Care for Children and Adolescents: A Chartbook*,[1] the *National Healthcare Disparities Report*,[2] and the *National Healthcare Quality Report*,[3] have shown considerable variation in outcomes of care across providers and communities[4–5] and in utilization, safety, and quality care for all children[6–8] as well as significant disparities in these dimensions for minority children. A major opportunity exists to improve care in a way that will make a real difference in the lives of children and families. To close the gaps in children's health care, an initial step is the use of measures to identify opportunities for improvement and track changes in quality over time as interventions are implemented.

DEFINING AND MEASURING QUALITY

The Institute of Medicine (IOM) defines quality of care as "the degree to which health care services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge."[9] A quality measure is a quantification of the degree to which a desired health care process or outcome is achieved or the extent that a desirable structure to support health care delivery is in place.[8]

Quality measures assess 3 levels of health care and its intended results: structure, process, and outcome.[10] Structure measures address "sufficiency of resources and proper system design"[11] including organizational characteristics, such as the type of care provided (eg, primary or specialty) or the use of specific systems for improving care (eg, an electronic health record [EHR] or registry).

TABLE 1 **National Health Care Quality Report Matrix: Combines 4 of the IOM Health Care Quality Components and the FACCT Consumer Perspectives on Health Care Needs, With Equity as the Third Dimension**

Consumer Perspectives on Health Care Needs	Components of Health Care Quality			
	Safety	Timeliness	Effectiveness	Patient-Centeredness
Staying healthy	Fluoride only when needed	Access to well-child care	Immunizations	Social history assessment
Getting better	Drug-allergy check before prescribing medications	Access to urgent care	Appropriate antibiotics for upper respiratory infections	Family involvement during hospital rounds
Living with illness or disability	Medication reconciliation	Access to long-term care	Inhaled steroids for persistent asthma	Family involvement in developing long-term plan of care
Coping with the end of life	Avoid unnecessary painful interventions	Access to hospice care	Effective end-of-life pain management	Advance directive

Components of health care quality include (1) safety: "avoiding injuries to patients from care that is intended to help them"; (2) effectiveness: "providing services based on scientific knowledge to all who could benefit, and refraining from providing services to those not likely to benefit (avoiding overuse and underuse)"; (3) patient-centeredness: establishing "a partnership among practitioners, patients, and their families (when appropriate) to ensure that decisions respect patients' wants, needs, and preferences"; and (4) timeliness: "obtaining needed care and minimizing unnecessary delays in getting that care." Consumer perspectives on health care needs include (1) staying healthy: preventive care; (2) getting better: acute care; (3) living with illness or disability: chronic care; and (4) coping with the end of life: end-of-life care. Equity is "a crosscutting issue" that is "the provision of health care of equal quality to those who may differ in personal characteristics that are not inherently linked to health, such as gender, ethnicity, geographic location, socioeconomic status, or insurance coverage" and means that "quality of care is based on needs and clinical factors."

Process measures address the interaction between the patient and the provider.[11] How are care and services provided (eg, assessment, evaluation, diagnosis, and treatment)? How well is the patient able to access care once he or she accesses the health care system? Examples of process measures include the provision of a written asthma management plan to a family and the use of a standardized assessment to evaluate and diagnose comorbidities in a child with attention-deficit/hyperactivity disorder (ADHD).

Outcome measures describe how the care delivered affects the patient's health, health status, and function. Functional status, quality of life, and mortality are examples of outcome measures. Intermediate outcome measures are linked to end-point outcomes such as disability or death. Emergency department visits or hospitalizations attributable to asthma and control of blood pressure and high cholesterol are examples of intermediate measures.

Quality improvement efforts often focus on structural or process measures associated with health outcomes, because the outcomes of interest may occur too infrequently to demonstrate change in a practical time interval. For example, research has shown that the use of inhaled corticosteroids for persistent asthma, which can be assessed by use of a process measure, results in decreased hospitalizations and emergency department visits, which can be evaluated as outcome measures; therefore, an increase in the use of inhaled steroids has become a primary improvement objective in the care of children with persistent asthma.[12]

Frameworks for assessing and reporting health care quality[13] recommend that quality measures be available across a range of quality domains and address consumer needs across the continuum of care. The IOM[14] specified 6 domains for improving quality: safety, timeliness, effectiveness, efficiency, equity, and patient/family-centeredness. The Foundation for Accountability highlighted consumer needs with regard to navigating the health care system by identifying 4 domains: staying healthy, getting better (acute care), living with illness (chronic care), and care at the end of life.[13] FAACT, a now-closed national not-for-profit organization, coordinated the development of several child quality-measurement tools aligned with this framework under the rubric of the still-operating Child and Adolescent Health Measurement Initiative. Payers and purchasers are increasingly interested in measures of efficiency, which has been defined as the cost of care associated with a specified level of quality of care.[13]

Ultimately, quality measures should be available to address each domain of quality across all patient and family needs. Measures can be specific to conditions (eg, treatment of asthma in children), which is often the case for measures of clinical effectiveness. Other measures might cut across conditions to reflect a domain of quality (eg, health care–acquired infection, patient experience with care). The patient and family are key sources of information about many aspects of the quality of care they receive, in particular the degree to which care was family centered. The interface between the consumer and quality domains, as conceptualized by the IOM, is illustrated in Table 1.[13]

The inclusion of consumer perspectives on health care needs in the matrix is helpful in framing the pediatric approach to quality. A significant amount of pediatric health care, such as well-child care, focuses on the "staying healthy" part of the matrix. Management of conditions such as upper respiratory infections, acute otitis media, acute gastroenteritis, and bronchiolitis deals with "getting better." The component "living with illness or disability" addresses the fact that pediatricians routinely manage children with special health care needs (ie, congenital heart disease, cancer, chronic lung disease, diabetes, and ADHD). Also, as pediatricians treat increasing numbers of children with chronic illnesses, they may increasingly face management of end-of-life issues. Pediatric quality measures should also address

care at the beginning of life that affects infant mortality and morbidity and the transitions in care throughout the life span. For patients of all ages, safety, effectiveness, patient-centeredness, timeliness, efficiency, and equity are important as well.

THE USE OF MEASURES

Measurement for continuous quality improvement can be used to help a practice or organization understand its own care processes, understand how its performance compares with others, and track measures in response to changes. Data can be used by a practice or organization to compare its performance with (1) itself over time, (2) other practices or organizations using the same measures and collecting data in the same way, and (3) exemplary practices or organizations.[12] Initial steps in improvement efforts involve the use of measures to document performance gaps followed by a plan to address needed changes, monitoring of performance, and outcome. Practices and providers are encouraged to engage in quality improvement as part of daily pediatric practice. When paired with continuing education, quality improvement can be part of the process of ongoing focus on optimal patient care.

The pediatric community has been very active in researching the effectiveness of health care quality improvement strategies. Researchers at the University of California in San Francisco who worked with a large health plan found that chlamydia screening and a broader set of adolescent-focused preventive services could be increased during well-adolescent visits.[15] Cloutier worked with public- and private-sector primary care providers to increase the use of care processes outlined in asthma guidelines,[16] and Lozano and colleagues found that leadership training and practice redesign using a nurse educator reduced asthma-symptom days,[17] a strategy that was highlighted as effective in a recent evidence review of asthma quality improvement strategies.[18] Current pediatric quality improvement research focuses on using health information technology to facilitate improvement in delivery of effective care and in patient safety.[19]

A recent review summarized the characteristics of ideal quality measures and concluded that significant barriers exist in using clinical quality measures at the provider level to distinguish the performance of 1 physician compared with another.[20] These barriers include (1) the lack of adequate sample size for reliable estimates of individual physician performance, (2) the challenges of adjusting for confounding patient factors, (3) the difficulty of attributing care to the individual physician, and (4) inadequate systems for collection and analysis of clinical data, particularly process data.

The IOM has outlined uses of quality measures that involve accountability as well as improvement, including (1) ensuring the rapid translation of clinical research into practice, (2) holding providers accountable for delivering high-quality care, (3) setting standards for participation in federally sponsored programs including Medicaid, the State Children's Health Insurance Program (SCHIP), Title V, and community health centers, (4) helping parents and purchasers make choices, (5) establishing benchmarks to stimulate quality improvement, and (6) conducting ongoing national surveillance on trends in quality.[21] These applications have the potential to involve a variety of users including consumers, providers, medical specialty boards, purchasers, payers, business coalitions, accrediting organizations, and government.

CURRENT STATUS OF NATIONAL QUALITY MEASUREMENT INITIATIVES

Several diverse health care stakeholders are interested in and are developing standardized quality measures. The Congressionally mandated *National Healthcare Disparities Report*[2] and *National Healthcare Quality Report*[3] included a broad set of performance and outcome indicators to monitor the nation's progress toward improved health care quality. Recent calls for measures by national organizations have yielded hundreds of submissions, which is proof of the tremendous activity in this area.

There are many organizations actively involved in the development and promulgation of quality measures. The American Medical Association Physician Consortium for Performance Improvement (PCPI) includes representatives from more than 140 US medical specialty and state medical societies, federal agencies, and other organizations convened to identify and develop evidence-based clinical quality measures that enhance quality of patient care and foster accountability. The AAP is a member of the PCPI and has developed pediatric measures for or relating to acute gastroenteritis, otitis media with effusion, and otitis externa through the PCPI process.[22]

The National Quality Forum (NQF) leads a national effort around quality measures with broad participation from various health care stakeholders including national, state, regional, and local groups that represent health care professionals, consumers, public and private purchasers, employers, hospitals, health plans, and other organizations involved in health care research or quality improvement. The NQF was created to improve American health care through the endorsement of consensus-based national standards for measurement and public reporting of health care performance data that provide meaningful information about whether care meets the 6 IOM quality domains.[23] The AAP is a member of the NQF.

The AAP also participates in the Ambulatory Care Quality Alliance (AQA), an increasingly important and growing multistakeholder collaborative that comprises medical specialty boards and societies, purchasers, consumers, health plans, and accrediting organizations with a mission to coalesce around a single standardized set of physician-level measures.[24] The AQA primary care measure set includes several measures deemed appropriate for use in child health care settings.

In 2006, the AQA and the Hospital Quality Alliance, a public-private collaboration to improve the quality of care provided by the nation's hospitals, formed a new national Quality Alliance Steering Committee to better coordinate the promotion of quality measurement, transparency, and improvement in care. The new steer-

ing committee will work closely with the Centers for Medicare and Medicaid Services and Agency for Healthcare Research and Quality (AHRQ).[25]

Various policy makers, payer organizations, and purchasers and employer groups are developing provider incentive or pay-for-performance (P4P) programs based on standardized measures to drive improvements in the quality of care. Many of these groups also are using measures for public reporting, an approach that requires rigorous evaluation and greater transparency in the development and use of these measures. Although there is little research on the effectiveness of reward programs on quality,[26] the current enthusiasm for P4P programs is based on the belief that these incentive efforts will lead to significant improvements in the quality of care.[27]

To date, most national quality measurement efforts have not focused on children. Measures exist for a few conditions and domains, such as asthma, patient safety, some preventive services (eg, immunizations, well-child care visits), and patient experience with care (eg, timeliness, communication, and respect). However, measures for other important pediatric issues, such as the evaluation of developmental assessment and perinatal/neonatal care, have not been frequently used.

Measurement activities that focus on children and adolescents include efforts to develop quality measures for Medicaid and the State Children's Health Insurance Program[28] and measures developed by the Child and Adolescent Health Measurement Initiative,[29] including the online data resource center for child and adolescent health.[30] The data resource center provides information about children's health, health care needs, and quality of care for many subgroups of children nationally and in each state.

The National Association of Children's Hospitals and Related Institutions, Child Health Corporation of America, Medical Management Planning/BENCHmarking Effort for Networking Children's Hospitals, and others have been working collaboratively to develop measure sets. These have focused on hospital care for children and adolescents to date.[31] The California Hospital Assessment and Reporting Taskforce, a voluntary statewide effort to measure inpatient quality, has focused on adult inpatient care but began reporting on select pediatric measures in 2007.

The National Committee on Quality Assurance has generated several pediatric measures for the Health Plan Employer Data and Information Set, including measures for child and adolescent immunization, overuse of antibiotics in pharyngitis, asthma treatment, and follow-up for ADHD.[32] In addition, the Health Plan Employer Data and Information Sheet 2006 reporting set includes Consumer Assessment of Healthcare Providers and Systems (CAHPS) 3.0H surveys directed to sampled adult and child Medicaid beneficiaries and sampled adults and children with commercial coverage who are managed care members. The child surveys include supplemental items that can be used to assess the experience of care for children with chronic conditions. In 2007, the AHRQ released clinician and group CAHPS surveys, including a child primary care survey.

The AHRQ recently released the Pediatric Quality Indicators, which can be used with hospital inpatient discharge data to identify potential quality improvement opportunities.[33]

Finally, the new Alliance for Pediatric Quality recently launched the Improve First plan to select improvement priorities on the basis of pediatric health care issues that have broad impact and for which there are ongoing, evidence-based improvement programs with associated quality measures.[34] The Alliance for Pediatric Quality was formed by 4 organizations recognized as leaders in pediatric care—the AAP, the American Board of Pediatrics, the Child Health Corporation of America, and the National Association of Children's Hospitals and Related Institutions—which came together to establish a unified voice for issues related to improving the quality of pediatric health care. The founding member organizations represent large segments of the pediatric health care community and bring unique and synergistic perspectives to the field of quality care for children. One of the first areas of focus for the Alliance for Pediatric Quality will be operationalizing quality improvement in pediatric health care through the use of quality measures, evidence-based medicine, health information technology, shared data, and policy to systematically improve children's health care.

Additional activities that will drive further focus on the use of quality measurement in practice include the adoption of maintenance of certification (MOC) by the American Board of Pediatrics,[35] which emphasizes assessment and improvement of quality of care in practice as a requirement for ongoing certification, and the Accreditation Council for Graduate Medical Education adoption of core competencies for physicians in training, which include competency in practice-based learning and quality improvement.[35]

Some health plans are beginning to incorporate MOC as 1 dimension of P4P programs. For example, Aetna Inc and UnitedHealthcare officially recognized the American Board of Internal Medicine's MOC in their respective P4P programs.[36] Under the American Board of Internal Medicine's MOC program, physicians complete Web-based tools called practice improvement modules that guide them through a quality improvement process that uses data collected from their own clinical practice.[37]

Quality measurement and assessment can be facilitated significantly through the use of well-designed and well-implemented EHRs. Programming specific measures into the design and production of EHRs would not only allow for standardization but also ease the burden of data collection and aggregation.[38] The AAP is working closely with the EHR industry and certification groups (eg, Certification Commission on Health Information Technology[39]) to ensure the inclusion of standard measures in the design and production of EHRs to facilitate quality data collection, which is incorporated into the workflow of clinical practice.

CHILD-SPECIFIC ISSUES

The 2004 IOM publication *Children's Health, the Nation's Wealth*[40] emphasizes the critical differences between chil-

dren and adults that warrant special attention to children's health. This report notes that data on children's health and its influences are needed to maximize the health of individuals from childhood through adulthood. Children represent a population with unique health care needs, often called the "4 Ds."[41]

- Development: Children experience rapid developmental changes during infancy, childhood, and adolescence. These changes should be taken into account when developing and using measures. For example, different schedules and types of immunizations should be measured at different ages. Developmental changes also affect the extent to which children's own assessments can be used to measure aspects of quality, such as patient-centeredness and timeliness.[42]
- Dependency: Children depend on caregivers for many aspects of care. Parents and guardians play substantial roles in aspects of quality, such as the actual use of prescribed drugs, devices, and services. Careful specification of data sources and risk adjustment are essential for adequately adjusting for factors that influence specific care.
- Differential epidemiology: Most adult and generic quality indicators focus on specific diseases rather than health. The relatively low rates of children with most specific serious chronic illnesses and disabilities can make quality measurement and use of measures difficult, because the provider, practice, and plan-level sample size may be too small for meaningful comparison. Measures of preventive services and cross-cutting measures of quality for children with special health care needs can be used in addition to condition-specific measures.[43]
- Demographics: Currently, two fifths of the nation's children are from minority groups[44] and almost one fifth live in poverty,[45] which are rates higher than those for adults.[46] Health care quality for children differs according to race, ethnicity, and income, and these factors are important to capture in measurement strategies.

These 4 Ds create unique challenges in development of valid quality measures for children and children's health care. It is necessary to consider these child-specific factors when developing and using appropriate quality measures for pediatric health care issues. In addition, children, adolescents, and families play an important role in providing information about the quality of clinical care. Learning about their experiences of care and engaging in partnerships to improve care are essential for achieving the best outcomes. One way to achieve this engagement is by using measures that address factors important to families.

Those who develop and use pediatric measures must acknowledge that much of children's health care is focused on promoting healthy development and prevention. In addition, because of the relatively low numbers of children with any 1 condition, non–condition-specific measures may need to be considered (eg, coordination of care for children with special health care needs).

RECOMMENDATIONS

The AAP and its members are committed to providing the best and safest health care for infants, children, adolescents, and young adults. The AAP strongly supports health care quality improvement endeavors and believes that measures are an important component of improving quality. The AAP believes that the primary purpose of quality measurement should be to identify opportunities to improve patient care and outcomes, including health status and satisfaction. The AAP supports the use of quality measures in the spirit of continuous quality improvement and affirms the importance of partnership with children and families in these improvement efforts. Toward this end, the AAP offers the following recommendations for quality measurement.

1. Measures should address important issues for children. Measures should address topics of substantial impact, whether defined by prevalence, severity, and/or functional status, and should be chosen for their potential influence on children's health by addressing a significant gap between current and ideal practice. In addition, measures should enable an assessment of systematic disparities in the quality of care for vulnerable groups.
2. Measures should be appropriate for children's health. Any effort to measure quality should take into account the unique features of children's health and health care and recognize the importance of development, dependency, demographics, and disparities. Measures must reflect the differential epidemiology in children as compared with adults and include patient and family participation.
3. Measures should be scientifically valid. Measures should be based on best evidence available and linked to evidence-based practice. The strength and quality of evidence on which the measures are based should be transparent and explicitly documented. The AAP will continue to produce evidence-based pediatric clinical practice guidelines, which will add to the foundation for the continued development of valid quality measures.
   In addition, measures should be reliable and be field-tested to demonstrate the potential for improvements in quality. Rigorous testing should clearly demonstrate that they accurately assess what they are intended to measure.
   When appropriate, measures should include risk adjustment or stratification to take into account factors beyond a practice's or health system's control, such as socioeconomic status, health insurance, and comorbid conditions.
4. Measures should be feasible. Collection of data to support the measures should not cause undue burden on the clinician or patients and families. Issues to be considered include the number of required measures, the time interval of collection, and the resources re-

quired for collection. Ideally, data automatically collected in patient care and other health care processes should be used for measurement. Measures must have clear definitions and specific instructions for collection. Data collection must include adequate sampling.

Measures should be appropriate for the use and setting proposed (eg, ambulatory or hospital care, primary or specialty care). Measures also should be tailored to various practice settings (eg, solo practice, large group practice, academic practice) as appropriate.

Measures and results should be easily interpretable by users. The format used to report measures should include appropriate data analysis and display and prove useful to clinicians. Measures displayed over time and augmented with control limits when enough data are available (eg, time-series charts) will dissuade users from misinterpreting random variation in the measure and can focus analysis of performance on important changes in care delivery, whether stimulated by quality improvement efforts or other factors. The interpretation of measures should include the use of methods to allow a focus on both the causes of variation and the benchmarks or targets.

In addition, collection and reporting of measures must ensure patient privacy.

5. Measures should address what can be improved. Quality measures should focus on improvable issues that clinicians and health systems can influence.

In addition to the recommendations defined above, the AAP also supports the P4P principles outlined by the American Academy of Family Physicians[47]:

1. focus on improved quality of care;
2. support the physician-patient relationship;
3. use evidence-based clinical guidelines;
4. involve practicing physicians in program design;
5. use reliable, accurate, and scientifically valid data;
6. provide positive physician incentives; and
7. offer voluntary physician participation.

CONCLUSIONS

The AAP and its members are committed to providing the highest-quality and safest health care for infants, children, adolescents, and young adults. Quality measurement is necessary for the continuous improvement of the health care system. As a result, national attention has increasingly focused on quality measurement; however, these national efforts often have failed to recognize the unique needs of children and their families. The pediatric community must take a leadership role.

The AAP is taking the lead in assessing quality measures proposed for children's health and health care by developing pediatric measures in collaboration with national health care quality organizations, monitoring the validity of measures developed by other organizations, and advocating for the appropriate use of measures to support improvement in the health care of children. These activities are strengthened by the AAP continuing to develop evidence-based pediatric clinical practice guidelines and being involved with the EHR industry and certification groups to facilitate quality data collection. The AAP will advocate for the use of pediatric measurement data, including use in public reporting, when data are based on validated pediatric measures that are appropriately constructed for quality improvement in children's health care and pediatric practices.

In partnership with the Alliance for Pediatric Quality and other organizations, the AAP will endeavor to ensure that quality metrics are used to accelerate changes in care that result in measurably improved health and outcomes for children and their families.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Policy Statement—Professional Liability Insurance and Medicolegal Education for Pediatric Residents and Fellows

abstract

FREE

The American Academy of Pediatrics believes that pediatric residents and fellows should be fully informed of the scope and limitations of their professional liability insurance coverage while in training. The academy states that residents and fellows should be educated by their training institutions on matters relating to medical liability and the importance of maintaining adequate and continuous professional liability insurance coverage throughout their careers in medicine. *Pediatrics* 2011;128:624–629

BACKGROUND

The American Academy of Pediatrics (AAP) first developed a policy on professional liability coverage for pediatric residents in 1989.[1] The policy was updated to include fellows in training in 1993. In the 2000 iteration of the statement,[2] the original positions were strengthened to address changes in the professional liability insurance industry, the structure and settings of residency training, and mandated reporting to national health provider databanks of malpractice payments. The 2000 policy also emphasized the need to provide pediatricians-in-training with adequate professional liability insurance coverage. This revision of the policy statement updates the recommendations in light of the current requirements of the Accreditation Council of Graduate Medical Education (ACGME) for approved residency programs and emphasizes the need for medicolegal education for pediatric residents and fellows. Pediatric training programs are urged to voluntarily adopt the AAP recommendations.

MEDICAL LIABILITY AND RESIDENTS/FELLOWS

Because pediatric residents and fellows-in-training are closely supervised, their medical malpractice risks are theoretically less than those of other pediatricians. Under the legal doctrine of *respondeat superior*, "let the master answer," the educational institution that conducts the residency program is responsible for the medical care provided by its residents and fellows during training. Therefore, typically, the institution is liable for defense costs, settlements, and awards for malpractice attributed to physicians-in-training.[3] Their trainee status, coupled with their lack of financial assets, often precludes residents and fellows from being targeted in a malpractice suit. In those instances in which residents and fellows are named in a malpractice complaint,

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

they are often dropped from the case early in the legal proceedings. However, they are often deposed as fact witnesses.

However, physicians-in-training are not entirely free from malpractice risks. Malpractice suits accounted for the majority of litigation involving medical residents from 1950 to 1989.[4] This prominent malpractice risk has continued, and from 1990 to 2007, 3 in 10 pediatricians were sued for malpractice at least once during their career in medicine, and approximately 1 in 10 was party to a malpractice suit from care provided during residency.[5] The mean number of months that elapsed between the alleged error or negligent event and the malpractice complaint being filed was 32 months in 2007, almost equivalent to the entire length of general pediatric residency training.[5] It is possible that those pediatric residents and fellows named as codefendants in medical liability cases will have already completed their residency by the time the claim is filed.

It is also possible that former residents and fellows may not know when they have been included in a malpractice claim. Depending on the specifications of the medical malpractice insurance policy, a settlement may be reached without the consent or knowledge of the defendants. In fact, pediatricians might not find out about the settlement until after the payment is reported to the National Practitioner Data Bank (NPDB). As of its most recent report in 2004, the Health Resources and Services Administration Bureau of Health Professionals noted that the NPDB contained 1669 malpractice payments made for the benefit of residents and interns, which is 1% of all malpractice payments for physicians.[6,7] The long-term effects of having a malpractice payment reported to the NPDB so early in a physician's career on his or her subsequent employability and insurability have yet to be studied.

GAUGING RISK FOR PEDIATRIC RESIDENTS AND FELLOWS

Pediatricians are exceptionally vulnerable to malpractice allegations because of the long tail associated with care rendered to patients under the age of majority. The tail is the length of time established by state law from when an incident involving a minor occurs or is discovered to when a malpractice claim can be filed. Every state has established a statute of limitations to allow extra time for a malpractice complaint involving a minor to be reported. Therefore, for most physicians, this lag time is measured in years, but for pediatricians, the statute of limitations is often measured in decades. In some states, the limitation period begins when the incident occurred, but in other states, the statute of limitations begins only after the injury is discovered.

Although pediatricians are not accused of malpractice as frequently as other specialists, when they are sued, the stakes are high. The Physician Insurers Association of America, whose member companies insure 60% of all physicians in private practice in the United States, reports that pediatricians had one of the highest average payments for settlements and court awards per claim at $395 997, behind only neurosurgeons, neurologists, obstetricians, and cardiovascular surgeons.[8,9]

CURRENT ACGME REQUIREMENTS FOR PROFESSIONAL LIABILITY INSURANCE

The AAP joins other responsible medical and hospital organizations in applauding the ACGME for requiring that any educational institution seeking accreditation of its residency and/or fellowship programs provide adequate professional liability insurance for its physicians-in-training. This requirement is specified in the ACGME *Institutional Residency Training Program Requirements* (see section II-D.4.f, effective July 1, 2007), as follows:

1. The sponsoring institution must provide residents with professional liability coverage and a summary of pertinent information regarding this coverage.
2. Liability coverage must include legal defense and protection against awards from claims reported or filed after the completion of the program(s) if the alleged acts or omissions of the residents are within the scope of the program(s).[10]

Despite the ACGME requirements, a large proportion of pediatric residents know little about their professional liability insurance coverage. A 1993 study of pediatric residents in Pennsylvania revealed that 90% did not know the policy limits of their liability insurance or whether a malpractice claim against them could be settled without their permission.[11] Deficiencies in pediatric residents' training about professional liability insurance persist. According to an AAP survey of graduating pediatric residents in 2007, only 52% reported receiving any instruction on medical liability insurance.[12] The AAP believes that pediatric residents and fellows should be fully informed of the rights and responsibilities afforded by their professional liability coverage and should be educated on important considerations applicable to maintaining adequate professional liability coverage throughout their careers in medicine.

AAP RECOMMENDATIONS

Given the severity of pediatric malpractice settlements and jury awards, the permanent nature of databank reports, and the prolonged length of the statutes of limitations for incidents that involve minors in many states, the AAP has strengthened and clarified its

recommendations on professional liability coverage for pediatric residents and fellows.

Therefore, the AAP reaffirms its recommendations that the ACGME's *Institutional Residency Training Program Requirements*[10] include the following:

1. Adequate Coverage

Pediatric training programs must provide adequate professional liability coverage (or its equivalent in military/governmental institutions) for their residents and fellows to indemnify them from liability for potential medical misadventures that may occur during training activities. This coverage should last throughout the training period and continue to provide coverage for these training activities after residents and fellows leave the program. This coverage must apply to all activities considered part of the training program's related learning experiences regardless of the setting (eg, rotations in private medical office settings, community-based clinics, out-of-state and overseas program training experiences, etc).

A. Professional liability coverage for residents and fellows must be comparable to that offered to other physicians employed by the hospital or training facility.
B. The residents and fellows policy should cover expenses associated with legal defense and should provide loss protection against malpractice awards and/or settlements.

2. Documented Proof of Insurance

Pediatric training programs must furnish resident and fellow applicants with detailed information on the professional liability coverage provided during training, and this information should be available for the applicant before selecting a training program. On acceptance into the program, each physician-in-training should receive a written description of his or her professional liability coverage. If the residency or fellowship program self-insures or insures its trainees under a master policy that also covers the teaching facility's professional staff, the contract that residents and fellows sign should clearly and explicitly state the provisions of the professional liability coverage applicable to physicians-in-training. Likewise, if physicians-in-training are covered under a separate policy written specifically for the program's residents and fellows, a copy of the insurance policy contract should be provided to each trainee.

3. Provisions of Professional Liability Insurance Policy

Whether covered under a master policy or a separate policy for trainees or self-insured by the institution, the resident/fellow should be provided, at a minimum, a written document that delineates the following specific provisions of the professional liability insurance policy.

A. The name of the company or institution that serves as the insurance carrier and appropriate contact information; if the training program self-insures its physicians-in-training for professional liability, that information should be clearly noted in writing as well.
B. The type of professional liability coverage provided for physicians-in-training (ie, occurrence, claims made, self-insured, or other); a brief explanation of the differences between various professional liability insurance products should be distinctly addressed in terms of what the variations mean to the insured resident or fellow both during training and after training is completed.
C. An explanation of how settlements are reached; residents and fellows should receive written descriptions of whether the policy allows the insurance carrier to settle a malpractice case without the permission and/or signature of the insured physician.

4. General Information on Liability Insurance

Residents and fellows should be educated on the following kinds of professional liability insurance policies.

A. Self-insurance—Many academic medical centers self-insure their staff. Instead of purchasing professional liability insurance, the resources of the training program (or its related institutions) will be used to cover any losses associated with medical malpractice claims or suits against the institution, supervising physicians, and/or physicians-in-training.
B. Occurrence—A type of professional liability insurance policy in which the insured is covered for any incident that occurs during the term of the policy regardless of when a claim arising from the incident is made. For example, if the alleged error or omission happened anytime during the residency training, it would be covered by the teaching facility's professional liability insurance, even if the claim is filed after the policy has expired. Occurrence policies are no longer commonly offered but may be available through select insurance carriers or if the program self-insures its residents and fellows.
C. Claims-made—An insurance policy that provides coverage for claims arising from incidents that both occur and are reported to the insurance company while the policy is in force. A claims-made policy is in effect from the starting date of the initial policy period and remains in force from that date until it is re-

newed. Once terminated, future claims that arise from incidents that occurred during the policy period are not covered. Typically, claims-made policies do not cover previous acts (liability for actions that took place before the effective date of the policy). Claims-made policies are often heavily discounted in the first years, but as the policies mature (usually after 5 years), the rates often increase and become comparable in price to occurrence policies. The major drawback of claims-made policies is the lack of coverage should they be terminated for any reason (eg, premiums are not paid or the physician completes training, changes employers, and/or medical malpractice insurers, moves to another state, or retires). Unless a special policy is purchased (ie, tail coverage), a physician can end up with a gap in coverage and possibly an uninsured malpractice claim.[9]

D. Claims-paid—A variant of claims-made insurance, this policy is a professional liability insurance that provides coverage for claims that arise from incidents that occur while the policy is in force. However, claims must be reported and paid before the policy is terminated.

E. Tail coverage—A supplemental policy to claims-made liability insurance that provides coverage for any incident that occurs while the claims-made insurance was in effect although the claim was filed after the insurer-policyholder relationship was terminated. Sometimes referred to as an extended reporting endorsement, tail coverage is necessary whenever a physician insured under a claims-made policy changes carriers, completes training, becomes disabled, retires, or dies.[13] Insurance carriers often have strict policies on when tail coverage can be purchased. Most commonly, insurance companies will offer the option to purchase the addition of tail coverage to an existing claims-made policy only before its coverage's termination, although likely at a higher price as the policy gets closer to its termination. Tail coverage, in fact, is never inexpensive. It can cost up to 3 times as much as the annual premium for a claims-made policy.[14]

F. Nose coverage—Supplemental insurance to a claims-made policy that provides coverage for previous acts or incidents that may have occurred before the claims-based policy went into effect but have not yet been filed as claims. Because the physician is seeking up-front coverage before securing a relationship with the insurance carrier, it is usually comparable in price to tail coverage.

5. Extracurricular Activities/Moonlighting

The residency program should inform its residents and fellows of the institution's definition of and policies concerning moonlighting and whether these activities are included in the program's professional liability coverage provided.[10] Residents and fellows should be given explicit documentation of any specific liability policy inclusion/exclusion clauses. In addition, the program should warn its trainees of the potential long-term liability exposure associated with moonlighting or other professional activities that are excluded from the program's liability insurance policy.

Pediatric training programs that are recognized by the ACGME currently are required to monitor the effects of outside activities, including moonlighting in or outside the primary hospital, to ensure that the quality of patient care, the educational experience, and duty-hour limitations are not compromised.[10] Accredited training programs must provide trainees with formal written policies on their participation in outside professional activities.

The AAP urges pediatric educational programs to notify physician trainees whether medical malpractice allegations that derive from such extracurricular activities are excluded from the training program's professional liability coverage for its residents and fellows. Trainees should be instructed not to assume that a nontraining extracurricular activity must be for pay or outside the primary training facility to be considered moonlighting. Some apparently benign activities may be considered external to the residency training experience and, thus, outside the scope of liability coverage provided by the training program. Pediatric residents and fellows who provide care outside of the auspices of the training program should verify that liability insurance with tail coverage is provided by the agency or health care facility at which the moonlighting activity occurs.

The program should give its physician trainees specific examples of what constitutes moonlighting to obviate potential misunderstanding. The following situations may be examples of extracurricular activities and, as such, are likely to be excluded from a training program's liability coverage for its residents and fellows: volunteering as a physician at a camp for children with special health care needs; serving as an infection-control consultant to a child care facility; providing sports physicals for a local high school; and staffing the emergency department in the primary training institution when not on official duty as a trainee.

If tail coverage is not provided and an individual tail policy to cover extracurricular activities is too costly for the resident or fellow to purchase, he or she should carefully reconsider the

potential costs, benefits, and risks of moonlighting.[15] If available, the residency program should inform its trainees that they can purchase supplemental coverage for any excluded activities as an add-on to the training program's standard professional liability insurance.

6. Settlement Decisions

The residency training program should inform its residents and fellows in writing whether their professional liability policy allows the insurer to settle malpractice claims without the signature of the parties named in the malpractice claim. Because federal law requires malpractice payments made on behalf of health care providers to be permanently registered in the NPDB, physicians-in-training should be given the right to make informed decisions on whether to settle a malpractice claim or to pursue litigation.

7. Statute of Limitations for Minors

Because the length of time for which a physician may be liable for previous acts is particularly long for incidents that involve pediatric patients, residents and fellows need to understand the provisions of the statute of limitations for minors in the state in which they are being trained. The training program should provide examples of how the length of exposure risk affects the residents' and fellows' current professional liability insurance coverage and future needs.

8. Notification of Suit and Participation in Defense

Should a pediatrician be named as a party to a suit that arises from events or actions that took place during his or her training period, it should be the program's responsibility to do the following.

A. Promptly and confidentially notify the current or former physician-in-training.
B. Provide paid time off for current residents and fellows to testify or provide a deposition in a malpractice case in which they are named. Time spent testifying or being deposed should be considered training-related business; therefore, it should not be deducted from the resident's vacation or other personal time.
C. Reimburse physicians-in-training for reasonable expenses incurred when required to testify or provide a deposition in a malpractice case.
D. Reimburse former physicians-in-training for necessary reasonable expenses incurred if required to testify or be deposed in a malpractice case for an alleged error or omission that occurred as part of the residency training program's educational experience. This provision would make it possible for former residents and fellows no longer in the vicinity of the training program to participate in their own defense without undue financial hardship.
E. Promptly and confidentially notify current or former physicians-in-training if the training program has filed a reportable action to the NPDB, the Health Integrity Protection Data Bank, or other federal or state repositories of disciplinary actions taken against physicians.

9. No Coverage Gaps

The pediatric training program should educate its residents and fellows on the importance of not allowing any gaps in professional liability coverage to occur, particularly during career changes (including, but not limited to, changing residency training programs, employers, or insurance carriers). The pediatric training program should also notify the residents and fellows of any changes in their exposure risk to malpractice claims and suits attendant on leaving the training program.

10. Other Liability Issues

The pediatric training program should educate its residents and fellows in risk management, medical record documentation, and other strategies for improving outcomes. Residents and fellows, however, should be aware of other types of liability such as, among others, sexual harassment, intentional acts, and failure to comply with health care regulations, which are not usually covered by medical malpractice liability insurance.

11. Career Changes

Pediatricians who are seeking new employment, particularly early in their careers, should make sure that there are no gaps in their malpractice insurance coverage. If the insurance that was in force during training was a claims-made policy, the resident or fellow either should negotiate tail coverage from the residency training institution or nose coverage from the prospective employer. In addition, pediatricians considering a claims-made/claims-paid policy through a new carrier should anticipate the need for coverage for their subsequent tail. If a new employer has offered to pay the premiums for the professional liability insurance, it is reasonable to request that the employer also be financially responsible for providing the tail coverage. It is reasonable for employers, however, to specify a minimum length of employment as a condition for the provision of tail coverage.

12. Voluntary Adoption

Until the ACGME requirements for accredited residency training programs are amended to reflect the specific provisions of this policy statement in full, the AAP urges pediatric training programs to adopt these recommenda-

tions voluntarily. By so doing, resident and fellow educators can adequately equip their trainees to make informed decisions regarding liability insurance coverage, risk management, and future employment risk coverage options. More importantly, medicolegal education programs prevent the careers of future pediatricians from being jeopardized by inadequate or interrupted liability coverage during or immediately after the training period.

13. AAP Support

The AAP will continue its partnership in educating residents and fellows as well as pediatricians beginning practice on medicolegal issues through its chapters, sections, and committees.

POLICY STATEMENT

Professionalism in Pediatrics: Statement of Principles

Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of All Children

Committee on Bioethics

ABSTRACT

The purpose of this statement is to delineate the concept of professionalism within the context of pediatrics and to provide a brief statement of principles to guide the behavior and professional practice of pediatricians.

STATEMENT

Pediatricians and pediatric subspecialists occupy an important place in society as privileged and trusted advocates for the well-being of children. Within this environment, how should professionalism be defined, and what should it mean to the practicing provider? The purpose of this statement is to clarify the definition of professionalism in pediatric care and to translate these concepts into clinical practice. One of the unique aspects of professionalism within the pediatric context is the multilateral interactions of the child patient, the family, other health care and support services providers, and other pediatric professionals. The principles outlined here apply to trainees, pediatric training-program faculty, and private practitioners.

Educational initiatives in medical school curricula and continuing medical education for practicing pediatricians must include the principles and practice of professionalism. An appreciation of these concepts depends on an ability to define and assess professionalism within pediatrics.

On balance, the concept of professionalism in pediatrics is similar to that in other specialties in the field of medicine,[1–5] except that working with children creates unique circumstances that deserve special consideration. For example, an appreciation of the informed-consent process in pediatric practice requires the provider to consider how best to involve the child patient at a given developmental level into conversations and decision-making despite incomplete maturation. A definition of professionalism will include, but is not limited to, the principles set out by the American Board of Pediatrics as specific guidelines for the teaching and evaluation of professionalism as part of the core curriculum for residency training in pediatrics.[6] These principles are:

- Honesty and integrity—embody the principles of fairness, the ability to meet commitments and keep one's word, and the duty to be intellectually honest and straightforward in interactions with patients and peers and in all professional communication.
- Reliability and responsibility—represent accountability to children, families, other physicians, medical staff, community, and ultimately society. They require acceptance of responsibility for errors made, including the willingness to ac-

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

knowledge and discuss errors and their consequences with the family and with peers, and collaborate in the search for systematic actions to prevent future harm.

- Respect for others—involves treating all persons with respect and regard for individual worth and dignity, including sensitivity to gender, race, and cultural differences as well as maintenance of patient confidentiality when appropriate.
- Compassion/empathy—the ability to understand children's and family members' reactions to pain, discomfort, and anxiety from their point of view, not that of the physician.
- Self-improvement—involves a commitment to lifelong learning and education.
- Self-awareness/knowledge of limits—the maturity to recognize when a problem involves knowledge or technical skills beyond the experience of the provider and to ask for consultation or assistance in those situations.
- Communication and collaboration—involve the recognition that patients' families and the health care team must work cooperatively with each other and communicate effectively to provide the best patient care and appropriate community interventions, including home health services; rehabilitation services such as occupational, speech, and physical therapy; and school reentry.
- Altruism and advocacy—refer to the unselfish regard or devotion to the welfare of others. Patient well-being should be the primary motivating factor in patient care, ahead of physicians' own interests and needs.

The integration of values that emphasize not only individual rights and freedoms but the teamwork that is essential to the practice of medicine is key to achieving one's professional goals within pediatrics. These values include:

- Responsibilities to patients and families—refer to the collaborative relationship that involves pediatricians, patients, and parents, with recognition of appropriate boundaries in patient care, and promotion of the concepts of respect for privacy, nondiscrimination, and conflict resolution. Pediatricians should not refuse to care for acutely ill children on the basis of the ability of the family to pay for services rendered. However, practice overhead expenses preclude the provision of comprehensive health services for every child whose family requests routine or preventive health services unless there is some means of compensation. The American Academy of Pediatrics believes that the medical care of infants, children, and adolescents should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, culturally effective, and provided according to the medical home concept.[7]
- Responsibilities to other health professionals and health care and support services providers—entail treating each other and all other professionals, including individuals who provide ancillary services to patients, with integrity, honesty, and respect in daily interactions.
- Responsibilities to communities—refer to the collaborative relationship between a pediatrician and the wider community to address issues of advocacy for child health and effective use of health care and public health resources.
- Responsibilities to the profession—involve subscribing to and acting on the concepts of lifelong learning, willingness to teach and contribute to medical knowledge, engaging in self-care, treating one's team with respect, and communicating effectively; promoting the practice of medicine with integrity now and in the future; and working toward a system of medical regulation that combines professional, organizational, and patients' perspectives with a goal of strengthening the medical profession's accountability for its own performance.

This brief statement of principles emphasizes the core professional values that pediatricians and pediatric subspecialists should adopt and that will serve as an ethical foundation for quality health care for children and their families.

abstract

FREE

Pediatricians are rendering care in an environment that is increasingly complex, which results in multiple opportunities to cause unintended harm. National awareness of patient safety risks has grown in the 10 years since the Institute of Medicine published its report *To Err Is Human*, and patients and society as a whole continue to challenge health care providers to examine their practices and implement safety solutions. The depth and breadth of harm incurred by the practice of medicine is still being defined as reports continue to uncover a variety of avoidable errors, from those that involve specific high-risk medications to those that are more generalizable, such as patient misidentification. Pediatricians in all venues must have a working knowledge of patient-safety language, advocate for best practices that attend to risks that are unique to children, identify and support a culture of safety, and lead efforts to eliminate avoidable harm in any setting in which medical care is rendered to children. *Pediatrics* 2011;127:1199–1210

Patient safety is defined as "freedom from accidental injury" caused by medical care, such as harm or death attributable to adverse drug events, patient misidentifications, and health care–associated or health care–acquired infections.[1] Although patient safety is but 1 of the 6 domains of quality of care defined by the Institute of Medicine (IOM), it is undoubtedly one of the most pressing domains, given the IOM estimate that 44 000 to 98 000 inpatient deaths attributable to medical errors occur each year in the United States. The phrase "patient safety" may be mistakenly interpreted as the focus on injury-prevention strategies such as the use of car seats and helmets.[2] However, pediatricians can help champion the concept that pediatric patient safety means preventing injury to children caused directly by the health care system itself.

Over the past 10 years, patient safety has become a key priority for health systems. Starting with the 1999 IOM report, *To Err Is Human*, there have been dramatic increases in research, standards, collaborative efforts, education, and measures focused on patient safety.[1,3–6] In 2001, after recognizing the necessity to coherently guide and understand pediatric patient-safety issues, the American Academy of Pediatrics (AAP) published the statement "Principles of Patient Safety in Pediatrics,"[7] and in 2003 it published "Prevention of Medication Errors in the Pediatric Inpatient Setting."[8] In 2007, the AAP released the statement "Patient Safety in the Pediatric Emergency Care Setting."[9] Since

the publication of these seminal policy statements, much has been learned about pediatric patient safety.

This statement, "Principles of Pediatric Patient Safety: Reducing Harm Due to Medical Care," elucidates the current understanding of issues and practices to minimize pediatric medical errors and improve the quality of care. Three key issues are the focus of this statement: (1) the significance of pediatric patient safety; (2) the science behind the culture of safety; and (3) patient-safety strategies. (Definitions of patient-safety tools and terms and other references are provided in Appendices 1–4.)

SPECIAL CONSIDERATIONS FOR CHILDREN

Medical errors and patient harm differ in several ways for children compared with adults. First, children are at greater risk of medication errors than are adults because of children's development, demographics, dependency on parents and other care providers, and different epidemiology of medical conditions.[10] Errors in prescribing, dispensing, and administering medications represent a substantial portion of the preventable medical errors in children.[11–14] Second, computerized physician order entry (CPOE) systems that are designed for adults have limited effectiveness in reducing pediatric medication errors.[14] Also, efforts that eliminate catheter-related bloodstream infections in adults do not have the same effect for children.[15,16] Pediatric patient-safety efforts need to be researched further to determine the best strategies for reducing these preventable harms in children.

Reasons for the unique attributes of patient-safety problems and solutions for children are multifactorial.[17] Woods et al[17] detailed these factors as involving 3 key overarching domains: (1) physical characteristics; (2) developmental issues; and (3) minor legal status issues. Layered onto these distinguishing characteristics is a general patient-safety approach that involves 3 main strategies: (1) understanding the epidemiology of errors and having sources of error identification; (2) understanding the science behind improvement, including the safety culture; and (3) having a source of core patient-safety solutions. Each of these overarching strategies should be incorporated into pediatric patient-safety risk assessment and solution development, and attention should be paid to each of the unique domains of pediatric patient-safety risks as defined by Woods et al.

EPIDEMIOLOGY OF PEDIATRIC PATIENT HARM

Pediatric errors in the inpatient setting have been reviewed by several investigators.[18–20] The authors of 1 study reported 12.91 adverse events per 1000 hospital discharges among patients from birth through 15 years of age.[21] Negligence was determined in 27.6% of the events. Among 10 778 orders reviewed by Kaushal et al[13] in 2 academic pediatric hospitals, 616 medication errors (5.7% of all orders) were identified. One-fifth of these errors were near misses, and 1% caused patient harm. Adverse drug events were identified in 2.3% of hospitalizations, and 19% were deemed preventable. Serious errors occurred more often in critical care settings, and adverse drug events occurred 3 times more frequently among pediatric patients than among adults. In the Vermont Oxford Network, an analysis of medical errors in NICUs revealed that 47% of the errors involved medications, 11% involved patient misidentification, 7% involved delays or errors in diagnosis, and 14% involved errors in the administration or method of using a treatment.[22] In addition, a review of charts among 15 NICUs revealed that adverse event rates are more common than previously described.[23] Analysis of the Agency for Healthcare Research and Quality patient-safety indicators further revealed the breadth and variability of patient-safety events, revealing rates per 10 000 pediatric discharges of less than 1 (in-hospital postoperative hip fractures, transfusion reactions) to 68 (birth trauma), 103 (postoperative sepsis), and 703 (failure to rescue, failure to prevent a clinically important deterioration).[24]

Errors in pediatric emergency department (ED) settings may be attributable to improper patient identification, lack of experience of adult emergency staff with pediatrics, and challenges with performing technical procedures on and calculating medication doses for children.[25,26] Other sources of error include communication between prehospital and ED staff; among ED staff, particularly during change-of-shift sign-off; between ED and inpatient staff; and between ED staff and family members. Other important sources of error in the ED include diagnostic mistakes, medication errors, and environmental deficits such as equipment malfunction. In a Canadian pediatric ED, 100 prescribing errors and 39 medication-administration errors occurred per 1000 patients.[27]

Studies on errors in pediatric ambulatory care have been limited.[28] The Learning From Errors in Ambulatory Pediatrics study[29] found 147 medical errors reported from 14 practices. The largest group of errors was attributed to medical treatment (37%). Other errors included patient identification (22%); preventive care, including immunizations (15%); diagnostic testing (13%); patient communication (8%); and less frequent causes. Among medical treatment errors, 85% were medication errors. Of these errors, 55% were related to ordering, 30% were related to failure to order, 11% were re-

lated to administration, 2% were related to transcribing, and 2% were dispensing errors. In a prospective cohort study at 6 Boston, Massachusetts, area pediatric practices over a 2-month period, 3% of 1788 patients ($n = 57$) had preventable adverse drug events.[30] Although none of these events were found to be life-threatening, 8 (14%) were serious. The preventive strategies with the most preventive potential were improved communication between providers and parents and between pharmacists and parents. Among new prescriptions for 22 common medications in outpatient pediatric clinics, 15% were issued with potential dosing errors.[14] In addition, medication samples are often dispensed with inadequate documentation.[31]

THE SCIENCE OF PATIENT SAFETY

The Safety Culture

In addition to understanding the epidemiology of medical harm to children, the awareness and attitude of health care providers regarding patient safety is important. Specifically, a "culture of safety" is fundamental for avoiding patient harm and emphasizes improving systems rather than blaming individual people.

Society is demanding a safer health care system. State and federal agencies (eg, Centers for Medicare and Medicaid Services), certifying organizations (eg, the Joint Commission), and professional societies (eg, AAP, American Board of Pediatrics) also have patient-safety expectations. These combined forces are placing greater pressure on the health care community to develop a culture of safety in which leaders and members understand and act on the basis of a systems approach.

Human Factors Perspective

A culture of safety approaches human fallibility by concentrating on the conditions under which people work and building defenses to avert errors or mitigate their effects.[32] The culture of safety does not focus on errors of individual people, because errors within organizations that deal with high-hazard processes rarely have their ultimate cause rooted in individual behavior. High-reliability organizations recognize variability as a constant and are focused on minimizing that variability and its effects.[32] The basis for this framework in health care rests on research in high-hazard industries (eg, aviation, nuclear power, and petrochemical industries) that have significantly decreased the incidence of catastrophic events.[33–35] Although the complexity of medical care may present difficulties in creating a culture of safety, the science of human factors provides common principles that can endow all facets of our medical system with the resilience to avoid errors and adverse events.

The optimal culture of safety requires an organizational culture that supports 4 key elements: reporting, being just, being flexible, and learning. The goal of a culture of safety is to be an informed culture with constant attentiveness and commitment to avoiding failures such as giving a wrong dose of medicine or failing to wash hands before seeing patients; reluctance to simplify interpretation; commitment to resilience; deference to expertise; and sensitivity to systems-based practices.[36]

For an organization to be informed, it must be a "reporting culture." A reporting culture collects, analyzes, and disseminates data about medical errors and adverse events. Front-line staff must be willing and able to report errors and adverse events without fear of retribution. Crucial to this culture are the abilities to communicate easily, confidentially, or anonymously[37] to separate entities responsible for data analysis from those with disciplinary functions and to provide rapid and useful feedback.

Organizations with a "just culture" encourage and reward error-reporting by maintaining a nonpunitive environment. A just culture focuses on a systems approach to human fallibility while holding accountable those who intend to harm or intentionally fail to adhere to policies and procedures designed to keep patients safe.

An optimal culture of safety has a "flexible culture" that is capable of adapting effectively to changing demands. Although a flexible culture depends on a disciplined staff, it ignores rank to defer to technical expertise. For children, defining this expertise should include assessment of specific training and skills necessary to safely render care while attending to factors such as varied ages, disease states, and developmental needs. This culture depends on teamwork; shared values; use of well-tested standardized operating procedures and prospective risk assessment, such as failure modes and effects analysis; and investment in staff training.

Finally, a "learning culture" has the competence and will to make the right conclusions on the basis of safety information and to implement changes when needed. This culture learns from its mistakes through system-oriented assessments such as root-cause analysis; shares that learning throughout the whole organization; and does not hide its mistakes. A culture of safety promotes compassionate disclosure of its mistakes to those who have suffered harm from those mistakes.

These optimal human factors interact to create an informed system that perpetuates safety independent from individual personalities or external forces and provide a set of principles that promote a common culture of safety across our complex medical system.

PATIENT-SAFETY STRATEGIES

Despite best efforts, active error detection, and ideal safety culture, errors will inevitably occur in systems as complex as health care.[32,38] The 1999 IOM report identified key safety-design concepts to consider when striving to reduce medical errors. Additional guidance on creating systems can be found in the IOM principles for the design of safety systems in health care organizations[1] (Appendix 1).

Methods used to assess and resolve patient-safety issues incorporate the IOM's broad key safety-design concepts to improve reliability through redundancy, simplification, and standardization.[1] Specific goals, such as accurate patient identification and prevention of indwelling catheter infections, are amenable to the introduction of checklists, double-checks at the bedside, or forcing functions such as mandated bar-code scanning before a drug can be administered to a given patient.

Other safety goals, such as recognition of a change in a patient's status or encouraging patient and family involvement in the patient's care, require a composite of changes to health care systems and expectations of both providers and the consumer. Many institutions involve patients and families in critical care unit rounds, which is felt to enhance the prevention and identification of problems.[39] Patient- and family-centeredness play important roles in the culture of safety, including consideration of ethnic culture and language.[40]

Leadership

In *To Err Is Human*, the IOM addressed the need for national leaders to set goals for patient safety but also charged that "Chief Executive Officers and Boards of Trustees should be held accountable for making a serious, visible and ongoing commitment to creating safe systems of care."[1] This charge applies to leaders in all settings including solo practices. Leaders and clinicians who strive to improve patient safety need to appraise their organization's safety culture to determine the best means for implementing safety strategies.

Clinicians must be involved to ensure the success of patient safety as part of larger quality-improvement efforts. Roles vary and depend on the type of clinician, practice setting, and system. In all settings, individual physician participation includes taking responsibility for maintaining knowledge of patient-safety principles, providing patient and parent education, positively engaging safety efforts, and working effectively within a multidisciplinary structure. Although financial incentives may be used to facilitate involvement, providing physicians with data and reminders and ensuring their involvement in designing processes of care is most compelling.[41,42] Group leaders can perform a physician/practice patient-safety assessment on topics such as medication management or clinical (eg, laceration repair) or administrative (eg, acknowledgment of laboratory results) procedures.[43] Leaders also can initiate patient-safety projects such as creating a tracking system for high-risk pregnant teenagers or a tool for parents of children with special needs that clearly defines what changes in clinical status should prompt a call to which specific clinician[44,45] (see Appendix 3). System leaders also can use knowledge of organizational goals and external agency mandates to target changes with wider impact, such as a multidisciplinary approach toward medication reconciliation.[5]

In community and adult settings, there is an added need to advocate for pediatric-specific issues. Physician participation on key hospital committees, such as pharmacy and therapeutics, information technology, sedation, rapid-response team, and ambulatory clinical practice, is invaluable. Creation of a pediatric multidisciplinary safety committee that reports to the hospital or larger medical group board can be a productive way to link specialists and ancillary providers to ensure cross-communication on safety issues for children.

Role of Information Technology

Pediatric-specific technological support of safety endeavors is improving, yet most interventions are still in the development phase. Although information technology cannot solve all ails of patient safety, some safety issues are particularly amenable to information technology. Since publication of the AAP statement "Prevention of Medication Errors in the Pediatric Inpatient Setting," it has become more apparent that CPOE systems require robust decision support to be safe and effective.[7,46–48] Some decision-support rules for drug and dosing schedules and CPOE systems are commercially available for children; however, most of them are created locally.[11,49–51] Order sets, reminders, and clinical practice guidelines embedded within information systems increase adherence to best practice.[52,53] Use of electronic equipment—specifically, programmable "smart" infusion pumps—has resulted in improved documentation of medication errors and decreases in calculation and administration errors.[54–56]

Technological solutions to more generalized medical safety concerns have been applied to pediatric settings. Barcoding has been used to compare identification bands with medications and blood products before administration.[57] Computers can generate code sheets for bedside posting and link to a patient's most recently updated visit

list for patients within an enclosed system. Electronic patient-tracking systems assist with patient flow and notification of abnormal study results.[58] Although electronic health records have been reported to yield an overall economic benefit to ambulatory practice, only a small percentage of this financial gain is associated with proven improvements in patient safety, such as avoidance of adverse drug events.[59,60]

Despite noted advantages, some limitations to technological support still exist, such as variable ease of use, physician acceptance, cost, software integration into existing facility systems, standardization across systems, the increase in errors after implementation, and ability to address only a subset of potential medical errors.[60,61] Other examples of medical errors that currently elude decision-support programs include inappropriate selection of medication for the condition being treated and failure to recognize a change in patient status.

Patient-Safety Goals and Efforts

Current national patient-safety efforts are best described by the Joint Commission's national patient safety goals[6] and campaign initiatives by the Institute for Healthcare Improvement. The Joint Commission requires for all venues of patient care: verbal, written, and electronic communication of test results; information transfer at transitions of care (hand-offs); medication reconciliation; and ensurance of patient/family understanding of care plans.[5] The Joint Commission requires hospitals to reduce the risk of health care–associated infections such as multidrug-resistant organism infections, central line-associated bloodstream infections, and surgical-site infections and to improve recognition and response to changes in a patient's condition, for which many pediatric hospital rapid-response teams are using the Pediatric Early Warning System.[62] Family-centered care is of particular importance and value for children in high-risk settings such as the emergency department and for children with special needs.[63,64] Patients and families should be able to articulate care plans and demonstrate understanding of the anticipated treatment outcome. Stress and fatigue also have been associated with errors, and national efforts focused on reducing workplace stress for physician trainees and other staff are being promoted.[65–69] Diagnostic errors have been recognized as an important issue as well.[70] Medication management continues to be a specific focus for children because of variations in body weight, body surface area, organ system maturity, developmental stage of absorption and excretion ability, dependence on others for medication administration, and need for specially compounded formulations.[7] Accurate weight scales, standardized equipment throughout a system, drug dose-range limits, programmable "smart" infusion pumps for hospitals, and standardized order sets should be used.[52–56,71–73] Clinical pharmacists trained in pediatrics should be integrated into inpatient rounds and used for education of staff and families in all settings as often as possible.[42,73–75]

The AAP has launched webinars and Web sites and has partnered with other national leaders to offer specific tools, resources, and links to best health care safety practices for children[44,45,76–78] (Appendix 4). Collaborative implementation and measurement of both the process (adherence to practice) and clinical outcomes of shared strategies are necessary to track and refine care practices for all children.

RECOMMENDATIONS

Reducing pediatric patient harm attributable to medical care requires not only preventing errors but also identifying and reporting errors and adverse events, disseminating best practices, and cultivating a culture of safety. Many interventions to improve the culture of safety are available and are based on principles derived from the experience of other high-risk industries. These processes have been successful in reducing the incidence of catastrophic events, and their implementation in health care should be encouraged. The outcomes of these interventions should be rigorously measured with valid and reliable tools and monitored for their effectiveness in health care. Leadership is needed to continue to make and accelerate a transformation that acknowledges that providers (1) work in high-risk, complex environments, (2) are fallible, and therefore, medical errors do happen to children, (3) are independently and collectively accountable for patient safety, and (4) are integral to the success of systems change. Continuous system improvements are central to creating a culture of safety through reporting of errors and adverse events, being just and flexible, and learning and implementing change on the basis of experience and rigorous science.

The following are recommendations to ensure a comprehensive, accelerated approach toward pediatric patient safety:

1. Raise awareness and improve working knowledge of pediatric patient-safety issues and best practices throughout the pediatric community.
   a. Educate: Expand educational efforts to reach a broad scope of clinicians. Ensure that all clinicians can identify pediatric patient-safety issues in the med-

ical setting and describe what they can do to improve them both individually and within systems. Include patient-safety curricula for all child health trainees.

b. Network: Create standing patient-safety programming at national and regional meetings to encourage sharing of patient-safety issues and best practices among pediatric clinicians.

c. Create a safety culture: Challenge all organizations, including small practices, to adopt a plan that informs, supports, and educates on pediatric patient safety by using appropriate local examples. Strive to develop programs that support members to improve their safety culture in their clinical care settings.

d. Expand focus: Direct attention to ambulatory settings. The majority of work in patient safety to date has been in hospitals, yet the majority of children in this country interact primarily with the health care system in ambulatory settings. Develop patient-safety metrics for the ambulatory pediatric setting.

2. Act and advocate to minimize preventable pediatric medical harm by using information on pediatric-specific patient-safety risk.

   a. Develop pediatric-specific error-reporting: Develop and support broad-scale pediatric error-reporting systems and analysis of submitted events. Identify trends and areas in need of action by using these data to guide action on pediatric patient-safety risks.

   b. Foster leadership: Take individual responsibility for maintaining awareness of pediatric patient-safety issues. When possible, lead or participate in practice-based safety initiatives and quality or patient-safety committees in any setting, including ambulatory, hospital-based, community, or tertiary care centers. Spread the current hospital-based focus on patient safety to the ambulatory setting through designation of patient-safety officers for practices.

   c. Enhance family-centered care: Actively engage patients and families in safety at all points of care and address issues of ethnic culture, language, and literacy. Direct families to appropriate resources, and review patients' rights and responsibilities from the perspective of safety.

3. Improve health care outcomes for children by adhering to proven best practices for improving pediatric patient safety.

   a. Adhere to best practices: Disseminate and exercise proven patient-safety interventions such as vigilant hand-washing, time outs before procedures, and medication reconciliation, particularly in ambulatory settings and for children with special health care needs. Embed safety strategies, such as redundancy, forcing functions, bar-coding, standardized order sets, and office protocols (Appendix 2), whenever possible.

   b. Target drug safety: Focus efforts on medication safety by advocating for the development of effective and safe pediatric medications and formulations and for the withdrawal of medications with unfavorable risk/benefit ratios; developing, spreading, and advocating for pediatric-specific health care information technology for drug delivery; educating providers on methods to reduce medication errors; ensuring that providers maintain access to and proficiency in the use of a comprehensive and current pharmaceutical knowledge base; and creating policies that advocate for safe medication delivery to children in all health care settings.

   c. Redesign clinical systems: Instill safety-design concepts when renovating or creating medical care systems and processes. Focus on human-factor issues in patient safety and include pediatric-specific information technological advancements whenever possible (eg, when implementing bar-coding and CPOE systems).

   d. Support research: Expand research to identify and refine effective pediatric patient-safety interventions. Motivate national health care research-funding systems to include a mandatory pediatric patient-safety component.

CONCLUSIONS

The field of pediatric patient safety has matured much in recent years; there are now more robust epidemiology of errors for children, a deep understanding of the concept and measurement of a culture of safety, clear guidance on key elements of patient-safety solutions, and introduction of successful pediatric patient-safety solutions. Nonetheless, continued work is needed to infuse these data and concepts into everyday pediatric practice for all clinicians, and special attention should be paid to the training of new clinicians to ensure that the future workforce can exercise all the tenets of pediatric patient safety as part of their everyday work life. It is only through complete incorporation of the culture of safety, assumption of personal responsibility for patient care

outcomes, increasing examination of the risk areas for pediatric patient safety, and deployment and rigorous evaluation of systems enhancements that the risks of medical errors to children can be reduced further.

APPENDIX 2: GLOSSARY OF TERMINOLOGY

Adverse event: An injury that results from a medical intervention[1] or an event that results in unintended harm to the patient because of an act of commission or omission rather than the underlying disease or condition of the patient.[79]

Cause-and-effect diagram: A diagram that organizes potential causes into general categories, such as methods, materials, machines, and people, and illustrates the common relationships with quality characteristics.[80]

Checklist: "Algorithmic listing of actions to be performed in a given clinical setting . . . to ensure that, no matter how often performed by a given practitioner, no step will be forgotten."[81]

Clinical decision support: "Any system designed to improve clinical decision-making related to diagnostic or therapeutic processes of care. [Clinical decision-support systems] thus address activities ranging from the selection of drugs (eg, the optimal antibiotic choice given specific microbiologic data) or diagnostic tests to detailed support for optimal drug dosing and support for resolving diagnostic dilemmas."[81]

Control chart: A statistical tool used to distinguish variation in a process attributable to common causes and variation attributable to special causes.[80]

Error: Failure of a planned action to be completed as intended or use of a wrong plan to achieve an aim (the accumulation of errors results in accidents)[1] or the failure of a planned action to be completed as intended (ie, error of execution) and the use of a wrong plan to achieve an aim (ie, error of planning). Error also includes failure of an unplanned action that should have been completed (omission).[79]

Failure mode and effect analysis: "[A] methodological approach to analyzing potential problems, errors, and failures and evaluating the robustness of a product design" that "can be used to evaluate systems, product designs, processes, and services" and to identify "how a part, subsystem, or system might fail, as well as the impact of failure on safety and effectiveness. Thus, [failure mode and effect analysis] provides an opportunity to design a potential failure mode out of a product or process."[83]

Flowchart: A display of the various stages in a process in which different types of symbols are used to demonstrate the flow of product or service over time.[80]

Forcing function: "Constraints" designed into processes "that guide the user to the next appropriate action or decision."[1]

High-reliability organizations: Organizations such as "power grid dispatching centers, air traffic control systems, nuclear aircraft carriers, nuclear power generating plants, hospital emergency departments, wildland firefighting crews, aircraft operations, and accident investigation teams" that "operate under very trying conditions all the time and yet manage to have fewer than their fair share of accidents" have "a mindful infrastructure that continually does all of the following: tracks small failures; resists oversimplification; remains sensitive to operations; maintains capabilities for resilience; [and] takes advantage of shifting locations of expertise."[33]

Mistakes/slips: Mistakes are failures of planning, whereas slips are failures of execution.[1]

Pareto chart: A bar graph in which the "lengths of the bars represent frequency . . . and are arranged with longest bars on the left and the shortest to the right. In this way the chart visually depicts which situations are more significant."[84] Pareto charts are used to focus quality-improvement efforts on the basis of the "80/20" rule, which postulates that 80% of problems come from 20% of causes.

Process map: Same as a flowchart.

Root-cause analysis: A process for identifying the basic or causal factors that underlie variation in performance, including the occurrence or possible occurrence of a sentinel event. Typically, the analysis focuses primarily on systems and processes, not individual performance.[79]

Redundancy: Duplication of critical components of a system with the intention of increasing reliability of the system, usually in the case of a backup or fail-safe.

Run chart: Plot of data in time order.[80]

Smart infusion pumps: Intravenous pumps that contain a "brain" consisting of customized software that contains a drug library. This software transforms a conventional intravenous pump into a computer that alerts staff if an infusion is programmed outside of a particular medication's recommended parameters such as dose, dosing unit (eg, mg/kg per minute), rate, or concentration. Smart pumps log data about all such alerts, including the time, date, drug, concentration, programmed rate, and volume infused. In addition, smart pumps have free-flow protection, which includes safety features that are designed to prevent unintentional overdoses of medication or fluid.

Standardized order sets: Algorithmic listing of orders to be performed in a given clinical setting to ensure that, no

matter how often performed by a given practitioner, no step will be forgotten.

Trigger tool: Clinical data related to patient care indicating a reasonable probability that an adverse event has occurred or is occurring. An example of a trigger tool for an adverse drug event is a physician order for an antidote, a medication stop, or a dose decrease.[79,82]

APPENDIX 3: TOOLS, PROJECT GUIDES, AND CULTURE-OF-SAFETY INTERVENTIONS

AAP Tools and Project Guides

Chapter Quality-Improvement Resources

Many chapters, or leaders with quality-improvement knowledge, may not have the infrastructure or resources to implement quality-improvement activities. The following resources will help chapters and their partners move toward quality-improvement work and build chapter capacity to better support pediatric practices.

"A Resource Guide for Chapters, Building Local Capacity for Improvement" (based on the 4 principles of raising awareness, building knowledge, building infrastructure, and implementing improvements to improve the quality of care provided to children).

Measuring for quality improvement: the AAP policy statement "Principles for the Development and Use of Quality Measures" (AAP Steering Committee on Quality Improvement and Management and AAP Committee on Practice and Ambulatory Medicine).

Quality-improvement literature (evidence-based literature, reports, and other publications about the implementation science of quality improvement).

2007 chapter quality-improvement needs assessment (summary of needs-assessment findings and full report of needs-assessment findings).

"Who's Doing What?" A list of chapters involved in quality improvement (a list of quality-improvement activities in which chapters are involved).

Chapter quality-improvement champions and committee chairs (log in using AAP member ID and password to access a list of chapter quality-improvement champions and or quality-improvement committee chairs).

Chapter spotlight (the Chapter Quality Improvement Spotlight recognizes chapters that are making great strides in supporting their members in quality improvement and building infrastructure for quality-improvement work).

To access these resources, visit www.aap.org/member/chapters/caqi/index.html.

AAP Quality-Improvement Programs and Resources

Education in Quality Improvement in Pediatric Practice (EQIPP): EQIPP allows one to evaluate his or her practice online using tools that can be easily implemented to enhance patient care. The goal of eQIPP is to help physicians collect and analyze practice data over time to document improved quality of care. For more information, visit www.eqipp.org.

Quality Improvement Innovation Network (QuIIN): The QuIIN is a network of practicing pediatricians and their staff teams who use quality-improvement methods to test tools, interventions, and strategies to improve health care and outcomes for children and their families. The QuIIN serves as a practical working laboratory for pediatricians to test how improvements can be implemented in practice while sharing strategies and learning from colleagues who are members of the QuIIN. For more information, visit www.aap.org/qualityimprovement/quiin.

Medical home initiatives: The AAP's medical home Web site is the premier resource for improving the lives of children and youth with special health care needs and their families through a medical home. For more information, visit www.medicalhomeinfo.org.

Partnership for Policy Implementation (PPI): In June 2005, the AAP, with funding support from the federal Maternal and Child Health Bureau, launched the PPI, a pilot program to integrate health information technology functionalities into AAP policy. The goal of the PPI is to create fundamental paradigm shifts in the development of policy statements, clinical reports, technical reports, and clinical practice guidelines—specifically, how they are written. For more information, visit http://practice.aap.org/content.aspx?aid=2712 (log-in required).

Practice Management Online (PMO): The quality-improvement section of PMO provides pediatricians with theoretical and practical content as well as applicable tools that can be incorporated into the practice. Examples of topics included are quality-improvement basics, evidence-based medicine, improving and measuring quality in the pediatric practice, patient safety, and maintenance of certification for pediatricians. For more information, visit http://practice.aap.org.

Safer Health Care for Kids: This comprehensive Web-based resource center for pediatric safety information and strategies is designed for physicians, allied health professionals, administrators, parents, and caregivers who share a commitment to ensuring a safe health care environment for infants, children, adolescents, and young adults. For more information, visit www.aap.org/saferhealthcare.

AAP Steering Committee on Quality Improvement and Management (SCOQIM): The SCOQIM was established in 2001 in response to the increasing national emphasis on quality in health care and serves as the academy's integrated

voice for quality. The committee comprises pediatricians with expertise in quality improvement, health information technology, and evidence-based medicine. Committee priority areas include quality measurement, patient safety, evidence-based guideline development and implementation, open-access scheduling, and other innovative practice models. For more information, visit www.aap.org/visit/scoqim.htm.

APPENDIX 1 IOM Key Safety-Design Concepts and Principles for the Design of Safety Systems in Health Care Organizations

	Examples/Components
Key safety-design concepts	
Make things visible so that the user can determine what actions are possible at any moment	Defibrillator dials should be clearly visible to the user on the front display
Simplify the structure of tasks to minimize the load on working memory, planning, or problem-solving	Concentrations for continuous-drip medications should be limited and standardized on the hospital formulary
Use affordances—characteristics of equipment or workspace that communicate how it is to be used	Oral syringes are designed to administer oral medications and cannot be connected to an intravenous line because of the bulbous tip, except with exceptional force
Use natural mappings—relationships between a control and its movement	Turning a medical instrument knob to the right should make the related dial needle point further to the right
Use constraints or "forcing functions" that guide the user to the next appropriate action or decision	CPOE systems can be programmed so that they do not allow the prescriber to proceed without the patient's weight and allergy history
Assume that errors will occur and design and plan for recovery by making it easy to reverse operations and hard to perform nonreversible ones	Machine-readable patient-identification systems, such as bar-coding, act as a final check to prevent harm in situations in which another patient's medication has been mistakenly retrieved to administer to the wrong patient
If applying the earlier strategies does not achieve the desired results, standardize actions, outcomes, layouts, and displays	Chemotherapy protocols and order sets should be standardized and preprinted or programmed into CPOE systems
Principles for the design of safety systems in health care organizations	
Provide leadership	Make patient safety a priority corporate objective
	Make patient safety everyone's responsibility
	Make clear assignments for and expectation of safety oversight
	Provide human and financial resources for error analysis and systems redesign
	Develop effective mechanisms for identifying and dealing with unsafe practitioners
Respect human limits in process design	Design jobs for safety
	Avoid reliance on memory
	Use constraints and forcing functions
	Avoid reliance on vigilance
	Simplify key processes
	Standardize work processes
Promote effective team functioning	Train in teams those who are expected to work in teams
	Include the patient (and/or family) in safety design and the process of care
Anticipate the unexpected	Adopt a proactive approach: examine processes of care for threats to safety and redesign them before accidents occur
	Design for recovery
	Improve access to accurate, timely information
Create a learning environment	Use simulations whenever possible
	Encourage reporting of errors and hazardous conditions
	Ensure no reprisals for reporting of errors
	Develop a working culture in which communication flows freely regardless of authority gradient
	Implement mechanisms of feedback and learning from error

FREE

This clinical report reviews the currently known health benefits of probiotic and prebiotic products, including those added to commercially available infant formula and other food products for use in children. Probiotics are supplements or foods that contain viable microorganisms that cause alterations of the microflora of the host. Use of probiotics has been shown to be modestly effective in randomized clinical trials (RCTs) in (1) treating acute viral gastroenteritis in healthy children; and (2) preventing antibiotic-associated diarrhea in healthy children. There is some evidence that probiotics prevent necrotizing enterocolitis in very low birth weight infants (birth weight between 1000 and 1500 g), but more studies are needed. The results of RCTs in which probiotics were used to treat childhood *Helicobacter pylori* gastritis, irritable bowel syndrome, chronic ulcerative colitis, and infantile colic, as well as in preventing childhood atopy, although encouraging, are preliminary and require further confirmation. Probiotics have not been proven to be beneficial in treating or preventing human cancers or in treating children with Crohn disease. There are also safety concerns with the use of probiotics in infants and children who are immunocompromised, chronically debilitated, or seriously ill with indwelling medical devices.

Prebiotics are supplements or foods that contain a nondigestible food ingredient that selectively stimulates the favorable growth and/or activity of indigenous probiotic bacteria. Human milk contains substantial quantities of prebiotics. There is a paucity of RCTs examining prebiotics in children, although there may be some long-term benefit of prebiotics for the prevention of atopic eczema and common infections in healthy infants. Confirmatory well-designed clinical research studies are necessary. *Pediatrics* 2010;126:1217–1231

INTRODUCTION

Microbes are ubiquitous and are important factors in the overall health of humans as well as the Earth. Efforts to optimize the intestinal microbial milieu have increased the interest in adding probiotics and prebiotics to nutritional products. As with antibiotics, the use and efficacy of probiotics and prebiotics should be supported by evidenced-based medicine. The purpose of this clinical report is to review the medical uses of probiotics and prebiotics and to summarize what is currently known about their health benefits as dietary supplements added to food products marketed to children, including infant formula. The guidance in this report will help pediatric health care providers to make appropriate decisions regard-

ing the usefulness and benefit of probiotics and prebiotics for their patients.

DEFINITIONS

Probiotic: An oral supplement or a food product that contains a sufficient number of viable microorganisms to alter the microflora of the host and has the potential for beneficial health effects.[1–3]

Prebiotic: A nondigestible food ingredient that benefits the host by selectively stimulating the favorable growth and/or activity of 1 or more indigenous probiotic bacteria.[1–4]

Synbiotic: A product that contains both probiotics and prebiotics. Evidence for synergy of a specific prebiotic for a probiotic in the product is not essential. Synbiotics may be separate supplements or may exist in functional foods as food additives.[1–3]

Postbiotic: A metabolic byproduct generated by a probiotic microorganism that influences the host's biological functions.[5,6]

Functional food: Any modified food or food ingredient that provides a health benefit beyond that ascribed to any specific nutrient/nutrients it contains. It must remain a food, and it must demonstrate its effect in amounts normally expected to be consumed in the diet. Benefits may include functions relevant to improving health and well-being and/or reduction of risk of disease. Any food that contains probiotics or prebiotics is a functional food. An example of a functional food is live-culture yogurt that contains probiotic bacteria, prebiotics, and other dietary nutrients. Human milk may also be considered a functional food; it contains substantial amounts of oligosaccharides (prebiotics) and may contain some naturally occurring probiotic bacteria (10^3 of bifidobacteria per mL of expressed human milk, as reported in 1 study).[7]

WHAT ARE PROBIOTICS?

Probiotic microorganisms are typically members of the genera *Lactobacillus*, *Bifidobacterium*, and *Streptococcus*.[1–3,8–14] These bacteria are fermentive, obligatory, or facultative anaerobic organisms, which are typically nonmotile and of varying shapes. They typically produce lactic acid. Their inherent biological features enable them to predominate and prevail over potential pathogenic microorganisms in the human digestive tract. It is currently hypothesized that these microbes generate small molecular metabolic byproducts that exert beneficial regulatory influence on host biological functions, including short-chain fatty acids such as butyrate. These metabolic byproducts are sometimes referred to as "postbiotics" and may function biologically as immune modulators.[5,6,15] The most studied probiotic bacteria to date include *Lactobacillus rhamnosus* GG (LGG), *Bifidobacterium lactis*, and *Streptococcus thermophilus*. These probiotic bacteria are biologically different from the Gram-negative, motile, non–lactic-acid–producing bacteria such as *Klebsiella*, *Pseudomonas*, *Serratia*, and *Proteus* species, which also may be prominent flora in the human digestive system. These potentially harmful bacteria may translocate across the intestinal epithelium and could result in disease in humans.[16,17] Some yeasts and yeast byproducts have also been studied and have been frequently used as probiotic agents, such as the yeast *Saccharomyces boulardii*. Probiotic bacteria can be delivered and ingested separately as medicinals or supplements. They can also be mixed with, added to, or naturally exist in functional foods.

WHAT ARE PREBIOTICS?

Prebiotics are usually in the form of oligosaccharides, which may occur naturally but can also be added as dietary supplements to foods, beverages, and infant formula.[4] Although indigestible by humans, their presence in the digestive system selectively enhances proliferation of certain probiotic bacteria in the colon, especially *Bifidobacteria* species. Prebiotic oligosaccharides often contain fructose chains with a terminal glucose and typically consist of 10 or fewer sugar molecules. Examples of prebiotic oligosaccharides include fructo-oligosaccharides (FOSs), inulin, galacto-oligosaccharides (GOSs), and soybean oligosaccharides. Inulin is a composite oligosaccharide that contains several FOS molecules. The complex polysaccharides that constitute dietary fiber can also be considered to be prebiotic agents.

Although dietary nucleotides do not fit the exact definition of a prebiotic, they are prebiotic-like agents and have immunomodulating and direct intestinal biological properties.[18] Some infant formulas contain a limited amount of added free nucleotides (7–20 mg/dL).[18] Human milk, on the other hand, contains a substantial but variable amount of oligosaccharides (14 g/L) as well as free nucleotides (up to 20% of nonprotein nitrogen).[19] Some infant-formula manufacturers now add prebiotic oligosaccharides to their products.

Beverages and nutritional supplements marketed for older infants, children, and adults contain oligosaccharides and nucleotide additives in varying amounts.

INTESTINAL BACTERIAL COLONIZATION AND DEVELOPMENT OF THE INTESTINAL MUCOSAL DEFENSE SYSTEM

Similar to the fetus, an infant at the time of birth has a sterile gastrointestinal tract, but bacterial colonization occurs rapidly.[20–22] The newborn in-

fant's gestational age, mode of delivery, and diet seem to have significant effects on this process. Neonates who are born by Caesarian delivery, born preterm, and/or exposed to perinatal or postnatal antibiotics have a delay in intestinal commensal probiotic bacterial colonization. When delivered vaginally, breastfed infants and formula-fed infants have a similar pattern of bacterial colonization at 48 hours of age. However, by 7 days of age, approximately two-thirds of formula-fed infants have a predominance of *Bacteroides fragilis*, compared with only 22% of breastfed infants.[20]

Toward the end of the first month of life in developing countries, breastfed infants are found to have *Bifidobacteria*-predominant colonization, whereas formula-fed infants have equal colonization with *Bacteroides* and *Bifidobacteria* species. In resource-rich countries, however, differences are less pronounced between breastfed and formula-fed infants.[15]

The composition of intestinal microflora does not change significantly after infancy. Therefore, the composition of fecal flora in older children and adults is less variable and not as dependent on diet. In fact, beyond infancy, bacterial concentrations in the colon are typically 10^{12} colony-forming units per mL of intestinal contents (10-fold the total number of human cells in the human body), and anaerobic bacteria far outnumber aerobic coliforms.[23] Typically, 500 different bacterial species contribute to an adult's colonic microflora, but 99% of the microflora are accounted for by 30 to 40 species.[23] The descriptive terms of "microbiota" and "microbiome" are newer terms that are replacing such terms as "microflora" in an attempt by researchers in the field to better define one's microbial environment.[24] "Microbiota" refers to a population of microscopic organisms that inhabit a bodily organ or portion of a person's body, and human "microbiome" refers to the unique entire population of microorganisms and their complete genetic elements that inhabit one's body.

The intestinal mucosal defense system is an integral part of a sophisticated immunoregulatory network that includes the intestinal microflora.[21,25–30] Recognition of self- and non–self-antigens begins early in life, perhaps even in utero, and is significantly influenced by events that occur within the digestive system soon after birth. The immunoresponsiveness of the digestive system is significantly affected by the young infant's diet, state of bacterial colonization, and early exposure to potential infectious pathogens and antibiotics as well as the infant's genotype. It is thought that the occurrence of many diseases, both intestinal and nonintestinal, can be related to dysregulation or interference with the early development of the intestinal mucosal defense system.[28,29] Examples of these diseases include those thought to be atopic (asthma, eczema, and allergic rhinitis) or autoimmune (multiple sclerosis, type 1 diabetes mellitus, and chronic inflammatory bowel disease [IBD]).[28] Certainly, the overriding determining factor in development of the immune system is one's genetic predisposition.[25]

The molecular basis for innate and acquired immunity is thought to reside in the recognition and response of mature T lymphocytes to trigger molecules, such as those derived from dietary and bacterial-breakdown products within the intestinal tract.[29] Trigger molecules also include dietary nucleotides and oligosaccharides. Toll-like receptors located in the surface membrane of T lymphocytes facilitate recognition of these trigger molecules, which eventually leads to specialized T-lymphocyte recognition and response to subsequent exposure to the same or very similar molecules. Thus, T-lymphocyte recognition of specific oligosaccharides bound to intestinal pathogens plays an important role in preventing gastrointestinal illness.

Given these important influences on intestinal microflora colonization and immune function, the infant's early diet and intestinal microbial environment are thought to serve as pivotal factors in overall health. Probiotic bacteria, postbiotic bacterial byproducts, and dietary prebiotics are believed to exert positive effects on the development of the mucosal immune system. It is also believed that exposure to "nonbeneficial" microorganisms and antimicrobial agents in the newborn period may result in immune dysregulation in susceptible individuals and may lead to some chronic disease states. There is evidence that human milk contains mononuclear cells that traffic intestinally derived bacterial components from the mother to her infant. The ingested human milk containing the bacterial components derived from the mother are thought to influence her young infant's developing immune system. This process is termed "bacterial imprinting," and its overall biological effect requires further study.[31]

USE OF PROBIOTICS IN PREVENTION AND TREATMENT OF CLINICAL DISEASES

Reviews on the clinical applications of probiotics and prebiotics can be found in the references.[4,8–14] Results of evidence-based analyses of the clinical effectiveness of probiotics and prebiotics are discussed below. It must be stressed that the current lack of evidence of efficacy does not mean that future clinical research will not establish significant health benefits for probiotics and prebiotics.

Acute Infectious Diarrhea

Prevention of Acute Infectious Diarrhea

Results of published randomized controlled trials (RCTs) have indicated that there is modest benefit of giving probiotics in preventing acute gastrointestinal tract infections in healthy infants and children.[32–35] Most of the studies were conducted in child care centers. The strains of probiotics used included LGG, *S thermophilus*, *Lactobacillus casei*, *B lactis*, or *Lactobacillus reuteri* mixed with milk or infant formula or given as an oral supplement. Rotavirus was the most common cause of acute diarrhea in the RCTs.

In a double-blind, placebo-controlled trial by Weizman et al,[36] 201 infants (4–10 months of age) received either a probiotic-supplemented formula containing either *B lactis* or *L reuteri* or a control formula without an added probiotic over a 12-week study period. The study was conducted at 14 different child care centers over a 2-year period. Infants fed a probiotic-supplemented formula had fewer and shorter episodes of diarrhea than did infants in the control group. Infants in the control group had a mean of 0.59 days of diarrhea (95% confidence interval [CI]: 0.34–0.84 days) per infant compared with 0.37 days (95% CI: 0.08–0.66 days) in the *B lactis* and 0.15 days (95% CI: 0.12–0.18 days) in the *L reuteri* probiotic-supplemented study groups ($P < .001$). During the 12-week study period, the infants in the control group were found to have a mean of 0.31 episodes of diarrhea (95% CI: 0.22–0.44 episodes) compared with 0.12 episodes (95% CI: 0.05–0.21 episodes) and 0.02 episodes (95% CI: 0.01–0.05 episodes) in the *B lactis*– and *L reuteri*–supplemented study groups, respectively ($P < .001$). There was no significant effect found on the incidence of acute respiratory illnesses. In another study conducted in child care centers in France,[37] 928 healthy children were randomly assigned to be fed either standard yogurt or yogurt supplemented with *L casei* for 4 months. The children who were fed the probiotic-supplemented yogurt had fewer episodes of diarrhea during the study period than did those who were fed standard yogurt (15.9% vs 22%; $P = .03$).

The results of a meta-analysis of probiotic prevention of acute rotavirus gastroenteritis in child care centers indicated that approximately 7 children would need to have been given LGG to prevent 1 child from developing nosocomial rotavirus gastroenteritis in a child care center setting.[38] To date, the available data do not support routine use of probiotics to prevent nosocomial rotavirus diarrhea in child care centers. However, there may be special circumstances in which probiotic use in children in long-term health care facilities or in child care centers is beneficial. The use of the newly available pentavalent rotavirus vaccine in the United States[39] will likely be a more formidable preventative agent than the use of probiotics in reducing the incidence of the most common form of acute infantile infectious diarrhea.

Treatment of Acute Infectious Diarrhea

Well-conducted RCTs in healthy children in developed countries have provided good data on the therapeutic benefit of probiotics in children with acute infectious diarrhea. In a randomized, double-blind, placebo-controlled trial by Szymanski et al,[40] administration of LGG significantly shortened the duration of acute rotavirus diarrhea by a mean of 40 hours, but duration of diarrhea of any other etiology was not affected. Probiotic administration also shortened the time necessary for intravenous rehydration by a mean of 18 hours. Results of several other meta-analyses[41–43] and a Cochrane review[44] have been published on the benefit of probiotics for treatment of acute infectious diarrhea in children. These reports indicate that probiotics reduce the number of diarrheal stools and the duration of the diarrhea by approximately 1 day. The benefit is strain-dependent. LGG is the most effective probiotic reported to date and is dose-dependent for doses greater than 10^{10} colony-forming units. Probiotics also seem to be more effective when given early in the course of diarrhea and are most helpful for otherwise healthy infants and young children with watery diarrhea secondary to viral gastroenteritis but not invasive bacterial infections. Thus, there is evidence to support the use of probiotics, specifically LGG, early in the course of acute infectious diarrhea to reduce the duration by 1 day.

Antibiotic-Associated Diarrhea

Prevention of Antibiotic-Associated Diarrhea

Meta-analysis of published results of RCTs of probiotic use in the prevention of antibiotic-associated diarrhea in children indicates a beneficial effect.[45–48] Treatment with a probiotic was started when antibiotic therapy was initiated for treatment of an acute respiratory infection (otitis media) in most of these studies. Treatment with probiotics compared with placebo reduced the risk of developing antibiotic-associated diarrhea from 28.5% to 11.9% (relative risk [RR]: 0.44 [95% CI: 0.25–77]; $P = .006$).[45] LGG, *B lactis*, *S thermophilus*, and *S boulardii* have been the most common agents used in RCTs. Approximately 1 in 7 cases of antibiotic-associated diarrhea was prevented by the use of a probiotic.[45] Children in these studies received either a probiotic-supplemented formula or a separate

probiotic as preventive treatment. According to 1 reported meta-analysis, probiotic treatment significantly reduced odds of antibiotic-associated diarrhea as compared with placebo (odds ratio [OR]: 0.39 [95% CI: 0.25–0.62]; $P < .001$) for both the yeast byproduct *S boulardii* and LGG. There was no significant difference between the 2 treatments; the overall combined OR was 0.37 (95% CI: 0.26–0.53; $P < .001$) in favor of active probiotic treatment over placebo.[48] Thus, probiotics can be used to reduce the incidence of antibiotic-associated diarrhea.

Treatment of Antibiotic-Associated Diarrhea

There have been no published RCTs of children that have investigated the effect of probiotics for treatment of antibiotic-associated diarrhea. Thus, their use cannot be recommended. The clinician who is caring for a child with antibiotic-induced diarrhea must weigh the benefits of considering therapy with a probiotic or discontinuing or modifying the antibiotic treatment when possible. No RCTs have been published concerning treatment with probiotics of children with *Clostridium difficile* antibiotic-associated diarrhea.

Atopic Diseases

Prevention of Atopic Disease

As previously mentioned, the sequence of bacterial intestinal colonization of neonates and young infants is probably important in the development of the immune response.[21] Recognition by the immune system of self and nonself, as well as the type of inflammatory responses generated later in life, are likely affected by the infant's diet and acquisition of the commensal intestinal bacterial population superimposed on genetic predisposition. During pregnancy, the cytokine inflammatory-response profile of the fetus is diverted away from cell-mediated immunity (T-helper 1 [Th1] type) toward humoral immunity (Th2 type). Hence, the Th2 type typically is the general immune response in early infancy. The risk of allergic disease could well be the result of a lack or delay in the eventual shift of the predominant Th2 type of response to more of a balance between Th1- and Th2-type responses.[49] Administration of probiotic bacteria during a time period in which a natural population of lactic-acid–producing indigenous intestinal bacteria is developing could theoretically influence immune development toward more balance of Th1 and Th2 inflammatory responses.[50] The intestinal bacterial flora of atopic children has been demonstrated to differ from that of nonatopic children. Specifically, atopic children have more *Clostridium* organisms and fewer *Bifidobacterium* organisms than do nonatopic study subjects,[15,51] which has served as the rationale for the administration of probiotics to infants at risk of atopic diseases, particularly for those who are formula fed.

In a double-blinded RCT, LGG or a placebo was given initially to 159 women during the final 4 weeks of pregnancy. If the infant was at high risk of atopic disease (atopic eczema, allergic rhinitis, or asthma), the treatment was continued for 6 months after birth in both the lactating woman and her infant.[52] A total of 132 mother-infant pairs were randomly assigned to receive either placebo or LGG and treated for 6 months while breastfeeding. The primary study end point was chronic recurrent atopic eczema in the infant. Atopic eczema was diagnosed in 46 of 132 (35%) of these study children by 2 years of age. The frequency of atopic eczema in the LGG-treated group was 15 of 64 (23%) versus 31 of 68 (46%) in the placebo group (RR: 0.51 [95% CI: 0.32–0.84]; $P < .01$). The number of mother-infant pairs required to be treated with LGG to prevent 1 case of chronic recurrent atopic eczema was 4.5. By 4 years of age, eczema occurred in 26% of the infants in the group treated with LGG, compared with 46% in the placebo group (RR: 0.57 [95% CI: 0.33–0.97]; $P < .01$). However, only 67% of the original study group was analyzed at the 4-year follow-up. These results support a preventive effect for giving a probiotic to mothers late in pregnancy and to both mothers and infants during the first 6 months of lactation for the prevention of atopic eczema in infants who are at risk of atopic disease. However, these results have not been confirmed in subsequent clinical trials, as summarized in a recent review by Kopp and Salfeld.[53] Conversely, Taylor et al[54] found that probiotic supplementation did not reduce the risk of atopic dermatitis in children at high risk with the report of some increased risk of subsequent allergen sensitization. As concluded in a review by Prescott and Björkstén[55] and in a 2007 Cochrane review,[56] despite the encouraging results of some studies, there is insufficient evidence to warrant the routine supplementation of probiotics to either pregnant women or infants to prevent allergic diseases in childhood. Explanations for varied study results include host factors such as genetic susceptibility, environmental factors such as geographic region and diet, and study variables including probiotic strains and doses used.[55,57]

Treatment of Atopic Disease

In an RCT, 53 Australian infants with moderate-to-severe atopic dermatitis were given either *Lactobacillus fermentum* or placebo for 8 weeks. At final assessment at 16 weeks, significantly more children who received the probiotic had improved extent and severity of atopic dermatitis as measured by the Severity of Scoring of

Atopic Dermatitis (SCORAD) index over time compared with those who received placebo ($P = .01$).[58,59] These results are encouraging, but as summarized in a 2008 Cochrane review,[60] probiotics have not yet been proven to be effective in the treatment of eczema.

Prevention of Necrotizing Enterocolitis in Low Birth Weight Neonates

A newborn's gut is sterile at birth, with bacterial colonization beginning shortly after birth.[20–22] Preterm infants frequently have delayed and aberrant acquisition of the "normal" digestive microflora, possibly because of restricted enteral feedings and frequent use of antibiotic therapy.[61,62] Delayed enteral feeding, frequent use of antibiotic therapy, and altered acquisition of normal digestive microflora are believed to be primary contributing factors for the increased risk of necrotizing enterocolitis (NEC) in preterm infants[63,64] and is the rationale for probiotic supplements.

In a 2008 Cochrane review[65] based on 9 RCTs,[66–74] enteral probiotic supplementation significantly reduced both the incidence of NEC (stage II or more) (RR: 0.32 [95% CI: 0.17–0.60]) and mortality (RR: 0.43 [95% CI: 0.25–0.75]).[65] Nosocomial sepsis was not reduced significantly (RR: 0.93 [95% CI: 0.73–1.19]). A total of 1425 infants who were born at less than 37 weeks' gestational age and/or less than 2500 g birth weight were included in this meta-analysis. No systemic infections or serious adverse events that were directly attributed to the administered probiotic organism were reported for these RCTs. The authors concluded that the results of their analysis supported a change in clinical practice to supplement preterm infants who weighed more than 1000 g at birth with a probiotic. Data regarding the outcome of preterm extremely low birth weight infants who weighed less than 1000 g at birth could not be used by the authors to reliably estimate the efficacy and safety of probiotic supplementation to this high-risk group. A large RCT was recommended to investigate the potential benefit and safety of probiotic supplementation to extremely low birth weight infants.

However, because the of large heterogeneity of the studies included in the Cochrane review,[65] caution is urged in interpreting the results, which are somewhat problematic. The studies all used different probiotics, including LGG, *Bifidobacterium breve*, *Saccharomyces* species, and mixtures of *Bacteroides bifidus*, *S thermophilus*, *Lactobacillus acidophilus*, *and Bifidobacterium infantis*. Doses of individual probiotics varied and were administered with human milk feedings, formula feedings, or both human milk and formula feedings in some studies. Not all of the studies had the same end points, including the primary outcome of NEC. A second and larger study by Lin et al,[75] the results of which were published after the Cochrane review, repeated the 2005 study[71] by using a different mixture of probiotics: *L acidophilus* and *B bifidus*. The overall incidence of NEC and death was less in the second study[75] compared with that in the first[71] in the controls, and the second study revealed that probiotics did not reduce the incidence of sepsis compared with that in the first, and the intervention group actually had a higher incidence of sepsis. The number needed to treat to prevent 1 case of NEC was 27 in the first study by Lin et al[71] and 21 in the second study.[75] Another point that makes the data problematic is that the combinations of probiotics used in the Lin et al studies, which are the most convincing for NEC prevention, are not available in the United States. Not all probiotics have been studied; therefore, all probiotics cannot be generally recommended.

Treatment of Helicobacter pylori *Infection*

There is a modest and encouraging benefit in published RCT results for probiotics used as adjunctive therapy for *H pylori* gastritis in adults.[76] One RCT in children has been published,[77] and the results demonstrated that the probiotics-supplemented treatment group had better *H pylori* eradication than did the placebo group (84.6% vs 57.5%; RR: 1.47 [95% CI: 1.1–2.0]). The adverse effects of diarrhea, nausea, and vomiting in both the placebo and probiotic treatment group did not differ significantly. Thus, probiotics may be of some benefit in the eradication of *H pylori* in children, but more studies are required.

Chronic IBD

The term IBD is inclusive of patients with either chronic ulcerative colitis (CUC) or Crohn disease. It is estimated that approximately 40% to 70% of children and adult patients suffering with IBD routinely use alternative medicines, including probiotics, as adjunctive or replacement therapy for prescribed medications.[78–80] In theory, probiotics may be beneficial in the treatment of IBD.[21] It has been proposed that in individuals with genetic susceptibility to IBD, chronic inflammation occurs in response to commensal digestive microflora because of various inherited defects of innate inflammatory-response pathways. One such identified inherited defect found in patients with Crohn disease is a mutation of the *CARD15* gene on chromosome 16, which results in abnormal chronic inflammation in response to bacteria such as *Escherichia coli* in the digestive tract.[21] Hence, modulating the commensal intestinal bacterial environment with probiotic supplements

may reduce the inflammatory response in patients with IBD.[80]

Treatment of Chronic Ulcerative Colitis

Data from RCTs of probiotics for the treatment of adults with CUC are encouraging.[81–84] The administration of probiotics to adults with mild-to-moderate CUC disease activity has comparable efficacy when compared with treatment with anti-inflammatory drugs used to treat CUC, such as mesalamine, as reported in a recently published Cochrane review.[85] The same is true in adult patients with ileoanal pouchitis after colectomy surgery for CUC. Most of these studies use the probiotic mixture VSL#3 (Sigma-Tau Pharmaceuticals, Gaithersburg, MD), which is a combination of *S thermophilus*, *Bifidobacterium* species, and *Lactobacillus* species. The probiotic *E coli* Nissle 1917 (Ardeypharm GmbH, Herdacke, Germany) has also been used successfully to treat mild-to-moderate pouchitis or CUC in adults.[86] One RCT in which 29 children with newly diagnosed CUC were randomly assigned to receive either VSL#3 or a placebo for 1 year had promising results.[87] All study patients were also given standard corticosteroid induction therapy combined with mesalamine maintenance therapy. Remission occurred in 13 patients (92.8%) in the VSL#3 group and 4 patients (36.4%) in the placebo group ($P < .001$). Relapse occurred in 3 of 13 (23%) patients in the VSL#3 group versus 11 of 15 (73.3%) in the placebo group within the 1-year study period (RR: 0.32 [95% CI: 0.25–0.773]; $P = .014$). Although these results are promising, more studies are needed in larger numbers of children to substantiate the benefit of probiotics in managing children with mild-to-moderate CUC. Thus, probiotics for CUC cannot be generally recommended at this time without further confirmatory research.

Treatment of Crohn Disease

One RCT in which LGG was used in pediatric patients with Crohn disease resulted in no significant benefit.[88] Treating adults with Crohn disease with the probiotics *S boulardii,* LGG, and *E coli* Nissle 1917 has not yielded promising results thus far.[89–92] A recent Cochrane review indicated that there is, as yet, no proven benefit for maintaining remission by administering probiotics to adults with Crohn disease.[93] Because of the lack of efficacy, treatment of Crohn disease with probiotics cannot be recommended for children.

Irritable Bowel Syndrome and Constipation: Treatment

There has been a single published RCT of the treatment of irritable bowel syndrome (IBS) in children.[94] LGG reduced abdominal distension and discomfort in a group of 50 pediatric patients over a 6-week study period. Response to therapy was recorded and collected on a weekly basis by using the Digestive Symptom Rating Scale. Various probiotics were shown to be helpful in several other RCTs of treatment of IBS in adults.[95–97] One published RCT addressed the use of probiotics (LGG) or a placebo as adjunct therapy to a stool softener (lactulose) to treat functional constipation in 84 children.[98] LGG was not an effective adjunct to lactulose in treating constipation in children. Thus, probiotics may be of benefit in children with IBS on the basis of a single RCT, but a recommendation for them use cannot be made without further confirmatory studies. Probiotics cannot be recommended at this time for treatment of constipation.

Infantile Colic

Prevention of Colic

To date, no RCTs have been conducted with colic as a primary end point.

Treatment of Colic

Colic is a common condition that typically affects infants in the first 4 months of life. The primary mechanism remains unknown. Available evidence suggests that colic potentially has a number of independent causes, including dietary protein hypersensitivity.[99,100] A recent unblinded RCT examined the effect of the administration of *L reuteri* versus simethicone in the treatment of colic in 90 exclusively breastfed infants in Italy.[100] The administration of *L reuteri* improved the symptoms of colic (minutes of crying per day) within 1 week of treatment, compared with simethicone therapy. The breastfeeding mothers were instructed to eliminate dairy products from their diets during the study period to minimize potentially confounding adverse effects of dietary protein hypersensitivity. The authors of the study proposed several theories for a positive therapeutic benefit, including probiotic modulation of proinflammatory responses. Further confirmatory RCTs are required to recommend routine use of probiotics in the treatment of infantile colic in both breastfed and formula-fed infants. On the basis of limited information, probiotics may be of benefit in treatment of colic in exclusively breastfed infants, but more studies are needed before they can be recommended.

Extraintestinal Infections

Prevention of Extraintestinal Infections

In a 2001 RCT in 17 Finnish child care centers, 571 healthy children 1 to 6 years of age were studied for 7 months in winter.[33] Children were randomly assigned to receive milk 3 times per day with or without LGG. When the data were adjusted for age, children who were fed milk with LGG, compared with controls, did not have significantly fewer days with respiratory symptoms

or fewer days of child care absences because of illness. There were also no significant differences in the numbers of children with a doctor's diagnosis of infection or number of prescriptions for antibiotics when adjusted for age, although the trends favored the children who were fed milk with LGG. Thus, probiotics for the prevention of extraintestinal infections in children cannot be recommended at this time.

Treatment of Extraintestinal Infections

No RCTs in children have demonstrated definite beneficial effects of administering probiotics to treat extraintestinal infections. The beneficial effects that have been reported in uncontrolled trials in adults with 1 or more types of extraintestinal infection have typically used LGG as a supplement or probiotics added to dairy products.[101–103] Thus, probiotics are not recommended for children for treatment of extraintestinal infections.

Cancer: Prevention and Treatment

Results of published studies have demonstrated the positive benefits of functional foods, such as yogurt, and the administration of probiotics to prevent carcinogenic processes in animal models.[104] As yet, no published RCTs warrant recommendation of routine administration of probiotics to either treat or prevent cancer in adults or children.

USE OF PREBIOTICS IN PREVENTION AND TREATMENT OF CLINICAL DISEASES

Few RCTs have been conducted to evaluate the use of prebiotics in preventing or treating specific childhood diseases.[8]

Prevention and Treatment of Allergy

A 2007 Cochrane review[105] concluded that there was inconclusive evidence for giving prebiotics to prevent allergic disorders in infants. However, in 2008, Arslanoglu et al[106] reported on a 2-year follow-up of an RCT in 132 infants at risk of atopy because of parental atopy. Infants were fed a partially hydrolyzed formula with either an added mixture of FOS and GOS or maltodextrin placebo in the first 6 months of life. Those given the prebiotic mixture of FOS and GOS had a reduced incidence of atopic disease. Cumulative incidences of atopic eczema, recurrent wheezing, and allergic urticaria were higher in the maltodextrin placebo group (27.9%, 20.6%, and 10.3%, respectively) than in the intervention group (13.6%, 7.6%, and 1.5%) ($P = .05$). In a 2009 review, van der Aa et al[107] analyzed relevant publications to date and concluded that there is presently not enough evidence to support the use of probiotics, prebiotics, or synbiotics for the prevention or treatment of allergic dermatitis in children. Confirmatory studies of the benefits of prebiotics, especially for children fed formula that is not partially hydrolyzed or infants fed partially hydrolyzed formula, which are already being promoted to reduce the incidence of atopic disease, are needed before any recommendations can be made for the use of prebiotics in infants and toddlers to prevent infection or atopic disease.

Other Disorders

It has been shown that the addition of dietary fiber has ameliorated diarrheal stools when added to infant formula.[108] Prebiotics, such as oligosaccharides, inulin, and dietary fiber supplements that are contained in bran, psyllium, and barley fiber, are beneficial in maintaining clinical remission in adult patients with CUC,[109] but no RCT results support their use. There have been controlled animal research studies that have shown that prebiotics may prevent or lessen carcinogenic processes,[104] but there have been no RCTs in humans.

COMBINED PREBIOTICS AND PROBIOTICS TO PREVENT ALLERGY

Clinical benefit in preventing allergic diseases by co-therapy with probiotics and prebiotics in pregnant women and their infants was demonstrated in an RCT in Finland.[110] A total of 1223 pregnant women who had been identified to deliver infants who would be at high risk of atopic disease because of parental atopic disease history were randomly assigned to be given a mixture of 4 probiotic strains plus GOS or placebo daily for 2 to 4 weeks before delivery. After delivery, their infants then either received the same probiotic mixture plus GOS or the same placebo as the mother. Probiotic/prebiotic treatment showed no effect on the cumulative occurrence of allergic diseases but tended to reduce immunoglobulin E–associated (atopic) diseases (OR: 0.71 [95% CI: 0.50–1.00]; $P = .052$). Probiotic and prebiotic treatment reduced the occurrence of eczema (OR: 0.74 [95% CI: 0.55–0.98]; $P = .035$) and atopic eczema (OR: 0.66 [95% CI: 0.46–0.95]; $P = .025$). Confirmatory studies are necessary.

PREBIOTICS AND PROBIOTICS IN INFANT FORMULA

Prebiotics

As mentioned earlier in this review, human milk contains a number of substances that are prebiotic, the most plentiful of which are oligosaccharides.[19,30] Oligosaccharide prebiotics are also added to many commercially available dietary food supplements. Regarding their addition to infant formula, the European Commission's Scientific Committee on Food concluded in 2003[111] that they had no major concerns regarding the addition of oligosaccharides to infant formulas, including follow-up infant formulas (formulas modified especially for 6- to 12-month-old infants), up to a total

concentration of 0.8 g/dL in ready-to-feed formula products.

Few RCTs have examined the effects of adding prebiotic oligosaccharides to infant formula.[106,112,113] Boehm et al[113] studied the effect of the addition of oligosaccharides at a concentration of 1 g/dL to preterm infant formula for 1 month (90% GOSs and 10% FOSs). Stool bifidobacteria counts in the oligosaccharide-supplemented group increased significantly compared with the nonsupplemented group, and the bifidobacteria counts reached the range of a breastfed reference group. In a separate study, Moro et al[114] fed term infants the same oligosaccharide-supplemented formula. These infants had higher counts of bifidobacteria as well as lactobacilli in their stools. Schmelzle et al[115] conducted a multicenter trial that also examined the efficacy of the addition of prebiotics to infant formula. They reported good overall tolerance and no adverse effects during the 12-week study period. A large multicenter trial to evaluate the safety of FOS-supplemented infant formula was conducted in the United States in 2004.[116] The study demonstrated that infant growth was maintained during the 12-week study period for the FOS-supplemented infant-formula group without any adverse effects. After weaning infants from formula, the addition of prebiotics to solid food seems to have a bifidogenic effect, as shown by the results of a recently published RCT by Scholtens et al.[117] Infant formulas that contain either GOS or FOS are now marketed in the United States. However, more information, including data from RCTs, is needed before the efficacy of adding prebiotics to infant formulas can be determined.

Probiotics

Two infant formulas currently contain a probiotic. One contains *B lactis*, and the other contains LGG. These probiotics are only added to powdered formulas at present. The rationale for adding probiotic organisms to infant formula was discussed in the introduction of this clinical report. The overall health-benefit efficacy of adding probiotics to infant formula remains to be demonstrated in large RCTs.

SAFETY OF PROBIOTICS AND PREBIOTICS IN INFANTS AND CHILDREN

Concerns exist about the overall safety of administering probiotic products to high-risk patient groups, including adults, children, and term and preterm infants. Cases of serious infection have occurred and been reported in the literature.[10,118–125] Patients at risk would be those who are immunocompromised, including ill preterm neonates, and/or children who have intravenous catheters or other indwelling medical devices. In most cases, the offending organism that caused the sepsis seems to have stemmed from bacteria from the individual's own endogenous flora. Sepsis has also been reported in adults, children, and infants who received probiotic supplements.[118,124–126] Land et al[126] recently reported LGG probiotic sepsis occurring in immunocompromised infants and children. A medically fragile infant 6 weeks of age became septic with a strain of LGG that was being provided as a supplement. Molecular DNA-fingerprinting confirmed that the LGG probiotic supplement was the bacterial isolate from the infant. Neonatal sepsis and meningitis that were apparently associated with the administration of a probiotic supplement were also reported.[118,120]

A recent report focused on probiotic tolerance and safety in healthy term infants who were randomly assigned to be given a high-dose probiotic formula, a low-dose probiotic formula, or control formula for 18 months.[35] There were no apparent reported adverse events. All infants demonstrated normal growth. Reports of colic were significantly fewer in the 2 probiotic-formula–fed groups, and the frequency of health care visits and antibiotic use was less ($P < .001$) compared with those in the control formula group. In a separate study, Petschow et al[127] reported that healthy term infants given varying amounts of LGG in infant formula for 2 weeks resulted in good overall feeding tolerance with successful intestinal tract colonization, without adverse events.

The apparent safety to date of adding prebiotics to infant formula has been evaluated in the previously discussed RCTs reported by Boehm et al,[113] Moro et al,[114] Schmelzle et al,[115] and Bettler and Euler.[116]

SUMMARY ON SAFETY

The Committee on Nutrition of the European Society of Pediatric Gastroenterology, Hepatology and Nutrition previously concluded that more studies are required to establish the safety and efficacy of probiotic and prebiotic products in children.[12] To date, these products seem to be safe for healthy infants and children. The committee also stated that it would be optimal to have a centralized mechanism of oversight to ensure probiotic microorganism safety, identity, and genetic stability.[12] Centralized oversight and probiotic product monitoring was also recommended in a report from the Food and Agriculture Organization of the United Nations World Health Organization.[1,2,128] This organization supports the addition of prebiotic products to infant formulas designed as follow-up formulas meant for infants aged 5 months and older. It was reasoned that these infants are more likely to have a more mature immune response and established intestinal

colonization. In terms of oversight and product safety in the United States, products marketed as dietary supplements, such as probiotics, do not require premarket review and approval by the US Food and Drug Administration (FDA). However, probiotics or prebiotics that are marketed specifically for the treatment or prevention of a disease are classified as biological products and do require FDA review and approval. Infant formulas must be made with compliance with what are considered good manufacturing practices under the Infant Formula Act of 1980 and are under the regulatory auspices of the FDA[129] because these products are often used as the sole source of nutrition by infants during a critical period of growth and development. Additional statutory and regulatory requirements address appropriate infant formula manufacture, composition, and nutrient content. All ingredients used in infant formula must be safe and lawful—that is, food ingredients that are, to date, generally regarded as safe (GRAS) for use in infant formula and those that are used in accordance with the food-additive regulations of the FDA. Prebiotics and probiotics now being added to commercial infant formulas are classified as GRAS. Information on FDA regulations for infant formula and food ingredients and packaging may be found at www.fda.gov/Food/FoodSafety/ProductSpecificInformation/InfantFormula/default.htm and www.fda.gov/Food/FoodIngredientsPackaging/default.htm.

DEVELOPMENT OF THIS REPORT

The AAP Committee on Nutrition and Section on Gastroenterology, Hepatology, and Nutrition used review of the literature, including Cochrane reviews, and reports from other groups.[12,111,128] Comments also were solicited from committees, sections, and councils of the AAP; 9 entities responded. Additional comments were sought from the Centers for Disease Control and Prevention, the National Institutes of Health, the US Department of Agriculture, and the FDA because these governmental agencies have official liaisons to the Committee on Nutrition and were present during the development of the statement. For recommendations for which high levels of evidence are absent, the expert opinions and suggestions of the members of the Committee on Nutrition and other groups and authorities consulted were taken into consideration in developing this clinical report.

SUMMARY

1. Human milk, a natural prebiotic, is preferred for infants through 6 months of age.[130] The oligosaccharide content of human milk is substantial and is part of the prebiotic components of the human milk. Breastfed infants typically have a preponderance of naturally occurring probiotic bacteria in their digestive systems. There may be some naturally occurring probiotic bacteria contained in human milk.
2. There is some evidence in otherwise healthy infants and young children to support the use of probiotics early in the course of diarrhea from acute viral gastroenteritis and that use of probiotics reduces its duration by 1 day. However, the available evidence does not support the routine use of probiotics to prevent infectious diarrhea unless there are special circumstances. There is some evidence to support the use of probiotics to prevent antibiotic-associated diarrhea but no evidence that it is beneficial for treatment.
3. Although the results of some studies support the prophylactic use of probiotics during pregnancy and lactation and during the first 6 months of life in infants who are at risk of atopic disorders, further confirmatory evidence is necessary before a recommendation for routine use can be made.
4. There is some evidence to support the use of probiotics to prevent NEC in preterm infants with a birth weight of 1000 g or higher. However, the amount and specificity of which probiotic or mixture of probiotics to use is problematic, given the many unanswered questions from a review of the available literature. Furthermore, many of the probiotics used and cited in the literature for treatment in preterm infants are not readily available.
5. At the present time, the sustained or long-term benefit of using probiotics for treating disorders such as Crohn disease, IBS, constipation, and extraintestinal infections requires further RCTs and cannot be recommended in children. There may benefit for treating *H pylori* infections, CUC, and infantile colic with probiotics in childhood, but further studies are necessary.
6. Long-term health benefits of probiotics in the prevention of cancer, allergy, or other diseases or providing sustained beneficial results on the developing immune system beyond early infancy remain to be proven.
7. Addition of probiotics to powdered infant formulas has not been demonstrated to be harmful to healthy term infants. On the other hand, evidence of clinical efficacy for their addition is insufficient to recommend the routine use of these formulas. No RCTs have directly compared the health benefits of feeding human milk versus infant formula supplemented with probiotics.

8. Probiotics should not be given to children who are seriously or chronically ill until the safety of administration has been established.
9. Prebiotics may prove to be beneficial in reducing common infections and atopy in otherwise healthy children. However, confirmatory studies, especially in children fed formula that is not partially hydrolyzed, are needed before any recommendations can be made.
10. Addition of oligosaccharides as prebiotics to infant formula is not unreasonable but lacks evidence demonstrating clinical efficacy at this time. Cost/benefit studies are also necessary to support their addition to infant formulas.
11. Important questions remain in establishing the clinical applications for probiotics, including the optimal duration of probiotic administration as well as preferred microbial dose and species. The long-term impact on the gut microflora in children is unknown. It also remains to be established whether there is significant biological benefit in the administration of probiotics during pregnancy and lactation, with direct comparison to potential biological benefit derived from probiotic-containing infant formulas. Similar questions exist for the use of prebiotics.

Appendix 1 contains examples of currently available probiotic products and the probiotic content of various functional foods in the United States. This list demonstrates the wide variation in probiotic content in these products. Information about other probiotics can also be found on a Web site maintained by industry (www.usprobiotics.org).

TECHNICAL REPORT

Professionalism in Pediatrics

Mary E. Fallat, MD, Jacqueline Glover, PhD, and the Committee on Bioethics

ABSTRACT

The purpose of this report is to provide a concrete overview of the ideal standards of behavior and professional practice to which pediatricians should aspire and by which students and residents can be evaluated. Recognizing that the ideal is not always achievable in the practical sense, this document details the key components of professionalism in pediatric practice with an emphasis on core professional values for which pediatricians should strive and that will serve as a moral compass needed to provide quality care for children and their families.

INTRODUCTION

Professionalism has been a central and defining feature in medicine since Hippocrates.[1] The concept of professionalism is now receiving renewed attention because of advances in technology, managed care and other business arrangements in health care, and a growing sense of the erosion of public trust in the medical profession.[2]

Pediatricians have a special status in society as privileged and trusted advocates for the well-being of children. Pediatricians have a responsibility to use their knowledge, skills, and influence to advocate for children and their interests in all domains of society, not just in health care. A child's health is broadly understood to include emotional, social, educational, psychological, and spiritual well-being.

As the pediatrician-child/family relationship has been threatened over time with the imposition of a business model, it has become more important than ever to adopt a standard of professionalism for pediatricians. The ability to promote professionalism across the continuum of medical education, from medical school curricula through continuing medical education for practicing pediatricians, depends on the ability to define and assess professionalism in the context of pediatrics.[3,4] Various professional groups have supported the need for a normative definition of professionalism, and there is considerable overlap in the definitions that they have formulated.[5–8] The American College of Physicians astutely noted in its recent iteration of their ethics manual that written guidelines are not a substitute for the experience and integrity of individual physicians but may serve as a reminder of the shared duties and obligations of the medical profession.[9] Allowing that the ideal may not be fully achievable in the practical sense, the purpose of this document is to provide a background on professionalism in pediatrics that serves a dual role: (1) to provide a concrete overview of the ideals for which pediatricians should strive and (2) to describe standards of professional behavior by which practicing pediatricians and trainees can be evaluated. This document begins with a general discussion of statements concerning professionalism in pediatrics and proceeds to the application of these statements in the central relationships in

www.pediatrics.org/cgi/doi/10.1542/peds.2007-2230

pediatric practice—to patients and families, to students and residents, to other health professionals, to the profession, and to society in general.

STATEMENTS OF PROFESSIONALISM IN PEDIATRICS

The American Board of Pediatrics (ABP) began its discussion of professionalism when it defined the optimal attitudes, knowledge, clinical judgment, technical skills, and interpersonal skills that applicants should possess in its 1974 publication *Foundations for Evaluating the Competency of Pediatricians*.[10] Since 1976, residency program directors have been asked to evaluate interpersonal skills, work habits, and personal qualities of residents, and beginning in 1982, the ABP requested that program directors also evaluate and attest to applicants' ethical and moral behavior as it affects their professional performance.

The ABP continued its pediatric-specific efforts to clarify ethics and professionalism issues in practice with the pioneering 1987 publication "Teaching and Evaluation of Interpersonal Skills and Ethical Decision Making in Pediatrics."[11] Admittedly, the content area in ethics is not straightforward. To assist residents and pediatricians in practice with difficult ethical decisions, the American Academy of Pediatrics (AAP) Committee on Bioethics has been publishing guidelines on key ethical issues since 1983 (available at http://aappolicy.aappublications.org). Most recently, the ABP added more specific guidelines for the teaching and evaluation of professionalism as part of the core curriculum for residency training in pediatrics. The following 8 components of professionalism have been endorsed by the ABP as the most appropriate for teaching and evaluation[12]:

- Honesty and integrity—embody the principles of fairness, the ability to meet commitments and keep one's word, and the duty to be intellectually honest and straightforward in interactions with patients and peers and in all professional communication.
- Reliability and responsibility—represent accountability to children, families, other physicians, medical staff, community, and ultimately society. They require acceptance of responsibility for errors made, including the willingness to acknowledge and discuss errors, consequences, and alternatives with the family and with peers.
- Respect for others—involves treating all persons with respect and regard for individual worth and dignity, including sensitivity to gender, race, and cultural differences as well as maintenance of patient confidentiality when appropriate.
- Compassion/empathy—the ability to understand children's and family members' reactions to pain, discomfort, and anxiety from their point of view, not that of the physician.
- Self-improvement—involves a commitment to lifelong learning and education.
- Self-awareness/knowledge of limits—the maturity to recognize when a problem involves knowledge or technical skills beyond the experience of the provider and to ask for consultation or assistance in those situations.
- Communication and collaboration—involve the recognition that patients' families and the health care team must work cooperatively with each other and communicate effectively to provide the best patient care and social activism.
- Altruism and advocacy—refer to the unselfish regard or devotion to the welfare of others. Patient well-being should be the primary motivating factor in patient care, ahead of physicians' own interests and needs.

PEDIATRICIANS' RESPONSIBILITIES TO PATIENTS, FAMILIES, AND COMMUNITIES

The connotation of "good doctor" historically brings to mind a physician who embodies both the art and science of medicine. The concept is epitomized in the pediatrician who can give advice without being patronizing, who is concerned about how an illness and its consequences (financial, emotional, psychological) will affect the family, and who strives to help the child and/or parent understand a disease process and its natural history (compassion/empathy). This doctor is thorough and technically skillful and continually incorporates new knowledge into his or her practice (self-improvement).[13] To other physicians, a "good pediatrician" is a colleague with whom they would entrust the care of their own child.[14]

To be effective, the relationship between a pediatrician, his or her patient, other medical professionals, and the parent or surrogate (hereafter, "parent") of that child must be collaborative. The role of the parents is to take an interest in and responsibility for their child's health care, seek attention for medical problems in a timely manner, and communicate and work effectively with their child's pediatrician to create an acceptable treatment plan. In return, the pediatrician's obligation is to provide appropriate information regarding the child's health care, including the benefits, risks, and costs of all reasonable treatment alternatives (communication and collaboration). Parents should have their questions answered, feel free to seek second opinions, and be advised of the pediatrician's potential conflicts of interest (honesty and integrity). Pediatricians should communicate to parents any errors in patient care, including any consequences that have resulted or may result because of the error (honesty and integrity; reliability and responsibility).

Children, as patients, should be afforded continuous

access to care. On-call pediatricians should be responsive in a timely manner, coverage should be available during absences, and notice of closing a practice or changing participation in insurance plans is expected (curtailing access). Except in cases of emergency or in which state law allows otherwise, the permission of a parent will be necessary before a pediatrician can offer medical treatment to a child. Parents may accept or refuse a recommended medical treatment on behalf of their child. Pediatricians and pediatric medical subspecialists have a duty to respect the wishes of the child and family when these wishes are intended to do good (beneficence) and avoid harm (nonmaleficence). A child's parent usually is the most appropriate person to determine what actions will be in the best interest of the child (communication and collaboration; altruism and advocacy). Children and adolescents who desire to participate should be included in the decision-making process (patient assent) when their neurologic status, development, and level of maturity allow, although state laws that affect the minor's ability to consent to (provide legally binding authorization for) medical care are complex.[15]

Resolving Conflicting Goals of Care

Conflicts may occur when the parent, child, and physician fail to agree on what would be optimal care under a given set of circumstances. When pediatricians and parents disagree, the pediatrician should explain the basis for the disagreement, educate the parent, and attempt to meet the child's needs within the constraints that exist. In these cases, the physician must seek to understand the reason for the disagreement and determine if the child would be put at significant risk of serious harm by following the wishes of the child and/or parent. In cases in which serious harm to a child is likely if the parent's wishes are followed, the pediatrician must get a second opinion and act to protect the best interests of the child. Institutional ethics committees should be consulted for guidance, education, and advice regarding unusual or complicated ethical problems that involve the care and treatment of children.[16]

If a physician or other health care professional is unwilling to honor a family's refusal of intervention in a situation in which the family has chosen an established alternative, he or she should withdraw from the case and must provide reasonable assistance to the parent in making alternative arrangements for care. A physician may not discontinue care of a child as long as additional treatment is medically indicated or until another physician has assumed care.

Nondiscrimination, Societal Obligations, and Continuity of Care

The AAP believes that the medical care of infants, children, and adolescents should be delivered or directed by well-trained pediatricians who provide primary care and help to manage and facilitate essentially all aspects of pediatric care.[17] A pediatrician has broad authority to enter into or decline a medical relationship with a family except in emergency situations. Once a relationship is established, however, the pediatrician should assume responsibility for the medical care of the child and also recognize when the child needs to be referred to a pediatric medical subspecialist, pediatric surgical specialist, or other physician or qualified clinician for diagnosis or treatment of a condition or symptom complex outside of the physician's scope of practice (self-awareness/knowledge of limits).[18]

Pediatricians or pediatric subspecialists who offer their services to the public should not refuse to accept children into their practice because of race, color, religion, national origin, disability, sexual orientation, or any other basis that would constitute discrimination (respect for others). Pediatricians should not refuse to care for acutely ill children on the basis of the ability of the family to pay for services rendered. However, practice overhead expenses preclude the provision of comprehensive health services for every child whose family requests routine or preventive health services unless there is some means of compensation. The AAP believes that the medical care of infants, children, and adolescents should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, culturally effective, and provided according to the medical home concept.[17] Pediatricians have a special obligation to work together to help secure access to health care for all children, including those who are uninsured or underinsured.[19]

Pediatricians have an obligation to refrain from providing nonbeneficial interventions and should also be good stewards of health care resources by using the most efficient means to diagnose a condition, using resources of optimal quality wisely, and helping to ensure that resources are available equitably.[5] A pediatrician may not refuse to treat a child whose condition is within the physician's current realm of competence solely because the child has a communicable disease. A pediatrician should honor requests for second opinions and should be available to provide guidance to the parents and child after they have obtained opinions from other physicians. Pediatricians and subspecialists to whom they refer their patients should make every effort to communicate effectively and in a timely manner with each other about their assessments of the patient and coordinate their treatment plans (reliability and responsibility).

Boundaries in Patient Care

Compassionate and empathetic care for the child historically has been balanced with the need to remain objective and avoid becoming overinvolved. Boundary violations can pose a serious threat to professional judgment.[20] An increase in trust and change in bound-

aries is likely to occur as a child/family-pediatrician relationship evolves. Boundary transgressions might include abusive behaviors, sexual behavior between the physician and the patient or members of the patient's family, a physician who treats family members, and gift-giving between a family and the physician.[21–23] The development of strong empathetic and nonromantic, nonsexual feelings of affection for a patient or family do not constitute boundary violations and are deeply valued by patients and families, and it provides an opportunity for personal growth for the pediatrician.

The pediatrician may wish to continue providing care for a patient who is an adolescent or a young adult (eg, during high school and college matriculation or for older children with special health care needs) to minimize fragmentation of care. The pediatrician, the family, and the patient should discuss whether, for any reason, the patient might instead wish to change physicians. Mature patients should be encouraged to take increasing responsibility for their personal health care by communicating directly with the pediatrician and making their own appointments while informing parents of these appointments. As the new patient-physician relationship evolves, it may be appropriate to develop an option under which the adolescent can obtain confidential care if needed.[24,25]

One of the most common and difficult boundary issues occurs when a pediatrician treats his or her own family members. Because the close relationship carries a potential for the pediatrician to lose objectivity or fail to explore sensitive issues and areas with the patient, family members should be encouraged to seek another pediatrician. Exceptions include underserved areas in which there may be only 1 pediatrician, which would make this impractical, or in the case of an emergency. Regarding nonurgent care rendered to minor patients, the American Medical Association (AMA) has stated, "In particular, minor children will generally not feel free to refuse care from their parents."[19] This same concern may carry over to medical care that is provided to minors by other relatives.

Occasionally, a pediatrician may receive a gift from a patient or the parents of a patient. Small gifts given in gratitude may sometimes be accepted if they do not affect professional clinical judgment. Repeated attempts at gift-giving or the offer of expensive gifts may represent an attempt by the family to consciously or unconsciously control the patient-physician interaction. Larger or more expensive gifts are clear and serious boundary transgressions unless they are given as a charitable donation to a nonprofit institution.[26] There is also a potential conflict of interest when patients who make large contributions to medical institutions receive preferential treatment (eg, they are seen immediately, moved to the top of the operating room schedule, etc).

Privacy and Access to Health Information

Respecting the privacy of patients and their families, including protecting the confidentiality of patient information, is a central feature of professionalism in pediatric practice. The importance of privacy has been underscored by federal regulation, known as the Privacy Rule, issued pursuant to the Health Insurance Portability and Accountability Act (HIPAA).[27,28] HIPAA was intended to create national standards to protect individual personal health information and give patients or their surrogates increased access to their medical charts.

Under the HIPAA Privacy Rule, parents have new rights to control and have access to the health information about their minor children, with limited exceptions. When a minor has the right to consent to care or a parent has agreed that the minor may receive confidential care, the minor may exercise his or her own rights to access and control protected health information. However, state or other applicable law governs if it has explicitly addressed disclosure of a minor's health information or medical charts to a parent. If state or other law does not define the parent's ability to access the child's health information, a licensed health care professional is allowed to exercise discretion to grant or deny such access.

The HIPAA Privacy Rule also dictates the need for privacy regarding patient identification that extends to inpatient rounds, patient charts, and telephone and casual conversations that formerly might have been conducted in public places such as elevators and hall corridors. Teaching conferences, computerized presentations, and radiographic exhibits all must avoid the use of patient identifiers and preferentially take place in areas where strict confidentiality can be preserved. Physicians are expected to take a leadership role in safeguarding the patient's privacy in contracts and organizational policies and procedures.[27]

Advocacy

At the very heart of professionalism is the pediatrician's commitment to put the interests of children and their families above his or her own. Altruism may be the defining feature of professionalism and the one that is most at risk with the corporate transformation of American health care. In particular, managed care arrangements can intensify the inherent conflict between the health care interests of children and the pediatricians' financial interests.[29]

Financial incentives to reduce or limit access to care are viewed by many as particularly problematic[29,30] and are a source of growing distrust of both pediatricians and managed care organizations. Pediatricians must not allow financial considerations to affect clinical judgment about a child's health and welfare. Managed care, with its emphasis on primary and preventive care, has the potential to increase access to a full range of pediatric

clinicians and services but can also result in underutilization of appropriate services.[30]

Pediatricians must be advocates for their patients. They should facilitate access to appropriate and effective pediatric services and challenge treatment-authorization policies that delay or deny needed treatments, including mental health services, social work services, developmental evaluations, occupational and physical therapy, child life interventions, dental services, and vision, hearing, and speech and language services. It is permissible and even desirable for pediatricians to discuss their concerns about specific insurance policies with parents and to ask parents to help by bringing these concerns to the attention of their insurance companies to effect a resolution.

Pediatricians should exercise due diligence in contracting with payers to avoid assuming legal or financial obligations that would put them in conflict with the health and well-being of their patients.[31] Physicians are legally responsible for the claims submitted for their professional services and for the accuracy and completeness of information in the medical chart. Pediatricians should ensure that coding and billing appropriately reflect the level of services provided to the patient.[32] To do so, some pediatricians choose to implement compliance programs in accordance with the guidance from the Office of Inspector General.[33,34] If an insurance company is perceived to be conducting business unethically, it should be reported to the relevant state board of insurance.

As advocates, pediatricians play a necessary role in quality assurance. This may include the need to provide feedback to referring physicians. A pediatrician should make every effort to determine all of the facts in a specific case before making a judgment about the quality of care that was rendered by another physician, particularly if opinions are being sought by the parents. Generally, feedback can and should ultimately be provided in an educational and noncritical manner to both provider and parent. The pediatrician receiving feedback should recognize this is an opportunity for learning. Qualifying feedback as a source of continuing education rather than criticism will help pediatricians care for future patients. Pediatricians, pediatric medical subspecialists, and pediatric surgical specialists should all respect one another as critical partners in the optimal delivery of care.

Information and Education

Pediatricians should inform and educate patients and parents and help them understand clinical recommendations and make informed choices among all reasonable care options and referrals. "Gag orders" or insurance policy clauses that prohibit the primary care physician from full disclosure of medical options and/or specialty referrals are never appropriate. Pediatricians are obligated to disclose the full range of medically, scientifically, legally, ethically, and practically acceptable treatment options, even those that are not included in the family's insurance coverage and those with which the pediatrician may philosophically disagree. Health plans must disclose all relevant information about benefits, including any restrictions in coverage and financial incentives that might negatively affect a child's access to care.[35,36] Descriptions should be clear, simply written, and easy for any family to understand. It remains the obligation of parents to understand their children's insurance benefits. Pediatricians cannot and should not be expected to counsel parents on the details of their insurance plans. Parents bear the ultimate responsibility to understand who and what is covered or not covered. In the inpatient setting, social workers and case managers often can assist with these issues.

Appeals Processes

Patients and families should have access to fair appeals processes, and pediatricians should be child advocates within that system. However, health plans are not obligated to pay for treatments that are not justifiable on clinical or scientific grounds even if some patients might desire them. Pediatricians should take an active role in the development of practice guidelines and familiarize themselves with the attributes/recommendations that will enable them to distinguish medical management guidelines that are based solely on cost/utilization data from those that are based on scientific evidence.[37]

MEDICAL SCHOOL TEACHING FACULTY RESPONSIBILITIES TO RESIDENTS AND STUDENTS

The obligations of medical school academic and clinical faculty to residents and students should include:

- Instructional development of academic competency—adequate, up-to-date academic preparation of residents and students to be competent and ethically responsible pediatricians.
- Modeling appropriate behaviors—using systems or standards that nurture professionalism, interdisciplinary collaboration, respect, and partnership with child and family, including a humane working environment.
- A caring and compassionate environment for learning—active involvement in bedside teaching, with fostering of an appropriate learning environment, including faculty treatment of residents and students.
- Fair assessment processes—fair assessment of professionalism, including remedial education, and one-on-one direct oversight with interim evaluations if there are problems.

Communication

Pediatric training should focus on providing a core foundation of knowledge, attributes, skills, and competencies to all pediatric residents regardless of their future career paths. Communication is a key element of medical practice. Clinicians should be capable of effective, respectful, and compassionate 2-way communication with patients, parents, and other members of the health care team. Health care communication must be formally taught, learned, and evaluated. Students and residents should be taught the principles of cultural effectiveness to enhance their understanding of the child and family in the context of the medical home.

Modeling Appropriate Behavior

Within pediatric training programs, residency program directors and pediatric faculty members must model the professional behavior they seek to instill in their trainees. Recently, both informal and formal residency curricula have become more challenging as a consequence of the 80-hour workweek limitation on house officers. Opportunities to model behavior can occur in the clinic, at the bedside, on the telephone, or in the patient's chart. Being able to communicate clearly in the medical chart and document medical care concisely and correctly are equally important as verbal communication with families, patients, physicians, and other health care professionals. Medical liability risk managers have described this as an area of professionalism that is in need of improvement and recommend use of the acronym OLFACTORY to help physicians improve their documentation skills: O = original, L = legible, F = factual, A = accurate, C = consistent, T = timely, O = objective, R = rational, and Y = yours.[38]

Clinical teachers must teach by example and be capable of demonstrating how to manage difficulties that occur in relationships with patients, medical staff, or colleagues; effectively and compassionately communicate with patients, families, colleagues, and members of the interdisciplinary team; gracefully and honestly acknowledge errors; confront poor practice in a colleague or trainee; and explain to children and parents when things have "gone wrong." Mentors of pediatric house officers and medical students should be aware of the process of socialization that exists and the various ways that trainees learn and internalize professional and humanistic values, attitudes, and behaviors. Students and residents may be more influenced by what is known as the "hidden curriculum" (what is taught by observing the daily behavior of health care professionals, both good and bad) than by formal training in ethics, although formal curricula in both ethics and professionalism are still valuable.[39] When pediatricians behave in ways that are contrary to ethical standards taught in formal courses, they reinforce the view that medicine is a profession that lacks integrity.[40] Perhaps more importantly, when pediatricians keep silent in the face of inappropriate behavior, the implication is that the status quo is acceptable, and the opportunity to discuss the professional behavior in the clinical context is lost. Currently, unprofessional and unethical physician behavior is often tolerated when it should not be. Students and residents should be encouraged and advised to evaluate faculty members as teachers of ethics, knowledge, and attitude, and faculty members should be encouraged to evaluate each other on the basis of professionalism as well as academic productivity.

Caring and Compassion

Caring and compassion are central to the effective practice of pediatrics. Students and residents must be taught to attend to the emotional, spiritual, and practical realities of illness and its effects on children and families as well as themselves.[41] Historically, medicine has defined its mission in terms of "curing" disease while overlooking illness (ie, the patient's experience of disease). Patients and families require a caring physician who is empathetic and strives to understand the illness experience of each child and affected family. How does one teach or remediate sensitivity and caring? Personal reflection, small-group discussions,[42,43] participation in family conferences, and longitudinal experiences with families who are living with chronic illness[44] are all examples of key strategies that may be used in nurturing professionalism among trainees. More focused methods include role modeling, one-on-one discussion, closer supervision, observation of resident interactions with families under stressful situations, and feedback sessions in which the resident specifically asks for guidance about how they could or should have handled difficult interactions with parents or patients.[45] Exposure to parent panels, former patients, and siblings of patients through small-group discussion; support group attendance; grand-rounds formats; use of standardized patients in teaching venues; and supervised role-playing are other ways.[46]

Because students and residents develop their professional identities over time, professionalism should be viewed as a developmental process across all stages of a medical career.[47,48] More emphasis on stress management is essential, and incoming residents might benefit from improved orientation regarding the demands of residency and ways of coping. In addition to learning how to care for others, young physicians also must learn to care for themselves.[49] Those who have their personal needs met are, in turn, more supportive of their patients' and families' needs,[50] and this self-nurturing will promote the ability to show compassion and empathy for others.[45] Those who create pediatric training programs need to be mindful of the ways that students and residents are treated. It is more likely that pediatricians in training will become caring and compassionate toward

their patients if they feel that they are treated in a caring and compassionate manner.

Fair Assessment Processes

Students and residents are expected to treat patients, families, medical staff, and colleagues fairly. In return, they must be treated fairly in the educational system. This will require developing clear expectations for performance, providing adequate opportunities to learn expected competencies and receive clear and frequent feedback, and providing remediation when necessary.[3,51–53] There should be a safe mechanism for students and residents to appeal evaluations with which they disagree, including those related to professionalism.

Documentation of deficiencies, mentoring, and personal counseling sessions are critical in the process. The principles and practice of professionalism that are being taught must be in place continually during the process of counseling and remediation. It is inappropriate for training directors and medical school faculty members to allow residents who have failed to develop appropriate professional skills despite counseling and remediation to complete the training program and qualify for the ABP examination process.

PEDIATRICIANS' RESPONSIBILITIES TO OTHER HEALTH CARE PROFESSIONALS: TEAM RESPECT AND COMMUNICATION

Pediatricians must treat each other and all other health care professionals with integrity, honesty, and respect in their daily interactions, because effective patient care depends on effective team functioning.[54] All health care professionals share a primary bond in their mutual ethical concern for patients. Respectful treatment includes being truthful and responsible, following through on commitments, honoring the expertise of other health care professionals, being open to learn from others, and being collaborative in patient care. Pediatricians should raise concerns about trainees, colleagues, and individual health care professionals directly with the relevant parties instead of verbalizing issues in front of patients, families, and/or staff. There should be no tolerance of verbal or physical abuse on the part of either physician or staff members, because it undermines credibility and effectiveness with patients and other health care professionals.

Pediatricians also have obligations to provide appropriate supervision and referral. The AAP acknowledges the crucial role that nonphysician health care professionals play in pediatric care and stresses the importance of working collaboratively with nurses, social workers, chaplains, nurse practitioners, physician assistants, and others.[55,56] Pediatricians should respect the contributions of other health care professionals but also acknowledge the appropriate limitations and roles of these professionals. The AAP states that the relationship among pediatric professionals is one of interdependence.[56] Incorporation of the input of these colleagues into the plan of care instead of treating it as separate and unrelated ensures effective, coordinated care.

Sexual harassment in the workplace and in educational settings creates an environment that demeans people and has a negative effect on individual performance and effectiveness as well as organizational productivity and unit morale. It is incumbent on employers, organizations, and institutions to represent all their constituents, male and female, and provide education and guidance that discourages this destructive behavior. In particular, medical schools and training programs must be aware of the prevalence of the problem and have action plans available.[57]

PEDIATRICIANS' RESPONSIBILITIES TO THE PROFESSION

Peer Review

Professional self-regulation is a privilege, not a right, and has to be earned continuously to sustain public confidence in the profession.[58] Work toward a system of medical regulation that combines professional, organizational, and patients' perspectives should be aimed at making the medical profession accountable for its performance.

The use of explicit standards (such as clinical practice guidelines that are based on evidence evaluation), the adoption of collective and personal responsibility for observing standards of practice, effective local medical regulation that is based on quality reviews, a systematic process for ensuring continuing medical education, and swift and effective strategies for dealing with physician misconduct are integral to maintaining a professional practice.

Ironically, science and technology have provided the medical profession with powerful tools that empower and enable physicians to extend and improve quality of life while exposing patients to the potential for iatrogenic harm.[13] Although members of the public appreciate what medical technology can achieve, they also have heightened awareness of the risk of medical errors[59] and the historic reluctance of the medical profession to admit to these errors. Professionalism demands that each health care professional know and accept his or her own limits. It is our responsibility to be open about risks and variations in performance, to communicate effectively, to act promptly to protect pediatric patients from poor practice, and to admit to the errors that are an expected and everyday occurrence in judgment-based clinical decision-making.[13,60]

There is a general reluctance of doctors to report colleagues whose performance falls below a minimum standard because of a lack of absolute clinical guidelines, the question of what constitutes an acceptable degree of variation in practice and outcome, the influence of case mix on outcomes, and other variables. Poor performance

or substandard performance can have protean causes including stress, burnout, the effects of physical or mental illness, death of a loved one, chronic fatigue, communication or systems-of-care failure, and others. Examples include lack of attention to detail, failure to return telephone calls or pages in a timely fashion when on call, or failure to follow-up with families regarding test results when promised. Addressing these issues requires active intervention tempered by concern, compassion, and understanding, because the primary professional obligation of patient safety is at stake.

Clear evidence of what constitutes poor or unsafe practice is more certain and widely recognized. Examples include practicing medicine under the influence of drugs or alcohol or with untreated mental health disorders, falsifying medical information, or intellectual dishonesty with colleagues or patients.[19] Physicians have an ethical obligation to report such behavior in accordance with the legal requirements in each state, and the profession should show its determination to confront poor practice. Alcohol or drug impairment should be reported to the hospital's in-house impairment program, the chief of pediatrics, or the chief of the hospital staff. Some medical societies or state licensing boards have external impaired-physician programs to which individuals can be referred. Issues of incompetence and remediation should be addressed by the appropriate clinical authority. The hospital peer-review body should be notified when appropriate, and sentinel events should be discussed thoroughly and reported to the Joint Commission. A sentinel event is defined by the Joint Commission as an unexpected occurrence that involves death or serious physical or psychological injury or the risk thereof. Serious injury specifically includes loss of limb or function. The phrase "or the risk thereof" includes any process variation for which a recurrence would carry a significant chance of a serious adverse outcome. Incompetence that poses an immediate threat to the health of children should be reported directly to the state licensing board. Physicians who are under investigation or have been charged should be protected from destructive gossip and rumors, and communication should be governed by the rules of confidentiality until such charges are proven or the physician is exonerated.

We are in the midst of a professional evolution in which the language of professional quality review and improvement is replacing professional solidarity. Medical societies' ethics committees, hospital credentials and utilization committees, morbidity and mortality reviews, and other forms of peer review have long been established by organized medicine to scrutinize physicians' professional conduct. Pediatricians in both academic and private practice should welcome and support these methods of ensuring good medical practice. They balance the pediatricians' right to exercise medical judgment freely with the obligation to do so wisely, compassionately, objectively, and temperately.[19] They also demand acceptance of the tenet that mistakes happen, can affect any system and, thus, involve any doctor, have to be discussed openly, and provide critical opportunities for learning and creating systematic improvement. In states where peer review is considered "discoverable" by state law, which allows physicians who are engaged in good-faith peer-review activities to be sued after case review, the peer-review process is undermined by the lack of confidentiality, and the effectiveness of peer review is limited.

Medical Testimony

Pediatricians are often called to court to testify on behalf of children in cases of suspected abuse and/or neglect. Whether as expert witnesses or witnesses of fact, pediatricians have ethical obligations to give honest, objective, and accurate information and should not accept a commitment as an expert witness outside their defined area of expertise. When medical malpractice is an issue, an expert witness is key to ensuring a fair hearing for the physician in question as well as for the patient and family. The AAP has articulated recommendations for pediatricians who provide expert witness testimony in medical malpractice cases.[61] It is unethical for expert witnesses to base their fees for testifying contingent on the outcome of the case.[62,63] Reliable, objective, and accurate expert witness testimony and a truthful analysis of the standard of care are extremely important in pediatric cases in which juries can be manipulated out of compassion for injured children and their families.[61]

A witness of fact who, in the case of medical malpractice, is the treating physician, whether as the defendant or the previous or subsequent treating physician, has an ethical obligation to be adequately prepared and to testify honestly and truthfully to the best of his or her medical knowledge. A witness of fact is not to be an advocate or a partisan in the legal proceeding.

PHARMACEUTICAL AND OTHER INDUSTRIES AND POTENTIAL CONFLICTS OF INTEREST

Issues of professionalism and the integrity of the profession as a whole are raised when pediatricians are the recipients of special marketing incentives such as gifts and other perquisites from representatives of the health care industry. Such behavior challenges the physician's clinical objectivity[64,65] and poses a conflict of interest between the patient's welfare and the physician's financial interests. Also, issues of justice are raised as the increased costs of marketing are passed on to children and their families. Despite these concerns, the AMA acknowledges the fact that gift-giving has been a customary practice in medicine with a beneficial educational and service function to physicians and patients. The AMA recently launched an initiative to educate physicians and members of the health care industry

about the AMA guidelines on appropriate gifts from industry. The AAP has endorsed the AMA guidelines regarding gifts to physicians from industry. The AMA guidelines do not prohibit gifts outright but offer 7 basic guidelines for their appropriateness[66]:

- Any gifts should primarily entail a benefit to patients (eg, education to improve patient care) and should not be of substantial value.
- Individual gifts of minimal value should be related to the physician's work (eg, pens, notepads).
- Meetings should be primarily dedicated, in both time and effort, to promoting scientific and educational activities and discourse.
- Subsidies for meetings should be accepted by the conference's sponsor, not individual participants.
- Subsidies should not be accepted directly or indirectly to pay for the costs of travel, lodging, or other personal expenses of physicians attending conferences, including compensation for the physician's time.
- Scholarship funds are permissible as long as the selection of students is made by the academic or training institution.
- No gifts should be accepted if there are "strings attached."

The American College of Physicians took a slightly different approach in its ethics manual,[50] and strongly discouraged the acceptance of all types of individual gifts, hospitality, trips, and subsidies from the health care industry. The American Medical Student Association took the toughest policy stand on gifts from the health care industry and advocated for outright prohibition. Their recently initiated PharmFree Campaign urges medical students to take a pledge to accept no money, gifts, or hospitality from the pharmaceutical industry; to seek unbiased sources of information; and to avoid conflicts of interest in their medical education and practice.[67]

The Compliance Program for Pharmaceutical Manufacturers of the Office of Inspector General provides clear examples of the expectations regarding the manufacturers' conduct and relationships with purchasers, research funding for educational programs, and potential conflicts of interest.[68] It is advisable for physicians to heed this guidance as it pertains to the professional relationship between physicians and representatives of pharmaceutical manufacturers.

SUMMARY

The provision of health care in contemporary society is increasingly complex. Pediatricians are being asked to care for more patients with more complicated medical and social histories, using more technology, and often with less time and compensation for the care of each patient. The degree of bureaucratic oversight is growing exponentially. In the practical sense, this leaves pediatricians at risk of losing sight of what called them into the health profession in the first place—a desire to care for children and their families. This report outlines the key components of professionalism in pediatric practice in the belief that an emphasis on core professional values will serve as a moral compass in these turbulent times and will invigorate pediatric practitioners with the enthusiasm to strive to provide the quality care to which they committed and for which they trained and sacrificed when they began their medical careers.

AMERICAN ACADEMY OF PEDIATRICS

Committee on Pediatric Research

Promoting Education, Mentorship, and Support for Pediatric Research

ABSTRACT. Pediatricians have an important role to play in the advancement of child health research and should be encouraged and supported to pursue research activities. Education and training in child health research should be part of every level of pediatric training. Continuing education and access to research advisors should be available to practitioners and academic faculty. Recommendations to promote additional research education and support at all levels of pediatric training, from premedical to continuing medical education, as well as suggestions for means to increase support and mentorship for research activities, are outlined in this statement.

ABBREVIATIONS. AAP, American Academy of Pediatrics; NIH, National Institutes of Health; PROS, Pediatric Research in Office Settings.

INTRODUCTION

To promote the goal of the American Academy of Pediatrics (AAP) to advance the health and well-being of children and their families, it is necessary to enhance quality child health research in the 21st century. Pediatricians contribute significantly to child health research, and they should be supported to pursue research activities. Education in research methodology should be provided to all pediatricians-in-training, and continuing education and access to research advisors should be offered to practitioners and academic faculty. The AAP encourages efforts to identify and reduce barriers experienced by trainees, practitioners, and academic faculty pursuing research.

Approximately 10% of all graduates of pediatric residency programs pursue traditional research careers. Funding by the National Institutes of Health (NIH) to support research training in pediatrics, including individual fellowship grants, is at only 10% of the level of support provided for research training in internal medicine.[1] This discrepancy challenges the ability of pediatric departments to continue to produce pediatric scientists capable of becoming NIH-funded independent investigators[1] or investigators who are competitive for research support from other federal agencies (eg, Agency for Healthcare Research and Quality, Maternal and Child Health Bureau) and foundations. Furthermore, graduates of fellowship programs who have received research training are finding it difficult to secure the necessary resources to conduct meaningful research. Protected research time is decreased as a result of an increasing demand for clinical service and administrative responsibilities. For example, a recent survey of developmental-behavioral pediatricians showed that, even for those who had completed fellowship training, on average, only 6% of their time was spent on research activities; most of their time was spent on direct patient care.[2]

Most pediatricians choose careers as practitioners, clinician educators, or both. Research training early in their careers will facilitate an understanding of research methodologies and an ability to critically evaluate scientific papers and the evidence base for current and future clinical practice. This is required to create an evaluative culture among pediatricians.[3] As Chambers observed, "Practicing evidence-based medicine without knowing how the evidence is assembled is as absurd as managing asthma without knowledge of respiratory physiology."[4]

In many situations, the evidence base for pediatric topics is quite limited. Given adequate training and support, practitioners can be valuable contributors to this evidence base through clinical research and can participate as part-time clinical investigators. The highly successful Pediatric Research in Office Settings (PROS) network is one example of how pediatricians in practice settings have been major contributors to the expanding evidence base of clinical pediatrics.[5]

The need exists at all levels of pediatric training for education regarding the widest possible spectrum of child health research, including not only biomedical science but also epidemiology, public health, behavioral sciences, health services, prevention, quality measurement, and quality improvement. Advances in clinical medicine do not result solely from translation of advances in basic or biomedical sciences to patient care settings. The process is bidirectional, wherein knowledge gained in clinical settings also informs inquiry in the basic sciences. The recent reorganization of institutional review groups at the NIH to convene reviewers of the basic science and clinical research disciplines, as opposed to a system that promoted the review of basic science and clinical research proposals in distinct review groups, reflects the growing recognition that multidisciplinary collaboration improves the quality of all medical research. To ensure that this collaboration is productive, all pediatric clinicians and researchers will need an appreciation, and at least a limited understanding, of the full continuum of child health research.

The practice of clinical medicine and the conduct of medical research are multidisciplinary. Such a

The recommendations in this statement do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

multidisciplinary approach requires research training to provide exposure to multiple disciplines so that pediatric researchers can draw on the expertise of other professionals and contribute to ongoing research within other disciplines. Some pediatricians may benefit from seeking secondary degrees (PhD, MPH, etc) to enhance their own research capabilities.

The AAP encourages all groups involved in medical education to collaborate on the development of a curriculum in research methodology for pediatric trainees that introduces core skills of designing, conducting, and interpreting child health research. Different competencies will be required at different levels of training and practice. To be able to evaluate and use medical literature competently, all pediatricians will require a basic knowledge of scientific methods, research design fundamentals, and core statistical principles and a familiarity with related terminology. Experience in conducting literature reviews, including Internet-based searches,[6] and awareness of options for continuing medical education related to research are necessary to maintain these core competencies. For pediatricians planning to continue research activities beyond residency, additional training and experience will be required in designing research, collecting and coding data, conducting and interpreting data analyses, and communicating results and conclusions effectively through oral, written, and electronic means.

The research knowledge and skills of practitioners and academicians need to be enhanced through continuing medical education. Effective advisors must be readily available for pediatric residents, fellows, practitioners, and academicians to nurture the evolving research skills of pediatricians throughout their careers. Attention should be given to ensure that adequate access to research advisors is available for women, minorities, and other groups that are currently underrepresented in child health research.

It is a high priority to implement strategies to maximize incentives and minimize barriers to entering pediatric research careers, such as excessive debt, or to pursuing research within clinical settings, such as demands for increased clinical productivity.

RECOMMENDATIONS

Research Training Before Medical School

- Research training must begin early, ideally as a component of premedical course work.[7] Toward this goal, health researchers, including child health researchers, should encourage high school and college students to become involved in research, thereby promoting an early interest in, appreciation of, and commitment to health research. They are encouraged to use funding mechanisms provided by NIH and other funders to support such efforts.

Research Training in Medical School

- Medical schools should provide formal course work on research methods for health research; faculty from pediatric departments should be encouraged to participate in the design and teaching of such courses.
- Medical schools should consider recommending or requiring thesis projects for their students and should provide the protected time, necessary resources, and faculty advisors. Electives in research for credit (such as during the summer after the first and second year of medical school) or a year out for fellowship for medical students to permit completion of a research project are additional options that can be established to support early development of the skills needed to conduct quality research.
- Groups involved in medical education are urged to collaborate in the development of a research methodology curriculum that covers the core skills of designing, conducting, and interpreting health research that could be part of the preclinical curriculum. The curriculum should also include the ethical dimensions of research, including informed consent, protection of research subjects, conflict of interest, and patient privacy, which are relevant to a research curriculum for physicians at any level of training or practice. Federal training dollars could be leveraged to support innovation in curriculum for the integration of research education throughout the training and careers of physicians.

Research Training in Pediatric Residency Programs

- A research curriculum for pediatric residents, which can be integrated into a conference schedule, should be developed. The primary goal of this curriculum is to equip pediatric residents with the skills necessary to evaluate and use medical literature competently and should equip the resident with a basic knowledge of scientific methods, research design fundamentals, core statistical principles, and the means to conduct literature reviews.
- Pediatric residency programs should promote research electives in block rotations or as longitudinal protected time (such as 4–6 hours per week throughout the 3 years of residency) and encourage trainees to participate in a research project during their residency, as is currently required by approximately one quarter of pediatric residency programs in the United States.[8] Protected time, necessary resources, and faculty advisors are critical components in developing a research career or becoming involved in clinical research as a pediatric practitioner and should be readily available at all levels of pediatric training.
- The Residency Review Committee and the American Board of Pediatrics should review requirements for accreditation and certification and ascertain if current requirements promote attainment of necessary research knowledge.

Research Training in Pediatric Fellowship Programs

- Fellowship programs should include advanced formal course work in research methodology that covers the widest possible spectrum of child health research. A research methodology curriculum for all fellowships in pediatrics should be developed that will outline the minimal core

knowledge and skills expected of all child health researchers across subspecialties and general pediatrics to facilitate collaboration and to improve the quality and practical relevance of research conducted.
- Programs should assign all fellows to work with experienced faculty research preceptors. As recommended by Kelch and Novello,[9] programs should consider establishing a research advisory committee, similar to a doctoral thesis committee, to provide guidance to the trainee.
- To support mentorship, federal training grants should provide faculty salary support in addition to trainee stipends. Institutions applying for fellowship training support should describe their plans for mentorship activities. Federal agencies can develop means to offer, and perhaps even require, formal training for proposed research mentors as part of their agreement for funding fellowship programs.[10]

Research Training Within Continuing Medical Education

- For continuing education of practitioners and academic faculty, centers of excellence and professional organizations can establish training programs in which intensive, brief training in research methodology is provided.
- Opportunities for pediatric practitioners to participate in research activities should be expanded. Practice-based research networks, such as PROS,[5] as well as research mentoring programs (such as the recently created AAP research mentorship program for primary care pediatricians) are already affording many practitioners this opportunity. Efforts like these should be further promoted and expanded to reach practitioners previously underrepresented in these activities, especially those who care for minority and underserved populations.

Loan Forgiveness and Research Support

- Programs should be developed that provide federal support for repayment of educational debt for physicians pursuing careers in child health research[11,12] similar to those currently in place for physicians who practice clinical medicine in underserved communities or physicians who research acquired immunodeficiency syndrome, infertility, or contraception.
- Mechanisms should be developed for distribution of federal research funds to academic centers for start-up funding of child health research, especially for junior investigators.
- Secure and sustained resources need to be identified to cover costs of research education at all levels, including subsidizing faculty time, space, supplies, and equipment.
- Innovative means to promote financial support for child health research should be pursued. Because child health research is central to efforts to improve quality of medical care, mechanisms need to be explored by which managed care companies and health insurers could be encouraged to invest in health research generally, and particularly in child health research activities.
- Professional organizations providing oversight for training of pediatricians and major federal funders of child health research (eg, NIH, Health Resources and Services Administration, and Agency for Healthcare Research and Quality) should collect data to monitor the quality of pediatric research training, the number of pediatric researchers completing training and their productivity as researchers, and the level of support for child health research activities to ensure that there is ongoing progress in these areas. Training institutions and individual trainees should appreciate the importance of collaborating in these efforts.

CLINICAL REPORT

Promoting the Participation of Children With Disabilities in Sports, Recreation, and Physical Activities

Guidance for the Clinician in Rendering Pediatric Care

Nancy A. Murphy, MD, Paul S. Carbone, MD, and the Council on Children With Disabilities

ABSTRACT

The benefits of physical activity are universal for all children, including those with disabilities. The participation of children with disabilities in sports and recreational activities promotes inclusion, minimizes deconditioning, optimizes physical functioning, and enhances overall well-being. Despite these benefits, children with disabilities are more restricted in their participation, have lower levels of fitness, and have higher levels of obesity than their peers without disabilities. Pediatricians and parents may overestimate the risks or overlook the benefits of physical activity in children with disabilities. Well-informed decisions regarding each child's participation must consider overall health status, individual activity preferences, safety precautions, and availability of appropriate programs and equipment. Health supervision visits afford pediatricians, children with disabilities, and parents opportunities to collaboratively generate goal-directed activity "prescriptions." Child, family, financial, and societal barriers to participation need to be directly identified and addressed in the context of local, state, and federal laws. The goal is inclusion for all children with disabilities in appropriate activities. This clinical report discusses the importance of physical activity, recreation, and sports participation for children with disabilities and offers practical suggestions to pediatric health care professionals for the promotion of participation.

THE BENEFITS OF physical activity are universal for all children, including those with disabilities. Although ~18% of children and adolescents in the United States have a chronic condition or disability, opportunities for their participation in fitness and activity programs, whether for leisure, recreation, or competition, are limited.[1] International efforts to promote the social and emotional well-being of children with disabilities through participation in recreational sports and physical fitness activities began with the first competitive sporting event for individuals with disabilities in 1948, followed by the first Paralympics competition in 1960, and the establishment of the Special Olympics in 1968.[2] The Special Olympics is now the largest recreational program for children with intellectual disabilities, with >1 million athletes in 125 countries.[3] Despite these efforts, children with disabilities have lower levels of cardiorespiratory fitness, lower levels of muscular endurance, and higher rates of obesity than typical children. In addition to the physiologic benefits of decreased body fat and increased fitness overall, regular physical activity for children with disabilities has been shown to help in controlling or slowing the progression of the chronic disease, improving overall health and function, and mediating the psychosocial impact of the condition on children and their families (J. H. Rimmer, PhD, written communication, 2007). Pediatricians and other medical home professionals may overestimate the risks or overlook the benefits of physical activity in children with disabilities. Parents often seek information about recreational opportunities, but some pediatricians are relatively unaware of the value of these opportunities for children with disabilities.[4] This clinical report discusses the importance of physical activity, recreation, and sports participation for children with disabilities and offers practical suggestions to pediatric health care professionals for the promotion of participation.

BENEFITS OF SPORTS PARTICIPATION

The term "participation" is defined by the World Health Organization as the nature and extent of a person's involvement in life situations and includes activities of self-care, mobility, socialization, education, recreation, and community life.[5] Participation in activities is the context in which people form friendships, develop skills and competencies, express creativity, achieve mental and physical health, and determine meaning and purpose in life.[6] Children with disabilities tend to be more restricted in their participation than their peers: a gap that widens as children become adults.[7] One way in which health care professionals can assist children with disabilities to

participate fully in the lives of their families and communities is by promoting participation in sports, recreation, and physical activities in the least restrictive environment.

The primary goals for increasing physical activity in children with disabilities are to reverse deconditioning secondary to impaired mobility, optimize physical functioning, and enhance overall well-being. Regular physical activity is essential for the maintenance of normal muscle strength, flexibility, and joint structure and function and may slow the functional decline often associated with disabling conditions.[8] Children with cerebral palsy (CP) are significantly weaker than age-matched controls, and strengthening and weight-bearing programs are recommended.[9] Moreover, female adolescents with CP have a lower self-concept than their counterparts without disability in the domains of physical appearance, social acceptance, athletic competence, and scholastic competence.[10] Adequate levels of muscular strength and endurance are associated with increased bone mass, reduction in injury from falls, and a greater ability to complete activities of daily living.[9,11] A strength-training program for young patients with CP demonstrated increased strength, improved mental well-being, and better overall function.[12] Another example is that of children with Down syndrome; although they have less muscle strength than typical children, they show increased exercise endurance and work capacity after participation in a specialized aerobic training program.[13]

The current epidemic of obesity associated with inactivity is a global health care concern for all children, including those with disabilities.[14] Children with disabilities are more likely than other children to be sedentary, placing them at higher risk of obesity and associated health conditions.[15] In fact, children with certain developmental disorders have higher prevalences of being at risk of overweight and being overweight than do children without developmental disorders.[16] Physical consequences of inactivity for persons with disabilities include reduced cardiovascular fitness, osteoporosis, and impaired circulation. In addition, the psychosocial implications of inactivity include decreased self-esteem, decreased social acceptance, and ultimately, greater dependence on others for daily living. Overall, the participation of children with disabilities in sports and physical activities can decrease complications of immobility.

Sports participation enhances the psychological well-being of children with disabilities through the provision of opportunities to form friendships, express creativity, develop a self-identity, and foster meaning and purpose in life.[17] Special Olympics participants show heightened self-esteem, perceived physical competence, and peer acceptance when compared with nonparticipants.[18] Parents of Special Olympians reported that their child's participation promoted social adjustment, life satisfaction, family support, and community involvement.[19] Such events provide a much-needed venue for informal peer support and sharing of experiences among families of children with disabilities.[20] Mildly strenuous exercise has been shown to reduce stereotypic movements, maladaptive behaviors, and fatigue in children with autism and other developmental disabilities.[15,17,21] Last, participation in regular physical activity can foster independence, coping abilities, competitiveness, and teamwork among children with disabilities.[22]

PREPARTICIPATION CONSIDERATIONS

Currently, a wide variety of sporting activities are accessible to children with disabilities, and guidelines are available to assist pediatricians in recommending activities appropriate for children with specific conditions.[23] The American Academy of Orthopedic Surgeons has developed a "participation possibility chart" that outlines sporting options for individuals with the most frequently occurring physical disabilities.[13] For example, it is recommended that children with Down syndrome, after being screened radiographically for atlantoaxial instability, participate in sports they enjoy, with the exception of those that involve contact or collision.[24] Similarly, children with asthma should have readily available medications for use before participation as needed and should be permitted to modify participation as needed for airway exacerbations or environmental conditions without negative ramifications. Rather than exclusion from sports participation, the goal is inclusion for all children with disabilities in appropriate activities. It is important that children are empowered with an "I can do" attitude rather than discouraged by the message "you can't do that."[2]

Properly designed and implemented programs of sports and physical activities for children with disabilities should target cardiovascular endurance, flexibility, balance, agility, and muscular strength and accessibility, safety, and enjoyment.[8] Strategies to minimize the risks of illness or injury to children with disabilities during sporting activities should be implemented before participation. Exercise that is of longer duration, greater frequency, and lower intensity compared with programs for typically developing children is recommended.[8] In the example of an adolescent with a cervical spinal cord injury, participation in wheelchair rugby should be permitted only after the athlete, parents, and coaches can readily recognize acute sweating, sudden and often severe headache, apprehension, and hypertension as autonomic dysreflexia and quickly identify and remove the triggering factor(s).[22] Latex-safe environments should be provided, and resuscitation medications should be readily accessible when children with spina bifida (25%–65% prevalence of latex allergies) are participating.[22]

Children with neurodevelopmental disabilities often demonstrate abnormalities of thermoregulation secondary to impaired vasomotor control, decreased muscle mass, and impaired central temperature-regulating mechanisms.[22] Anticholinergic medications may further increase the risk of hyperthermia in children with spinal cord injuries. Approximately one half of athletes in a Junior National Wheelchair Games competition experienced hyperthermia, and 9% of swimmers in the same study experienced hypothermia.[22] Careful attention must be directed at proper training, hydration, clothing,

and equipment. Some children with disabilities have impaired motor coordination, decreased endurance, limited mechanical efficiency, and osteopenia, factors that can predispose to musculoskeletal injuries and overuse syndromes. For example, athletes in wheelchairs have increased rates of shoulder overuse injuries and carpal tunnel syndrome.[2] Pediatricians are encouraged to access published resources for sports-specific and condition-specific guidelines regarding the participation of children with disabilities in sports and physical activities.[25]

Health supervision visits afford pediatricians, children with disabilities, and parents with opportunities to collaboratively generate goal-directed activity "prescriptions." The longitudinal relationship between the pediatrician, child, and family provides a broad and deep understanding of the implications of participation for each child. Conditions that may limit a child's participation or predispose the child to injury, individual preferences, and the availability of appropriate local programs must be individually considered. The child's current health status, the level of competition, the specific sport and position to be played, availability of protective or adaptive equipment, whether the sport can be modified to allow safer participation, and the ability of child and parent to understand and accept the risks involved must all be addressed before participation.[23]

For example, a child with autism and communication impairments might struggle with verbal instructions from coaches during certain team sports and benefit more from participation in individual sporting activities. Because standardized preparticipation forms may not adequately communicate the issues involved in safe participation for children with disabilities, alternative forms have been developed.[2] Overall, the sports preparticipation evaluation for children with disabilities may not occur in the context of a single office visit, but rather, over a period of time with input from physicians, coaches, physical education teachers, physical and occupational therapists, and others. The American Academy of Pediatrics policy statement on care coordination for children with special health care needs provides guidance on the complexities of this process.[26] With the proper guidance, the risk of injury to physically challenged children is no greater than that to athletes without disability.[22]

What Determines Participation?

The most frequently identified barriers to the active participation of children with disabilities in sports and physical recreation are the child's functional limitations (18%), high costs (15%), and lack of nearby facilities or programs (10%).[27] In fact, adolescents with disabilities cited the cost of specialized equipment as the most frequent reason for nonparticipation.[27] Participation is further influenced directly by time, the home environment, and the child's perceived self-competence and indirectly by social support from schools and communities, family demographics, and family and child preferences.[27] Families who engage in physical activities themselves tend to promote similar participation for their children with disabilities.[14,27] Moreover, inactive role models, competing demands and time pressures, unsafe environments, lack of adequate facilities, insufficient funds, and inadequate access to quality daily physical education seem to be more prevalent among populations with special needs.[14] Overall, environmental and family factors seem to be more significant determinants of participation than characteristics of the children themselves.[27] The establishment of short-term goals, emphasizing variety and enjoyment, and positive reinforcement through documented progress toward goals can help spark and sustain the motivation for participation.[8]

Many individuals with disabilities are still, to a large extent, socially segregated and experience negative societal stereotypes and low performance expectations, rendering them with limited opportunities for participation in group physical activities.[27] These attitudinal barriers in the community contribute to a lack of awareness regarding current programs and opportunities for participation. Although specialized programs are beneficial, the participation of children with disabilities with other children in community activities can reduce societal barriers. It is a common misconception that children with disabilities are susceptible to trauma and, therefore, should avoid rigorous sporting activities that are typically associated with injury. Although athletes with disabilities have rates of injury similar to those of other athletes, fear of injury frequently remains a barrier to participation. Overall, misconceptions and attitudinal barriers at the level of the individual, the family, and the community need to be addressed to integrate children of all abilities into recreational and sports activities.

The Right to Participate

Federal laws exist to protect the rights of children with disabilities to participate in sports and physical activities. The Individuals with Disabilities Education Act mandates free, appropriate public education in the least restrictive environment. Section 504 of the Rehabilitation Act of 1973 states that no individual shall be excluded because of disability in programs that receive federal funds.[28] Physical education is a federally mandated component of special education services, including the promotion of physical and motor fitness, fundamental motor skills, and skills in individual and group games and sports.[29] Pediatricians and parents of children with disabilities can advocate for programs of adapted physical education and recreation in each child's individualized education plan.[17] Schools are required to modify programs or activities according to the abilities of each child. Students with disabilities have the same right as all students to compete for inclusion on interscholastic teams that use performance criteria to determine who will participate.

Although national initiatives from the US Department of Health and Human Services (*Healthy People 2010*),[30] the Centers for Disease Control, and the American Academy of Pediatrics stress the daily participation of all students in programs of physical education, this

goal remains unmet. In fact, according to a 2000 study, only 8% of American elementary schools, 6.4% of middle schools, and 5.8% of high schools with existing physical education requirements provided daily physical education classes. More than three fourths of elementary, junior/middle, and senior high schools allow students to be exempted from required physical education; cognitive and physical disabilities are among the most common reasons for these exemptions.[31] The combined advocacy efforts of well-informed pediatricians, parents, educators, and others are needed to ensure and promote the participation of all children in sports and physical activity programs, each according to his or her abilities.

ADVICE FOR PEDIATRICIANS

Overall, it is important for pediatricians to:

1. Understand the benefits of the participation of children with disabilities in sports and physical activities.
2. Perform preparticipation evaluations for children with disabilities in collaboration with the child and family, pediatric specialists, therapists, coaches, and others.
3. Identify strategies to minimize risks of illness and injury related to participation through activity adaptations and safety precautions.
4. Recognize and reduce child, family, and societal barriers to the participation of children with disabilities in athletics.
5. Advocate for the participation of all children, including those with disabilities, in sports and physical activity programs.
6. Be aware of resources regarding appropriate sports and physical activity programs for children with disabilities in their local communities. The National Center of Medical Home Initiatives for Children with Special Needs (www.medicalhomeinfo.org/health/recreation.html) reviews the benefits of recreation for children with disabilities, provides information on national initiatives, and identifies Web sites of organizations such as Special Olympics and the National Center on Physical Activity and Disability.[32]

SUMMARY AND CONCLUSIONS

All children benefit from physical activity, and children with disabilities are no exception. Participation of children with disabilities in sports and physical activity programs promotes physical, emotional, and social well-being. Well-informed decisions regarding each child's participation must consider overall health status, individual activity preferences, safety precautions, and availability of appropriate programs and equipment. Child, family, financial, and societal barriers to participation need to be directly identified and addressed in the context of local, state, and federal laws. Pediatricians are urged to promote the participation of children with disabilities in competitive and recreational sports and physical activities. The benefits are substantial.
