Management includes the use of systemic antibiotics, local heat and massage, fluids, and sialogogues (lemon juice, sour candy). Penicillinase-resistant antistaphylococcal antibiotics are recommended to cover gram-positive and anaerobic organisms until culture results return. Rarely, patients not responding to initial therapy may require intravenous antibiotics and hospitalization. Screening for immunocompromised states is thereby recommended. Bacterial disease not responding to standard therapy should also be evaluated for underlying granulomatous or neoplastic processes including mycobacterial infections, cat-scratch disease, and lymphoma.

Abscess

Persistent inflammation, hyperpyrexia, and progressive edema overlying the parotid gland suggest the possibility of an abscess. The gland will not be fluctuant until late in abscess formation because of the numerous fascial investments within the gland. Ultrasonography can help diagnose and potentially guide FNA of a parotid abscess, so it should be employed initially in these cases. Significant involvement of adjacent structures or evidence of deep soft tissue disease warrants a CT examination of the head and neck. If an abscess is identified, surgical incision and drainage is appropriate. Drainage is accomplished through a standard parotid incision along the preauricular crease, raising a skin flap, and then opening the superficial glandular fascia parallel to the branches of the facial nerve. Drains should be placed, and the wound closed loosely to heal by secondary intention. One must observe for spread of disease into the contiguous fascial spaces of the neck and mediastinum.

Submandibular abscesses are frequently associated with proximal ductal sialolithiasis. Rapid enlargement of the submandibular triangle suggests diffuse disease within this confined space. Patients will complain of submandibular and floor-of-mouth pain shortly after a meal. Extension beyond the submandibular space can lead to Ludwig's angina and airway obstruction and should be treated urgently. Removal of the involved gland is recommended therapy with drainage of the overlying abscess within the submandibular and sublingual fascial compartments. Airway status and the need for temporary tracheotomy should be evaluated when managing patients with Ludwig's angina.

Recurrent Sialadenitis

Repeated infections of the salivary glands have been shown to cause ductal metaplasia, parenchymal restructuring, and an increase in mucin production and quantity of viscous secretions that can lead to recurrent salivary stasis. Patients with recurrent disease present with low-grade edema and tenderness of the gland with slightly purulent secretions. Unfortunately, once the glandular architecture is altered, opportunistic oral flora are more likely to cause recurrent disease. These patients are frequently chronically infected with various organisms, and immunologic dysfunction such as IgA deficiency appears to play a role in its development.[27,28] Broad-spectrum antibiotics should be used and measures to increase salivary flow and reduce viscosity need to be instituted. Ductal dilatation may improve cases of recalcitrant disease. Gland excision remains the last resort for treatment. Although the most effective

and reliable mode of therapy is parotidectomy, many surgeons delay definitive surgery for fear of injuring the facial nerve during surgical dissection. A total parotidectomy with facial nerve preservation is appropriate for recurrent parotitis because superficial parotidectomy alone is thought to increase the risk of recurrent disease.

Neonatal Sialadenitis

Neonatal sialadenitis is more common in the parotid gland than in the submandibular gland. Possible causes of neonatal sialadenitis are anatomic deformities of the oral cavity, dehydration, sialolithiasis, and prematurity. Approximately 40% of neonates with parotitis are premature. The most common organism in neonatal sialadenitis is *S. aureus.* Other organisms identified are *E. coli, Pseudomonas aeruginosa, Moraxella catarrhalis,* and various streptococci. The salivary secretions should be cultured and a Gram stain obtained. The disease is usually limited to a single gland and signs and symptoms of systemic disease may not be seen. Diagnosis is confirmed by physical examination when a warm, tender, erythematous mass is palpated and pus is expressed from the accompanying salivary duct. Appropriate antimicrobial therapy and adequate hydration result in resolution of the disease in less than 1 week. Recurrence is uncommon.[29] Lymphadenitis of nodes surrounding the parotid or submandibular gland, or both, can mimic sialadenitis. This may be difficult to determine on physical examination. Ultrasonography is helpful in cases not responding to conservative medical management (hydration, antibiotics). Infections involving the scalp, face, or nasopharynx need to be considered.

Viral sialadenitis is seen infrequently during the perinatal period but may occur when there is maternal transmission of virus. This is influenced by the onset of maternal disease, the mode of transmission (transplacental or at delivery), the type of virus, and the host's defenses. A mumps infection in the newborn can range from mild to severe and careful observation is necessary. Cytomegalovirus is another potential viral source of sialadenitis in newborns. Diagnosis can be determined by urine examination. However, its course may be devastating and should be considered early in infants with salivary inflammation. Clearly, infants with suspected viral sialadenitis should be isolated from other newborns.

Necrotizing Sialometaplasia

Necrotizing sialometaplasia is a benign, self-healing (reactive) inflammatory process of salivary gland tissue that clinically and histologically mimics a malignant neoplasm. It most commonly affects adults but has been reported in adolescents. It arises in mucus-secreting cells and can be found in the parotid gland, sublingual gland, hard and soft palates, and lower lip. Its clinical appearance ranges from minor submucosal edema with overlying erythema to an erosive ulcer. It usually presents as a painless ulcerated lesion or a nodular swelling. Most cases involving the extrapalatal minor salivary glands and major salivary glands are iatrogenically induced after surgery, trauma, or radiotherapy, with a mean duration of 18 days from the insult to the development of the lesion. In the major salivary glands, necrotizing sialometaplasia occurs secondary to focal lobular sialadenitis and prior surgical manipulation.[25,30] Typically, the process appears as a 1- to 3-cm crater-like ulcerative lesion. Histologically, lobular necrosis is present with pools of mucin that elicit a granulation tissue reaction with associated acute and chronic inflammation. In addition, extensive squamous cell metaplasia is present. The lesion heals spontaneously in 6 to 12 weeks. Although total excision of the lesion may be carried out as definitive therapy, it is not necessary or indicated.[30]

Granulomatous Disease

Granulomatous diseases are characterized by intense inflammatory reactions, sponsored by the host, around a central pathogen or antigen within one or more organ systems. Granulomatous processes, despite the etiology, rarely involve the salivary system. However, several pathogens causing granulomatous inflammation of the major salivary glands have been identified. In particular, actinomycosis, tuberculosis, atypical mycobacterial infections, and sarcoidosis have all been implicated. Their incidence in children remains unknown, but they are considered unusual. In these conditions, salivary gland involvement is often the result of inflamed periglandular lymph nodes. Regardless, granulomatous diseases should be included in the differential of pediatric patients with atypical and chronic salivary gland inflammation.

Mycobacterial

Nontuberculous mycobacterial infections of the salivary glands are most frequently seen in children. The average age at presentation is 16 to 36 months. Cervicofacial lymphadenitis is the most common manifestation. *Mycobacterium avium-intracellulare* accounts for 70% to 90% of cases. Involvement caused by *Mycobacterium bovis* has become less common since the widespread pasteurization of milk. Infection may occur by *Mycobacterium kansasii* and *Mycobacterium scrofulaceum.*[31] Periparotid and submandibular lymph nodes are frequently involved with the formation of cutaneous sinus tracts (Fig. 201-5). The Mantoux test will likely be weakly positive, whereas chest radiography is generally normal. Diagnosis is based on clinical judgment and exclusion of other diseases. FNA may help to rule out an abscess; however, culture results can take 6 weeks until an organism is seen. Management of nontuberculous mycobacterial infections may be conservative but usually requires surgical removal of the disease process. If the parotid gland is affected,

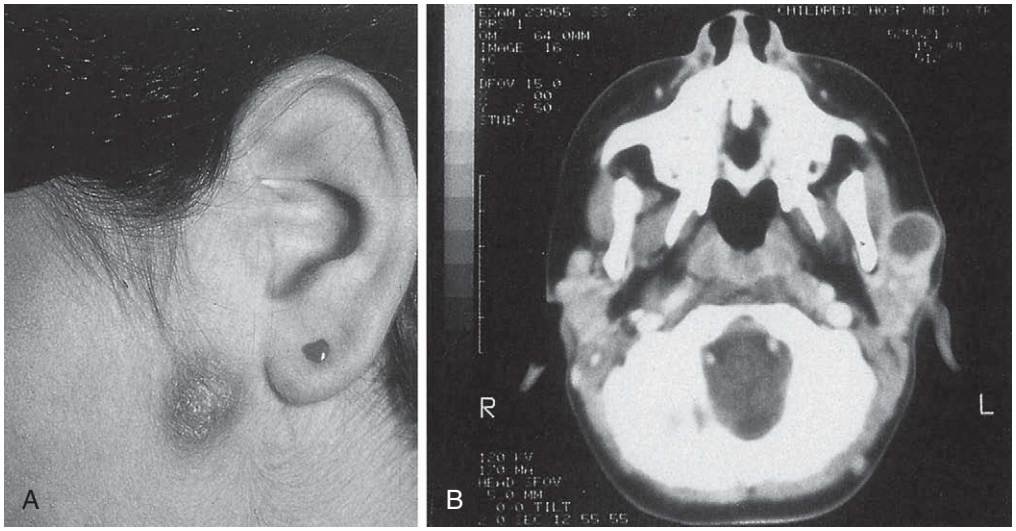

Figure 201-5. **A,** Patient with an atypical mycobacterial infection involving the parotid gland. **B,** Computed tomography with contrast of the same patient. Notice the rim-enhancing parotid lesion.

a superficial parotidectomy with facial nerve preservation is necessary. Removal of involved skin is often necessary during excision. Antituberculous drugs have not been effective in managing this condition. Use of a macrolide (e.g., clarithromycin) as an adjunct to surgery, especially in cases of incomplete excision, appears to be effective in some cases.

Primary tuberculosis of the salivary system is uncommon. No more than 100 cases affecting the salivary glands have been reported, but this disease entity should always be considered in patients with a slow-growing firm to hard nodular mass.[32] The parotid gland is most frequently involved and the disease generally stays unilateral. Primary tuberculosis parotitis is thought to develop from disease spreading via fascial communication with infected tonsils or teeth. Diagnosis may occur by FNA with aspirated material of the involved gland revealing *Mycobacterium tuberculosis* var. *hominis*. Polymerase chain reaction (PCR) testing of FNA contents has proven useful in difficult-to-diagnose cases. Treatment usually involves typical systemic antituberculosis drugs, but excision is frequently curative.

Actinomycosis

Actinomycosis is an infectious disease caused by a gram-positive anaerobic organism. Occurrence is usually in the cervicofacial region and frequently involves the salivary glands. Infections often follow dental extraction or oral trauma. The precipitating event allows mucosal invasion of the organism and a slowly progressive inflammatory reaction. Typically, patients have a painless, indurated enlargement of the gland that mimics a neoplasm. Lymph node necrosis characteristically leads to multiple draining cutaneous fistulae. FNA or fistulous tract drainage culture will reveal characteristic sulfur granules and gram-positive rods. Biopsy specimens are often multiloculated abscesses with whitish-yellow pus. Anaerobic cultures are positive. Management is with penicillin and consists of a 6-week parenteral course followed by 6 months of oral administration.[33] Cure rates approach 90%.

Sarcoid

Sarcoidosis is an idiopathic granulomatous disease. Sarcoidosis is less common in children but, when present, occurs in the second decade of life. It presents with bilateral diffuse enlargement of the parotid glands. Uveoparotid fever (Heerfordt's syndrome) is a form of sarcoidosis characterized by uveitis, parotid enlargement, and facial paralysis. Symptoms may include fever, malaise, weakness, nausea, and night sweats. Chest radiography looking for hilar adenopathy and an acetylcholinesterase level will assist with the diagnosis. A biopsy from the lip or tail of the parotid will confirm the diagnosis. The disease is self-limited, so no specific management is necessary with regard to salivary gland disease. Systemic involvement or complications may necessitate corticosteroid use.

Autoimmune Disease

Benign Lymphoepithelial Disease

Benign lymphoepithelial disease is typically seen in children older than 5 years of age. Although the cause is unknown, an autoimmune mechanism is suspected. It is characterized by unilateral or bilateral enlargement of the major or minor salivary glands or lacrimal glands.[34] Salivary gland enlargement in children with benign lymphoepithelial disease is usually sudden and is characterized by a tender gland accompanied by a fever. It persists for a variable length of time. In some cases, episodes of swelling are recurrent and the gland can remain enlarged. The condition usually resolves spontaneously during adolescence.

Benign lymphoepithelial disease is managed in an identical fashion to acute sialadenitis when purulent secretions are present. With recurrent disease, sialectasis and, rarely, cavitary changes can be shown on CT sialography or MRI. Medical therapy is appropriate unless cavitary changes occur, whereby the gland should then be removed. If an affected gland develops nodularity, distinction from a neoplasm is necessary. If FNA cannot differentiate the two, surgical excision is required.

Sjögren's Syndrome

Primary Sjögren's syndrome in children is uncommon. Sjögren's syndrome is characterized by lymphocyte-mediated destruction of the exocrine glands leading to xerostomia and keratoconjunctivitis sicca. Symptoms include burning oral discomfort and a sandy sensation in the eye. Patients with Sjögren's syndrome have a greater incidence of recurrent parotitis. If a child has recurrent parotitis and a history of dry eyes or xerostomia, further evaluation is indicated. Immunologic tests for antinuclear antibodies and antibodies to Sjögren's syndrome antigens A and B (SS-A and SS-B) are present in 50% to 80% of infected individuals. The sialographic abnormalities show varying degrees of sialectasis. This entity involves the minor salivary glands in 70% of patients and a diagnosis can be obtained with a labial, palatal, or tail of parotid biopsy. Management is symptomatic. In adults, this lesion is associated with an increased incidence of lymphoma.

Chronic Sialadenitis

Chronic inflammatory disease of the salivary glands, also known as *sialectasis,* is associated with repeated episodes of acute sialadenitis and subsequent obstruction of the glandular drainage pathway. The primary causative event is considered to be lowered secretion rate and salivary stasis. Chronic obstructive sialadenitis is associated frequently with salivary duct strictures or sialolithiasis. The strictures may have several causes including recurrent infection, trauma, neoplasms, or congenital abnormalities. Regardless of the cause, progressive dilation and sacculation of the salivary ductal system can lead to chronic uniglandular enlargement. This condition can lead to permanent damage to the gland with ductal ectasia, progressive acinar destruction, and lymphocytic infiltrate.[35]

A child with chronic sialadenitis usually presents with diffuse enlargement of a salivary gland. Massage of the gland will usually produce only small amounts of saliva at the duct orifice. Recurrent swelling will occur during eating, which is followed by gradual relief as emptying of the gland occurs over a 2-hour period. Over time, xerostomia becomes a complaint in up to 80% of patients. A stricture may sometimes be identified by sialography showing ductal dilation proximal to the stricture and delayed emptying of the ducts. Simple dilation or incision may correct the stricture. Repair of the parotid duct requires more elaborate surgery with a higher risk of failure. If a stricture is not found, chronic conservative therapy (sialogogues, massage, and antibiotics) will frequently control disease and prevent progression. When conservative measures fail, excision of the submandibular or parotid gland with facial nerve preservation is occasionally required. Chronic recurrent parotitis may lead to development of a benign lymphoepithelial lesion that may need removal for cosmetic reasons.

Juvenile Recurrent Parotitis

Although rare, juvenile recurrent parotitis (JRP) is the second most common inflammatory condition of the parotid gland next to mumps. It is marked by recurrent pain and swelling of one (60%) or both (40%) parotid glands that can have associated systemic features of fever and malaise. Xerostomia may be present as well. Nonpurulent secretions can be elicited from the parotid duct and set this disease apart from recurrent bacterial parotitis. The age of onset appears bimodal, with peak incidence around 3 to 6 and 10 years of age.[36] A decrease in the frequency of infections is observed during adolescent years.

Thought to be associated with nonobstructive sialectasis within the gland, JRP should be managed nonsurgically with conservative therapy such as analgesics, sialogogues, oral rinses, warm compresses, parotid massage, and antibiotics directed toward oral flora. JRP is an international phenomenon, but no consensus of etiology has been established. Causative factors may be congenital aberrations of the ductal architecture, autoimmune disease, genetic predisposition, allergy, or occult viral and bacterial infections. Regardless, ultrasound and sialography have been shown to help delineate JRP from other parotid entities. The heterogeneous echoes of JRP identified by ultrasound differ from the homogeneous echogenicity of parotid glands infected by mumps. Sialectasis identified by sialography or MRI supports the diagnosis.

Sialolithiasis

Salivary gland ductal calculi are unusual in children but should be considered in patients with chronic or recurrent salivary gland inflam-

mation. Retrospective reviews suggest that only 3% to 13% of cases of sialolithiasis occur in the pediatric population. The average age of onset in this group is 12 years, with only rare presentations in children younger than 10 years old. As in adults, more than 90% of cases involve Wharton's duct of the submandibular glands, whereas calculi within Stensen's duct or the parotid gland are extremely unusual.[37] Salivary gland calculi form by deposition of calcium salts, predominantly calcium phosphate, around a central organic nidus (e.g., desquamated epithelial cells, bacteria, foreign body). Bacterial infection may initiate the process due to changes in pH, fluid composition, and ductal morphology. The submandibular glands release alkaline and viscous secretions that must traverse a long, tortuous, and narrow duct against gravity before entering the oral cavity. This leads to increased fluid stasis and susceptibility to calculi formation in contrast to the parotid gland, which expels serous material from a relatively short, broad, and dependent cannula.

Signs and symptoms of sialolithiasis in children are of shorter duration but more common than that seen in adults. Glandular pain and postprandial swelling are significant indicators of disease. In contrast to bacterial sialadenitis, purulent discharge is uncommon (2% to 12% of cases). Ductal obstruction leads to tenderness and inflammation of the involved gland. Symptoms increase with enlargement of the stone, ultimately requiring medical attention. Fevers may be present, too. In children younger than 10 years of age, tenderness is more often intraoral. A single calculus less than 1 cm in diameter within the distal aspect of the involved duct is generally the rule in children.[37] Often this can be palpated by bimanual examination and makes extraction easier. If necessary, dental occlusal radiographs and ultrasonography allow visualization and confirm the presence of calculi along the submandibular duct or parenchyma.

Management of a calculus near the orifice of the submandibular duct can be performed by probing the duct or through a small intraoral incision. If the calculus is positioned in the parenchyma of the submandibular gland, gland removal is required. During excision, the duct should be ligated as close to the mouth as possible to prevent infection of the ductal remnant. Parotid calculi near the orifice of the duct can be removed intraorally, but the duct should be repaired and stented to prevent postoperative stricture. If a calculus within the parenchyma of the parotid gland causes persistent symptoms, a parotidectomy, with facial nerve preservation, may be required.

Sialendoscopy is a novel option in addressing pediatric salivary gland stones. Endoscopes approaching 1.1 mm in size are now available. The endoscope constitutes two channels, one for the irrigation and the other for endoscopy. Continuous irrigation during endoscopy is required to maintain duct patency following standard dilatation. Wire baskets, YAG laser, and lithotripsy have proven effective in treating small obstructing stones from the salivary duct orifice of adult patients.[12] Some evidence suggest the applicability of sialendoscopy in children.[13,38]

Cysts and Mucoceles

Acquired

Acquired salivary cysts may be associated with neoplasms, benign lymphoepithelial lesions, trauma, parotitis, calculi, duct obstruction, or mucus extravasation. Mucous retention cysts usually involve the minor salivary glands and are commonly seen on the lips, buccal mucosa, and tongue. These true cysts with an epithelial lining result from duct obstruction. A ranula is a mucous retention cyst of the sublingual gland and is described as plunging when it extends from the floor of the mouth through the mylohyoid musculature into the neck. Mucoceles, in contrast, are not true cysts and do not contain an epithelial lining. Mucoceles represent mucous extravasation into the surrounding soft tissue. If necessary, management of mucous retention cysts and mucoceles is by excision or marsupialization.

Congenital

Congenital salivary gland cysts can be classified into dermoid cysts, congenital ductal cysts, and branchial cleft anomalies. Dermoid cysts characteristically contain white keratinizing squamous epithelium that is apparent on excision. These cysts are composed of elements from all three germinal layers. Dermoid cysts usually appear as isolated masses within the substance of the parotid gland. Total removal is necessary to prevent recurrence. This is best accomplished by a subtotal parotidectomy with facial nerve preservation. Congenital ductal cysts most commonly occur within the parotid gland and are rare at other salivary locations. In contrast to dermoids, congenital ductal cysts generally manifest in infancy as enlargement of the parotid gland. The diagnosis can be confirmed with sialography and observation is advised unless recurrent infections occur.

Derivatives of embryologic branchial clefts can also emerge within or adjacent to major salivary glands. The parotid gland is often involved when a first branchial cleft anomaly is present. These can be either type 1 or type 2 first branchial cleft anomalies, which are defined by their location and presence of ectoderm, with or without mesoderm, within the cyst parenchyma (see Fig. 201-8). Type 2 anomalies are more frequently associated with the parotid gland as they course anterior and inferior to the auricle into the gland parenchyma along their path toward the neck. The tract always passes close to the facial nerve and often ends inferior to the angle of the mandible. Infections or drainage of these anomalies often lead to their diagnosis. Safe removal of these anomalies requires preoperative CT or MR imaging and intraoperative facial nerve dissection.

Type 1 branchial defects are duplication anomalies of the membranous external auditory canal. These defects are composed only of ectoderm. Located within the periauricular soft tissues and the parotid gland, they commonly present as sinus tracts or areas of localized swelling near the postauricular sulcus, concha, or anterior tragus. The tympanic membrane and middle ear space are rarely involved. Complete surgical removal is curative. Histologic examination reveals a squamous epithelial lining without skin appendages. When the lesion extends into the parotid gland, the facial nerve should be identified and preserved.

Vascular Anomalies

Vascular anomalies of the head and neck commonly involve one or more salivary entities. On the basis of the histologic classification derived by Mulliken and Glowacki,[39] and agreed on by the International Society for the Study of Vascular Anomalies in 1996, vascular anomalies are classified as either vascular tumors or vascular malformations. Hemangiomas are the most frequently encountered representative of the former. They are composed of aberrant and rapidly proliferating endothelial cells often confined within the substance of the cutaneous and subcutaneous tissue. Extension into deeper structures may occur as seen in the parotid gland. Most will present within the first 6 weeks of life and, unlike other tumors, will characteristically involute over time. This has led to a benign neglect approach to hemangiomas because most will resolve without sequelae. Other vascular tumors include Kaposi-like infantile hemangioendotheliomas and glomus tumors that develop from aberrant proliferation of vascular cells but do not follow the natural course of hemangiomas. In contrast, vascular malformations consist of ectatic development of vascular channels of one or more elements of the normal circulatory system. On the basis of their source vessels, they are subclassified into venous, lymphatic, arterial-venous, and lymphatic-venous malformations. They grow by expansion and vascular recruitment and, without intervention, can eventually invade normal structural architecture including muscle and bone. Although rare, vascular malformations can be notoriously difficult to cure because recurrence is common depending on their type.

Hemangiomas

Hemangiomas are the most common benign tumor of the parotid gland. Of salivary gland hemangiomas, 80% occur in the parotid gland, 18% in the submandibular gland, and 2% in the minor salivary glands. This parotid tumor is generally contained within the subcutaneous and intracapsular portion of the gland with rare extension into the submucosa, mucosa, or dermis (Fig. 201-6). They are usually discovered shortly after birth (3 to 6 weeks). After it appears, the hemangioma grows rapidly over months and plateaus for a period of time before its slow but progressive involution. Of affected children, 50% have com-

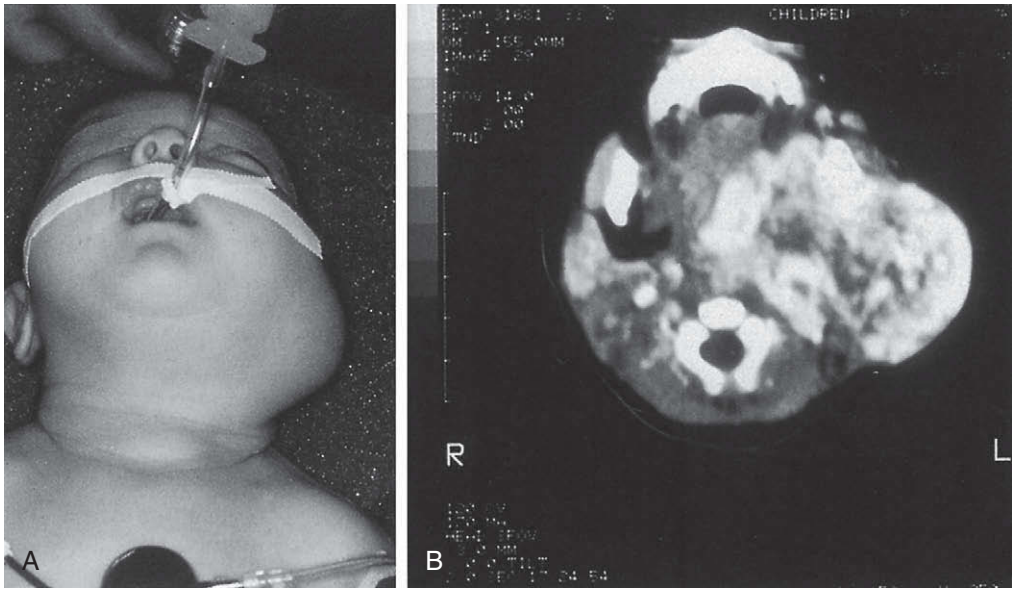

Figure 201-6. **A,** Patient with a hemangioma of the parotid gland. **B,** Computed tomography with contrast shows a parotid gland mass consistent with a hemangioma and extension into the retropharyngeal space.

plete involution of the lesion by age 5 years, 70% have involution by 7 years of age, and 90% by 9 years of age.[40]

Infants with parotid hemangiomas typically present with asymptomatic facial asymmetry and a fluctuant cheek mass that is soft to rubbery on palpation. Vascular staining may indicate disease. Bright red macules or bluish discoloration will indicate either superficial or deep (subcutaneous) disease, respectively. Parotid hemangiomas can be either segmental or focal with the former often engaged in other locations of the face either in a random or more frequently encountered "beard" distribution with involvement of both parotid glands. Hemangiomas can cause the parotid gland to increase up to five times its normal size. Focal disease frequently undergoes a defined proliferative phase up to 1 year of life that is followed by gradual involution. The proliferative phase of segmental disease is less clear because these lesions generally grow larger, take longer to involute, and are more difficult to eradicate than their focal counterparts. Regardless, the general lobular architecture of the native gland is typically preserved with limited or no impact on the acini and ductal structures.

Diagnosis is usually by history and physical examination. If necessary, ultrasound, CT, or MRI will confirm the diagnosis. Biopsy is unnecessary; however, if the mass is firm, painful, or rapidly grows, histologic sampling may be necessary to rule out a malignancy. Most of these tumors undergo spontaneous involution, which requires the use of observation to follow up most of these lesions. Potential complications of hemangiomas may include a localized consumptive coagulopathy known as the *Kasabach-Merritt syndrome.*

Excision of a salivary gland hemangioma is indicated when there is excessively rapid growth of the mass, severe facial deformity, functional impairment, infection, hemorrhage, or ulceration. Laser therapy has not proven completely effective over natural involution to reduce vascular staining or speed involution of these tumors.[41] However, use of the flash pump dye laser is appropriate for ulcerative and bleeding lesions because this can lead to rapid epithelialization and repair of these sites.[42] If necessary, subtotal parotidectomy, with facial nerve preservation, or total submandibular gland excision can be performed and only after the end of the proliferative phase of these lesions. Bipolar cautery is recommended because it eases dissection of these highly vascular tumors. Segmental disease is likely better managed with either systemic or intralesional injections (triamcinolone acetonide/betamethasone [Kenalog/Celestone] mixture) of corticosteroids because resection of these multiple lesions and sites can be difficult. Steroids should be instituted only during the proliferative phase. Although controversial, recent investigation into these treatment modalities has illustrated improved functional and cosmetic results.[43,44] Nonetheless, the risk of systemic side effects of corticosteroids including hypertension, irritability, Cushing's syndrome, and adrenal insufficiency should be respected and frequently monitored during their use. Tapering systemic doses to therapeutic response is advocated.[44] Interferon is no longer recommended for fear of spastic diplegia and has been circumvented by the use of vincristine for complicated disease. Of final note, patients with segmental facial hemangiomas involving the parotid should be screened for associated anomalies of PHACES syndrome including Posterior fossa abnormalities, Arterial anomalies, Cardiac anomalies, Eye abnormalities, and Sternal defects, with MRI, echocardiogram and ophthalmologic referral.

Lymphatic Malformations

Of the vascular malformations, lymphatic malformations are those that most commonly affect the salivary structures, making them the second most common vascular anomaly found in the salivary glands. Before the recent classification of vascular anomalies, these lesions have been previously named cystic hygromas and lymphangiomas. A venous component to these lesions is also common (lymphatic-venous malformations) and should be considered at initial evaluation and when surgical resection is considered.

Lymphatic malformations are soft, painless, and compressible benign masses that represent areas of regional lymphatic dilation. Lymphatic malformations have been divided into two categories on the basis of the size of their lymphatic channel aberrations. Lesions consisting predominantly of small lymphatic spaces, less than 2 cm in diameter, are considered microcystic. Those with spaces greater than 2 cm are known as *macrocystic lymphatic malformations* and have been known as cystic hygromas in the past. Mixed lesions of these two types are also common.

Lymphatic malformations involve the head and neck in more than 50% of cases. Infiltration of the salivary glands is common but not frequently the source of disease.[45] These malformations can involve any of the major salivary glands and usually present as an asymptomatic fluctuant mass (Fig. 201-7). They are present at birth and grow at unpredictable rates. However, rapid growth and ectasia can occur with upper respiratory tract infections. Approximately 50% to 60% of patients present with these tumors before age 1 and about 90% of the tumors occur before the end of the second year of life. The diagnosis can be confirmed when cystic areas, septations, and air fluid levels are found on imaging with ultrasound, CT, or MRI. Gadolinium-enhanced MRI will provide clarity of all soft tissues involved and is recommended

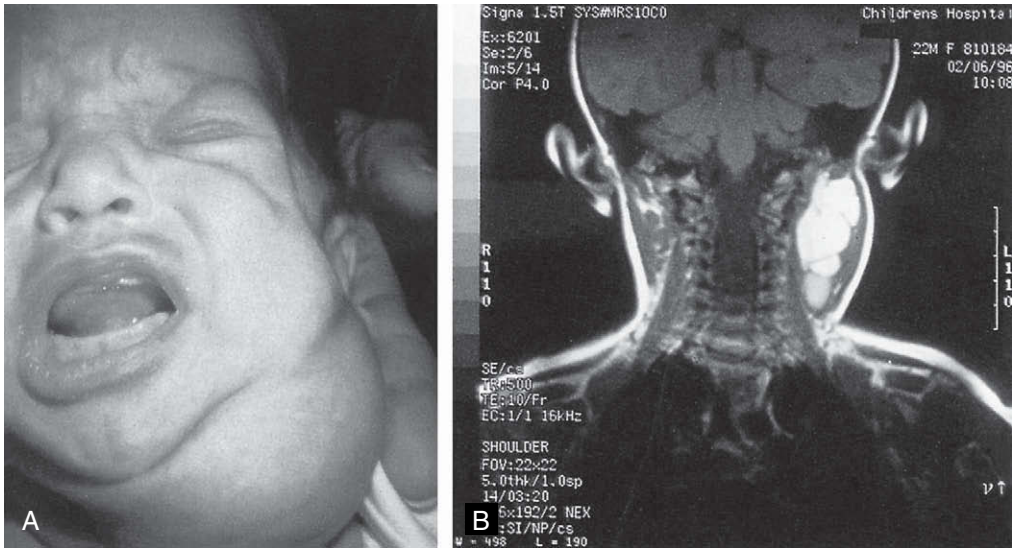

Figure 201-7. **A,** Lymphangioma with involvement of the submandibular and parotid glands. **B,** Magnetic resonance imaging (T1-weighted) shows multiple loculated spaces consistent with a lymphangioma.

as a primary imaging modality. Examination of the chest, mediastinum, and airway is recommended in larger lesions that are seen in approximately the lower third of the neck.

Unlike hemangiomas, lymphatic malformations rarely undergo spontaneous resolution. Although it has been reported in small lesions, resolution is thought to occur as a result of autosclerosis of the cystic space. More frequently, infiltration of local tissue, especially with microcystic disease, can lead to destruction and deformation of normal bone and muscle leading to significant functional and cosmetic consequences. Macrocystic disease (cystic hygroma) can be approached with either sclerotherapy or surgical resection. Sclerotherapy is recommended for deep lesions not surrounding prominent vascular or nervous structures because various agents (e.g., ethanol, bleomycin) have a small risk of associated nerve and vessel injury. Sclerosis of superficial lesions can also lead to skin ulceration. Consultation with the interventional radiologist is paramount for these vascular malformations.

Surgical removal of macrocystic disease is often curative. OK-432 (Picibanil) sclerotherapy, although not currently FDA approved, has been reported as a successful treatment of these lesions.[46] Definitive therapy potentially can be delayed until the child is several years old to make surgical dissection less difficult. Prompt removal of lymphatic malformations is necessary when the potential for airway obstruction exists. This potential is highest in tumors of the sublingual glands, submandibular glands, or minor salivary glands. A tracheotomy may be necessary if the malformation cannot be removed completely. Recurrence of macrocystic lymphatic malformation is uncommon when all evidence of gross tumor is removed. If residual disease remains, recurrence is estimated to occur in up to 35% of cases.[47] Microcystic disease is difficult to erradicate and often requires staged surgical resections with bony recontouring. Infiltration of muscle and nerve is common. Perioperative systemic steroids reduced postoperative edema often encountered following partial resection of these lesions. Use of systemic steroids is also recommended during upper respiratory infection in children with lymphatic malformations to prevent lymphatic edema and growth.

Neoplasms

Salivary gland neoplasms in children are uncommon, with an annual incidence of 1 to 2 cases per 100,000 juveniles. Salivary gland tumors account for 8% of all pediatric head and neck tumors with less than 5% of these occurring in patients 16 years of age or younger.[47] Pediatric salivary gland neoplasms are classified into three histologic groups: benign, low-grade malignant, and high-grade malignant. Sometimes intermediate-grade classification is also used. Management choices inherently depend on histologic type because more aggressive therapy (resection with radiation) is advocated for high-grade lesions.

As mentioned previously, the majority of benign salivary lesions are of vascular origin. The second most common are epithelial tumors. These are predominantly benign and occur most frequently in children in the second decade of life.[2,4,48] Overall, the most common epithelial tumor in children is the pleomorphic adenoma (Table 201-3). Others include Warthin's tumor, oncocytoma, and various adenomas. In contrast to adults, the incidence of malignant tumors is inversely proportional to the age of the patient. Several reports suggest that 23% to 50% of all salivary gland tumors in children are malignant.[3] Fortunately, most of these are of low-grade histology. The most common are mucoepidermoid and acinic cell carcinomas, which account for 60% of the malignant epithelial salivary neoplasms in children.[4] Rare but most frequently encountered nonepithelial malignancies are rhabdomyosarcoma and lymphoma.[2]

The parotid gland is the primary location for salivary gland neoplasms (85% to 90%).[4] These frequently present as a slow-growing mass with average time of onset to ultimate diagnosis approximating 1 to 2 years.[48] Thus it is safe practice to consider all deep, painless, and noninflammatory parotid masses as neoplasms until proven otherwise. Submandibular gland lesions also present as painless swellings but are harbored within the submandibular triangle. A rare minor salivary gland lesion will tend to occur as an oral mass or ulceration. In general, submandibular and minor salivary gland neoplasms have a higher rate of malignancy. Perineural involvement with symptomatic paresthesias (lingual nerve) or weakness (facial nerve or hypoglossal nerve) is suggestive of high-grade processes. Fixation and pain are also indicative of aggressive malignant disease. Pain (30%) and facial paralysis (15%) often accompany malignant parotid tumors.

Benign

Pleomorphic Adenoma (Benign Mixed Tumor)

The most common nonvascular or epithelial salivary gland tumor in children is the pleomorphic adenoma.[49] The highest incidence of pleomorphic adenoma in children is in the pubertal and prepubescent child.[3] These adenomas consist of both mesenchymal and epithelial cell lines derived from the intercalated duct reserve cell. The tumor most often presents as a slow-growing, firm, discrete nodule that is freely mobile and about 1 cm in diameter. Facial paralysis is atypical and should alert the physician that a malignant process is present. Although pleomorphic adenomas appear encapsulated, they have a highly lobular

Table 201-3

Salivary Gland Neoplasms in Children

Benign*		Malignant†	
Hemangioma	111	Mucoepidermoid carcinoma	122

architecture with microscopic pseudopod extensions that prohibit enucleation as a therapeutic alternative. Recurrence rates approach 40% with this surgical technique. Multiglandular involvement in children is unusual. Most of these tumors are 1 to 3 cm in size and located within the superficial lobe or tail of the parotid gland.

The diagnosis of a pleomorphic adenoma, as is the case for most salivary neoplasms, is best confirmed by FNA with ultrasound guidance as needed. Incisional biopsies are contraindicated. MRI will provide better clarity of soft tissue extension in unusual cases. If FNA is inadequate or unavailable, excisional biopsy consisting of a lateral (superficial) parotid lobectomy with facial nerve preservation is appropriate. Total excision of the submandibular gland is necessary when pleomorphic adenomas are found in this gland. Rarely, a mixed tumor abutting the parotid gland, but not infiltrating it, can be removed with a completely intact capsule-sparing parotid tissue and facial nerve dissection. Recurrence after superficial parotidectomy for pleomorphic adenoma in the pediatric population is reported by Shikhani and Johns[50] to be as high as 19.5%, which is considerably greater than that seen in adults (1%). The reasons for this remain unclear but may be related to the misdiagnosis and drainage of previously presumed lymph node infections.

Other Benign

Several rare benign neoplasms have been described in the pediatric population. These include plexiform neurofibroma, Warthin's tumor (papillary cystadenolymphomatosum), embryoma, monomorphic adenoma (basal cell, clear cell, glycogen-rich adenoma), lipoma, and teratoma in descending frequency.[51]

Warthin's tumors theoretically arise from trapped ductal epithelium (striated ducts) within intraparotid lymph nodes and are histologically characterized by oncocytes lying among dense stoma of lymphatic origin. These are typically well-circumscribed lesions that are rare in children and occur in less than 2% of all benign epithelial salivary gland tumors. CT, MRI, and FNA will help diagnose these solid tumors that are often nestled within the tail of the parotid gland. Surgical excision with superficial parotidectomy is often curative, although small secondary lesions may arise later in the same gland. The remaining benign processes are managed similarly to Warthin's tumor both diagnostically and surgically with imaging and resection of the tumor with a wide cuff of adjacent normal gland. The exception is the plexiform neurofibroma that may involve numerous head and neck sites beyond the primary gland. Controversy on treatment, timing, and extent of resection is prevalent in the literature and beyond the scope of this chapter.

Malignant

Mucoepidermoid Carcinoma

Mucoepidermoid carcinoma is the most common malignant epithelial salivary gland neoplasm in children, accounting for approximately 50% of salivary gland malignancies. Most are low-grade lesions that tend to have a good prognosis.[2,49,52] These are also the most frequently encountered radiation-induced salivary gland tumors in children.[53,54] Mucoepidermoid carcinomas are composed of cells with squamous differentiation and cells with mucinous differentiation. Lower-grade neoplasms are commonly cystic, showing predominant mucinous differentiation. Higher-grade neoplasms show greater squamous differentiation and resemble squamous cell carcinoma. Again, histologic grade correlates well with prognosis.

Management is essentially the same in children and adults. Low-grade malignancies of the parotid gland are managed by an appropriate parotidectomy sufficient to remove the tumor with a generous cuff of normal parotid and preserving the facial nerve. The lymph nodes around the digastric triangle should be evaluated at the time of surgery and, if involved, a neck dissection should be done. High-grade malignancies are managed with total parotidectomy. Recurrence rates for superficial versus total parotidectomy for mucoepidermoid carcinoma of the parotid are 30.7% and 0%, respectively.[55] This underscores the

implementation of more extensive resection for this disease. This is offset by the risks to the facial nerve. Temporary facial nerve paralysis has been reported to occur in 25% and 16% of total and superficial parotidectomies, respectively, after removal of parotid lesions and facial nerve preservation in children. Permanent loss is rare but more common in malignant tumors.

The facial nerve is preserved in all cases unless gross tumor invasion into the nerve is present. Radical surgery with nerve sacrifice should not be performed on the basis of the results of frozen section alone. However, once confirmed by permanent histologic evaluation, invasion of the nerve should be managed with resection until final sections reveal no further disease. Surgeons need to be prepared for mastoidectomy and temporal bone dissection in suspected cases. In this scenario, immediate facial nerve grafting is performed. Postoperative radiotherapy often is given to patients with high-grade malignancies.[52]

Submandibular gland malignancies are managed with submandibular gland excision and submandibular triangle nodal dissection. High-grade tumors often are given postoperative radiotherapy. Ten-year survival rates for low-grade mucoepidermoid carcinoma have approached 95%.[4]

Acinic Cell Carcinoma

Acinic cell carcinoma is the second most common malignancy and accounts for approximately 12% of the total number of epithelial malignancies of the salivary gland in children.[38] Most acinic cell carcinomas are low-grade malignancies and are diagnosed in pubescent adolescents. They are characterized by cells with bland nuclei and an abundant basophilic cytoplasm. The behavior of acinic cell neoplasms is similar to mucoepidermoid carcinoma because patients present with a slow-growing solitary mass with or without associated pain. Management is the same as low-grade mucoepidermoid carcinoma: an appropriate parotidectomy sufficient to remove the tumor with a generous cuff of normal parotid tissue, preserving the facial nerve.

Other Malignant

Adenocarcinoma and undifferentiated carcinoma, adenoid cystic carcinoma, and malignant mixed tumors are rare but can occur in the pediatric population. Primary sarcomas of the salivary glands in children are also uncommon. When present, rhabdomyosarcoma is the most common. All of these malignancies demonstrate high recurrence rates and poor prognosis. Undifferentiated carcinomas tend to occur in children younger than 10 years of age.[48] Epithelial salivary gland tumors identified in the first month of life are termed *embryomas* or *sialoblastomas* and are malignant in 25% of cases.

Surgery remains the mainstay for the more aggressive lesions with the goal of complete removal. Total parotidectomy is advocated because it may affect local control. Lymph node disease in the neck is estimated to occur in less than 15% of cases, oncologically warranting cervical lymphadenectomy in cases of gross nodal involvement or poorly differentiated lesions. In particular, elective neck dissection without clear involvement should be done only for high-grade malignancies where occult disease is estimated to be greater than 15% (high-grade mucoepidermoid, rhabdomyosarcoma, undifferentiated, and rare squamous cell carcinoma).

Minor salivary gland neoplasms are rare in the pediatric population. Most are pleomorphic adenomas or low-grade mucoepidermoid carcinomas. Regardless of etiology, wide local excision with a cuff of normal adjacent tissue is recommended for both diagnosis and therapy. This is usually curative for these and other malignant neoplasms of these glands.

Role of Irradiation

Irradiation of the major and minor salivary glands in children is generally reserved for high-grade lesions in which significant risk of recurrence and mortality is evident. Other indications include those seen in adults and include remaining gross or microscopic disease, inadequate margins, nodal involvement, perineural spread, and adjacent soft tissue extension. The risk of postradiation sequelae is high in young patients and includes limitations in facial growth, development of secondary tumors, dental caries and trismus.[56]

Trauma

Most salivary gland injuries are seen in association with penetrating wounds of the cheek. Few cause serious injury to the facial nerve or salivary duct system. Any penetrating wound deep to the parotideomasseteric fascia can injure these structures. If the laceration extends anterior to a line dropped from the lateral canthus of the eye, the facial nerve does not need to be explored. Satisfactory reinnervation will occur through peripheral nerve branches. When a laceration is posterior to this line and the facial nerve is paralyzed, exploration of the wound and reapproximation of the proximal and distal segments of the nerve are obligatory.

Exploration of the facial nerve should occur within 72 hours of the injury so that electrical stimulation of the distal segment is possible. Epineural repair of the severed branches can be accomplished with the aid of an operating microscope. A 6-0 to 8-0 nylon suture is ideal for this purpose. If tension exists on the suture line, a cable graft is preferable. The best results are obtained when the anastomosis is accomplished with fresh, sharp nerve ends. Recovery of facial nerve function after transection and repair requires 6 to 12 months.

The parotid duct (Stensen's duct) is located on a line drawn from the tragus to the midpoint between the upper lip margin and the columella. The parotid duct is likely to be injured if a laceration courses through the masseter muscle. Pooling of saliva in the wound is a frequent finding. Lacerations involving Stensen's duct should be repaired when they are detected because the resultant inflammatory response leads to a high probability of a salivary fistula, sinus tract, or an obstructive cyst. This repair should occur as early as the patient is medically stable and staff are available. The preferable method is to perform the ductal repair using 6-0 or 7-0 nylon suture over a small stent (polyethylene tubing). The tubing remains in place approximately 10 days. When the orifice of Stensen's or Wharton's duct has undergone significant injury, surgical rerouting of the remaining duct through the buccal mucosa may be necessary. If this is not possible, ligation at this site is also a reasonable option.

Blunt trauma to the salivary glands may cause less obvious injury than penetrating trauma. Injury to the parotid duct can result in a salivary pseudocyst with associated swelling and recurrence after FNA. Repeat aspiration and a pressure dressing may be necessary. Children who require dental appliances can develop chronic irritation of the salivary ducts resulting in stasis. Salivary gland swelling has been described in neonates resulting from a compression-type birth injury from a forceps delivery.

Sialorrhea

Sialorrhea (drooling) is defined by the unintentional loss of saliva beyond the lip margin. This usually results from an inability to coordinate oral control and swallowing and is a natural phenomenon in infants as they gradually gain function of their oral-motor skills. Drooling normally subsides in these children during neuromuscular maturity and should resolve around 18 months of age. Persistent sialorrhea beyond 4 years of age is thereby considered abnormal and should be investigated for treatment options. This most frequently occurs in neurologically impaired children with the highest incidence in patients diagnosed with cerebral palsy (10% to 25%). Specific delay in oral motor function in these patients can last up to 6 years of age and should be kept in mind when considering sialorrhea therapy.

The submandibular and sublingual glands produce the most saliva (70%) during the normal, unstimulated basal state. The role of saliva is to maintain oral homeostasis with respect to pH, dental health, control of bacterial growth, lubrication, and digestion of food (amylase). On sympathetic stimulation (eating and preparation to eat) the parotid gland produces the preponderance of saliva with dramatic increase in flow.[57] Excessive production or ineffective dissolution (voluntary swallowing) can lead to persistent drooling and its consequences including maceration of the lips and chin, chapping, dehydration, infection, foul odor, and aspiration. This can lead to significant hygienic issues, costs, and social isolation as patients continuously soil their clothes, furniture, and caregivers. Assessment of sialorrhea is often determined by subjective scales answered by the patient's caregivers with specific rating of

the severity and frequency of drooling. The results thereby help guide management.

Medical Management

A multidisciplinary approach is appropriate for these patients because management decisions often include otolaryngologists, speech therapists, physical therapists, social workers, and pediatric dentists.[1] In otherwise healthy children with sialorrhea, nasal obstruction and dental disease are common sources and should be assessed carefully because management may be directed at this problem. Adenoidectomy, turbinectomy, allergic desensitization, and management of dental hygiene can be performed. In neurologically impaired children the approach is not as simple. In such patients with associated malocclusion, macroglossia, and orthodontic problems, surgical correction of these deformities or the application of orthodontic appliances can improve mild cases of sialorrhea.

However, neurologic dysfunction is the primary culprit for disease in sialorrhea patients. An initial attempt at speech therapy or physical therapy is appropriate before beginning extensive medical or surgical management. This method provides a physiologic approach to the problem using oral-motor and behavior modification. Conservative management includes correcting posture to more upright positions and techniques to improve oral competence (closing mouth) and reducing tongue thrust. Biofeedback has been used in higher-functioning patients and shown to be effective in mild to moderate cases of sialorrhea. This is aimed to elicit a swallow or mouth wiping by the patient on hearing a repeated tone. Unfortunately, habituation to the stimulus occurs in most patients over time.[58] Indications for delay in therapy include normally developing children up to 6 years of age with a sole complaint of sialorrhea, cerebral palsy patients with mild to moderate sialorrhea before 6 years of age, and sialorrhea following acute neurologic deficits (wait 6 to 12 months).[1]

Medical regimens have involved the use of oral (glycopyrrolate) and topical (scopolamine) anticholinergics. Unfortunately, these have generally been unsuccessful due to the broad side-effect profile, making their use unattractive. Even more selective agents with limited blood-brain barrier penetration such as glycopyrrolate have nearly 60% of patients experiencing various side effects such as hyperactivity, irritability, xerostomia, constipation, and urinary retention. Regardless, in patients without side effects, glycopyrrolate at dose 0.10 mg/kg has proven effective in maintaining reduction of sialorrhea. This is thereby often used before contemplating surgical intervention. Botulinum injection is also used in some cases and has been successful in temporarily reducing sialorrhea.

Surgical Management

Surgical management of sialorrhea is generally reserved for patients in whom nonsurgical measures have not been effective, those with moderate to profuse sialorrhea and older than 6 years of age, dramatically developmentally delayed children with moderate to profuse drooling, sialorrhea with more than one documented episode of aspiration pneumonia annually, and patients requiring chronic and frequent maintenance of secretions by their caregivers. Although less clear, patients who require several bib or clothing changes daily or hourly suctioning are considered appropriate candidates. Botox injections of the major salivary glands have proven effective in reducing sialorrhea and seems appropriate in patients with poor neurologic prognosis, surgical risk factors, and determining those in whom surgery may be effective.[1] However, repeated injections will be necessary, thus limiting its use in the general population of sialorrhea patients.

Bilateral submandibular gland excision with parotid duct ligation has most consistently controlled drooling. It has supplanted other surgical options including submandibular duct rerouting, submandibular duct rerouting with bilateral tympanic neurectomies and chorda tympani nerve sections, and tympanic neurectomies with chorda tympani nerve sections alone. This procedure is safe and reliable and results in few complications.[59] Another less invasive option is that of four-duct ligation, which includes ligation of both parotid ducts and both submandibular ducts all via transoral approach. No conclusive studies have determined the overall benefit from this less invasive procedure.

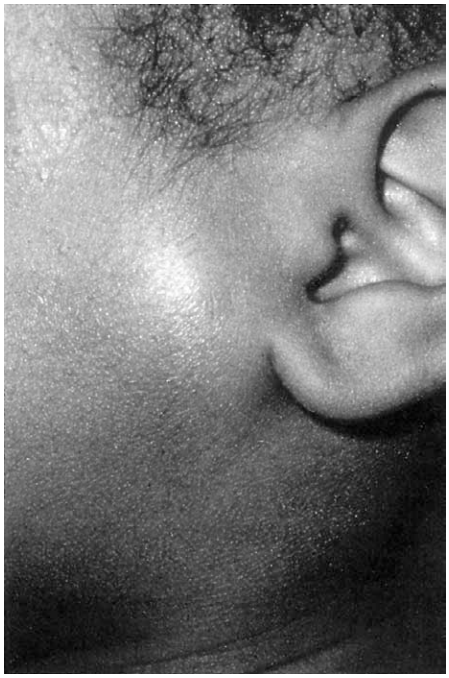

Figure 201-8. A first branchial cleft anomaly that has become an infected cyst.

Rare Disorders

Allergy

Allergic reactions can cause bilateral parotid enlargement. The enlargement is usually of rapid onset and transient nature. Resolution is usually spontaneous when the offending allergen is eliminated. Certain foods (seafood, strawberries) may precipitate this reaction. Investigation of the saliva or leukocyte differential may reveal a relative eosinophilia.

Cystic Fibrosis

Patients with cystic fibrosis can develop salivary gland enlargement. The submandibular gland is involved more frequently than the parotid gland. When a child younger than 2 years of age presents with diffuse parotid enlargement without an associated infection, a sweat chloride test should be performed to rule out cystic fibrosis. The mechanism of the swelling is unknown, but increased concentrations of calcium and phosphorus are found in the saliva.

Aberrant Salivary Glands

Heterotopic salivary gland tissue is defined as the existence of salivary tissue in locations external to the major and minor salivary glands. This is a rare entity and when present usually presents as a sinus tract in the right side of the lower neck along the anterior border of the sternocleidomastoid muscle with close proximity to the sternoclavicular joint. Most are noticed at birth or shortly thereafter. The tracts may drain saliva-like fluid related to meals. Excision is the treatment of choice. The sinus tracts are generally short in comparison with that of branchial cleft fistulas.[39]

Agenesis of the major salivary glands can occur. Diagnosis can be confirmed with pertechnetate nuclear medicine imaging. The scan may be diagnostic in a child with idiopathic xerostomia. Early identification is important so that proper oral hygiene can be started. The oral sequelae include dental carries and candidiasis.

Systemic Conditions and Medications

Systemic conditions in which bilateral diffuse salivary enlargement can occur include obesity, alcoholism, portal cirrhosis, malnutrition (kwashiorkor, hypovitaminosis A), gastrointestinal absorption disease (celiac disease, Chagas' disease), chronic pancreatitis, uremia, thyroid

disease (hypothyroidism), diabetes, bulimia, and abnormalities of the pituitary-adrenal axis. Salivary gland enlargement has been associated with several drugs including phenytoin, thiourea, isoproterenol, methimazole, phenothiazine, thiocyanate, iodine compounds, and heavy metals.

CHAPTER TWO HUNDRED AND TWO

Congenital Disorders of the Larynx

Anna H. Messner

Key Points

- The most common cause of stridor in infants is laryngomalacia—but not all stridor can be assumed to be due to laryngomalacia.
- Laryngomalacia is most likely due to altered laryngeal tone and sensorimotor integrative function, which improves with increasing age.
- Infants with laryngomalacia are likely to have gastropharyngeal reflux requiring evaluation and treatment.
- Supraglottoplasty is a highly successful treatment for severe laryngomalacia with a low complication rate.
- Noniatrogenic neonatal unilateral and bilateral vocal cord paralysis will resolve spontaneously in greater than 50% of patients.
- Posterior glottic stenosis and arytenoid fixation can mimic neurologic vocal cord paralysis.
- All children with anterior laryngeal webs should undergo genetic testing for abnormalities of chromosome 22q11.
- Patients with subglottic hemangiomas often present with a history of "recurrent croup" because the lesion mimics the subglottic swelling of croup, and the symptoms improve with steroid treatment.
- Laryngeal cysts, including vallecular thyroglossal duct cysts, saccular cysts, and subglottic cysts, are a source of potentially severe airway obstruction.
- In the patient with feeding problems, recurrent aspiration, and stridor, the otolaryngologist must maintain a high index of suspicion that a laryngeal cleft may be present, as well as a low threshold to perform direct laryngoscopy in the operating room to rule out potential clefts.

Stridor is the hallmark of any laryngeal obstruction. Much can be learned about the nature of the laryngeal problem by closely observing the infant and listening to the noise produced as air passes through the obstruction. Stridor resulting from supraglottic or glottic obstruction is typically present on inspiration, whereas biphasic stridor originates from obstruction at or below the level of the glottis in the upper trachea. Expiratory stridor is the result of lesions in the distal trachea or mainstem bronchi.

Dynamic evaluation of the larynx by flexible laryngoscopy is best performed in the patient who is awake. Although at least a 2.5-mm diameter fiberoptic laryngoscope is recommended for optimal viewing, fiberoptic laryngoscopes with diameters as small as 1.9 mm allow the neonatal larynx to be viewed with a minimum of trauma to the young patient. Direct laryngoscopy of the neonatal larynx with a telescope or microscope provides the best optics (Fig. 202-1). To fully evaluate the larynx, the endoscopist should note findings in the vallecula, piriform fossae, postcricoid region, arytenoids, interarytenoid area, aryepiglottic folds, epiglottis, false vocal cords, ventricles, true vocal cords, and the subglottis.

Laryngomalacia

Without question, the most common cause of stridor in infants is laryngomalacia, a disease more commonly found in term infants, and in males more than females.[1] The newborn with laryngomalacia typically develops intermittent, inspiratory stridor within the first 2 weeks of life, which resolves slowly over several months. Many authors describe the stridor as high-pitched, but compared to the stridor of vocal cord paralysis it is relatively low-pitched and does not have a musical quality. The stridor nearly always worsens with feeding, and often the baby will need to take breaks while feeding in order to breathe. The stridor of mild laryngomalacia often improves with crying as tone in the pharynx is increased. Conversely, in moderate-to-severe laryngomalacia, the stridor typically will worsen with crying because of the increased airflow through the severely collapsed larynx. Laryngomalacia may be an isolated finding in the otherwise healthy infant or may be associated with other neurologic disorders such as cerebral palsy.

The median time to spontaneous resolution of stridor is 9 months of age, and 75% will have no stridor by 18 months of age.[2] Infrequently, the laryngomalacia is severe, resulting in feeding difficulties, failure to thrive, apnea, pectus excavatum, or cyanosis. In these cases, surgical intervention is recommended to prevent worsening failure to thrive, cor pulmonale, and cardiac failure.[1-3]

The inspiratory stridor of laryngomalacia results from collapse of the supraglotttic larynx, creating a narrow airway and turbulent airflow (Fig. 202-2). The etiology of this collapse has been elusive but it appears to be related to neuromuscular hypotonia. Sensorimotor integration of peripheral sensory afferent reflexes, brainstem function, and the motor efferent response are responsible for laryngeal function and tone.[1] The laryngeal adductor reflex (LAR) is a vagal nerve-mediated reflex activated by sensory stimulation of the mechanoreceptors and chemoreceptors of the superior laryngeal nerve located in the region of the aryepiglottic fold. Dysfunction anywhere along the afferent, brainstem,

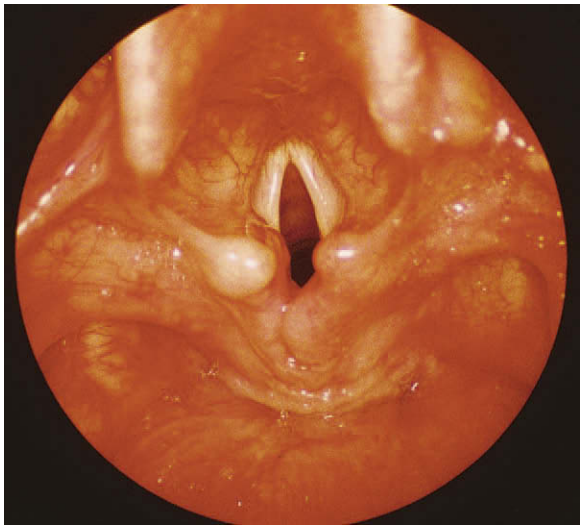

Figure 202-1. Normal infant larynx. Anatomic areas to be examined include epiglottis, vallecula, piriform sinuses, arytenoid cartilages, interarytenoid area, aryepiglottic folds, false vocal cords, ventricles, true vocal cords, anterior commissure, and subglottis. *(From Benjamin B. The pediatric airway, slide #2, Slide Lecture Series. American Academy of Otolaryngology–Head and Neck Surgery, 1992.)*

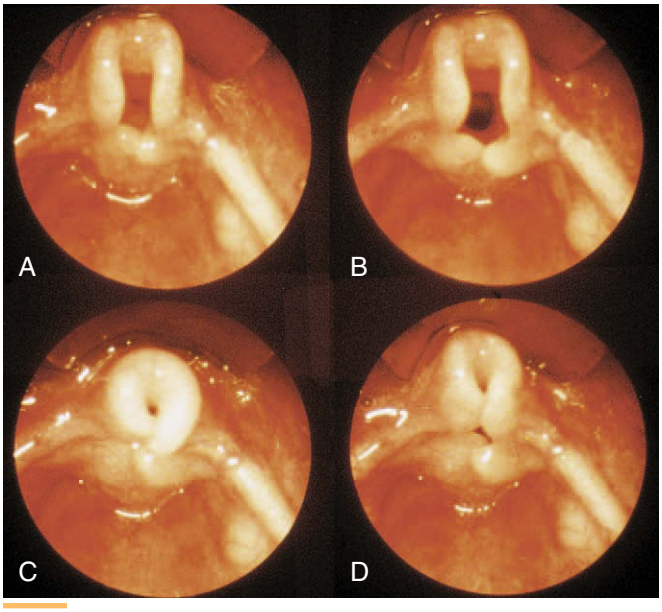

Figure 202-2. Laryngomalacia. Progressive airway obstruction on inspiration. Note omega-shaped epiglottis. *(From Benjamin B. The pediatric airway, slide #2, Slide Lecture Series. American Academy of Otolaryngology–Head and Neck Surgery, 1992.)*

or efferent pathway of the LAR can result in altered laryngeal tone and function. Infants with laryngomalacia have been found to have elevated laryngopharyngeal sensory testing thresholds, showing that the sensorimotor integrative function of the larynx is altered, likely leading to the weak laryngeal tone seen in infants with laryngomalacia.[1]

In several series, a high prevalence of gastroesophageal reflux disease (GERD) has been reported in patients with laryngomalacia (50% to 100%).[1,4-6] When present, GERD can cause airway edema and thus contribute to the airway compromise. Children with laryngomalacia should be evaluated for GERD and if airway surgery is needed, care should be taken to control GERD before surgery to avoid GERD-induced delayed healing.[6] Mild GERD may improve with the treatment of laryngomalacia when the negative intrathoracic intraesophageal pressures decrease. Conversely, treatment of GERD may improve laryngomalacia as acid ceases to irritate the larynx and edema resolves.[5] In the child with GERD related to airway obstruction, the GERD can be expected to improve significantly after aryepiglottoplasty.[7]

The diagnosis of laryngomalacia requires an endoscopic examination; however, the optimal type of endoscopic examination is somewhat controversial. If the patient is sedated and undergoes fiberoptic flexible laryngoscopy (FFL), the topical lidocaine typically used can cause increased collapse of the arytenoids and folding of the epiglottis during inspiration—possibly leading to overestimation of the severity of laryngomalacia.[8] These findings suggest that the optimal way to diagnose laryngomalacia is with FFL in the awake patient. Conversely, the awake technique has been found to miss mild laryngomalacia or lead to overdiagnosis in the patient with a normal airway.[9] The advantages of awake FFL compared to FFL under general anesthesia include the ability to perform the examination expediently in the clinic setting with the parents present, without the need for sedation, leading to less medical expense. The primary disadvantage of the awake FFL is that in nearly all cases the infant is crying during the examination, which can alter the appearance of the supraglottic structures. An omega-shaped epiglottis is often associated with laryngomalacia but can also be found in otherwise normal infants with no airway obstruction. If fluoroscopy is performed, downward anterior displacement and bowing of the aryepiglottic folds, horizontal infolding of the epiglottis, and in some cases, narrowing of the trachea are seen on inspiration, all of which reverse on expiration.[10]

Approximately 17% of infants with laryngomalacia have a second synchronous lesion that may lead to airway difficulties.[11] The decision to perform a bronchoscopy in patients who present with typical laryngomalacia is also controversial. Some contend that bronchoscopy need be done only in select infants with laryngomalacia who present with "apnea, failure to thrive, or features inconsistent with isolated laryngomalacia."[2,12] Others strongly recommend a complete evaluation of the tracheobronchial tree in all symptomatic infants to avoid missing life-threatening lesions.[13]

The anatomic abnormality causing the supraglotttic obstruction of laryngomalacia varies among infants. Most have anterior prolapse of the mucosa overlying the arytenoid cartilages (57%); others have short aryepiglottic folds that tether the epiglottis posteriorly (15%), posterior collapse of the epiglottis (12%), or some combination of these findings (15%).[2] Several classification systems have been proposed with none being predominant at this time.[2,14,15]

Approximately 10% to 31% of infants seen by a pediatric otolaryngologist require surgical intervention for their laryngomalacia.[1] Surgery is indicated if there is feeding difficulty with failure to thrive, cyanosis, apnea, respiratory distress, or hypoxia. The current standard treatment is supraglottoplasty (aryepiglottoplasty) (Fig. 202-3). The surgical resection can be performed using the carbon dioxide (CO_2) laser, laryngeal microscissors, or microdébrider.[1-3,5,16] Various types of supraglottoplasty have been described based on what portion of the prolapsing supraglottis is removed: the tissue overlying the arytenoids (with care taken to preserve the interarytenoid mucosa), the aryepiglottic folds, or the posterior portion of the epiglottis.[5] Unilateral supraglottoplasty has been advocated by some authors to relieve the airway obstruction while reducing the risk of postoperative supraglottic stenosis.[17,18]

Short aryepiglottic folds that tether the supraglotttic structures in close anterior and posterior approximation can be divided or excised.[19] If the epiglottis is displaced posteriorly, an epiglottopexy can be performed.[20] In this procedure the mucosa of the lingual surface of the epiglottis and the corresponding mucosa of the base of the tongue are removed with the CO_2 laser, then the epiglottis is sutured to the tongue base. These procedures are well tolerated by the infants, typically requiring only a short 1- to 3-day hospital stay. The success of the various forms of supraglottoplasty-epiglottopexy are high, with the vast majority of children obtaining relief from their obstruction.[3,16,19-23] Those children who do not improve with supraglottoplasty usually have underlying neurologic or syndromal abnormalities or associated tracheomalacia and may require a tracheotomy.[22,23] Complications are

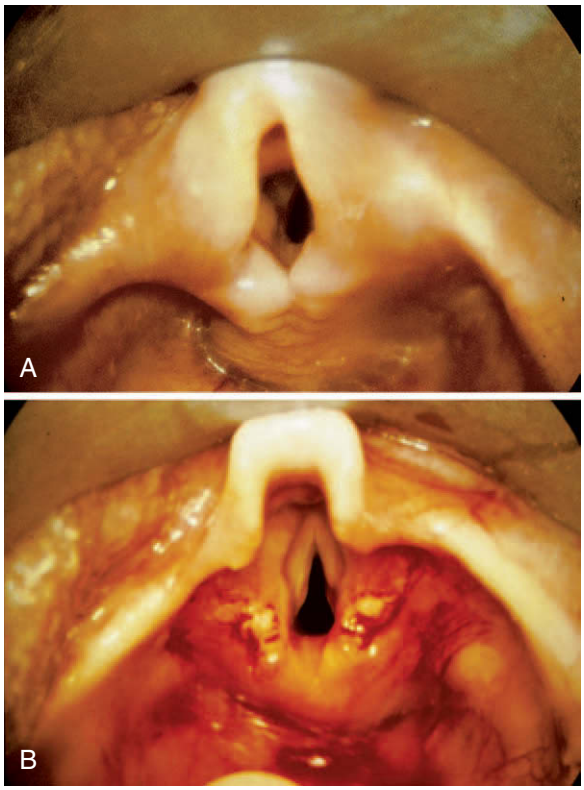

Figure 202-3. Laryngomalacia. Infant larynx before and after supraglottoplasty.

rare, with the most feared being supraglottic stenosis, which may occur in up to 4% of cases.[22] More frequently, transient dysphagia and aspiration can occur in approximately 10% to 15% of patients.[1]

Although laryngomalacia is typically thought of as occurring only in infants, it is occasionally observed in older children and adults. Neurologically impaired children (i.e., those with cerebral palsy) with poor pharyngeal control can develop laryngomalacia. Exercise-induced laryngomalacia results when enough inspiratory force occurs during exercise to draw the aryepiglottic folds into the larynx, partially obstructing the glottis.[24,25] In severe cases with redundant aryepiglottic folds, supraglottoplasty can be beneficial. Similarly, if the epiglottis is elongated and flaccid, a partial epiglottidectomy can be effective.[26]

Vocal Fold Paralysis

Vocal fold paralysis (VFP) is another common cause of neonatal stridor. The stridor is inspiratory or biphasic, with a high-pitched musical quality. VFP in a newborn may be idiopathic or can result from birth trauma, central or peripheral neurologic diseases, or thoracic diseases or procedures.[27,28] The diagnosis is best made by FFL in the awake patient so that the effect of anesthesia on vocal fold function is minimized.

Iatrogenic left VFP may be present following thoracic surgery, particularly patent ductus arteriosus (PDA) ligation or repair of an interrupted aortic arch. In these infants, the left recurrent laryngeal nerve is damaged at the point that it passes around the ductus arteriosus (unless a right aortic arch is present). The incidence of recurrent laryngeal nerve injury is estimated at 1% to 7.4% of PDA ligation cases.[29,30] Most infants with a unilateral VFP are brought to the attention of the otolaryngologist for evaluation of a weak cry or stridor or for inability to wean the infant off ventilatory support if thoracic surgery was performed.[30,31] Of those children evaluated by a pediatric otolaryngologist with a unilateral vocal fold paralysis after cardiac surgery approximately 35% will recover vocal fold function.[31] At least half of these patients will have swallowing dysfunction, usually aspiration or laryngeal penetration with modified barium swallow.[31,32] Although many of the patients with a unilateral vocal fold paralysis will be able to feed orally, many will initially require a gastrostomy tube.[31,32]

The more difficult problem is bilateral VFP. The degree of airway obstruction is often severe, requiring a tracheotomy in up to 73% of children.[33-35] The diagnosis of vocal fold paralysis can be made on FFL, but differentiation between bilateral vocal fold fixation and neurogenic VFP cannot be made unless direct laryngoscopy is performed and the glottis palpated. Laryngeal electromyography in the pediatric patient under a light plane of anesthesia can also be helpful to differentiate fixation vs paralysis and assist with prognosis.[36,37]

Workup of patients with idiopathic VFP should include a magnetic resonance imaging (MRI) scan of the brain to rule out an Arnold-Chiari malformation or other intracranial cause of brainstem compression.[38-40] If such a malformation is identified, then early decompression is recommended to obtain a better outcome.[40] If idiopathic congenital bilateral VFP is present, a genetics consultation is recommended to evaluate the patient for chromosome abnormalities.[41]

Approximately 70% of noniatrogenic unilateral vocal fold paralyses will resolve spontaneously, most within the first 6 months of life.[27] The patient with unilateral VFP is often able to compensate for purposes of feeding without medical intervention. Sometimes an infant will require nasogastric feeds on a short-term basis or a gastrostomy tube. An occupational or speech pathology feeding consult is helpful with these infants to rule out aspiration (as seen on modified barium swallow) and to counsel the parents on how to feed the patient. Most often, these infants should start with a slow-flow nipple, then work up to a regular nipple. The voice of most infants with a unilateral VFP is quiet but audible and gains strength with time.

Occasionally, the child with unilateral VFP has problems with severe aspiration and dysphonia. In these children, injection of the vocal fold can be helpful. Most commonly, injection materials used include cadaveric dermis (Cymetra), calcium hydroxyapatite (Radiesse or Radiesse Voice Gel), hydrated porcine gelatin powder (Surgifoam), or absorbable gelatin sponge (Gelfoam), or autologous fat.[42,43] Alternatively, in the older child a medialization laryngoplasty (thyroplasty) can be performed.[42-45] The retrospective review by Link and others of 12 type I thyroplasty procedures in eight pediatric patients ages 2 to 17 years demonstrated that the anatomically lower position of the vocal fold (compared with that in adults) must be taken into consideration if optimum outcomes are to be obtained in children.[45]

The vocal folds spontaneously become mobile in up to 65% of patients with bilateral VFP.[27,46] Prognosis is better if there are no associated anomalies.[33] Most recovery of vocal fold function occurs within 24 to 36 months, although it has been reported in patients up to 11 years of age.[33,34] If recovery occurs after 2 to 3 years, it is often incomplete because of laryngeal muscle atrophy, cricoarytenoid fixation, and synkinesis.[33] The timing of possible surgical intervention is debated. Some authors recommend intervention at a young age. Others suggest waiting until adolescence when the patient is able to decide.[33,34,47]

Many surgical options are possible to improve the airway of a patient with bilateral vocal cord paralysis.[48] The plethora of surgical options indicates that none is uniformly successful—particularly in the young patient. Endoscopically, a lateral cordotomy can be performed to increase the glottic area.[49,50] An arytenoidectomy can be performed via an endoscopic or external cervical approach or using the Woodman approach.[33,51] Alternatively, an arytenoidopexy can be performed using a laterocervical approach.[27,52,47] Triglia and colleagues performed an arytenoidopexy on 34 children with bilateral vocal cord paralysis who had a mean age of 20 months.[47] Of the 15 children who had a tracheotomy or endotracheal tube (ETT) before the procedure, 14 were successfully decannulated postoperatively. Another option is to expand the cricoid cartilage by placing a costal cartilage graft posteriorly, thereby separating the arytenoids and increasing the area between the vocal folds. This procedure can be performed with a laryngofissure or endoscopic approach.[53,54] Finally, lateralization of the paralyzed cord has been described as a potentially reversible approach to vocal cord paralysis.[55]

Hartnick and colleagues described 52 children who underwent surgery for bilateral VFP.[56] The procedures most successful in realizing tracheotomy decannulation were those that included vocal cord

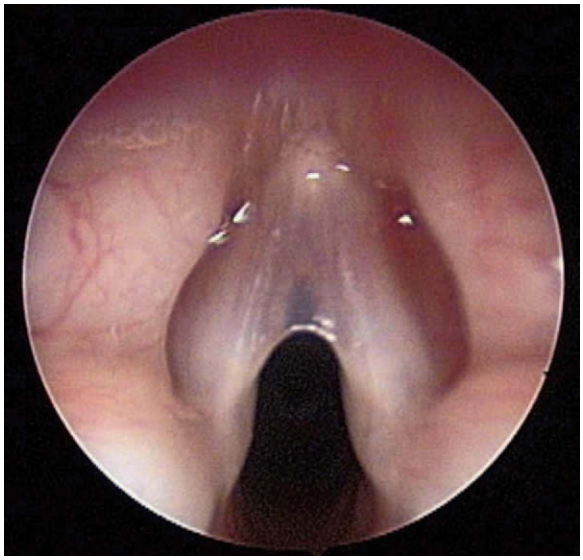

Figure 202-5. Anterior glottic web. Patient presented with chronic hoarseness and mild stridor. *(Copyright Peter Koltai, MD.)*

lateralization procedures combined with a partial arytenoidectomy (71% decannulation rate). These procedures were more successful than CO_2 laser cordotomy or arytenoidectomy procedures (29% decannulation), for isolated arytenoidopexy procedures (25% decannulation) or for posterior costal cartilage graft procedures (60% decannulation). No prospective randomized studies have been performed to evaluate the outcomes of these different surgical options, although meta-analysis has suggested that external arytenoidopexy and external arytenoidectomy are more effective than carbon dioxide ablation procedures.[57]

Laryngeal Web/Atresia

Posterior Webs

Apparent bilateral vocal cord paralysis may occur if an interarytenoid web is present in the posterior larynx causing limited vocal fold abduction (Fig. 202-4). This type of congenital web is rare and often necessitates a tracheotomy in the early years of life.[58] Stridor is the major presenting clinical feature, but patients can also present with obstructive cyanosis at birth or with episodes of apnea.

Diagnosis is made at the time of microscopic laryngoscopy with palpation of the interarytenoid area. Posterior webs may be associated with subglottic stenosis, and bulky arytenoids and abnormal laryngeal position are often present. Management options include long-term tracheotomy with probable decannulation after 3 to 5 years, division of the web (frequently unsuccessful), arytenoidectomy, or open airway reconstruction with a posterior cartilage graft.[58]

Anterior Webs

Anterior congenital laryngeal webs are also rare anomalies typically diagnosed in the neonatal period after an investigation for the source of aphonia and stridor (Fig. 202-5). Occasionally a minor web will not be diagnosed until the child is older and undergoes an evaluation for chronic hoarseness. Most commonly, a web will cause partial obstruction of the anterior glottis and will extend into the subglottic area, causing congenital subglottic stenosis.[59]

The most severe form of a laryngeal web is total atresia of the larynx (Fig. 202-6). A fetus with laryngeal atresia or a web obstructing nearly all of the larynx will develop congenital high airway obstruction syndrome (CHAOS). Magnetic resonance imaging of the affected fetus will show enlarged echogenic lungs, inverted diaphragms, massive ascites, and dilated airways (Fig. 202-7).[60,61] Death results in these infants unless a tracheotomy is performed at the time of birth, therefore delivery by ex utero intrapartum treatment (EXIT procedure) is recommended. The EXIT procedure establishes an airway before completion of birth, while the neonate remains on placental support.

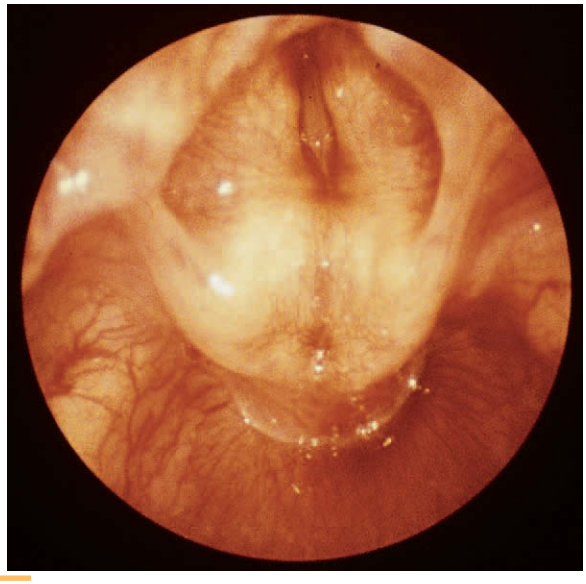

Figure 202-6. Laryngeal atresia. *(From Benjamin B. The pediatric airway, slide #33, Slide Lecture Series. American Academy of Otolaryngology–Head and Neck Surgery, 1992.)*

Many anterior laryngeal webs are associated with deletions of chromosome 22q11.[63] In a review of 17 patients with anterior glottic webs, 11 (65%) were found to be positive for chromosome 22q11.2 deletion.[63] These same microscopic and submicroscopic deletions cause a wide range of phenotypes including DiGeorge's syndrome, velocardiofacial (Shprintzen) syndrome, conotruncal anomaly face syndrome, and sporadic or familial heart defects (Table 202-1). The acronym CATCH 22 (cardiac defect, abnormal facies, thymus hypoplasia, cleft palate, hypocalcemia, and chromosome 22 deletion) has been used to describe the various phenotypes. For this reason, all patients with a diagnosis of laryngeal web should undergo genetic screening and a thorough cardiovascular evaluation, with particular attention being paid to the aortic arch. Delayed diagnosis of a vascular ring can occur in the patient with a laryngeal web whose stridor and dysphagia are attributed only to the presence of the web.[62]

Successful treatment of an anterior laryngeal web most often demands that an open approach be used so that the subglottic narrow-

ing can be corrected.[64,65] Laryngotracheal reconstruction or laryngofissure and silastic keel are used to correct the defect. If laryngotracheal reconstruction is performed, the approach can sometimes be single-staged. In rare cases in which the web is limited, endoscopic treatment may be successful.

Congenital Subglottic Stenosis

Subglottic stenosis in a term newborn is defined as a cricoid diameter of less than 3.5 mm.[66] Congenital, as opposed to acquired, stenosis is typically the result of malformation of the cricoid cartilage. Normally, at the inferior margin of the cricoid cartilage the transverse and anteroposterior diameters of the normal infant larynx are equal, resulting in a ring configuration. In some infants with congenital subglottic stenosis, an elliptical cricoid is present with a transverse diameter that is significantly smaller than the anteroposterior diameter, which may cause respiratory distress and predispose the larynx to injury from endotracheal tube intubation.[66,67] The elliptical cricoid may be found in association with a laryngeal cleft. An "occult" or submucous posterior laryngeal cleft may be associated with subglottic stenosis. This type of cleft is difficult to identify, however, because the soft tissue overlying the posterior cricoid appears normal.

In comparison with the elliptical cricoid, the transverse diameter may be greater than the anteroposterior diameter, causing a flattened cricoid, which again may lead to respiratory distress and intubation trauma. The flattened cricoid may be associated with a trapped first tracheal ring, where the first tracheal ring is inside the cricoid cartilage, thereby reducing the size of the lumen. A narrowed subglottic space can also be caused by a generalized thickening of the cricoid.

The stridor of subglottic stenosis may be inspiratory or biphasic and worsens with patient agitation (increased airflow). A mild stenosis may be asymptomatic until an upper respiratory tract infection causes subglottic edema and the child presents to medical personnel with symptoms consistent with croup. Prolonged or recurrent croup may be caused by mild subglottic stenosis.

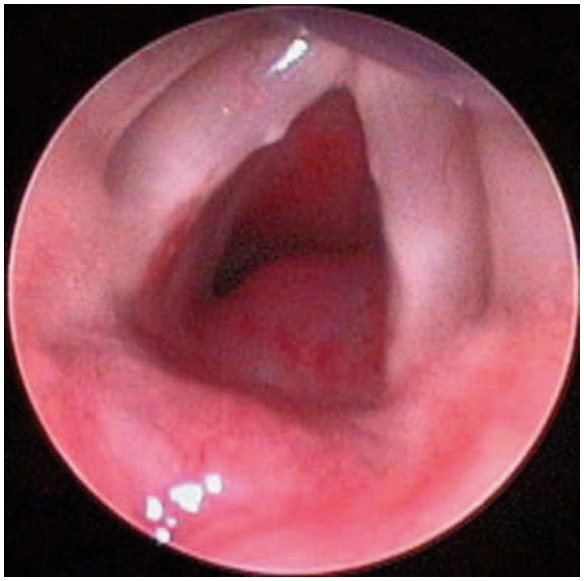

Figure 202-8. Right posterior subglottic hemangioma.

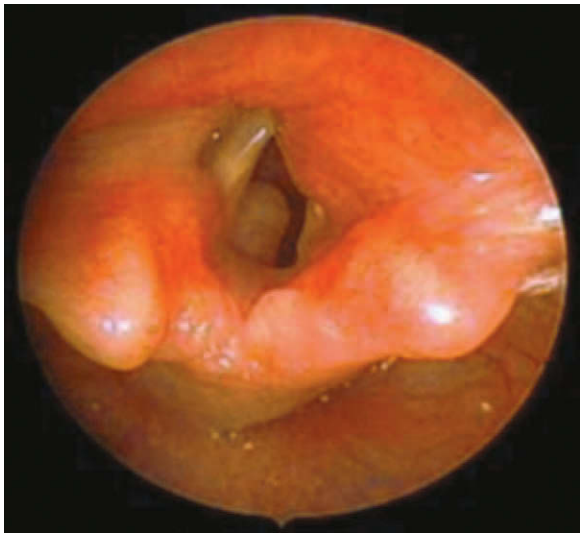

Figure 202-9. Left subglottic cyst.

Direct laryngoscopy and bronchoscopy are needed to fully evaluate subglottic narrowing. Objective measurement at the time of laryngoscopy by sequential gentle placement of endotracheal tubes of various sizes is recommended.[68] The stenosis is then graded: grade I, less than 50% obstruction; grade II, 52% to 70% obstruction; grade III, 71% to 99% obstruction; grade IV, no detectable lumen.[68]

In patients with grade I stenosis, a watchful waiting approach can be taken and the child will likely grow out of the problem as the cricoid cartilage grows. In the child with a more significant stenosis, surgical intervention is usually needed. Because it is primarily a cartilaginous problem, congenital subglottic stenosis does not typically respond to dilation or laser treatment, which is sometimes effective in soft tissue acquired stenoses. If the stenosis is grade II or III, a tracheotomy will likely be needed until the cricoid grows to a sufficient size to allow decannulation, or a laryngotracheal reconstruction performed to expand the cricoid ring. For further details of surgical management, see Chapters 71 and 206 on subglottic stenosis.

Hemangiomas and Subglottic Cysts

Mass lesions in the subglottic area can mimic the symptoms of subglottic stenosis. Subglottic hemangiomas are benign vascular malformations characterized by endothelial hyperplasia. They are twice as common in females as in males, and the patients typically present to medical caregivers in the first 6 months of life with inspiratory or biphasic stridor.[69,70] Often these patients are thought to have nonresolving croup, because they have a barking cough that responds temporarily to oral steroids. Hemangiomas grow rapidly in the first 6 months of life, stabilize for approximately a year, then slowly involute until they are gone, usually by the age of 3 years. To avoid total airway obstruction, medical or surgical intervention is usually needed.

Diagnosis is made at the time of direct laryngoscopy, with viewing of the subglottic area via telescope or microscope (Fig. 202-8). Narrowing of the subglottis can sometimes be seen on x-ray examination of the neck, and computed tomography (CT) or MRI scan can assist in the diagnosis.

The traditional medical treatment used for management of the patient with a subglottic hemangioma is systemic steroids. In most children, systemic steroids result in at least partial regression of the hemangiomas. Steroid therapy alone has been advocated as the primary method of management.[71] Long-term therapy lasting several months is needed if the hemangioma is to be controlled, leading to possible severe side effects such as Cushing's syndrome, hypertension, diabetes, and growth retardation. Intralesional steroids and short-term intubation also have been recommended as a method to control the subglottic hemangioma. Using a protocol of steroid injection followed by 1 week of intubation has resulted in patent airways at a mean of 9.5 months of age in 82% of the 15 patients treated at one institution.[72] Propanolol, a beta-blocking agent, has been used successfully to treat infantile hemangiomas. The conditions under which it will be most successful have not yet been identified.

The traditional surgical option to relieve the airway obstruction associated with subglottic hemangioma is a tracheotomy. The tracheotomy tube bypasses the lesion. Once the lesion involutes, the patient can be decannulated, on average 27 months after the tracheotomy was placed.[69] Accidental decannulation and tracheostomy tube obstruction are the major drawbacks of this approach. The mortality rate of a tracheostomy in an infant is generally accepted to be between 1% and 2%.[73] In addition, the care required to keep an infant with a tracheostomy tube safe is tremendous, causing a severe strain on the patient's family.

The carbon dioxide and potassium titanyl phosphate (KTP) lasers have been used to control hemangiomas.[69,74] Using a CO_2 laser has been reported to be successful,[70,75] but others have reported that the laser did not result in earlier tracheotomy decannulation.[69] It has been proposed that the KTP laser may be the superior instrument for treatment of the hemangiomas because the KTP beam is preferentially absorbed by hemoglobin, making it more applicable to the treatment of vascular lesions.[74] The most significant complication associated with the laser is subglottic stenosis, which has been reported in up to 18% of cases.[75,76] At least one report did not find any advantage of the tracheostomy and laser compared with the tracheostomy alone.[69]

Open surgical resection via a laryngofissure has been reported to be successful in several cases.[69,77,78] This approach seems to be particularly useful in the patients with circumferential or bilateral subglottic hemangiomas.

Another lesion that can mimic the symptoms of a subglottic hemangioma is the subglottic cyst (Fig. 202-9). In one review, 55 patients with subglottic cysts were identified.[79] All had been intubated in the neonatal period and 94% were born prematurely at 24 to 31 weeks of gestation. Intubation trauma is believed to be the cause of these lesions.[80] The cysts can be unroofed with either a laser or microlaryngeal instruments, but recurrence is common.[81,82]

Thyroglossal Duct Cyst

Cysts at the base of tongue in the vallecula are a rare but potentially lethal source of airway obstruction in a neonate (Fig. 202-10). Cases of acute airway obstruction with sudden death have been reported.[83-85] The obstructing cysts are of thyroglossal duct origin and have pseudostratified ciliated or squamous epithelium, with mucous glands and thyroid follicles in the subjacent stroma.[86] If thyroid follicles are not

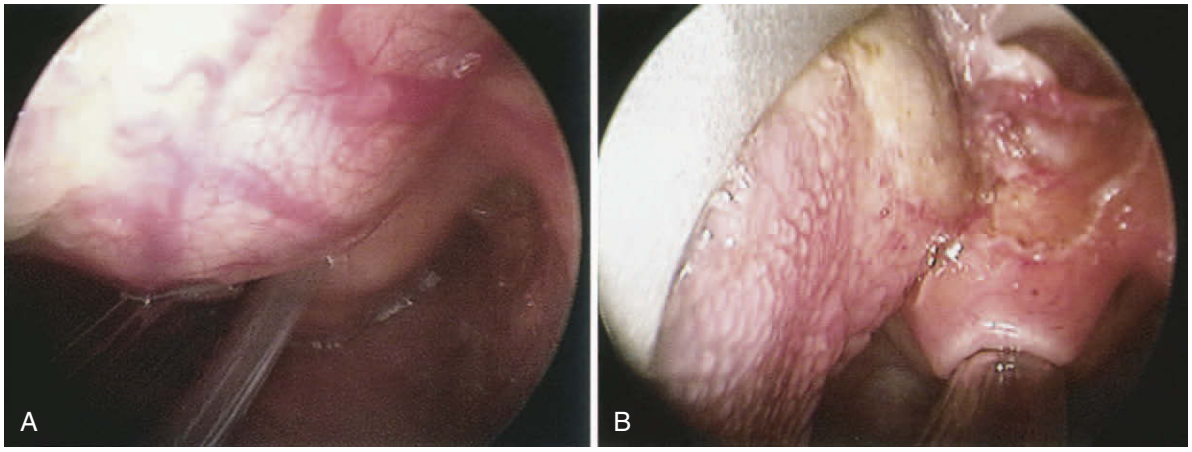

Figure 202-10. Vallecular thyroglossal duct cyst before and after marsupialization.

seen, the pathologist sometimes will call it a vallecular cyst instead of a thyroglossal duct cyst, but the origin is the same. In addition, cysts that occur on the epiglottis or in the vallecula and originate from obstruction of the submucosal glands are sometimes are called "ductal cysts."[87] Infants with thyroglossal duct cysts at the foramen cecum typically develop symptoms within the first few weeks of life. Most commonly the baby will present with stridor but feeding difficulties, coughing, cyanotic episodes, failure to thrive, and breath-holding spells may be present.[87-90] The voice may be normal or may have a muffled quality.

Diagnosis is made at the time of flexible or direct laryngoscopy. A lateral neck x-ray film, CT scan, or MRI scan may be helpful in the diagnosis, but endoscopy is the major diagnostic tool. Definitive treatment should not be delayed for these other investigations in the infant with airway obstruction.[88] The differential diagnosis of a vallecular mass in children also includes a dermoid, teratoma, lingual thyroid, lymphatic malformation, or hemangioma.[85] If a thyroglossal duct cyst or lingual thyroid is identified, then a thyroid scan or ultrasound should be performed to identify other functioning thyroid tissue.

Treatment of all types of vallecular cysts is by endoscopic surgical removal or marsupialization. Aspiration of the cysts for definitive treatment is not advocated because they will recur. In an emergency situation with a tenuous airway, the cyst can be aspirated, with definitive surgical treatment following.

Laryngeal Cysts

Saccular cysts and laryngoceles are unusual causes of respiratory obstruction in children. The anterior-superior portion of the laryngeal ventricle leads to a pouch of mucous membrane called the saccule. The saccule rises superiorly between the false vocal fold, the base of the epiglottis, and the inner surface of the thyroid cartilage. Scant muscle surrounds the saccule, compressing it to express its secretions on the vocal folds. Laryngoceles (abnormal dilation or herniation of the saccule) can be internal, confined to the interior of the larynx and extending posterosuperiorly into the area of the false vocal fold and aryepiglottic fold, or laryngoceles can be external, passing through the thyrohyoid membrane and presenting as a mass in the neck. If both an internal and external component are present, the laryngocele is termed a *combined laryngocele.* The radiographic finding of an air-containing rounded mass in the neck or supraglottic region, sometimes with air-fluid levels, confirms the presence of a laryngocele.[10]

Saccular cysts result from the obstruction of the laryngeal saccule orifice, or the collecting ducts of the submucosal glands located around the ventricle produce the saccular cysts. Saccular cysts may be anterior, protruding between the anterior and posterior vocal cords, or lateral, extending into the false vocal cord and aryepiglottic fold (Figs. 202-11 and 202-12). Laryngoceles produce intermittent upper airway obstruction and hoarseness because of episodic filling with air, whereas saccular cysts produce constant symptoms because of mucoid fluid within the cyst. Diagnosis is made at the time of flexible or direct laryngoscopy.

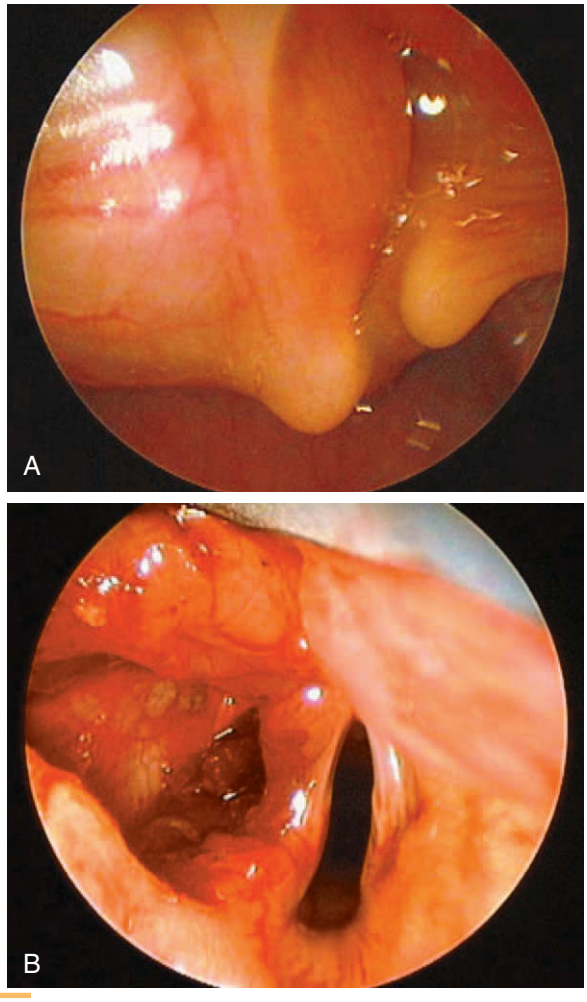

Figure 202-11. **A,** Left lateral saccular cyst. The 17-month-old female presented with a muffled cry and history of stridor when younger. **B,** Area of saccular cyst following endoscopic resection.

Other laryngeal lesions, such as hemangiomas, laryngeal duplication cysts, hamartomas, choristomas, and teratomas, can present with similar symptoms and appearance.[91-94]

Typically, treatment of the cysts involves endoscopic marsupialization of the cyst, most commonly with the CO_2 laser so that the back wall of the cyst can be ablated.[95] Recurrence after marsupialization of a posterior saccular cyst is common, often necessitating several

Figure 202-12. Computed tomography scan of child with a lateral saccular cyst.

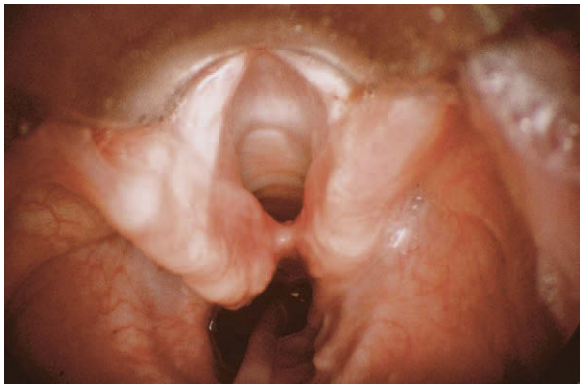

Figure 202-13. Laryngotracheal cleft—Benjamin-Inglis type 3. *(From Benjamin B: The pediatric airway, slide #34, Slide Lecture Series. American Academy of Otolaryngology–Head and Neck Surgery, 1992).*

endoscopic procedures.[96] Tracheotomy may be required and subglottic stenosis is a potential complication of the treatment. Alternatively, removal of the cyst can be achieved via a lateral cervical approach through the thyrohyoid membrane.[97]

Laryngeal-Laryngotracheoesophageal Cleft

Laryngeal cleft (LC) and laryngotracheoesophageal clefts (LTECs) are rare congenital anomalies caused by failure of the posterior cricoid lamina to fuse and incomplete development of the tracheoesophageal septum (Fig. 202-13). This developmental failure leads to an abnormal communication between the posterior portion of the larynx and esophagus.

Presenting symptoms depend on the extent of the cleft. Small clefts involving only the interarytenoid musculature (type 1) are difficult to diagnose and the need for a high index of suspicion cannot be overemphasized. There are wide variations in the reported incidence of presenting symptoms suggesting that the diagnosis of mild LCs is an inexact science. Feeding difficulties and aspiration have been reported to occur in 40% to 90% of patients, and stridor in 15% to 94% of patients.[98-100] Recurrent pneumonia and chronic cough are also commonly seen with this diagnosis. The severity of symptoms typically increases with the extent of the cleft. Patients with LTECs that extend into the trachea present with signs and symptoms of severe aspiration, respiratory distress, and cyanosis.[101]

Most patients with LC and LTECs have other congenital abnormalities, most commonly including tracheoesophageal fistula (TEF), esophageal atresia, congenital heart disease, cleft lip and palate, micrognathia, glossoptosis, laryngomalacia, and Opitz-Frias syndrome (see Table 202-1).[102] A tracheoesophageal fistula is present in approximately 25% of patients with an LC or LTEC and is an important prognostic indicator of possible failure of the surgical repair.[100-104]

Diagnosis is made at the time of microdirect laryngoscopy where the interarytenoid mucosa is spread laterally to reveal the cleft larynx. Care must be taken to look at and palpate the interarytenoid area, because the cleft may be missed if only a flexible bronchoscopy or direct laryngoscopy without palpation is performed. In a group of 20 children, the average interarytenoid notch height relative to the vocal folds has been found to be approximately 3 mm.[105] In this study, a low interarytenoid notch height was found to be significantly correlated with laryngeal incompetence and aspiration. In the patient with a laryngeal cleft, bronchoscopy and esophagoscopy should also be performed and a biopsy of the esophagus considered if there is any evidence of gastroesophageal reflux. Other diagnostic tests often performed include barium swallow, functional endoscopic evaluation of swallow (FEES), and chest x-ray study to evaluate the extent of aspiration.[98] Barium swallow shows spillover of barium from the esophagus into the trachea. High small clefts may be difficult to differentiate from high H-type tracheoesophageal fistulas.[10]

Multiple classification schemes have been described, all based on the vertical length of the cleft (Table 202-2), with the Benjamin-Inglis system being used most commonly (Fig. 202-14).[103,106-109] In addition, submucous "occult" laryngeal clefts have been described.[66,110,111] The submucous laryngeal cleft consists of a posterior midline cartilage defect, with intact soft tissue including mucosa and interarytenoid muscle. It is associated with subglottic stenosis and typically is not identified unless a postmortem examination is performed.

Early repair of LCs and LTECs are recommended to avoid irreversible pulmonary damage from continued aspiration.[108] The method of surgical repair for LCs and LTECs depends on the type of cleft present. For clefts that extend only through the interarytenoid musculature, antireflux therapy may be enough to control symptoms. At some centers, conservative treatment with temporary nasogastric tube feedings is recommended.[99] If a Benjamin-Inglis type I or II cleft is symptomatic, endoscopic or open surgical repair is possible.[100] If the significance of the cleft for a particular patient is unknown, Gelfoam can be injected into the interarytenoid area to determine whether symptoms are alleviated and to provide clarification of the contribution of the posterior laryngeal cleft to the clinical status of the patient.[112]

For some clefts that extend into the cricoid and all clefts that extend below the cricoid (Benjamin-Inglis type II-IV), an open procedure is required. These clefts are best repaired using an anterior laryngofissure to avoid injury to the vascular and neural structures.[113,114] If the cleft extends to the carina (type IV), an anterior laryngofissure and median sternotomy are recommended.[115] Most patients require a tracheotomy in at least the perioperative period. If the median sternotomy approach is used, then the intrathoracic part of the repair is performed with the patient on cardiopulmonary bypass or extracorporeal membrane oxygenation.[102,115] The prognosis is grim for patients with a type IV LTEC that extends all the way to the carina.[115]

Most commonly, a two-layer closure of the cleft is performed with absorbable sutures. If possible, the two layers should not directly oppose each other to minimize the chance for breakdown and recurrent clefting. Tracheoesophagoplasty with two overlapping flaps via an anterior approach has also been used with good results.[113] An interposition graft may be placed between the two suture lines. Possible grafts include a sternocleidomastoid or strap muscle flap (inferiorly based), tibial periosteum, auricular cartilage, or temporalis fascia.[101,104,114,115]

Outcomes of surgical repair vary.[101,113,114] A higher rate of suture line breakdown occurs in the more extensive clefts and after surgical repair of an LC or an LTEC in any child who also has a tracheoesopha-

geal fistula (see Fig. 202-14). In a retrospective review of 25 children who underwent a Myer-Cotton classification type LII, LIII, or LTEI cleft repair, 12 of 14 (86%) who had a previously repaired TEF subsequently developed a recurrent LC or LTEC (Fig. 202-15).[104] Of the remaining 11 patients who did not have a TEF, only one experienced a suture line breakdown. Gastroesophageal reflux and eosinophil gastroenteritis can also negatively affect the surgical repair and thus should be treated aggressively.[116-118]

Bifid Epiglottis

A bifid epiglottis is a rare anomaly defined as a cleft of the epiglottis encompassing at least two thirds of its length.[119] The infants typically present with stridor or aspiration, although they also can be asymptomatic. The diagnosis is made on laryngoscopy, and if the epiglottis is lax, prolapsing into the laryngeal inlet, supraglottoplasty can be performed.

Associated congenital anomalies are common and tend to be midline.[120] In the head and neck these anomalies include cleft palate, cleft uvula, micrognathia, and microglossia (see Table 202-1). Polydactyly has been reported in approximately 75% of patients with a bifid epiglottis.[121] The hypothalamic-pituitary axis is often disrupted in children with a bifid epiglottis. Congenital hamartomas or the absence of the pituitary gland can lead to growth hormone insufficiency with resultant growth retardation, secondary hypothyroidism with resultant cretinism, or secondary hypoadrenalism resulting in salt wasting and hypoglycemia.

Pallister-Hall syndrome (PHS), or congenital hypothalamic hamartoblastoma syndrome, is commonly associated with a bifid epiglottis.[122] Laryngoscopic examination of 26 subjects with PHS showed that 15 had a bifid or cleft epiglottis (58%). Other associated features of the syndrome include polydactyly, pituitary dysfunction, imperforate anus, and laryngotracheal cleft. It has an autosomal dominant inheritance pattern, with variable expressivity and is caused by a mutation in the GLI3 gene.[122] Because of the high incidence of hypothalamic-pituitary problems, all infants with a congenitally bifid epiglottis should undergo an MRI of the brain, an endocrine evaluation, and a genetics consultation.

Summary

Congenital laryngeal anomalies cause a spectrum of airway difficulties. In laryngomalacia, the stridor is transient and in most cases resolves spontaneously without intervention. Conversely, laryngeal atresia or obstructing vallecular cysts can lead to neonatal death. Although nearly all anomalies present with stridor, they can cause a host of other problems for the young child, including dysphagia, aspiration, failure to thrive, and dysphonia. Laryngoscopy, either direct or flexible, is the procedure most likely to diagnose the problem, although complete laryngotracheobronchial endoscopy may be needed to rule out a laryngeal cleft or other synchronous airway lesions.

CHAPTER TWO HUNDRED AND THREE

Voice Disorders

Sukgi S. Choi

George H. Zalzal

Key Points

- Evaluation and management of voice disorders in children can be more challenging because of their inability to cooperate, lack of awareness of the problem, and lack of motivation to change.
- Otolaryngologic evaluation of a child with voice disorder begins with detailed history, physical examination, flexible laryngoscopy, and videostroboscopy.
- Voice evaluation by a speech pathologist should include perceptual, acoustic, and aerodynamic analyses.
- Voice therapy plays an essential role in management of pediatric voice disorders and should be used liberally both preoperatively and postoperatively.
- Voice disorders can be due to functional and organic etiologies. Organic voice disorders requiring primarily surgical management include vocal fold paralysis, laryngeal web, posterior glottic stenosis, recurrent respiratory papillomatosis (RRP), and malignant tumors. Vocal fold granulomas typically require medical management. Vocal nodules, cysts, polyps, and sulcus are initially managed with voice therapy but may require surgery.
- Surgery, especially in very young children, should be undertaken with caution.

Voice production starts with the expiration phase of respiration, which provides the air pressure to vibrate the vocal folds. The lowest periodic component of vocal fold vibration is termed *fundamental frequency* and is perceived as pitch.[1] Harmonics are integer multiples of fundamental frequency in voiced sounds. The energy or intensity in the harmonic components decreases as frequency increases.

Sound waves generated by vocal fold vibration are modified by the size, shape, and tenseness of the resonating chamber, which consists of the oropharynx, the nasopharynx, and the nasal cavities. The resonance of the vocal tract is termed *formant*.[1] Although an infinite number of formants exist, only the first four formants (F1, F2, F3, and F4) are of clinical interest; the lowest frequency formant is F1. Each formant is characterized by its center frequency and bandwidth. Constriction of the vocal tract near a volume velocity maximum or minimum can respectively lower or raise the formant frequency. The resulting sound wave is further modified by the articulators (lips, teeth, tongue), resulting in voice and speech production. A normal voice should be pleasing in quality and have appropriate balance of oral and nasal resonance, intensity, fundamental frequency level, and prosody. Voice disorder can result in a voice that is unpleasant for the listener or can interfere with effective communication.

The underlying cause of a voice disorder can be organic or functional. Organic voice disorders result from congenital or acquired anatomic abnormalities. Functional disorders are caused by emotional or psychological problems but can lead to anatomic alterations. However, even when a voice disorder results primarily from an organic cause, there is often a psychological overlay.[2]

Although the reported incidence of voice disorders in children varies greatly, most voice surveys of children show a 6% to 9% incidence of voice disorders.[3] Voice disorders are categorized depending on the area of problem: voice quality, resonance, loudness, and pitch. This classification is arbitrary, and a voice disorder often has several problem areas. Any anatomic abnormality involving the free edge of the vocal fold can affect voice quality and result in harshness, breathiness, or hoarseness. Disturbances in resonance can be caused by hypernasality or hyponasality. Loudness or intensity problems occur when a child speaks too loudly or too softly. Deviations in pitch occur with inappropriate speaking fundamental frequency, narrow pitch range, or excessive pitch breaks. An algorithm for the evaluation and management of voice disorders is outlined in Fig. 203-1.

Evaluation

The evaluation of a voice disorder in a child requires a systematic approach. Additional evaluation by specialists from a variety of disciplines including a pediatrician, pulmonologist, gastroenterologist, psychologist, and social worker may be necessary. A detailed history, including medical, birth, growth and development, and speech and language history is obtained, followed by detailed voice history to determine the cause of the voice disorder and its contributing factors, potentially including any pulmonary disease. Typically, voice history should include a description of the disorder, time of onset, any known causes, severity of the disorder, exacerbating or alleviating factors, voice use history, and any previous history of voice or speech therapy.

Social and functional impact of voice impairment can be evaluated using rating scales such as Pediatric Voice Outcomes survey (PVOS), Pediatric Voice-Related Quality-of-Life Survey (PVRQOL), and Pediatric Voice Handicap Index (pVHI).[4-6] These rating scales are designed to provide physicians with the parents' perception of the severity of the child's voice disorder and its impact on the child's daily life; they are used to follow the child's progress before and after therapy and surgical intervention.

Physical examination should concentrate on the head and neck areas. The ears are examined for evidence of previous and current ear disease. A nasal examination should reveal any deviation of the septum

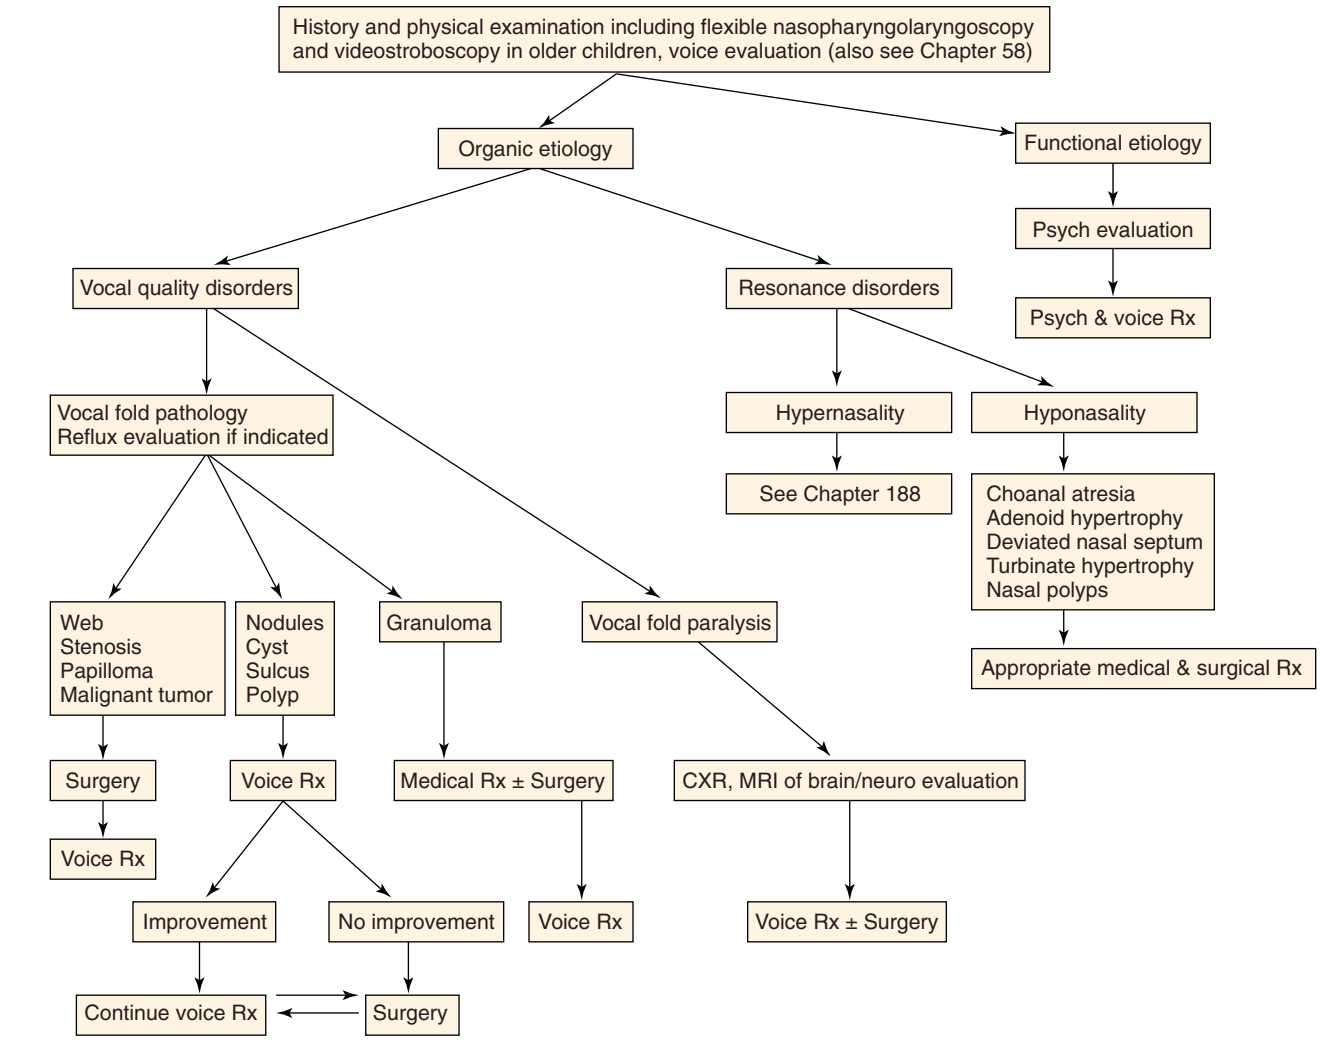

Figure 203-1. Evaluation and management of voice disorders in children.

and turbinate abnormalities. An oropharyngeal examination should focus on the structural integrity and mobility of the soft palate and is followed by flexible fiberoptic nasopharyngolaryngoscopy. Flexible fiberoptic scopes determine the size of the adenoid, velopharyngeal function, and any pathology in the supraglottic and glottic areas.

Stroboscopic examination, which uses a short burst of light in synchrony with vocal fold motion, can seemingly slow down the movement of the vocal folds and allow more careful examination of the vocal folds and their motion.[7] It is particularly useful in differentiating superficial from deep lesions. Laryngeal stroboscopy can delineate vocal fold symmetry, periodicity, vibratory amplitude, mucosal wave, glottal closure, and rigidity,[7] but it is not possible in many children. Bouchayer and Cornut[8] found that stroboscopic examination in children often had to be quick; therefore their results tended to be inconclusive. Hirschberg and colleagues[9] found that stroboscopy was possible only in children older than 6 or 7 years. McAllister and others[10] completed stroboscopic examination in only half of 60 patients age 10 years and older. The newer digital flexible endoscopes may allow stroboscopic examination in younger children.[11] In our voice clinic, digital flexible stroboscopy has been used successfully in children as young as age 3 years. Although stroboscopic examination can be instrumental in accurate diagnosis of a voice disorder, rigid endoscopy under anesthesia may be necessary in some children to establish diagnosis and for therapeutic intervention.

The child's voice is evaluated by a speech-language pathologist, usually in a voice laboratory. A typical voice evaluation consists of perceptual, acoustic, and aerodynamic analyses carried out as the child performs several speaking tasks. There are no universally accepted standards for speech and voice evaluation, and the speaking tasks, the speech parameters measured, and the method of measurement vary greatly.

There are several commonly used speaking tasks.[3] The first is oral reading, which is possible only in older children. Children who can read at third grade level or better are given a specific passage to read; younger children are allowed to select the reading material. The second task is conversational speech or connected speech at least 1 minute long. The child is asked to tell a story about a picture or talk about a specific topic (e.g., pets, a vacation, a hobby). Based on these two tasks, the speech-language pathologist can perceptually and acoustically analyze the child's speech for most voice parameters, including prosody.

The remaining speaking tasks are designed to evaluate more isolated aspects of the child's voice. The third task consists of counting from 1 to 10, 60 to 70, and 90 to 100.[3] The counting is done carefully, once slowly and then as rapidly as possible. This is repeated for three levels of loudness (soft, average, loud) and pitch (low, modal, high). This task reveals any problems with laryngeal tone, resonance, pitch, and loudness.

The fourth speaking task is the production of isolated speech sounds. This consists of sustaining certain vowel sounds (e.g., /a/, /i/) for at least 5 seconds and repeating them three times to determine laryngeal tone, resonance, and fundamental frequency. The child should then sustain /a/ at a comfortable pitch and loudness for as long as possible after a deep inspiration and repeat this three times with a break in between each attempt to determine the maximal phonation time and whether the child had adequate respiratory drive to maintain

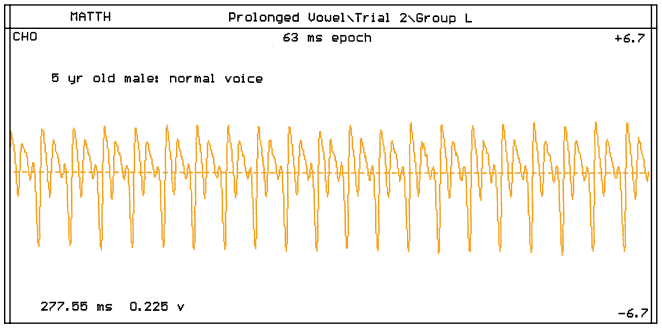

Figure 203-2. Voice tracing of a normal voice sustaining a prolonged vowel: mean fundamental frequency, 332.53 Hz; jitter, 0.36%; shimmer, 1.9%; harmonic/noise ratio, 12.37 dB.

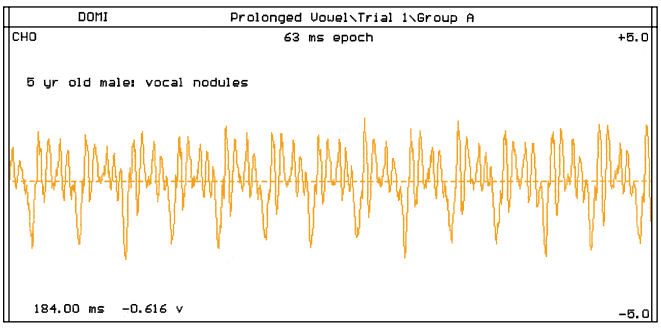

Figure 203-3. Voice tracing of a hoarse voice (caused by vocal nodules) sustaining a prolonged vowel: mean fundamental frequency, 220.60 Hz; jitter, 2.26%; shimmer, 4.34%; harmonic/noise ratio, 7.84 dB.

continuous voice.[3] This same procedure is repeated with /s/ and /z/. In a normally functioning larynx, the s:z ratio should be close to 1. However, a lesion in the vocal fold margins (e.g., vocal fold nodules) increases the amount of airflow and decreases the time on /z/, resulting in a ratio of 1.4 or greater 95% of the time.[12]

Finally, the examiner should instruct the child to repeat certain consonants, words, and short sentences to assess the child's articulation abilities and speech intelligibility. The words and sentences are typically chosen to bring out specific problems such as velopharyngeal insufficiency.

The speech samples are analyzed, and a voice profile can be then developed using scales such as the Buffalo III voice profile.[3] This voice profile classifies voice abnormalities as follows: 1, normal; 2, mild; 3, moderate; 4, severe; or 5, very severe. It evaluates laryngeal tone, pitch, loudness, nasal resonance, oral resonance, breath supply, muscles, voice abuse, rate, speech anxiety, speech intelligibility, and overall voice rating. Other perceptual scales such as GRBAS and Consensus Auditory-Perceptual Evaluation-Voice (CAPE-V) are also used in the evaluation of pediatric voice.[13,14]

Aerodynamic analysis provides objective measures of the velopharyngeal and vocal fold functions. The oral-nasal acoustic ratio and palatal efficiency rating computed instantaneously have been used to evaluate velopharyngeal function.[15,16] Laryngeal airway resistance can be measured to assess the effective closure of the vocal folds to airflow. This is measured noninvasively using an anesthesia mask, a pressure-sensing catheter, and a flow-sensing pneumotachometer. Values less than 30 cm H_2O/L/sec indicate inadequate closure, whereas values greater than 60 cm H_2O/L/sec are associated with hyperkinetic voice disorders.[17] Normative aerodynamic measures for children age 6 to 10 are available.[18] These techniques of aerodynamic analysis are being replaced by computer-assisted voice analysis programs.

Computer-assisted analysis of voice disorder was introduced in 1990 and is being used with increasing frequency.[19] This technology presents the opportunity to supplement perceptual evaluation of voice disorders and has replaced many traditional methods of evaluation. Evaluation of naturalness and intelligibility of speech still requires the human ear.

Computer-assisted voice analysis can provide the mean fundamental frequency, intensity, and amplitude of voice based on a small voice sample (0.5 second) for comparison with existing normative values for age and sex (Figs. 203-2 and 203-3).[19] Until recently, no normative data for children in these analyses was available and normative data from adult studies in the literature were used[20]; however, in 2002, Campisi and colleagues[21] published a pediatric normative database for computer-assisted voice analysis.

Other information provided by computerized voice analysis includes harmonics-noise ratio, amplitude perturbation (shimmer), frequency perturbation (jitter), and electroglottography. Aerodynamic measures can be obtained in less than 60 seconds using the pneumotachographic mask. Parameters that can be measured include subglottal pressure; transglottal airflow; oral pressure; nasal flow; airflow; resistance and efficiency; inspiratory, expiratory, and pause aerodynamics; and nasal and velopharyngeal resistance. Voice analysis is also discussed in Chapter 58.

Voice Therapy

There are important differences between voice therapy in children and in adults. Children often do not have the insight that their voice needs to be modified and they lack the motivation to change. Therefore, the therapist must work to increase the child's awareness of his or her vocal behaviors and awareness of behaviors that require change.

Voice therapy entails two stages.[22] The first stage consists of 10 exploratory sessions, each lasting 35 to 40 minutes. This stage helps determine the goals and specific procedures to be used in stage 2, which consists of regular voice therapy sessions for 2 to 5 months. The frequency of therapy is determined by the severity of the dysphonia. Therapy should be supplemented by practice at home to hasten resolution of dysphonia. The total therapy duration is approximately 4 to 5 months; improvement or resolution of dysphonia should be significant.

During the initial phase of voice therapy, the mechanisms of voice production and voice problems are explained to the child in simple terms, and a list of rules regarding good and bad voice are provided.[3,22] A main goal of therapy is to eliminate vocal abuse by decreasing the total amount of talking; however, even in highly motivated children, total voice rest may not be feasible. Listening training and auditory feedback are essential in voice therapy because, to correct a voice disorder, the patient should learn to differentiate normal and abnormal voices for comparison with his or her own voice.[3]

Problematic muscular tonus, loudness, pitch, and rate require therapy. These areas are often closely interrelated and should be managed simultaneously. The child is taught the following steps to correct a problematic voice parameter[3]: correct rules of specific voice parameters; identification of incorrect and correct voice habits in others; recognition of personal use of incorrect voice and modification of this habit; recognition of personal use of correct voice; recognition of situations that cause personal use of poor voice habits and good voice habits; and an increase in the amount of time that correct habits are used. These steps can be applied to any problematic voice parameter.

Voice production depends on well-coordinated movement of muscles involved in phonation. Hyperfunction or excessive muscular tonus frequently occurs in children with benign laryngeal pathology, whereas hypofunction with flaccid muscular tonus occurs in those with functional dysphonia. For both problems, control of muscular tonus and proper positioning of the laryngeal, pharyngeal, and oral structure should be taught. To correct hyperfunctional states, posture instruction, breathing exercises, relaxation procedures, muscle tension reduction technique, chewing method, muscle stretching exercises, and biofeedback can be used.[23-25] Wilson[3] found that the chewing method and progressive relaxation are particularly useful in reducing muscular tension. For hypofunctional states, the pushing method increases muscular tension.[26]

Excessive loudness of voice is accompanied by high pitch, rapid rate of speaking, and hyperfunctional state. Therefore it is often neces-

sary to manage these problems simultaneously. Eliminating loud speaking is particularly important in children with vocal nodules. Correct training for loudness, pitch, and rate involves teaching the child to listen and to monitor various voice parameters. Often, modifying loudness lowers pitch, and attention to loudness and pitch normalize the rate of speaking.

Functional Etiology

Functional voice disorder is diagnosed when no anatomic or organic cause can be found. Functional dysphonia is categorized as disturbed mutation, psychological dysphonia, imitation, and faulty learning.[3] Mutation is the change of voice that occurs during puberty. Pitch lowers in males and, to a lesser extent, in females. Mutation can be delayed, prolonged, or incomplete. High pitch, hoarseness, and voice breaks are characteristic. Mutational voice disorder can result from endocrine pathology.[3]

Functional dysphonia resulting from psychological causes seldom occurs in children; only isolated case reports can be found in the literature.[27] The underlying psychological problems are related to or are part of tensional symptoms, adjustment, anxiety, or personality disorders.[28] Functional dysphonia may be a form of conversion hysteria. The disorder may be complete aphonia or partial loss of voice. The dysphonia is often variable, with effortful voice production and easy fatigue. Laryngeal examination may show ventricular band approximation, bowed vocal folds, or hypoadducted vocal folds (hysterical aphonia). Vocal fold movement is normal with inhalation and cough.

Faulty learning[29] occurs when a child imitates cleft palate or hearing-impaired speech or learns to talk louder than normal because of the presence of hearing-impaired persons in the household.

In adults, several approaches have been used to manage functional dysphonia, including behavior therapy, hypnosis, speech therapy, psychotherapy, and a combination of speech therapy and psychotherapy. In children, the optimal management is unknown but psychotherapy or psychological counseling is often carried out in conjunction with voice therapy.

Organic Etiology

Resonance Disorders

Resonance disorders include hypernasality and hyponasality. Hypernasality is usually caused by velopharyngeal insufficiency from underlying palatal abnormalities. Hyponasality can result from any underlying condition that causes nasal or nasopharyngeal obstruction. The underlying pathology may be choanal atresia, deviated nasal septum, turbinate hypertrophy, nasal polyps, or, most frequently, adenoid hypertrophy. In performing adenoidectomy, particular attention should be paid to the structural integrity of the palate to decrease the incidence of postoperative velopharyngeal incompetence. Accurate diagnosis and appropriate medical and surgical management of these underlying conditions are further discussed in Chapter 188.

Vocal Quality Disorders: Surgical Management

Vocal Fold Paralysis

Vocal fold paralysis in children results from birth trauma and congenital anomalies of the central nervous system and the heart and great vessels. Any infant or child with vocal fold paralysis should be evaluated with chest radiograph and imaging of the central nervous system.[30-33] Vocal fold paralysis is the second most common cause of congenital stridor in children and represents 10% of congenital anomalies of the larynx.[34] Prognosis for spontaneous recovery is better for acquired, right-sided, and unilateral paralysis.[35-37]

More than 50% of vocal fold paralysis in children is bilateral.[32,38] Because arytenoid fixation can be mistaken for bilateral vocal fold paralysis, the cricoarytenoid joint should be palpated at rigid endoscopy. Laryngeal electromyography may be the most specific and sensitive test to determine the presence of vocal fold paralysis. More than 50% of the time, bilateral vocal fold paralysis requires tracheotomy for the establishment of an airway; however, the voice is often normal. Although spontaneous recovery of vocal fold function is possible after 2 to 3 years, late recovery is often incomplete because of laryngeal muscle atrophy, synkinesis, and cricoid fixation.[39] If vocal fold function does not return spontaneously after 10 to 12 months, surgery to decannulate the child should be considered.[31,40]

Surgical options to correct bilateral vocal fold paralysis consist of reinnervation with a nerve-muscle flap, cordotomy, lateralization procedures (e.g., arytenoidopexy), arytenoidectomy through a posterolateral external approach, arytenoidectomy through laryngofissure, or endoscopic arytenoidectomy.[31,40-44] Reinnervation of the posterior cricoarytenoid muscle is not universally successful,[38] although Tucker[45] reported it to be the management of choice in children. Because of the small size of the laryngeal structure, endoscopic techniques can be more difficult and less successful in children.[31,46] Cordotomy, a procedure in which the membranous vocal fold is sectioned from the vocal process of arytenoid, has limited use in children and may be useful as an adjunct to other procedures.[41,47] Narcy and colleagues[40] found Woodman's procedure to have a higher failure rate and recommended arytenoidopexy by an external posterolateral approach. However, Bower and colleagues[31] recommended arytenoidectomy through a laryngofissure because it provided better exposure, better control over the final fold position, and a high rate of success (84%). Although most patients have adequate voice postoperatively, breathiness, hoarseness, and pitch change are seen, and patients may require voice therapy. The resulting voice disorder is inversely proportional to the adequacy of the airway.

Unilateral vocal fold paralysis rarely requires airway intervention and often goes unrecognized until the child is older. The voice in unilateral vocal fold paralysis is hoarse, weak, and breathy. It usually improves spontaneously over 6 to 12 months by contralateral vocal fold compensation; recovery may be hastened by the use of voice therapy. However, in a few patients, persistent problems with dysphonia or aspiration require surgical intervention.[48] Surgical options include vocal fold injection, surgical medialization, and reinnervation. Surgical interventions should be done in conjunction with preoperative and postoperative voice therapy.

Polytef injection immediately improves voice; however, it is irreversible and changes vocal fold vibratory characteristics and thus results in poor vocal quality. Furthermore, in children, determining the amount of polytef to inject is difficult because general anesthesia is often necessary and airway obstruction is possible because of the small size of the larynx.[45] Levine and colleagues[48] recommended injection of an absorbable gelatin sponge, which is similar to polytef injection except that its effects are temporary. Fat injection appears to be well tolerated by the body, does not cause the vocal fold to become stiff, and is not absorbed extensively.[49] Recently, other injection materials such as AlloDerm and calcium hydroxyapatite have become available[50] but they have not yet been widely used in children.

Several surgical techniques are available for medialization of the vocal fold.[45,51-53] Isshiki type I thyroplasty is theoretically reversible and does not change the vibratory characteristics of the vocal fold; however, it does not restore tensioning capability of the vocal folds and requires external incision and a temporary tracheotomy in most cases. In children, this procedure is technically more difficult and may cause airway compromise. Experience with thyroplasty in children has been limited because of a lack of knowledge about the effect of this technique on thyroid cartilage growth.[48] Gray and colleagues[47] recommended thyroplastic operations only in patients with mature larynx because they believed that the operation may fix the distance between the arytenoid and thyroid cartilage. Link and others[54] have reported their experience with thyroplasty in children ages 2 to 17 years and have recommended modified surgical approach in children to compensate for their lower position of vocal folds. Although voice quality improves using objective measurement, the resulting voice is not ideal.[55]

Selective reinnervation of the adductors of the larynx does not compromise potential spontaneous recovery, necessitate tracheotomy, or preclude eventual use of other techniques; it restores tensioning capability, thereby providing better pitch control. However, it is an open procedure, and motion may not be observed for up to 6 months.[45]

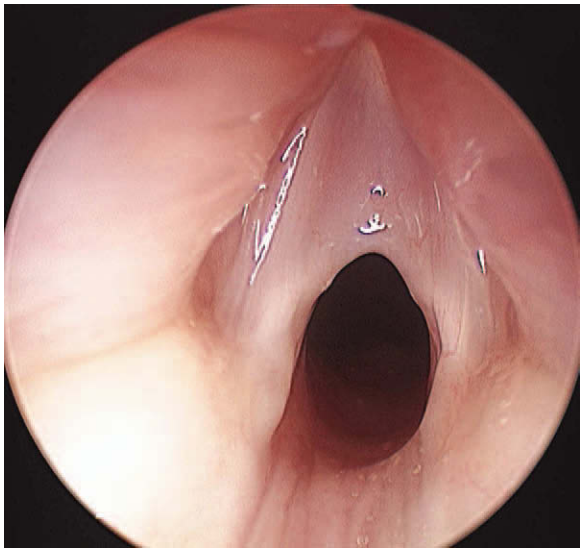

Figure 203-4. Type 2 laryngeal web.

Excellent results have been reported by Crumley[56] and Tucker.[45] Tucker advocated it to be the procedure of choice in children.[45]

Laryngeal Web

Smith and Caitlin[57] reported that glottic web and atresia account for 5% of congenital anomalies; however, some consider the true incidence of congenital web of larynx to be more common, whereas others consider it more rare. Web occurs because of failure of the epithelium, which temporarily obliterates the developing laryngotracheal lumen, to reabsorb during the eighth week of embryogenesis. Glottic web is classified depending on its severity.[58] Type 1 is an anterior web involving 35% or less of the glottis. True folds are visible within the web, and there is little or no subglottic extension. Although there is usually no airway obstruction, voice dysfunction is common. Type 2 is an anterior web involving up to 50% of the glottis (Fig. 203-4). True folds are usually visible within the web, and subglottic involvement is minimal. Voice disorder is the common presenting symptom. However, airway compromise can be seen with upper respiratory tract infections. Type 3 involves up to 75% of the glottis, and the anterior portion of the web is solid and extends into the subglottis. Most of the true folds are visible within the web. Airway obstruction and voice disorder are moderately severe. Type 4 involves up to 90% of the glottis, and the web is uniformly thick and extends into the subglottic area with resulting subglottic stenosis. Infants with this type of web are aphonic with severe airway compromise.

In 1985, Cohen and others[58] reviewed 51 cases of children with laryngeal web and recommended that surgery be tailored according to web severity. A type 2 web was divided with a knife, microsurgical scissors, or laser followed by dilations. Types 3 and 4 were managed by tracheotomy and insertion of a laryngeal keel through a laryngofissure. The anterior commissure is not adequately reconstructed by any surgical procedure, and the resulting voice continues to be abnormal and requires vocal rehabilitation.

Recommended management of a thin laryngeal web involves endolaryngeal division of the web with a knife or CO_2 laser with temporary placement of a keel to prevent readhesion. Thick glottic webs are approached through precise midline thyrotomy, a laryngofissure with removal of excess tissue under direct vision using a fiberoptic laryngoscope, and placement of a mucosal graft fixated with fibrin glue or stenting.[59] The use of CO_2 laser in cases of thick web is not recommended. The resulting voice is reportedly satisfactory, but objective postoperative analysis of voice is unavailable.

Posterior Glottic Stenosis and Cricoarytenoid Joint Fixation

Posterior glottic stenosis in children can be congenital (e.g., caused by interarytenoid web or cricoarytenoid fixation). More commonly, posterior glottic stenosis results from airway trauma from intubation. Bogdasarian and Olson[60] classified posterior glottic stenosis into four types. This classification was later modified for the pediatric population by Irving and associates.[61] Type I is vocal process adhesion, type II is posterior commissure or interarytenoid scar, type III is congenital or acquired unilateral cricoarytenoid fixation with or without interarytenoid scar, and type IV is congenital or acquired bilateral cricoarytenoid fixation with or without interarytenoid scar.

With interarytenoid web and scarring, there is bilaterally impaired abduction but normal adduction; these patients tend to have a normal voice.[62] The main presenting symptom in these cases is airway compromise. In cricoarytenoid joint fixation, adduction and abduction of the vocal fold are limited, which may also cause dysphonia. To distinguish cricoarytenoid joint fixation from vocal fold paralysis, palpation of the cricoarytenoid joint at rigid endoscopy is necessary. Laryngeal electromyography may be necessary for definitive diagnosis.

Benjamin and Mair[62] noted that interarytenoid webs are often associated with other airway abnormalities. They recommend that interarytenoid web be managed by long-term watchful waiting or by tracheotomy if associated abnormalities of the airway exist. In the case of pediatric posterior glottic stenosis, arytenoidectomy should be avoided to prevent the possibility of aspiration, deterioration of voice, and difficulty with future airway repair.[63] Although many techniques have been tried, anterior and posterior cricoidotomy with posterior graft appears to give the most consistent results and is considered the procedure of choice in children.[61,63] Improved vocal fold mobility has been observed postoperatively with this technique.[63,64]

The postoperative voice is considered to be functional in most children; a voice disorder consisting of hoarseness and breathiness often persists.[63] Bogdasarian and Olson[60] noted in adult patients that final voice results depended on the severity of stenosis; the same applies to children.

Recurrent Respiratory Papillomatosis

RRP is the most common benign neoplasm of the larynx. Papilloma patients present with hoarseness or airway obstruction. Papillomas have a predilection for anatomic sites where ciliated and squamous epithelia are juxtaposed. Common sites in the larynx are the mid zone of the laryngeal surface of the epiglottis, the upper and lower margins of the ventricles, and the undersurface of the vocal folds.[65] Recurrent respiratory papillomatosis is often diagnosed in patients between the ages of 2 and 3 years. Juvenile and adult-onset forms of the disease are possible; the juvenile form has a more aggressive clinical course. The need for tracheotomy in juvenile RRP is reportedly 14% to 21%.[66,67]

An association between cervical human papillomavirus (HPV) types 6 and 11 in the mother and RRP in the child has been established.[68-70] HPV is found in the genital tract of approximately 25% of women of child-bearing age and is clinically apparent in 2% to 5%. Shah and others[71] estimate the risk of HPV transmission to be 1 in 400 vaginal births in mothers with active condylomata.

Surgery is the management of choice, although it is only palliative because the natural history of RRP is one of recurrence. The goal of surgery is to establish a stable airway and a serviceable voice. Surgical options are CO_2 laser ablation and microlaryngoscopy with forceps removal; CO_2 laser ablation is generally accepted as the procedure of choice.[67] More recent reports indicate that removal of papillomas with microdébrider can be more efficient and atraumatic.[72] Papillomas are removed to the level of the mucosa or submucosa, avoiding the deeper muscular and ligamentous levels. Caution should be exercised in removing papillomas from the anterior and posterior commissure areas because irreversible scarring can result. Although removal of RRP temporarily improves the voice, the increasing number of required procedures results in scarring of the vocal folds and deterioration of the voice.

Leventhal and others[73] recommended the use of interferon in any patient requiring surgery every 2 to 3 months. The duration of management should be 6 months. If there is neither a response nor a complete response, management should be discontinued, but if there is a partial response management should be continued. However, the results of

interferon management of RRP have been disappointing. After the cessation of interferon therapy, there is a rebound effect and papillomas recur at an increased rate.[74] Intralesional administration of cidofovir, an acyclic nucleoside phosphate, has shown promise in treating severe cases of RRP in pediatric patients.[75] Other adjuvant therapies (e.g., photodynamic therapy, acyclovir, ribavirin, isotretinoin, indole 3-carbinol) are infrequently used.[67]

Malignant Tumors

Malignant tumors of the pediatric larynx are rare. Isolated case reports are seen in the literature, but more extensive experience is lacking. A 15-year review of malignant laryngeal tumors at a tertiary pediatric referral center revealed only four cases.[76] These laryngeal tumors are usually in the sarcoma group, most commonly rhabdomyosarcoma. Other malignancies include squamous cell carcinoma, lymphoma, mucoepidermoid carcinoma, neuroectodermal tumor, and metastatic carcinoma.[77-80] Spontaneous malignant degeneration of longstanding RRP has an incidence of 2% to 3%.[81] In addition, squamous cell carcinoma may be seen in patients who have RRP and a history of radiotherapy.

Patients with laryngeal tumors present with voice change (often hoarseness), stridor, and progressive airway obstruction. Delay in diagnosis is common because of a low suspicion for malignancy. Any child with persistent hoarseness should thus be fully evaluated. Management goals are patient survival and preservation of laryngeal function, when possible. Management depends on the tumor histology and consists of combination surgery, radiotherapy, and chemotherapy.

Radiotherapy of a prepubescent larynx can result in a fibrotic infantile larynx with no useful voice, airway, or swallowing function.[76] This should be considered when deciding on a management protocol. Ohlms and associates[76] provide an example of a prepubescent child with a laryngeal rhabdomyosarcoma. Although radiotherapy may have provided adequate local control, total laryngectomy was chosen to improve local control. Total laryngectomy was justified because it provided a better chance of cure, whereas the larynx may have been useless after undergoing radiotherapy.

Vocal Quality Disorders: Medical Management

Granuloma

Patients with vocal fold granuloma commonly exhibit hoarseness. Granuloma often results from intubation trauma. Habitual throat clearing, excessive glottal attacks, and reflux esophagitis are also important causal factors.[82] Inflammation over the vocal process of arytenoid progresses to infection involving the perichondrium and formation of granuloma. Histologically, the granulomas are nonspecific reparative granulation tissue covered by hyperplastic squamous epithelium.[83]

Children with vocal fold granuloma should be evaluated for gastroesophageal reflux disease (GERD). The most reliable means of diagnosing GERD is prolonged (24 hours) pH manometry study.[84] A reflux event is defined as a drop in the pH to less than 4. Normally, the time that pH is less than 4 is approximately 6.3% upright, 1.2% supine, and 4.2% total.[85] Other less specific and less sensitive methods are barium esophagography, radionuclide scanning, and lipid-laden macrophage testing for aspiration.

The primary management of vocal fold granuloma is management of the underlying GERD. Most granulomas resolve with medical management. Management of GERD involves[86] (1) dietary and lifestyle modifications and the use of antacids; (2) H_2 blockers (cimetidine, ranitidine, famotidine), prokinetic agents (bethanechol, metoclopramide, cisapride), and mucosal cytoprotectants (sucralfate) in combination; and (3) proton pump inhibitors (omeprazole, lansoprazole) combined with surgical repair of hiatal hernia and the reestablishment of lower esophageal sphincter function.

Surgical removal (CO_2 laser or sharp incision with microlaryngeal instruments) of the vocal fold granuloma is reserved for lesions causing airway obstruction (Fig. 203-5).[83,84] Regardless of the surgical technique used, recurrence is frequent. Although voice therapy has been recommended, it does not appear to be an effective primary management modality for vocal fold granulomas.

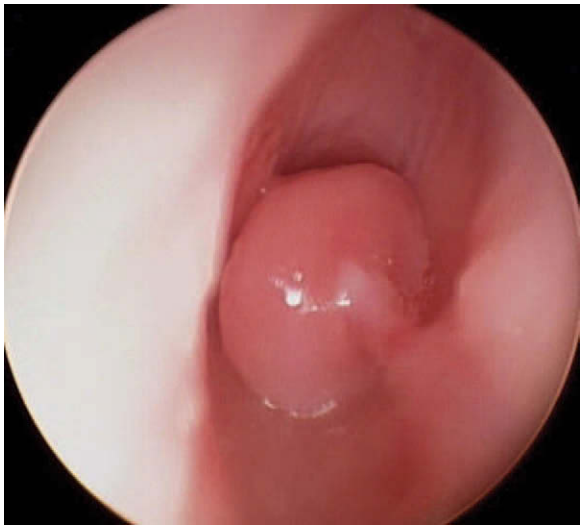

Figure 203-5. Large granuloma with laryngeal obstruction requiring surgery.

Vocal Quality Disorders: Voice Therapy with or without Surgery

Opinions about the management of cysts, polyps, sulcus vocalis, and nodules differ widely. Traditionally, surgery was discouraged in children because of the small size of the larynx, difficulty in reinforcing voice rest postoperatively, and high recurrence when underlying vocal behavior is not modified. Surgery was recommended for only the most recalcitrant and severe dysphonia. However, some surgeons have reported that surgery of the pediatric larynx is safe and technically feasible with good results, as seen in a series by Bouchayer and Cornut[8] of 191 children who underwent microsurgery. Advocates of surgery recommend waiting until the child is 8 to 9 years old.[8,87] This recommendation is in agreement with the recent report describing the development of the three-layered vocal fold in children approximating that of adult vocal folds by age 7.[88] In addition to the age, a highly motivated patient and involved parents are prerequisites to surgery.

Preoperative and postoperative voice therapy is essential. Surgical intervention is most often performed by microsurgical technique, although CO_2 laser is infrequently used. The principles of surgery are to remove the pathology with maximal preservation of normal mucosa and to avoid injury to the anterior commissure and vocal ligament.

Nodules

Most voice disorders in children result from vocal nodules. Vocal nodules occur frequently, often as a result of misuse or overuse of the larynx (hyperfunctional state). Other conditions that can lead to predisposition for vocal nodules include gastroesophageal reflux and velopharyngeal insufficiency.[47] The incidence of hoarseness, a symptom of dysphonia, in schoolchildren is estimated to be approximately 5%.[89] Of children evaluated by an otolaryngologist for chronic hoarseness, 38% to 78% have vocal nodules. Thus more than 1 million children in the United States have vocal nodules. Vocal nodules are most often seen as a child enters a group activity. They occur more commonly in boys. Patients with vocal nodules exhibit hoarseness and breathiness. A stroboscopic examination shows decreased mucosal waves and incomplete approximation of the free edges.[89]

Vocal nodules result from mechanical trauma and occur at the free edge of the anterior and middle third of the vocal fold (Fig. 203-6). Often, vocal nodules are bilateral, although unilateral nodules can occur. Vocal nodules develop in three stages[90]: (1) an inflammatory phase with increased vascularity and protein accumulation; (2) localized

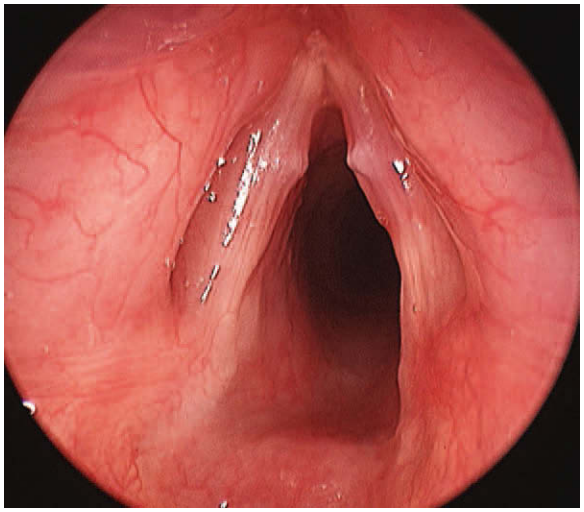

Figure 203-6. Vocal nodules.

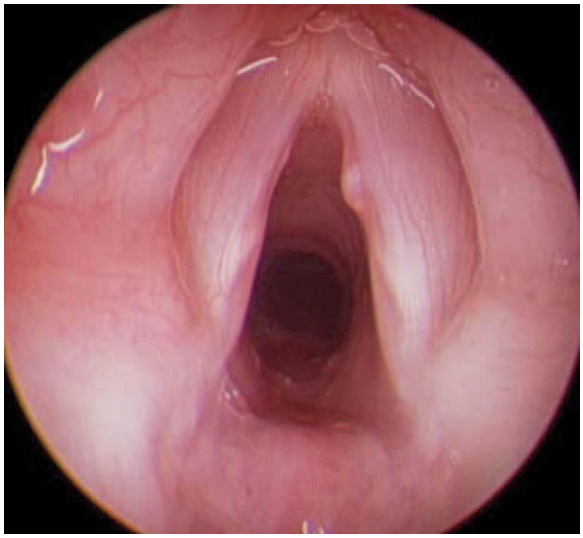

Figure 203-7. Right vocal fold cyst.

swelling on the edge of the vocal fold that appears as grayish, translucent thickening (nodules are reversible within 24 to 48 hours if trauma is eliminated); and (3) replacement of thickening by fibrotic tissue that appears gray or white. Histologically, circumscribed hyperplasia or hyperkeratinization and secondary hyaline degeneration in the lamina propria are seen.[91]

Management options include voice therapy, surgery, voice therapy plus surgery, and no intervention.[8,87,89,92-94] It is difficult to determine the success of differing modes of management because follow-up of control groups (no management) is rare. Because of the benign nature of nodules, patients who undergo medical or surgical management are often lost to follow-up evaluation. The fact that vocal nodules in children often resolve spontaneously by puberty may also influence management. The most widely accepted management option for vocal fold nodules in children is voice therapy. According to von Leden,[89] most nodules resolve or show significant improvement within 3 to 6 months of initiating voice therapy. Surgery is considered in children who fail to show improvement with voice therapy and in whom severe hoarseness interferes with daily functioning.[87,89]

The surgical management of choice is microsurgical excision, although CO_2 laser has been used. The nodule is stretched medially and removed at its base with microscissors without excessive mucosal removal. Bilateral nodules can usually be removed in one sitting; however, care should be taken to avoid injuring the anterior commissure. Some surgeons recommend removing bilateral nodules in stages that are 4 weeks apart.[87] Voice rest is recommended for 7 to 10 days. Long-term results depend on the quality of voice therapy, but they are generally good. Recurrences are frequent without voice therapy.

Cysts and Sulcus Vocalis

It is unclear whether epidermoid cysts and sulcus of the vocal folds are congenital or acquired lesions. Some authors[95,96] support the view that these lesions are acquired, whereas Bouchayer and colleagues[97] theorize that they are congenital. In a series of 2334 patients, Bouchayer and Cornut[8] found that congenital lesions of the vocal folds were the most frequently seen benign lesions requiring surgical intervention; they believe these congenital lesions are often overlooked or misdiagnosed.

Patients with either lesion often present with hoarseness, voice breaks, and vocal fatigue. With epidermoid cysts, unilateral submucosal swelling of the superior mid-third surface often occurs with associated edema of the contralateral vocal fold (Fig. 203-7). Reduced mucosal waves are seen on stroboscopy. Epidermoid cysts are lined with stratified keratinizing squamous epithelium and contain keratin debris. With sulcus vocalis, the surface epithelium invaginates into Reinke's space and adheres to the vocal ligament, resulting in a longitudinal furrow parallel to the edge of the vocal fold and an oval glottic chink. Stroboscopy shows incomplete closure of the free edges of the vocal folds.

Cysts and sulcus vocalis usually do not resolve spontaneously although voice can improve with therapy.[8,98] Epidermoid cysts are often mistaken for vocal nodules, and patients are thus referred for voice therapy. Referral to an otolaryngologist occurs when the voice disorder does not resolve after several months of voice therapy. Sulcus vocalis is often difficult to diagnose in children because careful examination of the larynx with a stroboscope is often impossible. These children are referred for voice abnormality that fails to improve with voice therapy.

Epidermoid cyst and sulcus vocalis are managed by microsurgery. For cysts, a mucosal incision is made on the superior surface of the vocal fold, parallel to the free edge, and the cyst is dissected. Bouchayer and Cornut[8] recommend intrafoldal injection of the surgical site with corticosteroid to decrease the inflammation. Woo and colleagues[99] reported improved laryngeal microsurgery results using 6-0 chronic Endoknot sutures to close the microflaps of the vocal fold. Sulci are resected by making incisions in the superior and inferior edges of the pocket and dissecting the pocket from the vocal ligament. A slicing mucosa surgical technique that detaches the mucosa of the sulcus and interrupts the longitudinal fibrotic tension line has been used with good results.[100] Although the resulting voice is improved compared with the preoperative state, it is not perfect. Postoperative voice therapy is important and has significant effect on voice results. Therapy is recommended for at least 3 to 6 months.

Polyps

Vocal fold polyps occur infrequently in children and adolescents.[101,102] They arise from chronic abuse of the larynx or from a single traumatic episode. Hoarseness is the most common presenting symptom. The polyps occur at the junction of the anterior and middle third of the vocal fold and may be fusiform, pedunculated, or generalized.[103] A recent study showed that polyps are caused by circulation impediment, thrombosis, exudation, and edema of the lamina propria. Inflammation and secondary atrophy of the vocal fold epithelium occur.[91]

Vocal fold polyps can improve with voice therapy but may require surgical removal.[8,90,98,103] Pedunculated polyps are removed at the base using CO_2 laser or microscissors. For generalized polyps, an incision is made over the superior surface of the vocal fold, and the fibrous exudate is suctioned out or vaporized.[8] The resulting voice quality depends on the degree of irreversible damage to the superficial layer of the lamina propria by fibrous or hyaline infiltration. Voice therapy is recommended before and after surgery to prevent recurrences.[8,22]

Summary

Voice disorders are commonly seen in children. Evaluation and treatment of voice disorders are more complicated in children than in adults because of their inability to cooperate, lack of awareness of the problem,

and lack of motivation for change. There have been significant recent advances in technology and establishment of normative data for pediatric voice parameters. Surgery should be undertaken cautiously, especially in very young children because the larynx is not mature and surgery is more difficult. Voice therapy should be used extensively both preoperatively and postoperatively.

CHAPTER TWO HUNDRED AND FOUR

Recurrent Respiratory Papillomatosis

Craig S. Derkay

Russell A. Faust

Key Points

- Recurrent respiratory papillomatosis (RRP) is a devastating, rare disease in which papillomas of the airway cause hoarseness and airway obstruction.
- The disease is caused by human papillomavirus (HPV) 6 or 11, the same subtypes responsible for the development of genital warts and low-risk cervical intraepithelial neoplasias of the genitourinary tract.
- The age of disease onset and clinical course are highly variable.
- Surgical therapy for RRP requires a team approach with otolaryngologists, anesthesia providers, and operating room personnel working together in a facility properly equipped to manage difficult airways.
- In addition to surgical débridement accomplished with the use of microdébriders, pulsed dye and carbon dioxide (CO_2) lasers and microlaryngoscopy "cold-steel" techniques, multiple medical modalities have been used without consistently effective results.
- Parental support and education are invaluable adjuncts to the safe care of children with RRP.
- The recent introduction of a quadrivalent HPV vaccine offers hope for prevention of transmission of the virus to neonates and may significantly reduce the future incidence of RRP and oropharyngeal cancers.

Recurrent respiratory papillomatosis (RRP) is the most common benign neoplasm of the larynx in children. Despite its benign histology, RRP has potentially fatal consequences and is often difficult to treat because of its tendency to recur and spread throughout the respiratory tract. Long neglected from an epidemiologic standpoint, initiatives to better understand this disease process have been launched in the United States through coordination between the Centers for Disease Control and Prevention (CDC) and the American Society of Pediatric Otolaryngology (ASPO) and internationally through the British Association of Paediatric Otolaryngology (BAPO) and by Canadian Paediatric Otolaryngology physicians.

This chapter discusses the etiology, immunology, epidemiology, and transmission of RRP. Clinical features including pertinent aspects of the history, physical examination, airway endoscopy, and other considerations are highlighted. Management principles for performing surgical and nonsurgical treatments, the indications and results for employing adjuvant therapies, and their results are discussed. Ongoing research initiatives, promising strategies, the potential for a quadrivalent human papilloma vaccine (HPV) to reduce its incidence and the RRP Task Force's contributions to understanding this frustrating disease are also reviewed.

Epidemiology

Recurrent respiratory papillomatosis is a disease of viral etiology, caused by human papillomavirus (HPV) types 6 and 11, and is characterized by the proliferation of benign squamous papillomas within the aerodigestive tract.[1-3] Although it is a benign disease, RRP has potentially fatal consequences because of its involvement of the airway and because of the risk, albeit low, of malignant conversion.[4] In addition to the emotional burden to the patients and their families associated with the need for repeated surgery,[5] the economic cost of this relatively rare chronic disease is high, having been estimated at $150 million annually.[6]

RRP is both the most common benign neoplasm of the larynx among children and the second most frequent cause of childhood hoarseness.[7] The disease is often difficult to treat because of its tendency to recur and spread throughout the aerodigestive tract. Although it most often involves the larynx, RRP may involve the entire aerodigestive tract. The course of the disease is variable, with some patients experiencing spontaneous remission, whereas others may suffer from aggressive papillomatous growth and respiratory compromise, requiring multiple surgical procedures through many years.

RRP may have its clinical onset during either childhood or adulthood. It may affect people of any age, with the youngest patient identified at 1 day of life and the oldest at 84 years.[6] Two distinct forms of RRP are generally recognized: a juvenile or aggressive form and an adult or less aggressive form. The aggressive form, although most prevalent in children, can also occur in adults. Children whose RRP was diagnosed at younger ages (younger than 3 years) have been found to be 3.6 times more likely to have more than four surgical procedures per year and almost two times more likely to have two or more anatomic sites affected than children whose RRP was diagnosed at older ages (older than 3 years).[6] Similarly, children with disease progression are generally diagnosed at younger ages than those who remain stable or become disease-free.[8-10] In most pediatric series, the delay in diagnosis

from the time of onset of symptoms averages about 1 year.[6,11] In 75% of children with RRP, diagnosis was made before the fifth birthday.[12]

The true incidence and prevalence of RRP are uncertain. It is estimated that between 80 and 1500 new cases of childhood-onset RRP occur in the United States each year.[6,13] While the incidence among children in the United States is estimated at 4.3 per 100,000 children, the incidence among adults is 1.8 per 100,000.[6,14] These figures are comparable with those found in a Danish survey. In a subpopulation incorporating 50% of the population of that country, the rate among children was 3.62 per 100,000, whereas adult-onset cases occurred at a rate of 3.94 per 100,000.[15] The National Registry of children with RRP, composed of the clinical practices at 22 pediatric otolaryngology sites, calculates a mean number of procedures at 19.7 per child with an average of 4.4 procedures per year.[6,14] Based on the incidence data, this translates into more than 10,000 surgical procedures annually for children with RRP in the United States.

Virology of Human Papillomavirus

HPV, belonging to the Papovaviridae family, is a small deoxyribonucleic acid (DNA)-containing, nonenveloped, icosahedral (20-sided), capsid virus with a double-stranded circular DNA of 7900 base-pairs long. HPV is epitheliotropic (infects epithelial cells). The HPVs have been grouped on the basis of shared genetic code homology, with viruses that share less than 90% identity in specific regions of the virus being defined as separate types. On this basis, the HPVs are numbered to distinguish them. Nearly 100 different HPV types have been identified. Grouping HPV types based on their DNA homology has allowed us to identify closely related types. Functionally, these groupings correlate with their tissue preference as well as similar pathophysiology.[16] The HPVs are members of a large family of papillomaviruses that infect vertebrates ranging from birds to humans, causing epithelial neoplasms that can be benign or malignant. These viruses are designated by their natural host species (e.g., bovine papillomavirus, murine papillomavirus, and human papillomavirus). Each papillomavirus is specific for its host species, and this specificity is thought to be absolute. Within each species, similar types of papillomavirus exhibit specificity for epithelial tissues of different sites (e.g., oral mucosa, genital mucosa, or skin). In humans, this tissue specificity is less absolute, and some HPV types exhibit more of a preference for certain tissues.

Until the 1990s, HPV had been suspected but not confirmed as the causative agent in RRP. This uncertainty resulted from an inability to culture the virus in vitro and from the failure to demonstrate viral particles consistently in papilloma lesions using electron microscopy or HPV antibodies. With the advent of molecular probes, HPV DNA has been identified in virtually every papilloma lesion studied. The most common types identified in the airway are HPV 6 and HPV 11—the same types responsible for more than 90% of genital condylomata. Specific viral subtypes may be correlated with disease severity and clinical course. Children infected with HPV 11 appear to have a more obstructive airway course early in the disease and a greater likelihood of undergoing tracheotomy to maintain a safe airway.[10,17]

In addition to the HPV group that includes HPV 6 and 11, two other major groups of HPV are associated with mucosal lesions in the aerodigestive and genital tracts. HPV 6 and 11, responsible for the majority of RRP, are members of a group believed to have a low malignant potential compared with some other groups. In contrast, the group that contains HPV 16 and HPV 18 is associated with malignancies in the genital and aerodigestive tracts.[16] The group that contains HPV 31 and HPV 33 exhibits malignant potential that lies somewhere in between.

HPV is thought to infect stem cells within the basal layer of mucosa.[18,19] After infection of the stem cells, the viral DNA can either be actively expressed or it can exist as a latent infection in mucosa that remains clinically and histologically normal. To produce viral proteins or to replicate the virus, the viral DNA must somehow reactivate the host replication genes. The viral genome consists of three regions: an upstream regulatory region and the two regions named according to the phase of infection in which they are expressed—early (E) and late (L) regions. The E-region genes are involved in the replication of the viral genome, interaction with the host cell intermediate filaments, and transforming activities, and are potential oncogenes, depending on the HPV type. The L-region genes encode the viral structural proteins.[20-22]

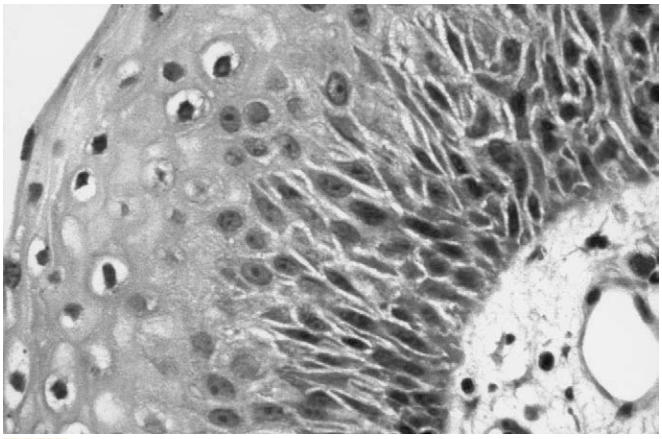

Figure 204-1. Histopathology of human recurrent respiratory papillomatosis. Micrograph of laryngeal mucosa infected with human papillomavirus.

Figure 204-2. Gross appearance of respiratory papillomas during laryngoscopy. Appearance of massive, exophytic papillomatosis of the larynx.

The induction of cellular proliferation is a fundamental property of HPV, although the mechanism of action remains unclear. We are slowly gathering information regarding the interaction of viral gene products with cellular proteins. For example, several of the viral E-region gene products have been shown to bind and inactivate certain cellular tumor-suppressor proteins.[21,23] Conversely, HPV has been shown to activate the epidermal growth factor (EGF) receptor pathway, known to be associated with proliferation of epithelial cells.[3] Thus there are likely several mechanisms by which HPV induces cellular proliferation in the aerodigestive mucosa.

Histologically, this mucosal proliferation results in multiple "fronds" or finger-like projections with a central fibrovascular core, covered by stratified squamous epithelium (Fig. 204-1).[18] When papillomas are microscopic, they may assume a superficial-spreading configuration, with a velvety appearance (Fig. 204-2). When they exhibit a more macroscopic or exophytic growth pattern, they appear grossly

as "cauliflower" projections (see Fig. 204-2). Papilloma lesions may be sessile or pedunculated and often occur in irregular exophytic clusters. Typically, the lesions are pinkish to white in coloration. Iatrogenic implantation of papilloma may be preventable by avoiding injury to nondiseased squamous or ciliated epithelium adjacent to areas of frank papilloma. Ciliated epithelium undergoes squamous metaplasia when exposed to repeated trauma and is replaced with nonciliated epithelium that creates an iatrogenic squamocellularly junction. This may also explain the observation that RRP flourishes in the presence of uncontrolled gastroesophageal reflux. Most RRPs do not exhibit dysplasia, abnormal mitoses, or hyperkeratosis.[18] Without exception, RRP exhibits delayed maturation of the epithelium, resulting in significantly thickened basal cell layer and nucleated cells in the superficial layers.[24] This is thought to be in part because of the interaction of HPV gene products with the EGF receptor pathway.[3] The sum result of these cellular effects is that, although HPV-infected cells do not rapidly divide, there is a disproportionate increase in the number of dividing basal cells. Thus expansion of the RRP tissue mass may occur very rapidly, because of the large number of dividing cells.[19]

During viral latency there is very little viral RNA expressed. Even so, HPV DNA can be detected in normal-appearing mucosa in RRP patients who have been in remission for years, and unknown stimuli can result in reactivation and clinical recurrence following years of remission.[25,26] Thus activation of viral expression can occur any time after the establishment of latent infection. Gene products of early region gene E6, E7, and possibly E5 are required for papilloma induction, but the details of the mechanism of HPV activation are unknown. To "cure" RRP, it is necessary to modulate the host response to the virus and, ideally, eliminate latent infection.

It is likely that the host immune system plays an important role in the pathogenesis of HPV-induced lesions. Both the humoral and the cellular immune responses may be compromised in children with RRP, and the patient's immunocompetence may be associated with the clinical course of the disease. The role of cytokines, such as interleukin-2, interleukin-4, and interleukin-10, and expression of the major histocompatibility complex (MHC) antigens in the dysfunction of the cell-mediated immune response in children with RRP has been demonstrated.[27,28]

Transmission

An association between cervical HPV infection in the mother and the incidence of RRP has been well established. However, the precise mode of transmission is still not clear.[18] The universality of HPV in the lower genital tract rivals that of any other sexually transmitted disease in humans. It is estimated that at least one million cases of genital papillomas occur per year in the United States.[29] These are most commonly manifested as condylomata acuminata involving the cervix, vulva, or other anogenital sites in women or the penis of male sexual partners of affected women. Colposcopic (subclinical) changes are seen in about 4% of women, whereas DNA positive biopsies without a visible lesion are seen in 10% of women. HPV antibody positivity (without DNA or a clinical lesion) is estimated in 60% of women (81 million). HPV has been estimated to be present in the genital tract of as many as 25% of all women of child-bearing age worldwide. One study reported that the incidence of HPV infections in sexually active young college women is highest, with a cumulative incidence of 43% during a 36-month period.[30] Clinically apparent HPV infection has been noted in 1.5% to 5% of pregnant women in the United States.[31] More than 30% of American women are currently infected with HPV with 7.5 million 14- to 24-year-olds currently infected and one fourth of women younger than 60 years of age infected at any given time.[32] Up to 90% of lesions are undetectable clinically at 2 years. The highest prevalence is in women 20 to 24 years of age. More than 50% of women will initially acquire HPV within 4 years of their first sexual intercourse. As in RRP, HPV 6 and HPV 11 are the most common subtypes identified in cervical condylomata.

Vertical transmission occurring during delivery through an infected birth canal is presumed to be the major mode of transmitting the infection in children whereas in utero and transplacental transfer of HPV, sexual abuse, and direct contact are thought to play a minor role. The support for vertical transmission lies in the fact that overt maternal condyloma are seen in more than 50% of mothers who give birth to children with RRP.[33] The same subtypes (HPV 6 and 11) are involved, and cesarean delivery of children seems to be preventive to some extent.[34]

Patients with childhood-onset RRP are more likely to be first born and vaginally delivered than are control patients of similar age.[35,36] Kashima and others hypothesized that primigravid mothers are more likely to have a long second stage of labor and that the prolonged exposure to the virus leads to a higher risk of infection in the first-born child. They also suggested that newly acquired genital HPV lesions are more likely to shed virus than longstanding lesions, accounting for the higher incidence of papilloma disease observed among the offspring of young mothers of low socioeconomic status—the same group that is most likely to acquire sexually transmitted diseases such as HPV.[35,36]

Despite the close association between maternal condylomata and the development of RRP, only a small portion of children exposed to genital condylomata at birth actually go on to development of clinical RRP.[37] Although HPV could be recovered from the nasopharyngeal secretions of 30% of infants exposed to HPV in the birth canal, the number of infants expected to manifest evidence of RRP is only a small fraction of this population.[37] Clearly, other factors (patient immunity, timing, length and volume of virus exposure, local trauma) must be important determinants in the development of RRP. Even though cesarean section delivery would seem to reduce the risk of transmission of the disease, this procedure is associated with a higher morbidity and mortality for the mother and a much higher economic cost than elective vaginal delivery. Furthermore, reports of neonatal papillomatosis suggest that, in at least some cases, transmission may occur in utero.[1] However, with such a high rate of subclinical maternal HPV infection and such a low rate of actual new cases of childhood RRP, elective cesarean delivery as a means of preventing RRP is currently not practical or recommended.[1] The risk of a child contracting the disease from a mother who has an active genital condyloma lesion during vaginal delivery is only approximately 1 in 231 to 400.[22,34,36] The characteristics that distinguish this one child from the other 230 to 399 remain elusive. In summary, a better understanding of the risk factors associated with RRP is needed before the efficacy of cesarean delivery or other preventive measures can be fully assessed.

Prevention

The new quadrivalent HPV vaccine (Gardasil, Merck and Co., Inc.), is licensed and indicated for the prevention of cervical cancer, adenocarcinoma in situ, and intraepithelial neoplasia grades 1-3; vulvar and vaginal intraepithelial neoplasias grades 2-3; and genital warts associated with HPV 6, 11, 16, and 18. The CDC Advisory Committee on Immunization Practices (ACIP)[32] has recommended vaccination for all girls ages 11 to 12, girls and women ages 13 to 26 who have not yet been vaccinated, and girls as young as age 9, in whom the physician believes it would be appropriate. Based upon the pivotal clinical studies, the vaccine is predicted to reduce the incidence, morbidity, and mortality of cervicovaginal HPV disease. An added and often overlooked benefit may be a concomitant decrease in the incidence of RRP and HPV-associated head and neck cancers.

The ability of the quadrivalent vaccine to prevent HPV 6/11/16/18-associated cervical and genital disease was established in the phase 3 FUTURE I and II trials, and their immunogenicity in the target group of vaccinees was established in immunogenicity bridging trials.[38] In FUTURE I, the quadrivalent vaccine was 100% effective in preventing cervical intraepithelial neoplasia (CIN) or worse, genital warts, and vulvovaginal neoplasia. In FUTURE II, the vaccine was 100% effective in preventing HPV 16/18-associated CIN. Both Future I and II were conducted in women in the age range at highest risk for HPV acquisition.[38,39] However, it appears that the vaccine will be most effective if administered to individuals who have not yet become sexually active. Immunogenicity bridging studies were conducted to assess the immunogenicity of the vaccine in this population, and established that immunogenicity among younger girls was equal to if not superior to the response among 16- to 23-year-old women, suggesting that the quadrivalent HPV vaccine is immunogenic in this population and thus likely to be effective in preventing disease.[40] A separate study in 9- to

15-year-olds established that in this younger population immunogenicity lasts at least 18 months.[41]

There is also a bivalent HPV vaccine currently in phase 3 trials. This vaccine provides protection against HPV 16 and 18, but not 6 and 11.[38] Early phase 2 data for this vaccine suggest that it is 100% effective in preventing incident and persistent cervical HPV 16 and 18 infections in the according-to-protocol (ATP) sample, and 93% effective in preventing HPV 16- or 18-related disease in the intention-to-treat analysis; efficacy against disease was not presented for the ATP cohort. This vaccine's efficacy against HPV 16 and 18 suggests that, like the quadrivalent vaccine, it may reduce the incidence of HPV-associated head and neck cancers. However, because the bivalent vaccine does not protect against HPV 6 and 11, it will not likely affect the vertical transmission of HPV 6 or 11 from mother to child.

Widespread use of the quadrivalent HPV vaccine promises to dramatically reduce the morbidity and mortality of cervical cancer and drastically reduce the incidence of genital warts. If the vaccine is as effective in preventing HPV infection of the oral cavity as of the cervix and genital tract, then, vaccination could be expected to reduce the incidence of HPV-associated oropharyngeal cancers by as much as 30%. In addition, a near-universal vaccination program providing the quadrivalent vaccine should all but eradicate RRP in future generations. Thus vaccination against HPV offers additional benefits above and beyond prevention of cervical cancers, some of which are unique to the quadrivalent vaccine.

Clinical Features

Inasmuch as the vocal fold is usually the first and predominant site of papilloma lesions, hoarseness is the principal presenting symptom in RRP.[42] The child's voice may be described as hoarse or weak from the time of birth. Particularly in very young children, changes in voice may go unnoticed. Stridor is often the second clinical symptom to develop, beginning as an inspiratory noise and becoming biphasic with progression of the disease. Less commonly, chronic cough, recurrent pneumonia, failure to thrive, dyspnea, dysphagia, or acute life-threatening events may be the presenting symptoms. The duration of symptoms before diagnosis varies. Not uncommonly, a mistaken diagnosis of asthma, croup, allergies, vocal nodules, or bronchitis is entertained before a definitive diagnosis is made. However, the initial presentation in infants, whose airway dimensions are small, may be with acute respiratory distress during an otherwise routine upper respiratory tract infection. The natural history of RRP is highly variable. After presentation, the disease may undergo spontaneous remission or persist in a stable state requiring only periodic surgical treatment. At the other extreme, RRP may become extremely aggressive, requiring frequent surgical treatment (every few days to weeks), prompting early institution of medical adjuvant therapy. A waxing-waning clinical course of remissions and exacerbations is common for RRP.

Because of the rarity of RRP and the slowly progressive nature of the disease, some cases may go unrecognized until respiratory distress results from papillomas obstructing the airway. The result is a relatively high need for tracheotomy to be performed in these children. Shapiro and others noted that RRP tracheotomy patients presented at a younger age and with more widespread disease, often involving the distal airway before tracheotomy.[43] In their experience with 13 patients, they did not believe that the tracheotomy itself led to spread of disease outside the larynx. In the CDC National RRP Registry, children with tracheotomy were initially diagnosed with RRP at a younger age (2.7 years) than those without a tracheotomy (3.9 years).[14] Others have suggested that tracheotomy may activate or contribute to the spread of disease lower in the respiratory tract.[44] Cole and colleagues reported that tracheal papillomas developed in half of their tracheotomy patients and that, despite attempts to avoid this procedure, 21% of their patients still required a long-term tracheotomy.[45] Prolonged tracheotomy and the presence of subglottic papillomata at the time of tracheotomy have been associated with an increased risk of distal tracheal spread. Most authors agree that tracheotomy is a procedure to be avoided unless absolutely necessary. Interestingly, Boston and colleagues from Cincinnati noted successful laryngotracheal reconstruction in a series of children with subglottic stenosis and RRP.[46] When a tracheotomy is unavoidable, decannulation should be considered as soon as the disease is managed effectively with endoscopic techniques. Children with bronchopulmonary dysplasia who require prolonged endotracheal intubation may also be at increased risk for development of RRP.[47] Through interruption of the continuous respiratory mucosal surface, an endotracheal tube may have the same role in the mechanical dissemination-implantation of RRP as tracheotomy, as a risk for distal spread of disease. Several authors have noted an association between RRP caused by HPV 11 (as opposed to HPV 6) and distal spread of papilloma.[10]

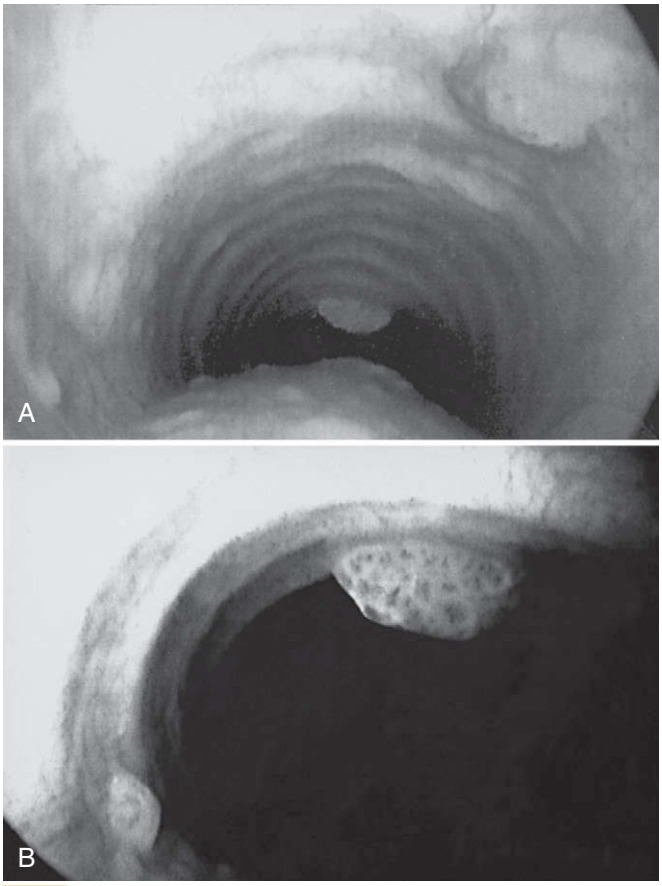

Figure 204-3. Tracheal spread of recurrent respiratory papillomatosis. Note nodular, exophytic lesions in distal trachea.

Extralaryngeal spread of respiratory papillomata has been identified in approximately 30% of children and in 16% of adults with RRP.[6] The most frequent sites of extralaryngeal spread were, in decreasing order of frequency, the oral cavity, trachea, and bronchi (Fig. 204-3).[6,42] Pulmonary papilloma lesions begin as asymptomatic noncalcified peripheral nodules.[48] These lesions eventually enlarge to undergo central cavitation and central liquefactive necrosis with air-fluid levels on a computed tomography scan (Fig. 204-4). These patients present clinically with recurrent bronchiectasis, pneumonia, and declining pulmonary status. The clinical course of the pulmonary spread of RRP is insidious and may progress through the years, but eventually manifests in respiratory failure because of destruction of lung parenchyma. For this reason, the finding of pulmonary lesions in a patient with RRP is a grave development with no currently available treatment modality that has shown more than anecdotal promise. Furthermore, pulmonary dissemination is anecdotally associated with a higher risk of malignant transformation of RRP.

Malignant transformation of RRP into squamous cell carcinoma has been documented in several case reports. A total of 26 patients was identified as having progressed to squamous cell carcinoma in the task force survey.[6] Dedo and Yu reported malignant transformation in 4 of 244 (1.6%) RRP patients treated during 2 decades.[49] When death occurs in a patient with RRP, it is usually as a complication of frequent

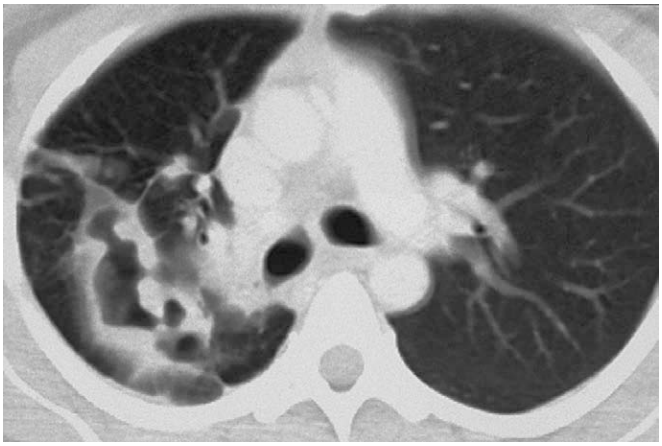

Figure 204-4. Pulmonary spread of recurrent respiratory papillomatosis. Note lytic, cavitary lesions on computed tomography.

surgical procedures or caused by respiratory failure because of distal disease progression. RRP presenting in the neonatal period is thought to be a negative prognostic factor, with a greater likelihood for mortality and need for tracheotomy.[8,9]

Patient Assessment

History

Persistent or progressive stridor and dysphonia, with the possible development of respiratory distress, are the most consistent signs and symptoms of RRP in children (see the Practice Pathway Flow Chart, Fig. 204-5). In the absence of severe respiratory distress, a careful history should be obtained. Information regarding the time of onset of symptoms, possible airway trauma including a history of previous intubation, and characteristics of the cry are obviously important. Hoarseness, although a common and often benign clinical complaint in young children, always indicates some abnormality of structure or function. Because of the precision of laryngeal mechanics, hoarseness may result from a remarkably small lesion and thus be an early sign in the course of a disease process. On the other hand, if the lesion's origin is remote from the vocal cords, hoarseness may present as a late sign. Although histologically the same lesion, a papilloma that produces hoarseness in one patient may produce stridor and obstruction in another, depending on the size and location of the lesion. The quality of the voice change may give only limited clues to its etiology, whereas other characteristics such as age of onset, rate of progression, associated infection, history of trauma or surgery, and the presence of respiratory or cardiac distress may be of much greater significance. A low-pitched, coarse, fluttering voice suggests a subglottic lesion, whereas a high-pitched, cracking voice; aphonia; or breathy voice suggests a glottic lesion. Associated high-pitched stridor also suggests a glottic or subglottic lesion. Although stridor that has been present since birth is more often associated with laryngomalacia, subglottic stenosis, vocal cord paralysis, or a vascular ring, it should be realized that neonates can also present with papillomatosis. Associated symptoms such as feeding difficulties, allergic symptoms, vocal abuse, and the presence of hereditary congenital anomalies may help distinguish RRP from alternative diagnoses, including vocal fold nodules, vocal fold paralysis, subglottic cysts, subglottic hemangioma, and subglottic stenosis. In the absence of any history suggesting these lesions, review of the perinatal period may reveal a history of maternal or paternal condylomata. If the onset of stridor and dysphonia is gradual and progressive through weeks or months, then neoplastic growth compromising the airway must be considered and investigated.

Certainly not every child with a hoarse voice or cry merits investigation beyond an assessment of symptoms. However, in the presence of hoarseness with respiratory distress, tachypnea, decreased air entry, tachycardia, cyanosis, dysphagia, chronic cough, failure to thrive, recurrent pneumonia, or dysphagia, the larynx must be visualized and a firm diagnosis of the cause of hoarseness must be made. Any child with slowly progressive hoarseness merits investigation and the clinician should not wait until total aphonia or airway problems occur.[50]

Physical Examination

Children presenting with symptoms consistent with RRP must undergo a thorough and organized physical examination. The child's respiratory rate and degree of distress must first be assessed. The physician should observe the child for tachypnea or the onset of fatigue that may indicate impending respiratory collapse. The child should be observed for flaring of the nasal ala and the use of accessory neck or chest muscles. Increasing cyanosis and air hunger may cause the child to sit with the neck hyperextended in an attempt to improve airflow. If a child is gravely ill, additional examination should not be undertaken outside the operating room (OR), the emergency department, or the intensive care unit, where resuscitation equipment for intubation of the airway, endoscopic evaluation, and possible tracheotomy are readily available. In the stable, well-oxygenated child, additional examination can proceed. The most important part of the examination is auscultation with the aid of a stethoscope. The physician should listen over the nose, open mouth, neck, and chest to help localize the probable site of the respiratory obstruction. The authors prefer to pull the bell off the stethoscope and listen over these areas with the open tube. The respiratory cycle, which is normally composed of a shorter inspiratory phase and a longer expiratory phase, should then be observed. Stridor of a laryngeal origin is most often musical and may begin as inspiratory, but will progress to biphasic as airway obstruction worsens. Infants with stridor should be placed in various positions to elicit any changes in the stridor. A child with RRP would not be expected to demonstrate much change in the stridor with position change in contrast to infants with laryngomalacia, a vascular ring, or a mediastinal mass. Pulse oximetry can add objective information on the child's respiratory status. In the stable patient in whom asthma is a likely diagnosis, pulmonary function testing may also be helpful.

Airway Endoscopy

The preoperative diagnosis of RRP is best made with a flexible fiberoptic nasopharyngoscope. Careful, sequential inspection of the pharynx, hypopharynx, larynx, and subglottis provides the critical information necessary to make the diagnosis of RRP and allows estimation of lumen size, vocal cord mobility, and the urgency of operative intervention. Advances in instrumentation of flexible nasopharyngoscopes have resulted in instruments as small as 1.8 mm in diameter, which when combined with the newest low-light, three-chip endoscopic cameras, allow passage in even the smallest newborns. Even the smallest diameter scopes provide excellent images that can be viewed on a video monitor and recorded for later review. Topical decongestant and local anesthesia can be applied by spray, dropper, or pledget. Oxymetazoline is the decongestant of choice because of its lack of cardiac side effects. Topical Pontocaine may be used to enhance patient cooperation, but the dosage must be critically monitored in the small infant to avoid cardiotoxicity.

Most clinicians find that visualization with the flexible nasopharyngoscope is far superior to that obtained with indirect mirror laryngoscopy in young children. Patient cooperation, however, is required even with good topical anesthesia. In infants, this is not a large issue because they can easily be restrained in an upright, sitting position in the parent's or nurse's lap for evaluation. Likewise, most children older than 6 or 7 years of age can be "talked into" cooperating for the examination. It is the intermediate age group, between 1 and 6 years of age, who may be the most difficult to examine, taxing the patience and skill of even the most experienced clinicians. Although dynamic evaluation can be appreciated when children are spontaneously breathing, endoscopy in the OR under anesthesia is warranted in any child suspected to have RRP who cannot be fully examined in the outpatient setting.[50]

Surgical Management

Classic Management

At present, there is no "cure" for RRP, and no single modality has consistently been shown to be effective in eradication of RRP. The

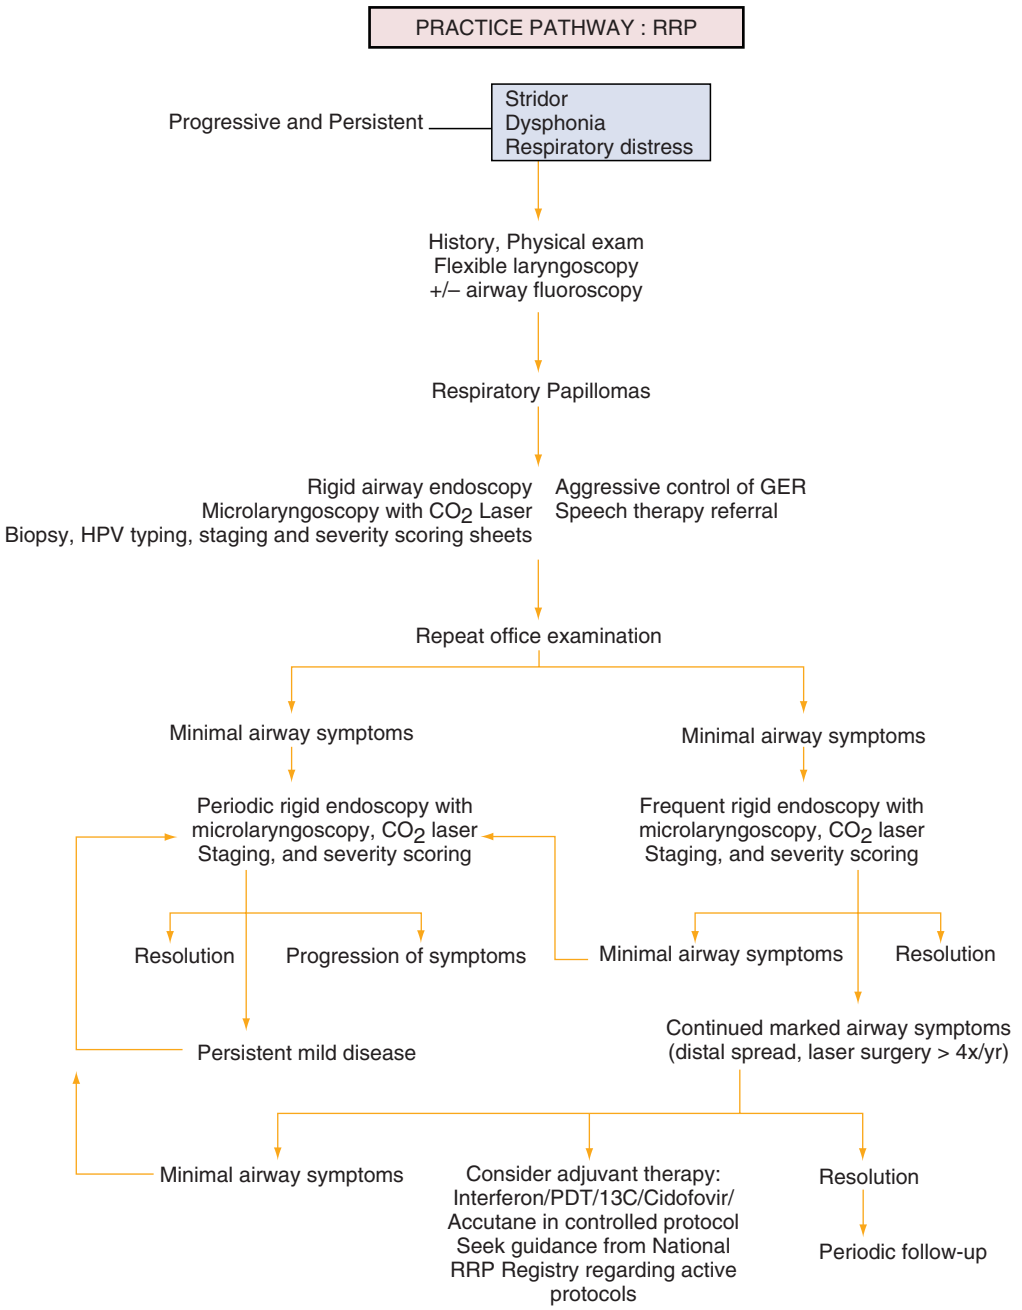

Figure 204-5. Practice pathway for recurrent respiratory papillomatosis. GER, gastroesophageal reflux; HPV, human papillomavirus; PDT, photodynamic therapy; RRP, recurrent respiratory papillomatosis.

current standard of care is surgical therapy with a goal of complete removal of papillomas and preservation of normal structures. In patients in whom anterior or posterior commissure disease or highly aggressive papillomas are present, the goal may be subtotal removal with clearing of the airway. It is advisable to debulk as much disease as possible while preserving normal morphology and anatomy and preventing the complications of subglottic and glottic stenosis, web formation, and resulting airway stenosis. Table 204-1 lists treatment options for RRP.

Until recently, the CO_2 laser has been favored over cold instruments in the treatment of RRP involving the larynx, pharynx, upper trachea, and nasal and oral cavities.[6] When coupled to an operating microscope, the laser vaporizes the lesions with precision, causing minimal bleeding. When used with a no-touch technique, it minimizes damage to the vocal cords and limits scarring. Dedo reported on a series of 244 patients with RRP treated with the CO_2 laser used every 2 months and achieved "remission" in 37%, "clearance" in 6%, and "cure" in 17%.[49] The CO_2 laser has an emission wave length of 10,600 nm and converts light to thermal energy. The CO_2 laser delivers energy that is absorbed by intracellular water, effectively vaporizing the cells.[51] It provides a controlled destruction of tissues with vaporization of water, and it cauterizes tissue surfaces. The smoke plume contains water vapor and destroyed tissue material. Its drawbacks relate to safety of the operating room personnel, patient, and surgeon. The laser may glance off metal used in the suspension of the larynx and injure eyes or skin that it hits. A misfire may also hit areas on the patient that are not protected by a wet towel to absorb the laser energy. In addition, the laser smoke or "plume" has been found to contain active viral DNA, a potential source of infection.[52-54] Smoke evacuators are necessary for safety of exposed individuals. Most importantly, since the laser generates heat, ignition of the endotracheal tube may occur with an inadvertent laser strike. In the oxygen-rich environment provided by anesthetic gases, this can lead to explosion or fire in the airway. The surgeon who

Table 204-1

Treatment Options in RRP

Treatment	Number of Patients Reported
Laser therapy The standard for papilloma removal.	**Hundreds**
Microdébrider removal An evolving standard for papilloma removal.	**Hundreds**
Acyclovir Inhibits thymidine kinase, an enzyme not encoded by HPV. 4 patients treated with postoperative acyclovir, with "no recurrence in 3 cases"[105] 4 patients treated with acyclovir as adjuvant therapy to routine surgical/laser treatment. One of the 4 patients exhibited "less aggressive disease during the treatment period." The authors conclude that acyclovir "is not recommended in the treatment of juvenile respiratory papillomatosis."[106]	**8**
Cidofovir First member of group of antiviral agents known as acyclic phosphonate nucleotide analogs; they inhibit viral DNA polymerase. Cidofovir is directly injected into laryngeal sites of RRP. Large-scale trials are ongoing. 14 of 17 patients with "severe" RRP who underwent cidofovir injections experienced a "complete response."[71] 10 of 10 children with RRP who underwent cidofovir injections showed a response with short-term follow-up.[72] 14 of 14 adults with RRP exhibited disease remission after 1 to 6 injections of cidofovir.[107] Similarly, percutaneous injections of cidofovir resulted in clinical improvement in 5 of 5 adults and 5 of 5 children undergoing intralesional injections.[108,109] A larger study of 26 adults and children receiving intralesional injections found that one third exhibited complete remission; two thirds of the patients exhibited reduction in disease; none exhibited worsening of disease.[75,76] A report of a single patient with pulmonary spread of RRP suggests that systemic cidofovir may be effective in some instances. A patient had documented regression of lung RRP lesions in response to systemic cidofovir.[78]	**>50**
Indole-3-carbinol (I-3-C) I-3-C affects the ratio of estradiol hydroxylation. 18 patients, Phase I trial: one third (6 patients) exhibited "cessation of their papilloma growth"; one third exhibited "reduced papilloma growth rate"; one third exhibited "no clinical response."[84]	**18**
Interferon-alpha This most widely used adjuvant therapy appears to modulate host immune response to virus. Most common adverse side effects include flulike symptoms, but can include severe central nervous system effects such as coma.[67,68]	**>100**
Mumps vaccine 11 children with RRP were treated with regular laser excision; 9 of 11 patients (82%) had "remission induced by 1 to 10 injections, with follow-up at 5 to 19 months." In subsequent series, remission was induced in 29 of 38 patients (76%) by 4 to 26 injections, with follow-up at 2 to 5 years.[95]	**49**
Retinoids ANY in RRP trials?	**?**
Photodynamic therapy (PDT-DHE)	**>100**
Photodynamic therapy (PDT-Foscan)	**Ongoing Clinical Trials**
Vaccines A fusion protein composed of heat shock protein and the E7 gene product of human papillomavirus (HSP-E7) has been used successfully as a novel vaccine in patients with anogenital warts, where 13 of 14 adult patients had resolution of warts at week 24.[110] This novel approach had been in clinical trials as potential therapy for RRP; however, the pharmaceutical company responsible was financially insolvent and clinical trials have been halted. The quadrivalent HPV vaccine indicated for the prevention of cervical cancer[32] promises to dramatically reduce the morbidity and mortality of cervical cancer, but also has the potential to reduce aerodigestive squamous cell carcinoma as well as to eradicate RRP in future generations.[32]	**Ongoing Clinical Trials**

is not aware of injury to deeper tissue layers with injudicious laser usage may cause unacceptable scarring and subsequent abnormal vocal fold function. Inappropriate and aggressive use of the laser may also cause injury to tissues that are not affected and create an environment suitable for implantation of viral particles. Use of the CO_2 laser can also result in delayed local tissue damage, which may be related to the total number of laser surgeries and the severity of RRP disease.

Although the CO_2 laser allows for precision of surgery and excellent hemostasis, multiple procedures are often necessary. Frequent interval laser laryngoscopies are recommended in an attempt to avoid

tracheotomy and permit the child to develop good phonation with preservation of normal vocal cord anatomy. The latest generation of laser microspot micromanipulator enables the surgeon to use a spot size of 250 mm at 400-mm focal length and 160 mm at 250-mm focal length.

Although the CO_2 laser is the most commonly used laser for RRP in the larynx, the potassium titanium phosphate (KTP), 585-nm flash dye, and argon laser could also be used. Papillomata that have extended down the tracheobronchial tree often require use of the KTP or pulse dye laser coupled with a ventilating bronchoscope for removal. Occasionally, the ventilating resectoscope can also be used in these circumstances.

Emerging Technologies

The use of the CO_2 laser on the true vocal folds must be judicious given the potential for significant postoperative scar tissue formation from unrecognized heat transfer. To minimize the risk of scar formation in the true vocal folds, cold steel excision can be used successfully following the principles of phono-microsurgery, submucosal dissection, and microinstrumentation. This approach may have treatment advantages over CO_2 laser surgery, especially in the adult RRP patient.[55-57] In their initial series, Zeitels and Sataloff report recurrence of papilloma in none of the six adults at 2 years follow-up after resection for primary disease. Of those who presented with recurrent papillomatosis, 6 of 16 (38%) continued to recur after their microflap procedure.[57]

Publications have highlighted the potential benefits of other surgical technologies in managing RRP. Bower and others evaluated the feasibility and safety of the flash pump dye laser in nine children and found good early results.[58] McMillan and others published preliminary results regarding their positive experience with the 585-nm pulsed dye laser in three patients.[59] Zeitels reported on office-based use of the 532-nm pulsed KTP laser for treatment of recurrent glottal papillomatosis and dysplasias, noting at least 75% regression of disease in two thirds of patients who could tolerate the procedure.[60] Rees and Koufman also demonstrated tolerance for in-office pulsed dye laser treatments involving 328 procedures in 131 adult patients, with patients overwhelmingly preferring the in-office pulsed dye laser over surgeries under general anesthesia.[61] Zeitels and others currently favor use of a solid-state fiber-based thulium laser that functions similarly to a CO_2 laser with the benefit of being delivered through a small glass fiber.[62]

A number of investigators are now replacing their use of the CO_2 laser with the endoscopic microdébrider as a means of quickly debulking laryngeal disease. In a small, randomized study, Pasquale and others observed improved voice quality, less OR time, less mucosal injury, and a cost benefit in direct comparison of the microdébrider and the CO_2 laser.[63] El-Bitar and Zalzal, and Patel and others, have observed similar improved outcomes with the use of the endoscopic microdébrider.[64,65] A web-based survey of members of the American Society of Pediatric Otolaryngologists (ASPO) found the majority of respondents now favoring the use of "shaver" technology.[4]

Because no therapeutic regimen reliably eradicates the HPV, when there is a question about whether papilloma in an area needs to be removed, it is prudent to accept some residual papilloma rather than risk damage to normal tissue and produce excessive scarring. Even with the removal of all clinically evident papilloma, latent virus remains in adjacent tissue. Therefore the aim of therapy in extensive disease should be to reduce the tumor burden, decrease the spread of disease, create a safe and patent airway, optimize voice quality, and increase the time interval between surgical procedures. Staged papilloma removal for disease in the anterior commissure is appropriate to prevent the apposition of two raw mucosal surfaces.

Anesthetic Techniques

Several different anesthetic techniques have been advocated in endoscopic procedures to remove papillomas in children. With all methods, the airway must be handled with the utmost delicacy to minimize iatrogenic microtrauma to the mucosa.

Spontaneous Ventilation

In spontaneous ventilation, intravenous agents such as propofol are used along with oxygen and anesthetic gases such as sevoflurane that are entrained through a side port of the laryngoscope or through an endotracheal tube or nasal trumpet placed in the pharynx. The patient's own efforts are responsible for maintenance of anesthesia. Advantages are the unobstructed surgical field, but the technique is hard to master and requires an anesthesiologist who is well attuned to his or her patient. Laryngospasm, awakening, and other movement can take place with disastrous results.

Intermittent Apnea-Reintubation

Intermittent apnea-reintubation allows for the widest range of anesthetic types and provides for an unobstructed surgical view. The patient is anesthetized, intubated, suspended, and examined. The microscope is used to visualize the larynx and the tube is withdrawn while the laser or microdébrider is used. The tube is then replaced under direct visualization if the patient's oxygenation diminishes and/or the carbon dioxide level rises. Although the time for operative intervention is limited, this method is simple and effective. It does have the drawback of potentially spreading the virus through the repeated placement of the tube, however.

Wrapped or "Laser-Safe" Endotracheal Tube

Use of a wrapped or "laser-safe" endotracheal tube to protect the tube from accidental ignition by the laser can be effective and permits no significant alteration in anesthetic or surgical management. The tube remains in the surgical field, potentially obscuring the posterior glottis and subglottis. A wrapped tube must be protected (usually with electromagnetic tape or foil) to reduce risk of airway fire. There are commercially available "laser safe" tubes. Cuffs must also be protected with moist surgical cottonoids to prevent their rupture.

Jet Ventilation

Another anesthetic alternative is the use of jet ventilation for microsurgery of the larynx. Jet ventilation eliminates the potential fire hazard inherent in the use of the endotracheal tube when used with the CO_2 laser and allows good visualization of the vocal cords. A limitation of this technique is the possibility of transmission of HPV particles into the distal airway. The jet cannula can be placed either above or below the vocal cords and each approach has its own particular benefit. It is preferable to place the cannula proximal to the end of the laryngoscope to decrease the risk of possible pneumothorax or pneumomediastinum. With large laryngeal lesions, narrowed airways, and ball-valve lesions, there may develop a high degree of outflow obstruction that could lead to increased intrathoracic pressure and a subsequent pneumothorax. This may also result if there is inadequate muscle relaxation. Jet ventilation also requires constant communication between the operating surgeon and the anesthesiologist. Excessive mucosal drying and damage can occur, as can insufflation of air into the stomach with gastric distention. As mentioned earlier in this chapter, there is also the potential risk of disseminating papilloma or blood into the tracheobronchial tree.

Although not appropriate for most children with RRP, office endoscopy using light or topical anesthesia can be used along with the pulsed dye laser in selected adults.

Adjuvant Treatment Modalities

Although surgical management remains the mainstay therapy for RRP, ultimately as many as 20% of patients with the disease will require some form of adjuvant therapy. The most widely adopted criteria for initiating adjuvant therapy are a requirement for more than four surgical procedures per year, rapid regrowth of papilloma disease with airway compromise, or distal multisite spread of disease. Some of these adjuvant treatment options are summarized in Table 204-1.

Antiviral Modalities

Interferon

The first widely employed adjuvant therapy was alpha-interferon.[6,66,67] The exact mechanism by which interferon elicits its response is unknown. It appears to modulate host immune response by increasing production of a protein kinase and endonuclease, which inhibits viral protein synthesis.[68] Interferons are a class of proteins that are manufac-

tured by cells in response to a variety of stimuli including viral infection. The enzymes that are produced block the viral replication of RNA and DNA and alter cell membranes to make them less susceptible to viral penetration.

Common interferon side effects fall into two categories: acute reactions (fever and generalized flulike symptoms, chills, headache, myalgias, and nausea that seem to decrease with prolonged therapy) and chronic reactions (decrease in the growth rate of the child, elevation of liver transaminase levels, leukopenia spastic diplegia, and febrile seizures). Thrombocytopenia has been reported, as have rashes, dry skin, alopecia, generalized pruritus, and fatigue. Acetaminophen has been found to effectively relieve fever, and interferon injections are best tolerated at bedtime. Interferon produced by recombinant DNA techniques appears to have fewer side effects and better efficacy than blood bank-harvested interferon. If the side effects can be tolerated then therapy is initiated at 5 million units/m^2 body surface area administered by subcutaneous injection on a daily basis for 28 days, then 3 days per week for at least a 6-month trial. After 6 months in children with excellent responses and no severe side effects, the dosage can be decreased to 3 million units/m^2 for 3 days a week with further slow weaning as tolerated.

Ribavirin

Ribavirin is an antiviral drug used to treat respiratory syncytial virus pneumonia in infants that has also shown some promise in the treatment of aggressive laryngeal papillomatosis. Ostrow and others at the University of Minnesota have completed a small trial in eight patients using ribavirin in an oral form at 23 mg/kg/day divided four times daily after an initial intravenous loading dose, showing an increase in surgical interval in those treated.[69]

Acyclovir

Another antiviral treatment that has been advocated in the treatment of RRP is acyclovir. Although the activity of acyclovir is dependent on the presence of virally encoded thymidine kinase, an enzyme that is not known to be encoded by papillomavirus, conflicting clinical results have been obtained in several small series. Theoretically, it would not be expected to have a positive effect. However, it has been postulated that perhaps acyclovir is most effective when there are simultaneous disease factors such as infection with herpes simplex virus. Such viral co-infections with herpes simplex virus 1, cytomegalovirus, and Epstein-Barr virus (HSV-1, CMV, and EBV) have been demonstrated in RRP patients, and these patients with viral co-infections appear to have a more aggressive clinical course.[70]

Cidofovir

Recent reports have stimulated interest in the intralesional injection of cidofovir (Vistide)—(S)-1-[3-hydroxy-2-(phosphonylmethoxyethyl)-propyl]-cytosine (HPMPC)—a drug approved by the U.S. Food and Drug Administration for use in human immunodeficiency virus (HIV) patients with cytomegalovirus under expedited, fast-track guidelines. Despite a lack of controlled, randomized, blinded clinical trials in children with RRP, cidofovir is currently the most frequently used adjuvant drug.[4] Snoeck and others reported a series of 17 patients with severe RRP treated with cidofovir at 2.5 mg/mL injected directly into the papilloma bed after laser surgery experienced a complete response in 14 days.[71] Pranksy and coworkets have used this therapy in 10 children with severe RRP with short-term follow-up showing a response in all 10 patients,[72] and long-term follow-up has been encouraging.[73,74] Similarly encouraging results have been reported by Naiman and others in a small cohort of adults and children treated with a protocol-driven approach using a high dose of cidofovir at 2-week intervals.[75,76] Co and Woo have also demonstrated efficacy in a small cohort of adults with RRP treated with serial office-based intralesional injections of cidofovir.[77] Finally, there has been one encouraging successful treatment of pulmonary multicystic papillomatosis using systemic cidofovir.[78]

Based on animal studies that demonstrated a high level of carcinogenicity, and on case reports of progressive dysplasia in patients with RRP,[79] the RRP Task Force has published guidelines for clinicians interested in using cidofovir in their RRP patients.[80] Despite the anecdotal nature of most of the cidofovir studies and reports, the preliminary results are encouraging enough to consider this a treatment option in severely affected RRP patients.

Photodynamic Therapy

Photodynamic therapy (PDT) applied to the treatment of RRP has been studied extensively at Long Island Jewish Hospital by Shikowitz and associates.[81] PDT is based on the transfer of energy to a photosensitive drug. The original drug used was dihematoporphyrin ether (DHE), which has a tendency to concentrate within papillomas more so than in surrounding normal tissue. Patients are typically treated intravenously with 4.25 mg/kg of DHE before photoactivation with an argon pump dye laser. A small but statistically significant decrease in RRP growth, especially in patients whose disease was worse, was seen with the use of PDT and DHE. The drawback of this therapy is that patients become markedly photosensitive for periods lasting 2 to 8 weeks. A new drug, m-tetra(hydroxyphenyl)chlorine (Foscan), has shown efficacy in HPV-induced tumors in rabbits with minimal tissue damage and less photosensitivity. A clinical trial using this drug in a parallel-arm, randomized trial of 23 severely affected patients ages 4 to 60 resulted in improvement in laryngeal disease; however, remissions failed to be maintained over 3 to 5 years and the therapy was poorly tolerated by a quarter of the patients.[82]

Indole-3-Carbinol

There has been recent interest in the dietary supplement, indole-3-carbinol, a compound that is found in high concentration in cruciferous vegetables such as cabbage, cauliflower, and broccoli. Results in an open label, multicenter study coordinated by Rosen of treating RRP with indole-3-carbinol were encouraging. During the short follow-up of the study (a minimum of 8 months), one third of the patients had a cessation of their papilloma growth and did not require further surgery, one third of the patients exhibited reduced papilloma growth rate, and one third did not show a clinical response.[83,84] The role of estrogens on the growth of RRP has been conjectured since the discovery that RRP exhibits increased binding of estrogen.[85] Subsequent to that report, inhibition of estrogen metabolism using indole-3-carbinol has been shown to reduce the formation of HPV-induced papilloma tumors in immunocompromised mice by nearly 75%.[86] Most recently, the clinical response to indole-3-carbinol in children with RRP was closely correlated with the ratio of hydroxylated estradiol in urine.[84] Longer follow-up of a larger, blinded, controlled trial seems warranted before universally recommending this therapy.

Celecoxib

Celecoxib (Celebrex) is a selective inhibitor of the enzyme COX-2, which is overexpressed in RRPs and stimulates their growth.[87] Preliminary encouraging results in a small cohort of adults with Celebrex has led to an NIH-funded multicenter trial led by investigators at Long Island Jewish Hospital that is currently active (no longer enrolling) for adults with RRP.

Retinoids

Retinoids, which are metabolites and analogues of vitamin A, are known modulators of cellular proliferation and differentiation of diverse histologic cell types. In the aerodigestive tract, excess vitamin A has been found to suppress squamous differentiation, and may result in mucous metaplasia.[88] In contrast, vitamin A deficiency may result in hyperkeratinization and squamous metaplasia.[89] However, there are a variety of retinoids with opposing effects on epithelial cell metabolism.[90-93] Thus to state that retinoids as a class of agents have a beneficial or deleterious effect on mucosal differentiation would be an oversimplification. With this caveat, 13-cis-retinoic acid (Accutane) has gained some popularity as a systemic treatment for RRP.[94] The dosage for retinoic acid is 1 to 2 mg/kg/day. This therapy is maintained for 6 months or until the patient develops side effects he cannot tolerate. Care has to be taken in sexually active patients because Accutane has well-known teratogenic effects.

Mumps Vaccine

Intralesional injection of mumps vaccine and MMR vaccine has been investigated in an open-label single-center trial with moderate success.[95]

STAGING ASSESSMENT FOR RECURRENT LARYNGEAL PAPILLOMATOSIS

PATIENT INITIALS : ___ DATE OF SURGERY:___ SURGEON:___
PATIENT ID #: ___ INSTITUTION:___

1. How long since the last papilloma surgery? ___days, ___weeks,___months,___years,
___ don't know, ___1st surgery
2. Counting today's surgery, how many papilloma surgeries in the past 12 months?___
3. Describe the patient's voice today: ___aphonic, ___abnormal, ___normal,___other
4. Describe the patient's stridor today: ___absent, ___present with activity, ___present at rest,
___ don't know
5. Describe the urgency of today's intervention: ___scheduled, ___urgent, ___ emergent

These positive results, however, have not been reproduced by other investigators.[96]

Antireflux Therapy

The role of gastroesophageal reflux in exacerbation of RRP deserves special mention. Recent case reports have shown that the rate of recurrence of respiratory papillomatosis in children may decrease significantly after antireflux therapy.[97,98] The H_2-antihistamine Cimetidine (ranitidine) has been shown to have immunomodulatory effects.[99,100] This has resulted in several reports of its use against various virally based diseases, including RRP.[98,101] A recent small case series from Buffalo demonstrated efficacy in previously resistant children with RRP.[102] It is for these reasons that optimal control of extraesophageal reflux disease has been advocated as a means of improving outcomes, along with surgical therapy. The authors routinely place their RRP patients on an antireflux regimen.

Staging Severity

It is helpful when tracking the progression of a child's disease, communicating with other surgeons, and treating patients in a protocol format to have a surgical scoring system to assess severity and clinical course of RRP disease. Although several scoring and staging systems have been proposed, clinicians and researchers have not yet adopted a uniformly acceptable nomenclature for describing RRP lesions that is simple yet comprehensive. This has created confusion in the RRP literature and in physician-to-physician communications regarding patients' response to therapies. In addition, the absence of a universally accepted staging system has hampered our abilities to accurately report the results of adjuvant therapies or document the natural course of the disease. We have introduced a severity-staging system for RRP in a format that incorporates the best qualities of the existing systems by numerically grading the extent of papillomatosis at defined aerodigestive subsites, assessing functional parameters, diagrammatically catalogs subsite involvement, and assigning a final numeric score to the patient's current extent of disease (Figs. 204-5 through 204-7).[47,103,104] Using software designed at the University of Washington (Seattle) and licensed to the ASPO, this staging system is now computerized and available to pediatric otolaryngologists and bronchoesophagologists to allow them to objectively and subjectively measure an individual patient's clinical course and response to therapy through time. Health Insurance Portability and Accountability Act–compliant encryption technology with this software offers promise to allow clinicians from

around the world to anonymously share some of their patient data to enhance our knowledge of this disease and promote multi-institutional investigations.

Registry and Task Force Initiatives

It should be stressed that participation in national and regional protocols of adjuvant treatment modalities is essential for the scientific community to learn more about RRP. A national registry of patients with RRP has been formed through the cooperation of the ASPO and the CDC.[14] The registry tracked nearly 600 children at 22 sites with data on more than 11,000 surgical procedures. Data from the national registry aided in the identification of patients suitable for enrollment in multi-institutional studies of adjuvant therapies and better defined the risk factors for transmission of HPV and the cofactors that may determine the aggressiveness of RRP. An RRP task force, made up of the principal investigators at each of the registry sites as well as representatives from the adult RRP research community and patient/parent advocacy groups, meets twice yearly to facilitate research initiatives. The RRP task force has completed a set of Practice Guidelines (RRP Task Force, 2000) to help guide the clinician in the diagnosis and management of children with RRP, and has authored public health guidelines regarding RRP and statements on the use of cidofovir. The Task Force is engaged in providing a statement on the value of viral typing and is facilitating an investigation of the genes responsible for aggressive RRP. They have also facilitated the development of similar groups of RRP investigators in Canada and Europe and are currently working with their colleagues outside of the United States to study the benefits of the quadrivalent HPV vaccine for treatment and prevention of RRP.

Other Considerations

Children with newly diagnosed RRP warrant a substantial time commitment on the part of the otolaryngologist to engage the family in a frank and open discussion of the disease and its management. Support groups such as the Recurrent Respiratory Papilloma Foundation (www.rrpf.org) and the International (www.rrpwebsite.org) can be a vital resource for information and support. RRP patients require frequent office visits and endoscopic procedures at the outset to establish the aggressiveness of their disease. The patients are encouraged to return to the office or call as often as necessary while family members and the health care team become familiar with the child's symptoms and level of distress. While infant home intercom-type monitors are often recommended, apnea-bradycardia monitors and pulse oximetry are generally not necessary. Repeat flexible fiberoptic laryngoscopy may be used in the office, and speech and language therapy is offered early in the course of the disease. Control of other medical factors such as reflux and asthma is also aggressively pursued.

Summary

RRP is a frustrating, capricious disease with the potential for morbid consequences because of its involvement of the airway and the risk of malignant degeneration. The goals of surgical therapy are to maintain a safe airway with a serviceable voice while avoiding excessive scarring. No single modality of therapy has been consistently shown effective in eradicating RRP. When children require surgical therapy more frequently than four times in 12 months or have evidence of distal spread of RRP outside of the larynx, adjuvant medical therapy should be considered. Many adjuvant therapies have been investigated to supplement surgical therapy. These range from dietary supplements and control of extraesophageal reflux disease to potent antiviral and chemotherapeutic agents and photodynamic therapies. Although several of these modalities have shown promise, no adjuvant therapy to date has "cured" RRP.

Strides are being made in learning more about the natural history of the disease. A registry of RRP patients, and software to help clinicians share information on and accurately follow their RRP patients, has been developed. Future research is needed regarding prevention of transmission of HPV from mother to child. Specifically, the roles of cesarean section and gynecologic surgery during pregnancy need to be elucidated. Universal or near-universal use of an HPV vaccine that provides protection against HPV 6 and 11 may do for RRP what the Hib vaccine has done for *H. influenzae* type B epiglottitis—virtually eliminating new cases in less than a decade. Further refinements in surgical techniques, including the use of new office-based lasers to minimize laryngeal scarring, also need to be studied. Surgical therapy for RRP requires a skilled team consisting of otolaryngologists, anesthesia providers, and operating room personnel working together in a facility properly equipped to manage difficult pediatric airways. Because of the recurrent nature of RRP and the potential for airway obstruction, parental support and education can be invaluable to the safety of the child with RRP.

CHAPTER TWO HUNDRED AND FIVE

Evaluation and Management of the Stridulous Child

David Albert

Simone Boardman

Marlene Soma

Key Points

- The quality of stridor may be *characteristic* of a particular pathology but is never *diagnostic*; the diagnosis can only be confirmed with certainty after endoscopy.
- Improvement in stridor can paradoxically be due to worsening airway obstruction and reduced airflow.
- Laryngotracheobronchoscopy is the gold standard in the assessment of the stridulous child. It is now a highly technical procedure and the whole team (surgeon, anesthetist, and nursing assistant) needs to work closely together to perform the examination safely and to optimize the assessment.
- Children with croup who demonstrate increased work of breathing in the clinics or emergency departments should be treated with glucocorticoids.
- The risk with low tracheobronchial obstruction is that neither intubation nor tracheostomy will relieve the obstruction, although positive pressure will tend to improve malacia and to a lesser extent stenosis.
- A difficult and potentially dangerous situation occurs if a tracheotomy is attempted for tapering long segment tracheal stenosis. Not only is it not possible to insert a normal neonatal size tracheotomy tube but the tracheotomy itself severely limits the therapeutic options for surgical reconstruction of the stenosis.
- Medical therapy with steroids, antireflux treatment, nebulized adrenaline (epinephrine), heliox, and antibiotics in some cases may avert the need for more invasive measures such as tracheotomy.
- Therapeutic surgical options to manage the stridulous child include tracheotomy, endoscopic and open laryngeal surgery. Treatment is individualized depending on the underlying pathology, associated comorbidity, and social circumstances.

A stridulous child with airway obstruction demands prompt attention from parents and clinicians alike. There are many good reasons to treat pediatric patients with great respect; they have less respiratory reserve and their smaller airways are more easily compromised. In the acute situation, the infant airway can deteriorate rapidly and provide significant clinical challenges. The history and examination are rarely sufficient for a firm diagnosis; however, deciding which patients require further investigation may be difficult. Even after appropriate noninvasive investigations (e.g., imaging), there may still be a number of possible diagnoses. Flexible endoscopy in the office is useful but gives limited information beyond the glottis. The definitive diagnostic tool of laryngotracheobronchoscopy requires highly specialized equipment and an experienced surgical, anesthetic, and nursing team.

Advances in medical technology impact the likely underlying diagnoses of modern-day stridor and its management.[1] Developments in neonatal intensive care have seen improved neonatal survival and the associated challenges of the airway pathology seen in these children. Routine childhood immunization with the *Haemophilus influenzae* type B (HiB) vaccine has led to a precipitous decline in epiglottitis, making it a rarity. Improvements in endoscopic equipment have revolutionized the quality of optical images obtainable and captured for digital recording. It has also allowed for the development of endoscopic interventions in the compromised pediatric airway, many of which may now be used in combination to avoid tracheotomy or open airway surgery.

This chapter describes a current and safe approach to assessing and treating the airway of the stridulous child. The diagnostic workup is reviewed in detail and the medical and surgical management of acute and chronic airway obstruction is reviewed, with special attention given to the situations of postextubation stridor and postpartum neonatal airway obstruction. The principles of tracheotomy, endoscopic, and open laryngeal surgery are discussed.

Definition and Physical Principles

Stridor is an audible respiratory noise derived from turbulent airflow due to narrowing or obstruction of the upper airway. Stridor may be inspiratory, biphasic, or expiratory in nature. It is classically a harsh sound, which can vary in quality from a squeak to a whistling noise. Stertor describes the snoring-like noise, which typically originates from nasopharyngeal or oropharyngeal obstruction. Clinically, however, the supraglottic larynx can occasionally produce this quality of noise.

Table 205-1

Differential Diagnosis of Airway Obstruction

	Supralaryngeal	Laryngeal	Tracheobronchial
Congenital	Choanal atresia	Laryngomalacia	Tracheomalacia/bronchomalacia
	Choanal/midnasal/piriform aperture stenosis	Vocal cord palsy	Tracheal stenosis
	Benign tumor	Laryngeal atresia	Extrinsic compression
	Nasal glioma	Laryngotracheal stenosis	Vascular compression (e.g., aberrant brachiocephalic, double aortic arch, vascular ring, pulmonary artery sling)
	Encephalocele	Laryngeal web	Mediastinal tumor
	Meningocele	Posterior laryngeal cleft	Tracheal atresia
	Nasopharyngeal mass (e.g., hairy polyp, teratoma)	Cysts	Complete tracheal rings
	Structural	Vallecular cyst	Tracheal cysts
	Midface hypoplasia (e.g., Apert's, Crouzon's, Down syndrome)	Laryngeal cyst	
	Micrognathia (e.g., Pierre Robin, Treacher Collins)		
	Macroglossia (e.g., Down syndrome, cystic hygroma, lingual thyroid)		
	Cysts		
	Dermoid		
	Thyroglossal duct cyst		
	Neurological dysfunction		
Acquired	Adenotonsillar hypertrophy	Trauma	Postintubation/instrumentation
	Infection	Intubation trauma (e.g., subglottic stenosis)	Tracheal stenosis
	Tonsillitis	Cricoarytenoid joint fixation	Foreign body
	Adenoiditis	Surgical trauma (e.g., laser)	Reflux
	Infectious mononucleosis	Thermal and caustic burns	Infection
	Retropharyngeal abscess	Infection	Croup
	Ludwig's angina	Croup	Bacterial tracheitis
	Rhinitis	Epiglottitis	Postsurgical malacia (e.g., tracheostomy, tracheoesophageal fistula repair)
	Foreign body	Reflux laryngitis	Extrinsic compression
	Thermal and caustic burns	Benign tumor	Mediastinal tumor (e.g., hemangioma, cystic hygroma, lymphadenopathy, thyroid mass)
		Papillomatosis	
		Hemangioma	
		Cystic hygroma	
		Malignant tumor (e.g., rhabdomyosarcoma)	
		Foreign body	

Obstruction from all levels of the airway should thus be considered when approaching the differential diagnoses of airway obstruction (Table 205-1).

It is helpful to review the physical principles of tubular flow according to Poiseuille's law, which states that $Q = [\pi r^4(P_1\text{-}P_2)]/8\eta L$; where Q is flow, r is radius, P is pressure, η is viscosity, and L is length of tube. From this law, resistance is inversely proportional to the radius to the fourth power. From a practical viewpoint, this explains why minor narrowing in a child's airway is of much greater consequence than in an adult. For example, 1 mm of edema in a 4-mm diameter pediatric airway will reduce the cross-sectional area by 75% (16-fold increase in resistance), whereas in a 12-mm adult airway, the same 1 mm of edema reduces the airway area by just 30% (twofold increase in resistance) as demonstrated in Fig. 205-1.[2]

Assessment

It is important to perform a rapid initial evaluation of the stridulous child to assess their degree of respiratory distress and thus the urgency of their clinical presentation. If the patient has acute airway obstruction with significant respiratory distress, particularly if the patient is tiring, then the history, examination, and initial resuscitation must take place simultaneously. A comprehensive history and exhaustive examination can be completed once the situation is controlled. If the child's condition is stable, then a thorough assessment can be conducted.

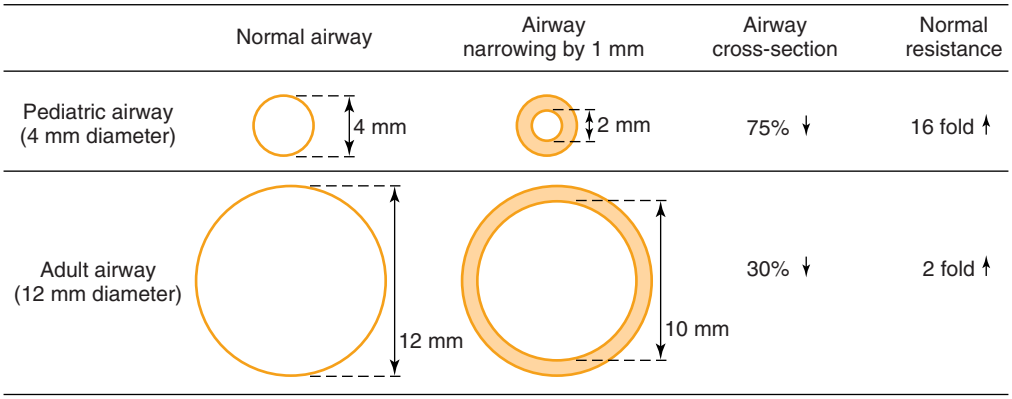

Figure 205-1. Effect of airway narrowing upon airway cross-section and resistance in the pediatric and adult airway.[2]

Stridor may be *characteristic* of a particular pathology but is never *diagnostic*. The diagnosis can be confirmed with certainty only after endoscopy. However, the combination of a thorough history, examination, and investigation can in some conditions (e.g., mild laryngomalacia) provide sufficient diagnostic probability to avoid initial rigid endoscopy. Seventeen percent of infants with laryngomalacia have a synchronous lesion that may be contributing to their airway compromise.[3] This may be missed without assessment via rigid endoscopy.

History

In an acutely stridulous child, even a brief history may aid in determining the source of the airway obstruction. Particular note should be taken of any possible foreign body ingestion or concurrent illness. A careful and thorough history will aid in formulating the differential diagnosis as long as the child has a stable airway.

Features of the stridor, including the timing of onset, progression, variability, and presence of exacerbating or relieving factors should be carefully established. Stridor present from birth suggests an underlying anatomic cause. This generally denotes a fixed congenital narrowing such as a laryngeal web, subglottic stenosis, or tracheal narrowing.[4] Dynamic conditions such as laryngomalacia typically become evident in the first few weeks of life, while congenital vocal cord palsy is also a common cause of neonatal stridor. A gradual increase in severity of stridor or airway compromise implies progressive obstruction. The obstruction may be luminal (as in a subglottic hemangioma) or extrinsic (as with a mediastinal mass or vascular anomaly). Alternatively over a longer period of time, increasing stridor may coincide with increased respiratory demands as the child becomes more active. Typically, laryngomalacia improves during rest or sleep but is worsened by crying, feeding, or physical activity. Airway obstruction associated with supine positioning may occur with supralaryngeal obstruction, such as micrognathia wherein there is associated airway obstruction by the tongue base. More rarely a pedunculated laryngeal mass, for example, a vallecular cyst, can give positional variation in the stridor as it is displaced in and out of the airway (Fig. 205-2). Improved airway obstruction with crying may occur in gross nasal obstruction such as bilateral choanal atresia.

Airway obstruction produces a number of associated symptoms (Table 205-2) that may be useful in formulating a differential diagnosis. Parents have often observed signs of increased respiratory work, including tracheal tug, subcostal recession, and suprasternal or sternal indrawing. Apneas with cyanosis may occur and parents often attempt resuscitation if these are severe. These episodes are typical of severe tracheobronchomalacia and are sometimes termed *dying spells*. The differential diagnosis includes underlying congenital cardiac disease, hence these episodes should be investigated further. Cough is typical of tracheoesophageal fistula and tracheomalacia, and raises the possibility of aspiration. Hoarseness suggests laryngeal pathology such as laryngeal papillomatosis (Fig. 205-3), whereas supralaryngeal pathology may give a muffled voice. Voice change may also occur in vocal cord palsy, although these children can also present with airway compromise and a normal voice.[5,6] Tachypnea and dyspnea are not limited to upper airway obstruction, but a clear description of exertional dyspnea in an older child may provide a useful functional assessment of severity.

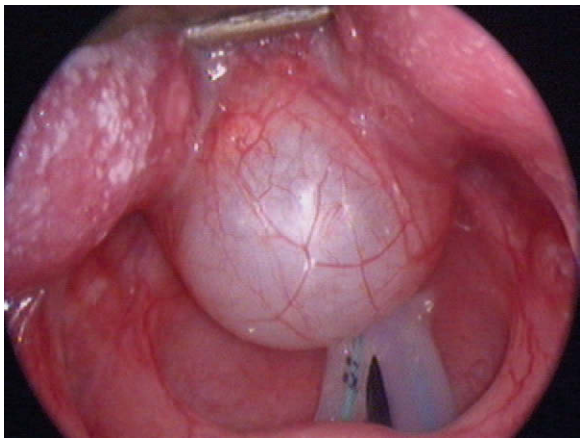

Figure 205-2. Endoscopic view of supraglottic larynx demonstrating a vallecular cyst.

The baby may feed slowly due to airway obstruction and "run out of breath" or "come up for air" during feeds. Bottle-fed babies may require thickened feeds or a "slow teat" (i.e., one with small holes). Uncomplicated slow feeding, although often a source of significant maternal anxiety, is not necessarily of concern in isolation. However, if there is failure to thrive and documented poor weight gain on the centile growth chart, further investigation and possible intervention should be considered. Laryngomalacia commonly gives rise to feeding difficulties but it is important to consider other causes. Choking episodes, documented aspiration, or recurrent chest infections may occur with vocal cord palsy, tracheoesophageal fistula, or rarely a laryngeal cleft (see Fig. 205-21). Gastroesophageal reflux is also common in infants with stridor and may exacerbate airway obstruction via edema.

The possibility of foreign body aspiration should always be raised with the parents although it is an unusual cause of isolated stridor. The clinician must however maintain a high index of suspicion to avoid missing this diagnosis, particularly if there is a history of a choking episode. The parent or caregiver may not necessarily witness events of foreign body aspiration and so the likelihood of this should be assessed. Caustic ingestion or thermal injury to the hypopharynx or supraglottis sustained by the infant drinking from microwave-heated bottles can also cause upper airway obstruction.

The clinician should determine whether the child has been systemically unwell, possibly with high temperatures. Acute episodes of airway infection will cause acute inflammation and obstruction. Viral laryngotracheitis (croup) classically has a barking cough with low-grade

Table 205-2

Features of History and Examination in the Stridulous Child

Symptoms	Signs
Stridor	Characteristics of stridor
Timing of onset	Quality, duration, timing
Progression	General appearance/syndromic features
Variability	Work of respiration:
Exacerbating/relieving factors	Respiratory rate, distress, fatigue, accessory muscle use, recession, nasal flaring, tracheal tug
Features of systemic infection	Positioning for optimal airway
Apneas/cyanosis (dying spells)	Drooling
Parental observation of recession	Quality of cry
Shortness of breath, respiratory rate	Observation chart: temperature, pulse rate
Cough	Nasal patency
Feeding difficulties	Oropharynx—mandible, tongue, tonsils
Aspiration/reflux	Neck—fullness/masses, torticollis
Cry/hoarseness	Auscultation of upper airway and chest
Specific questioning regarding foreign body aspiration	Remainder of earn, nose, throat assessment (e.g., ears)
Past history:	
Perinatal	
Intubation history	
Recurrent/persisting croup or bronchiolitis	
Comorbidities (e.g., neurologic—Arnold-Chiari, vascular malformation, cardiac disease/surgery, "birth marks"	

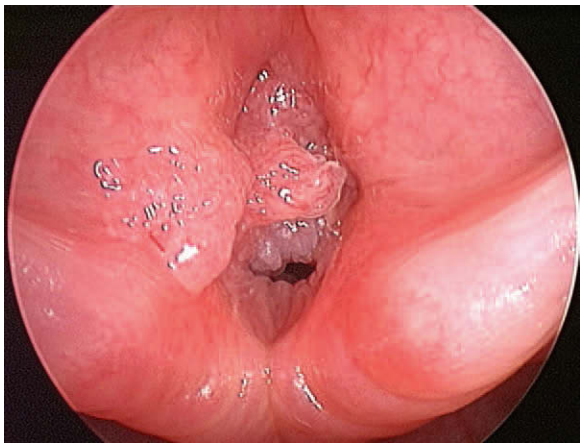

Figure 205-3. Laryngeal papillomata involving the vocal cords and extending onto the right false cord with significant airway obstruction and dysphonia.

fever and a preceding prodromal upper respiratory tract infection. Epiglottitis typically produces rapidly progressive upper airway obstruction in association with drooling, marked odynophagia, and a "muffled" voice. It is now very rare due to a dramatic reduction in incidence since implementation of Hib immunizations. Bacterial tracheitis has a variable onset with a toxic appearance, high fevers, cough, and stridor.

The obstetric and perinatal histories are often relevant, especially if the child was born prematurely and required ventilation. Parents

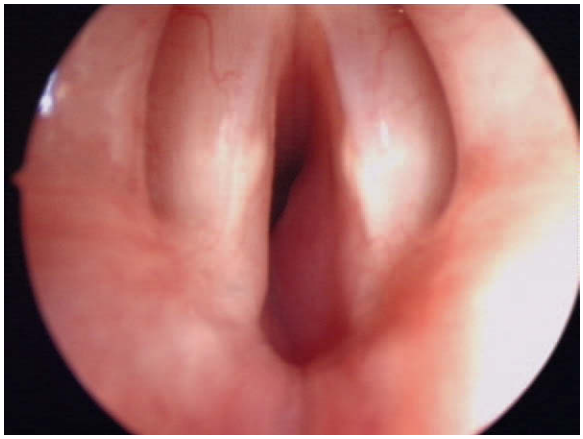

Figure 205-4. Endoscopic view of subglottic hemangioma presenting with increasing stridor.

should be specifically asked about neonatal intubation. This history must be taken carefully because the passage of nasogastric tubes for feeding or nasal/oral mucous suctioning may be mistaken for intubation. Previous intubation places the child at an increased risk of acquired subglottic stenosis (see Fig. 205-13). If the child was recently intubated or is being assessed due to failed extubation, it is worthwhile to obtain details, including size of the endotracheal tube used in comparison to the predicted age-appropriate tube, presence of a leak during intubation, use of steroids at the time of extubation, and any previous history of failed extubations.

Other comorbidities may predispose to airway obstruction, for example, vocal cord palsy in Arnold-Chiari malformation or birth injury, neurologic disease giving rise to hypotonia, or iatrogenic injury following cardiac surgery. A previously diagnosed syndrome may alert the clinician to potential pathology that is recognized as a component of the syndrome, for example, laryngeal webs in velocardiofacial syndrome. Vascular malformations, congenital cardiac disease, or vascular anomalies may give extrinsic compression of the airway and subsequent tracheomalacia. Parents should be asked about the presence of any "birthmarks," in that 50% of children with a subglottic hemangioma have a cutaneous lesion at the time of diagnosis (Fig. 205-4).[7] There is a markedly increased risk for children with cutaneous hemangiomas in a "beard" distribution, with 63% having significant airway involvement (Fig. 205-5).[8] The clinician should be particularly vigilant in assessing children with a history of recurrent episodes of laryngotracheitis or bronchiolitis that has been slow to settle. These children ought to be thoroughly assessed for an underlying source of airway obstruction that is being exacerbated by superimposed upper respiratory tract infection (Fig. 205-6).

Examination

An overall assessment of the degree of respiratory distress and airway compromise should be expedited in the acute situation and a full examination completed if the child's condition is stable (see Table 205-2). Observation of the child at rest in the parent's arms provides an initial assessment of the degree of respiratory distress, the characteristics of any stridor, and whether the child appears systemically unwell. It also allows time to gain the child's confidence before any further examination. A careful general examination is necessary to avoid missing subtle features of related syndromes or of other general pediatric disease. Syndromic features, if present, may suggest likely sources of airway obstruction associated with the particular syndrome, for example, micrognathia in Pierre Robin sequence, macroglossia in Beckwith-Wiedemann syndrome, or anterior glottic webs in velocardiofacial syndrome (Fig. 205-7).

Simple inspection of the child reveals valuable information regarding the work of breathing and degree of obstruction. Potential findings of increased respiratory work include suprasternal or sternal recession, subcostal indrawing, "see-saw" or paradoxical abdominal movement

Figure 205-5. Extensive cutaneous cervicofacial hemangioma in a "beard" distribution in an infant with transglottic, tracheal, and mediastinal hemangioma.

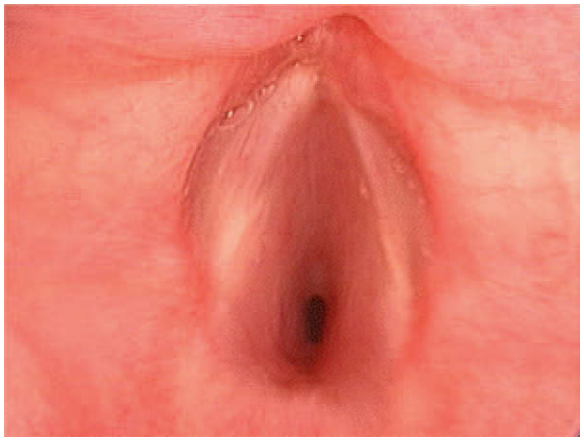

Figure 205-6. Severe congenital (grade III) subglottic stenosis presenting for rigid laryngobronchoscopy on a background of recurrent episodes of croup.

during respiration, nasal flaring, tracheal tug, anxiety, irritability, or evidence of fatigue. The amount of recession is a better indicator of the severity of airway compromise than the degree of stridor. Stridor can paradoxically become quieter and less apparent as the obstruction worsens due to the diminishing airflow and may be a sign of impending respiratory arrest. Pallor and subsequent cyanosis are late events in pediatric patients and no comfort should be taken from the fact that a child still appears pink. Children may position themselves to optimize their own airway as is classically described in epiglottitis, where children prefer to sit upright with their head in a "sniffing" position. Pectus excavatum may be seen in children with chronic airway obstruction due to negative intrathoracic pressure in their highly compliant rib cage.[2]

The observation chart should be checked for elevated temperatures, tachycardia, or tachypnea. Drooling may occur in epiglottitis, severe oropharyngeal inflammation, or deep neck space infection. Any cough or change in voice or cry should be noted. The clinician should listen carefully to the audible respiratory noise to differentiate between inspiratory stridor, biphasic stridor, expiratory stridor or wheeze, and stertor. This can be useful in determining the likely anatomic site of the pathology, although this is not absolute and is only useful as a guide.

Inspiratory stridor typically occurs due to obstruction at the level of the supraglottis or glottis. Obstruction arising in the bronchi or lower trachea classically produces an expiratory stridor or prolongation of the

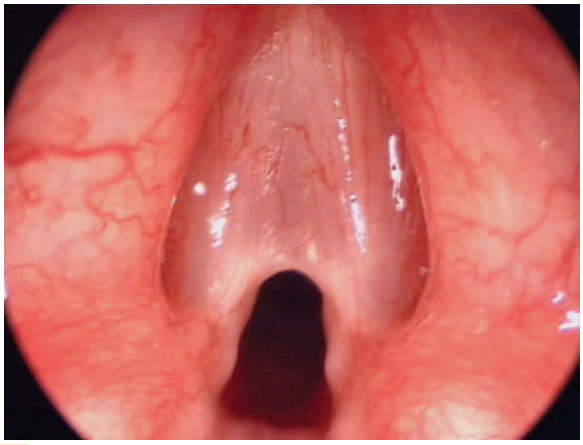

Figure 205-7. Anterior glottic web presenting with stridor in a child with velocardiofacial syndrome.

expiratory phase. Biphasic stridor can occur with obstruction anywhere in the laryngotracheobronchial tree but is classically associated with either upper tracheal or subglottic pathology where it is attributed to the fixed luminal diameter of the cricoid. The characteristic sound of stridor, even in a common condition such as laryngomalacia,[9] is so variable as to be of little diagnostic use in isolation. Laryngomalacia has been traditionally described as having stridor that is of a musical quality, while stridor in vocal cord palsy has a breathy quality, viral laryngotracheitis has a barking cough and tracheomalacia has a brassy cough. It is important to recognize that these descriptions are highly subjective and their assessment is not reliably reproducible.

Nasal patency is assessed via fogging of a mirror or metal tongue depressor. Nasal airflow may also be detected via a wisp of cotton wool or using the bell end of a stethoscope. This is particularly relevant if supralaryngeal obstruction is suspected. The clinician should also make a conscious assessment of jaw and tongue size. Stridor and recession vary as the child rests, cries, and sleeps. It can be useful to observe the child while the child feeds, particularly if poor feeding or aspiration has been reported. Auscultation may be used to aid in localizing the site of maximal obstruction but the transmission of sound through the thorax is variable, often making this technique difficult. Auscultation is useful to detect heart murmurs and wheeze.

The nose, throat, neck, and ears should also be examined. The oropharynx is examined to assess the size and appearance of tonsils and palate, and to check for oropharyngeal swelling or fullness. The neck is also inspected and palpated to identify swelling or masses. The usual caution should be used in examining a child with possible epiglottitis wherein sudden airway obstruction may be precipitated. In this situation, equipment for immediate intubation must be present if examination is to be attempted. It is also acceptable to make a provisional diagnosis of epiglottitis based on history and appearance of the child, with formal examination performed in the safety of the operating room under endoscopic control.

Nonendoscopic Investigations

Investigations should not be routinely conducted but judicious use may be helpful. Selection of investigations should be tailored to the clinical presentation on the basis of the history and examination findings and are not necessary in every patient.

O_2 Saturation Monitoring

O_2 saturation monitoring is noninvasive and readily accessible, although considerable airway obstruction may occur without desaturation, as long as the child is not tiring and continues to have the energy to overcome the obstruction. Care should be taken in administering supplemental oxygen because this can maintain O_2 saturations while masking raised levels of CO_2. Arterial blood gases are useful in this situation. From a clinical viewpoint, cyanosis occurs very late in pediatric respiratory distress.

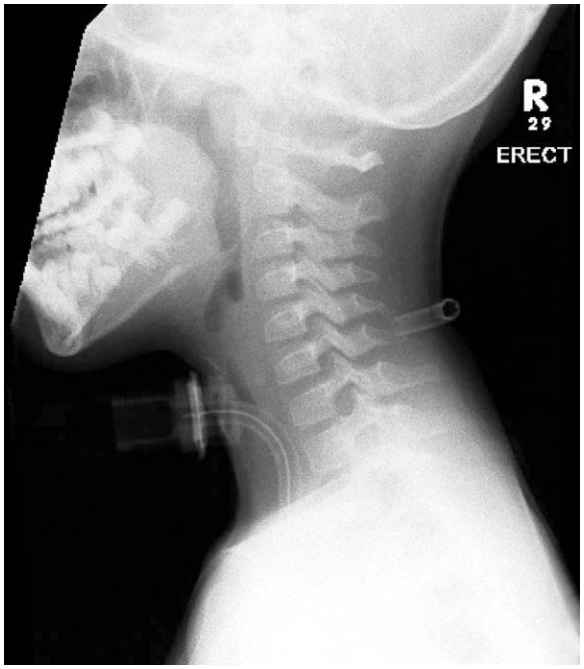

Figure 205-8. Lateral neck x-ray study with enhancement of the tracheal air column demonstrating a stenotic segment with obliteration of the airway for 7 mm craniocaudally from the glottic level.

Figure 205-9. Magnetic resonance imaging study of head and neck demonstrating cystic hygroma in the left cervical region with airway compression, tracheal displacement to the right, and mediastinal extension.

Radiology

Soft tissue lateral neck x-ray examination demonstrates the airway outline from the nasopharynx to the subglottis. Posterior-anterior chest x-ray study shows the lung fields and mediastinum. Persistent air trapping may be demonstrated on the side of a bronchial foreign body in inspiratory/expiratory views. A decubitus view may be useful in young children, where normally the dependent lung deflates.[10] A Cincinnati (high-kilovoltage filter) view enhances the tracheal air column while de-emphasizing bony cervical spine to demonstrate the major airways. These x-ray techniques may be useful as screening investigations (Fig. 205-8).[11,12] Careful consideration of the stability of the child's airway is mandatory and radiology should not be undertaken if there is any potential for acute airway deterioration. Policy for suspected epiglottitis differs between centers; however, the result of the x-ray study may not influence management[13] and may be associated with significant risk to the child. Further imaging should be performed according to the endoscopy findings.

Videofluoroscopy is an excellent way of demonstrating tracheomalacia and can be combined with a contrast swallow to exclude vascular compression,[14,15] tracheoesophageal fistula, or aspiration. It may demonstrate diaphragmatic immobility on the side of a foreign body airway obstruction. Bronchograms using safe nonionic contrast media are useful for outlining the luminal surface of the lower airway, demonstrating tracheobronchial stenosis and malacia. Opening pressures of the collapsed bronchi and lower trachea can also be measured to determine the level of airway support needed. Computed tomography (CT) and magnetic resonance imaging (MRI)[12,16,17] continue to lack sensitivity in assessing airway stenoses and cannot replace endoscopic assessment. They are useful in demonstrating vascular anomalies and extrinsic compression of the airway (Fig. 205-9). Virtual endoscopy uses radiologic data to create computer simulations that may be viewed as one would conventional endoscopy. Helical CT with multiplanar reconstruction provides three-dimensional images, which are used in real time to simulate endoscopy views. It is noninvasive and allows retrograde luminal airway views. Although it demonstrates some fixed airway stenoses, it is not helpful in detecting obstruction during dynamic movement as occurs in tracheomalacia or vocal cord palsy. There is also a lack of detail, with airway pathology such as glottic webs being poorly demonstrated.[18]

Other Investigations

Vocal cord ultrasound can be used, with experience, to demonstrate vocal cord palsy to complement the endoscopic findings.[19] The role of *laryngeal EMG* in the management of vocal cord immobility is yet to be fully defined.[20] Airway obstruction that worsens during sleep is usually a feature of pharyngeal obstruction, such as adenotonsillar obstruction or craniofacial anomaly. Laryngotracheal pathology at any level including laryngomalacia may, however, occasionally worsen during sleep, thus requiring *sleep study* investigation.[21] *Pediatric lung function tests* are seldom used because of compliance and cooperation issues. Flow volume loops[22] may help localize the site of obstruction and other tests such as peak flows or ventilation-perfusion scans may be used upon the advice of a pulmonologist. Gastroesophageal reflux[23-26] is not discussed in detail in this chapter but can be investigated via double probe pH studies, contrast studies, milk scan, or esophagoscopy with lower esophageal biopsy. Echocardiography detects congenital heart disease but does not demonstrate all abnormal vasculature, thus it cannot be used to exclude vascular anomalies.

Endoscopy

Pediatric airway endoscopy requires a full range of specialized pediatric endoscopy equipment and an experienced team. An inadequate evaluation needs to be repeated, and referral to an experienced center should be made as required to ensure a single comprehensive and definitive evaluation. A systematic approach provides a diagnosis in most cases.[27]

Flexible Endoscopy in the Office or Ward

The introduction of ultrathin endoscopes[28] in a range of diameters with good optics has allowed even neonates to undergo endoscopy without the need for a general anesthetic. This is usually considered a screening procedure, in that the view of the larynx may be suboptimal. Rigid endoscopy of the airway is superior in examining the airway for structural abnormalities. Flexible endoscopy is useful in assessing the dynamic airway for vocal cord movement or features of laryngomalacia. A systematic approach must be adopted, observing first the nasal cavity followed by the postnasal space, oropharynx, supraglottis, and glottis

during dynamic respiration and phonation. It is difficult to obtain good views of the subglottis. This is purely a diagnostic procedure, with no opportunity for therapeutic procedures, in contrast to a rigid laryngotracheobronchoscopy. Flexible endoscopy under sedation in an endoscopy suite is widely practiced by pediatricians and pulmonologists[29-31] and is used by otolaryngologists as an adjunct to rigid endoscopy.[32] Rigid endoscopy is helpful if the diagnosis remains unclear despite flexible endoscopy, if there is clinical suspicion of a second airway lesion, or if subglottic/tracheal or bronchial pathology is suspected.

Laryngotracheobronchoscopy

Laryngotracheobronchoscopy[33] is the gold standard in the evaluation of the stridulous child. It enables a thorough assessment to be performed while the airway is maintained and allows findings to be visually recorded for future reference. The airway may be formally sized to grade any narrowing. It also may incorporate therapeutic procedures, including foreign body removal or the endoscopic management of airway pathology. It requires an experienced team skilled in airway assessment, including the surgeon, anesthetist, and nursing assistant, who work closely to ensure an optimal and safe examination. The use of a video is essential to facilitate training and allows the anesthetist and nurse to follow the procedure and status of the airway on the monitor.

It is vital that accurate records are kept in a standardized form within a department.[34] Digital prints provide a valid record of static conditions while video clips record dynamic findings. Digital images and video recordings should be saved and archived. This provides an invaluable source of information for sequential clinical comparisons, teaching, and medicolegal purposes.

Anesthetic Considerations

This procedure requires a cooperative approach to airway management with both the anesthetic team and surgeon sharing the control of the airway. The use of atropine premedication provides a dry surgical field and improves the efficacy of topical anesthesia. It is most effective via intramuscular injection. Anesthesia is often induced using slow masked inhalational anaesthesia. Halothane is a volatile agent that has been traditionally used and is nonirritating to the airway, allowing for smooth maintenance of anesthesia during instrumentation of the airway. Halothane is now difficult to obtain and other inhalational agents such as isoflurane, sevoflurane, and intravenous agents are being used. Sevoflurane[35] is also nonirritating, rapid in onset, and allows rapid delivery of high concentrations. Topical lidocaine is applied to the airway to minimize airway stimulation during the procedure and helps avoid laryngospasm. Lidocaine dose needs to be carefully measured to avoid overdosage.[36,37]

Anesthetic practice varies between centers but most units use spontaneous respiration for pediatric patients rather than paralysis and jet ventilation simulating normal respiration. Jet ventilation prevents coughing or gagging[38-40] but requires pressures above physiologic levels[38,41] with an associated risk of pneumothorax in neonates and smaller children. Dynamic conditions such as malacia and cord palsy cannot be identified. Apneic endoscopy is also possible after initial hyperventilation with 100% oxygen, although progressive hypoxemia and hypercarbia limit the operating time and condition of the patient.[42]

After induction, the child is ventilated down to a level of anesthesia that allows the rigid endoscope to be passed without gagging but maintains spontaneous respiration. The child may be intubated before the endoscopy or alternatively the airway may be controlled via a mask. Ideally the endoscopist has a view of an airway that is not altered by the passage of an endotracheal tube and, if the child is intubated, the tube is withdrawn during the procedure. A transnasal endotracheal tube may be positioned with the tip in the hypopharynx to optimize delivery of anesthetic gases and oxygen without obstructing the view of the airway. Airway control can be regained at any stage via intubation or through the use of a bronchoscope.

A laryngeal mask[43] may be useful for fiberoptic bronchoscopy particularly if the patient is difficult to intubate due to mandibular hypoplasia.

Figure 205-10. Rigid laryngobronchoscopy using a zero degree telescope demonstrating optimal positioning of the child and operating room set-up to allow accurate airway assessment.

Operative Technique

A suspension laryngoscope and microscope are traditionally used to examine the larynx, with a ventilating bronchoscope to examine the tracheobronchial tree (Fig. 205-10). Rigid telescopes provide excellent images and many centers now perform the assessment using a telescope, with digital images recorded at each anatomic level. High-quality images may be captured via the use of a wide Storz photographic telescope. A 4-mm rigid telescope should provide adequate images for data records, provided there is careful focusing and appropriate camera settings to ensure optimal captured images. For routine examination, the telescope and camera can be held in the left hand with a probe used in the right while the laryngoscope is in suspension. The microscope is used if there is to be manipulation of the airway requiring both hands of the operating surgeon. Differing techniques are adopted, according to individual departmental preferences. The procedure may be combined with rigid esophagoscopy, according to departmental protocols.

Preparation and Positioning

It is essential to anticipate equipment requirements so all equipment can be checked and prepared before commencement. A range of Hopkins rod telescopes should be available, which includes all lengths and diameters that may be required, so the endoscopist is fully prepared for all eventualities. Charts that predict age-appropriate sizes of bronchoscopes should be consulted and be readily available in the operating room.[44] The appropriate bronchoscope needs to be checked and assembled and at least one size smaller must be on hand. A 30-degree telescope may be used to enable assessment of the supraglottis without splinting. It may also assist assessment of an anteriorly placed larynx. A microscope should be available with the 400-mm lens to be used with standard laryngeal instruments. A 350-mm lens may be useful in small neonates by "bringing the patient closer" to allow easier manipulation of larynx.

A small sandbag is placed under the shoulders, with supporting lateral sandbags placed for children with long thin heads, as is typically seen in ex-premature neonates. A Mayo table supports the laryngostat clear of the chest.

Microlaryngoscopy Technique

A suspension straight-blade laryngoscope is gently inserted while assessing the overall appearance of the laryngopharynx, taking care to protect the teeth, lips, and oral mucosa while keeping the tongue midline to provide a well-centered view. The laryngoscope is placed in the vallecula and the epiglottis is carefully lifted forward. An overall assessment of the larynx can be made while an endotracheal tube is in situ and while providing a degree of stability, particularly in a compromised pediatric airway. Removal of the endotracheal tube allows a superior view and a probe may be used to independently palpate the arytenoids

Figure 205-11. Ventilating bronchoscope.

to assess the mobility of the cricoarytenoid joints and any limitation in joint movement. Absence of independent arytenoid movement on palpation is indicative of interarytenoid scarring. A posterior laryngeal cleft should be excluded by passing the probe between the arytenoids to allow comparison of the inferior limit of the interarytenoid groove with the posterior commissure. The subglottis should also be inspected from above. Topical decongestion and vasoconstriction of the airway may be helpful, particularly in the presence of low-grade inflammation or edema. Any airway narrowing should be formally sized. The largest endotracheal tube that permits a leak at less than 30 cm H_2O of pressure provides a measure of the airway diameter. Subglottic stenosis may then be graded using the Cotton-Myer grading system,[45] thus allowing reproducible assessment of the stenosis and aiding in treatment selection. If there is airway compromise or instability, assessment time may be limited. It is thus essential to be prepared to move ahead with bronchoscopy at any stage.

Bronchoscopy Technique

Traditionally, a ventilating bronchoscope (Fig. 205-11) has been used to assess the distal airway, which provides a means of actively ventilating the patient during the procedure, if required. An age-appropriate sized bronchoscope is used unless stenosis is suspected. A smaller-diameter rigid Hopkins rod telescope can be used as an alternative to examine the airway in a spontaneously breathing child, particularly if there is significant subglottic stenosis. The rigid telescope may reduce local airway trauma and lessen airway splinting, while allowing the distal airway to be visualized.

An anesthetic laryngoscope is placed in the vallecula while passing the bevel of the bronchoscope through the vocal cords under vision or via the monitor. The subglottis, trachea, carina, and main bronchi are systematically examined and findings recorded via digital images and/or videos. Evidence of tracheomalacia should be sought in the absence of positive airway pressure to avoid splinting of the airway and using a small bronchoscope withdrawn from the area being assessed. The ratio of cartilage to trachealis is significant in recording the type of malacia. The presence of complete tracheal rings is of importance when considering slide tracheoplasty for the treatment of long segment tracheal stenosis.[46] Extrinsic compression and prominent transmitted pulsation may be evident where there is an underlying vascular anomaly, which can be confirmed with imaging.

Dynamic Airway Assessment

A dynamic assessment of the larynx may be performed as the child lightens and is observed while the child recovers from the anesthesia. Dynamic views can be achieved by withdrawing the bronchoscope so that it is positioned just posterior to the tip of the epiglottis. This allows a good view of the vocal cords to exclude vocal cord immobility. It is useful if the anesthetist calls the phase of respiration, thus allowing the endoscopist to check for paradoxical cord movement. The arytenoids and adjacent mucosa can also be visualized to check for evidence of laryngomalacia. Anterior collapse of the epiglottis may be masked, however. A 30- or 70-degree telescope may offer improved views for dynamic assessment.

An excellent technique for dynamic assessment of vocal cord movement utilizes a laryngeal mask with a fiberoptic bronchoscope passed through to visualize the airway. The flexible endoscope is positioned just proximal to the laryngeal inlet to observe airway dynamics.[47]

Complications

Complications are unusual in rigid laryngobronchoscopy with a reported overall complication rate of 1.9%.[48] Possible complications include oral injury, subglottic injury, pneumothorax, cardiac complications, loss of control of the airway, and bleeding. Blood in the airway impairs oxygenation and ventilation, rather than giving rise to difficulties due to volume of blood loss.[42] Risks associated with procedural complication include cardiac anomalies, airway foreign body, tracheal stenosis, and biopsy or abscess drainage,[48] and particular care should be taken in these cases.

Postoperative Care and Planning

Airway obstruction may increase following the procedure due to underlying pathology, edema, blood, secretions, or postintubation croup. Edema is usually maximal within 4 hours and settles by 24 hours. Humidified oxygen by mask is initially tried. Nebulized epinephrine (1:1000) may be tried but the child must be kept under observation and reviewed within an hour for recurrence due to its limited duration of action.[42] The patient may be given intraoperative dexamethasone if there is a potential for edema from instrumentation of the airway. Steroids may be continued in the postoperative period depending on the endoscopy findings and underlying airway pathology. The patient must be recovered by nursing staff experienced in the care of pediatric airways and remain as an inpatient for close observation until the airway is adequately stable for discharge.

The operative record should clearly record the endoscopy findings, ideally with a photographic record of the findings. Using the endoscopic assessment, a plan of management can then be decided upon and discussed with the parents postoperatively.

Treatment of Acute Airway Obstruction

Medical Treatment

The child who arrives in the emergency department with acute airway obstruction should undergo rapid evaluation. Assessment, history, and active resuscitation should proceed while measures are taken to stabilize the airway. The physician should determine the degree of airway obstruction by observing the child for recession and work of respiration while taking a brief history from the accompanying adult. Details will be obtained regarding the length of history, recent systemic illness, and possibility of foreign body inhalation. The nursing staff should check the oxygen saturation and set up humidified oxygen. Another team member should contact the operating room and anesthesiologist to advise that the child may require intubation. The otolaryngologist may also be contacted and asked to attend the intubation,[49] depending on the unit's protocol. This situation clearly benefits from careful planning, with most units having a protocol for how to deal with the stridulous child.

Supplemental oxygen reduces the ventilatory requirement to maintain adequate oxygen saturation in cases of airway obstruction with normal alveolar function. The potential for CO_2 retention should be kept in mind. Heliox (helium-oxygen gas mixture) may be used to relieve respiratory distress, decrease the work of breathing, and improve gas exchange.[50] It does this due to its low density, which results in a lower resistance to gas flow.[51,52] It has no direct effect on the underlying pathology and thus must be viewed only as a "therapeutic bridge," allowing time for definitive treatment to be commenced.[50] Steroids and nebulized epinephrine may also be used to help optimize the airway in the acute situation.

Laryngotracheitis (viral croup) can be treated with intravenous, oral, or nebulized steroids. There is no objective evidence that raising the humidity of the inspired air is beneficial.[53] Nebulized budesonide[54] is used in the home environment for children with recurrent croup. Corticosteroids are beneficial and are routinely recommended for the treatment of croup.[55] Klassen[56] recommends that children with croup symptoms and increased work of breathing should be treated with either nebulized budesonide (2 mg) or oral/intramuscular dexamethasone (0.15 to 0.6 mg/kg). Oral dexamethasone is easily administered, widely available, and low in cost. L-epinephrine (5 mL of 1 : 1000) or racemic epinephrine (0.5 mL) should be considered if there is moderate or severe distress because it has been found to give clinical improvement and reduce the need for intubation.[57]

Other infective causes of airway obstruction respond promptly to antibiotic therapy. This includes bacterial tracheitis or epiglottitis, which is rare, although vaccine failure[58,59] has been documented. Appropriate intravenous antibiotic therapy should be commenced while the airway is stabilized via short-term intubation if required.

Therapeutic Intubation

Intubation is increasingly used as an alternative to tracheotomy in acute airway obstruction. Pediatric tracheotomy is avoided if possible due to the potential for morbidity, even with short-term usage. Intubation may not be possible, for example, in severe subglottic stenosis, impacted foreign bodies, or advanced epiglottitis. As this situation may be unexpectedly encountered even by skilled, experienced pediatric anesthesiologists, most hospitals require an otolaryngologist to be informed if a child with airway obstruction is to be intubated. It may be necessary to have an emergency tracheotomy set open with the correct size tube already selected.

The child is "gassed down" slowly and the larynx is inspected to exclude epiglottitis. The child may then be manageable on a nasal pharyngeal airway with continuous positive airway pressure (CPAP). If intubation is required, it is important to minimize any damage to the inflamed subglottic mucosa. This is achieved by gentle intubation with a small, soft tube that is adequate for ventilation and suction of secretions. A nasotracheal tube is preferable to an oral intubation to help minimize tube movement. The secure nasotracheal tube ought to be placed and assessed by suctioning the secretions and testing for a leak. Any persisting element of airway obstruction or tenacious secretions should be further investigated by passing a ventilating bronchoscope. This helps exclude bacterial tracheitis[60,61] or a foreign body. Endoscopic suctioning and clearance of debris from the airway may be performed and is particularly beneficial in bacterial tracheitis. Significant tracheobronchomalacia may also give persisting obstruction after intubation and will usually respond to CPAP.

Emergency Tracheotomy

Emergency tracheotomy is a rare occurrence in departments with experienced pediatric anesthesiologists.[49,62] Otolaryngologists are often asked to attend a potentially difficult intubation but are rarely needed. If emergent tracheotomy is required, however, the surgical set and appropriate tube must be immediately available. The neonate needs to be in a straight supine position with the neck extended over a roll. A long, vertical, strictly midline incision is made through skin and down to the trachea, guided by palpation of the trachea. The main danger lies in drifting off the midline and a finger on either side of the larynx is helpful. If a pediatric tracheotomy tube is not available, a pediatric endotracheal tube can be used, ensuring it remains above the carina.

Endoscopic Removal of Foreign Bodies

Foreign body removal has been greatly facilitated by the introduction of foreign body optical extraction forceps that have a central channel for an extra-long Hopkins rod telescope. Different forceps are available for the removal of various types of foreign bodies. The foreign body and adjacent airway can be carefully examined while the removal is planned using a fine suction catheter in the bronchoscope alongside the rigid telescope. The use of topical adrenaline before any attempt at removal optimizes local conditions by vasoconstricting the mucosa and reducing bleeding.[63]

Table 205-3

Management Options for the Difficult to Extubate Neonate

Treat reflux
Leave tube in place for at least 1 week between trials of extubation
Steroids to cover extubation
Nasal prong ± CPAP postextubation to support airway
Endoscopic optimization of airway—removal of small granulations, cysts
Cricoid split
Single-stage laryngeal reconstruction
Tracheotomy ± stent to maintain airway

Approach to Postextubation Stridor

Extubation should not be attempted until the child has an optimal chance of success. Failed extubation requiring subsequent reintubation predisposes to further deterioration of the airway with additional edema, ulceration, and perichondritis. There should be no active respiratory infection, minimal pressure support, and a normal oxygen requirement at the time of extubation. Reflux should be adequately treated and steroids commenced if indicated. Extubation should proceed once sedation has worn off and the child is awake to maximize the likelihood of success. If postextubation stridor and obstruction occur, the airway can be further optimized with nebulized epinephrine,[64] intravenous dexamethasone[65] before and after extubation, and continuous positive airway pressure via nasal cannula. Therapeutic reintubation for laryngeal rest has been demonstrated to be beneficial,[66-68] allowing any reversible component of the airway inflammation to settle.

If extubation fails, despite appropriate medical measures and laryngeal rest, endoscopic procedures are being increasingly used to optimize the airway (Table 205-3). Alternatively, a cricoid split may be performed. Single-stage laryngotracheal reconstruction can be used in patients who fail cricoid split or who have a mature stenosis. Tracheotomy is reserved for those who are not suitable for an alternative approach. These surgical options are discussed later.

Expected Airway Obstruction in the Postpartum Neonate

Antenatal diagnosis of airway obstruction enables a definitive plan of management to be formulated before delivery. Routine prenatal ultrasonography may diagnose large masses, including cervical teratoma,[69,70] cystic hygroma,[71] or rhabdomyosarcoma[72] with associated airway obstruction. Further details of the anatomy can then be defined using MRI.[73,74] Airway obstruction may be detected on ultrasound, even in the absence of a mass. Antenatally diagnosed congenital high airway obstruction syndrome (CHAOS) exhibits features including tracheal dilation and lung hypertrophy, as seen in laryngeal atresia.[75] Polyhydramnios may also occur if an obstructing lesion is compressing the esophagus and impairing fetal swallowing.[76] Other ultrasound features may include diaphragmatic eversion, ascites, and ultimately fetal hydrops.[77] Holinger and others first described the successful airway management of an antenatally diagnosed cervical teratoma in 1985.[70] The technique of securing the neonatal airway while the uteroplacental blood flow was maintained was subsequently described in the early 1990s.[73,78] This procedure has become known as the ex utero intrapartum treatment (EXIT)[79,80] or OOPS (operation on placental support)[71] and should be considered when perinatal airway obstruction is anticipated. The multidisciplinary team usually includes pediatricians, obstetricians, anesthetists, and ENT surgeons. Other specialties may be involved, depending on the underlying pathology. At planned cesarean section, adequate uteroplacental flow is maintained while the airway is established. The placenta allows continued gas exchange while the airway is stabilized. Direct laryngoscopy and intubation is then

Figure 205-12. Computed tomography scan (axial view) demonstrating bilateral choanal atresia.

performed. Rigid laryngobronchoscopy may be used to define the anatomy and possibly place a guidewire for intubation guidance if there is marked distortion or poor visualization of the airway. If intubation is not possible, the trachea is exposed and a tracheotomy performed. The surgeon should be mindful that a large neck mass will hyperextend the neck and anteriorly displace the trachea. This may mean that the tracheotomy is placed more distally than planned. Once the airway is secured the umbilical cord is clamped and the delivery is completed.[76] Extracorporeal membranous oxygenation can be used particularly in the presence of severe congenital cardiac disease.[81] Resection of an obstructing mass is usually delayed until the child's condition is stabilized.[81]

Unexpected Airway Obstruction in the Postpartum Neonate

Airway obstruction may not always be antenatally diagnosed. The delivery team may be presented with a neonate with unexpected airway obstruction. An anatomic approach to the differential diagnoses and management of these infants is helpful.

Supralaryngeal

Nasal or nasopharyngeal obstruction can be highly significant in the newborn who is an obligate nasal breather. Nasal suction removes secretions and allows assessment of the patency of the nasal airway. Choanal atresia is the most common diagnosis in complete nasal obstruction and can be investigated via CT scan (Fig. 205-12). It may be difficult to pass a nasal suction catheter in a neonate with prominent turbinates or, less commonly, piriform aperture stenosis, midnasal stenosis, or choanal stenosis. Nasopharyngeal masses such as teratomas may also obstruct the airway. Nasal or nasopharyngeal airway obstruction is relieved by an oral airway. Oropharyngeal sources of obstruction (such as micrognathia with a retroposed tongue) may also be improved by positioning and oral airway placement.

Laryngeal

Laryngeal obstruction shows no improvement with an oral airway but is relieved by intubation. Airway obstruction associated with severe laryngomalacia, vocal cord palsy, laryngeal cysts, or polyps will improve with intubation. A small-shouldered tube may be temporarily positioned through a laryngeal stenosis to secure the airway. Some units now advocate using a laryngeal mask for neonatal resuscitation[82] to avoid exacerbation of the stenosis by attempts at intubation. It may be possible to ventilate a neonate with laryngeal atresia and a low tracheoesophageal fistula although this is rare. In these cases, there will be none of the characteristic findings of congenital upper airway obstruction on antenatal ultrasound. On closer examination in this instance, the tube is found in the esophagus with ventilation occurring via the fistula.[83]

If intubation is not possible and there is inadequate ventilation via a laryngeal mask or very fine endotracheal tube, the trachea must be opened to ventilate the neonate. In the emergency situation, needle puncture of the cricothyroid membrane or trachea is possible but not easy, while emergency open tracheotomy is also difficult unless the surgeon has current experience of neonatal tracheotomy. It may be difficult to palpate the laryngeal cartilage in a neonate. It is of greater importance to remain in the midline when locating the airway, rather than focusing on the level of entry. The principles of emergency tracheotomy are discussed earlier. In tracheal puncture, the first and second fingers of the left hand are placed either side of the trachea and the needle inserted vertically, strictly in the midline until air can be aspirated. Larger needles can be inserted above or below the first if necessary. A tracheotomy will bypass laryngeal lesions such as congenital webs or subglottic stenosis.

Tracheobronchial

Obstruction due to distal tracheal or bronchial pathology, including tracheobronchomalacia, may not improve with either intubation or tracheotomy. Positive pressure will aid in splinting the airway and improve malacia. It is less helpful for distal airway stenosis. Use of an extended (long) tracheotomy tube will physically support tracheomalacia but will not assist in carinal malacia or bronchomalacia. A tapering long-segment tracheal stenosis presents a difficult clinical situation, because it is often possible to insert only a very small tracheotomy tube. In addition the tracheotomy severely limits the therapeutic options for surgical reconstruction of the stenosis. The patient with a long-segment tracheal stenosis requires referral for consideration of slide tracheoplasty, which is recognized as the best treatment for this condition in the current era.[46]

Treatment of Chronic Airway Obstruction

The evaluation of a child with chronic airway obstruction is not dissimilar to the acute situation; however, one has the luxury of time to perform a thorough clinical assessment and systematic investigations as required. The management options are more complex as the emphasis shifts from acute resuscitation and relieving the obstruction to addressing the underlying condition and preventing complications. The choice of treatment is influenced by the severity of the symptoms and signs, coexisting morbidity, the patient's social situation, surgeon's preference, availability of equipment, and other pediatric services, particularly intensive care.

Conservative options include watchful waiting and the use of medical treatments to address general and specific conditions. Tracheotomy may be chosen to "buy time" until the child grows and the condition resolves, or in some situations it may be definitive. Other surgical treatments include a vast spectrum of endoscopic techniques available to open laryngeal framework surgery.

Medical Management

There are several conditions presenting with chronic airway compromise that may be managed expectantly with regular clinical review and supportive therapy only (e.g., mild to moderate laryngomalacia, unilateral vocal cord palsy, grade I subglottic stenosis). The input of allied health departments such as speech and language therapy and dietetics is beneficial with regard to concurrent feeding, swallowing, and aspiration issues. Respiratory review to manage underlying lung disease and the consideration of CPAP may be appropriate in some situations. The use of a nasopharyngeal airway to bypass supralaryngeal airway obstruction is highly effective and relatively noninvasive.[84] It may be used to avoid surgery in certain cases of midface hypoplasia, neuromuscular disorders, glossoptosis, and micrognathia/retrognathia. It is also a valuable postoperative adjunct following adenotonsillectomy in the child with severe obstructive sleep apnea.

Gastroesophageal reflux is thought to aggravate airway conditions and possibly contribute to apnea, recurrent upper respiratory tract infections, laryngomalacia, and subglottic stenosis, although consistent

Table 205-4

Indications for Pediatric Tracheotomy

- Upper airway obstruction
  - Anatomic, e.g., craniofacial abnormality, laryngeal pathology
  - Functional, e.g., vocal cord palsy
- Prolonged ventilatory support
- Neurologic dysfunction
- Facilitation of major head and neck surgery
- Management of secretions

evidence to support the hypothesis is limited.[85,86] Adjuvant antireflux treatment is generally well tolerated and effective in the pediatric population. Its use, although empirical at times, may improve airway symptoms, circumvent the need for surgery, and enhance surgical outcomes.

Systemic steroids are often used intermittently to treat acute deterioration in the setting of chronic airway obstruction. Long-term doses require careful monitoring for side effects but have been successfully used as an adjuvant treatment for conditions such as subglottic hemangioma in many series.[87-89] Airway edema from croup responds well to steroids and some children with this condition benefit from having dexamethasone available for recurrent attacks at home.[57]

Antibiotics are useful to treat acute infective exacerbations in the setting of chronic airway obstruction. The prophylactic use of antibiotics is also recommended in the setting of open laryngeal surgery to reduce the chance of postoperative wound infection from direct exposure to the respiratory tract.

Tracheotomy

The indications for insertion of a pediatric tracheotomy have changed over the past decades.[90] Tracheotomy is more commonly requested to bypass chronic airway obstruction from craniofacial or upper airway abnormalities, or to support prolonged ventilation than for acute infective conditions such as laryngotracheobronchitis and epiglottitis (Table 205-4). Tracheotomy may be a temporary treatment while waiting for the child to outgrow the underlying condition (e.g., subglottic hemangioma or severe laryngomalacia), or until the child is old enough to undergo other definitive procedures. Its insertion may be permanent but is generally not undertaken without consideration of care requirements and the potential morbidity associated with it. The overall complication rate is up to 44% and tracheotomy-related death as high as 3.6% in some series.[91,92]

Techniques to avoid tracheotomy include the use of maximal medical treatments to reduce edema and inflammation while surgical alternatives are directed toward addressing the site of obstruction and minimizing resistance to airflow. For example, in developing subglottic stenosis, the options of laryngeal rest,[67] cricoid split,[93-95] endoscopic balloon dilatation with mitomycin C,[96] and single-stage laryngotracheal reconstruction[97,98] may avoid the need for tracheotomy. A case of early subglottic stenosis and its response to balloon dilatation is shown in Figs. 205-13 and 205-14.

Once the decision has been made to proceed with a pediatric tracheotomy, a comprehensive discussion should take place with the primary care clinicians before surgery. Informed consent encompasses not only details of the operative procedure and possible complications, but also a full brief on the long-term implications of caring for a child with a tracheotomy, preferably meeting another family of a child with a tracheotomy. The family circumstances need to be assessed, home suctioning equipment arranged, basic life support training given, and other support offered if needed.

Surgical Procedure

The operation is usually conducted under general anesthesia with the child intubated or a laryngeal mask in place. The position is supine with a small shoulder roll to provide slight neck extension. An adhesive tape under the chin retracts any dewlap and anchors the head (Fig. 205-15). Skin marking of the cricoid and sternal notch is useful although may be difficult to palpate in a small infant. Either a horizontal or short vertical skin incision can be used. In children, removal of a subcutaneous fat plug is helpful and the thyroid isthmus can be simply divided using bipolar diathermy. It is crucial to stay midline in a pediatric tracheotomy and one should frequently pause to check the dissection plane. A vertical incision is made through the third and fourth tracheal rings without removal of cartilage and nonabsorbable stay sutures placed on either side of the incision (Fig. 205-16). These sutures assist in replacement of a tube ,which is dislodged before the tract is established. The sutures are removed with the first tube change at 1 week. If a future laryngotracheal reconstruction (LTR) or open laryngeal cleft repair is planned, the tracheal opening may be placed lower, being mindful of the innominate (brachiocephalic) vessels and lung apices. Occasionally, a high innominate vein needs to be protected from the tracheotomy tube by a small inferiorly based flap instead of the vertical incision. Vicryl maturation sutures from the tracheal opening to the skin reduce the chance of false passage creation and assist in establishment of the stomal tract. They have not been shown to increase the rate of tracheocutaeous fistula.[99,100]

Local policy will dictate tracheotomy tube type but beware inserting one that is too long, particularly in neonates, for whom special short tubes are available. Consideration of the underlying condition, patient anatomy, and frequency for tube change influences the choice of tracheotomy tube.[101] An extended length tube may be required if the neck and chest wall are bulky, or length may be required internally to

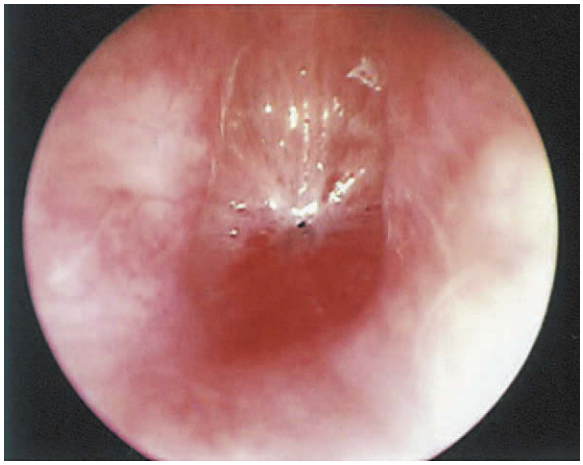

Figure 205-13. Balloon dilatation of early subglottic stenosis—before dilatation.

Figure 205-15. Ideal positioning for pediatric airway surgery using shoulder roll, head ring, and chin strap to stabilize the head.

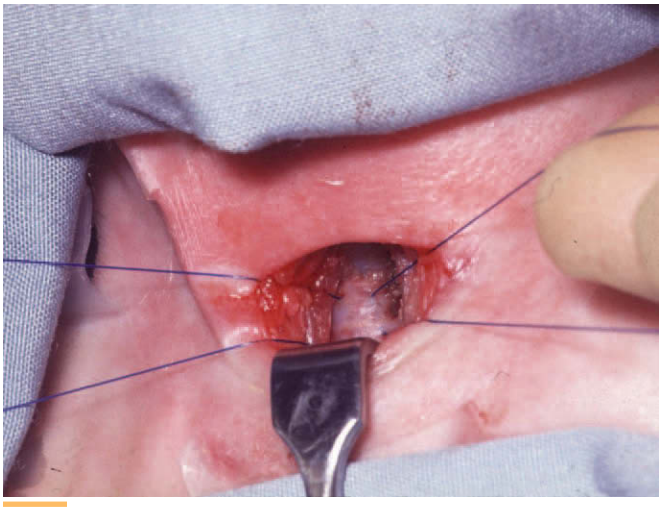

Figure 205-16. Nonabsorbable stay sutures placed on either side of the tracheotomy opening as a safety measure to assist in replacement of a dislodged tube.

support tracheomalacia or a tracheal stenosis. Cuffed tracheotomy tubes are placed infrequently in the pediatric population except to protect the airway in the presence of aspiration. The use of a cuffed tube is usually unnecessary and avoided if possible in that the pediatric airway is particularly sensitive to ischemic insult and prone to ulceration, granulation, and ultimately stenosis.[102] Lateral skin sutures to close the tracheotomy neck wound should not be applied tightly because this predisposes to surgical emphysema.

The percutaneous technique of tracheotomy is not suitable for children because the landmarks may be hard to distinguish, the trachea is soft, pliable, and mobile, the lumen is small, and one may easily drift from the midline.

Tracheotomy Complications

Early complications such as accidental tube dislodgment may be a life-threatening emergency in a small child. This can be prevented by adjusting the tapes carefully to only allow one fingerbreadth between the skin and the tapes, and by providing stay sutures through the trachea on either side of the incision (see Fig. 205-16). These sutures are pulled apart in the event of tube dislodgment to open the incision, bring the trachea to the surface, and guide tube reinsertion into the tracheal lumen. Conventional adult tracheal dilators are usually too large, but a small, curved artery clamp may help. The technique of using a cut suction catheter through the lumen of an appropriate sized tracheotomy tube to guide its insertion has the advantage of confirming tracheal position by successful suctioning of secretions and the opportunity for jet ventilation to maintain oxygenation if required.[103] An emergency box should always be at the child's bedside containing two spare tracheotomy tubes (one a size smaller), suction catheters, lubricant, scissors, and spare tapes. Tube blockage is avoided by humidification, frequent suctioning, and an awareness of the problem.

Postoperatively, a chest x-ray study is imperative to check the tube length and exclude a rare pneumothorax, which can occur from puncturing the lung apex or from positive-pressure ventilation. Hemorrhage is rarely a complication in children if the thyroid isthmus has been divided with electrocautery rather than ligated after division between clamps. Subcutaneous emphysema may be prevented by having a snug fit of the tube in the trachea and avoiding tight wound closure and excessively high-pressure ventilation. Tube dislodgment and blockage remain the most important late complications and are responsible for tracheotomy-related mortality. Stomal and tracheal granulations are the result of physical factors such as movement and plasticizers in the tube, combined with infective factors from the skin and airway. The use of antibiotic ointment around the tube may improve but never remove the granulations. Longstanding suprastomal granulations within the tracheal lumen are associated with the development of suprastomal collapse, which is commonly responsible for difficult decannulation that requires further surgery. Tracheal erosion may occur because of a poor-fitting tracheotomy tube, particularly if metal. Erosion can involve the mediastinum, esophagus, or major vessel. An acquired tracheoesophageal fistula requires closure with an open operation and interposition of muscle. Small bleeds around or from the tracheotomy tube may herald the dramatic erosion of a major vessel.[104] Although suprastomal and tracheal granulations can give rise to small hemorrhages, any tracheotomy bleeding should be taken seriously and investigated radiologically or endoscopically. In very longstanding tracheotomy, the tube may migrate and require surgical repositioning.

Tracheotomy Decannulation

Adults and children with a short-duration tracheotomy (less than 1 month) can be decannulated after appropriate assessment by simply having the tube removed and the stoma covered with an occlusive dressing.[105] Most children, however, are more difficult to decannulate because of multiple factors including suprastomal collapse and granulation, the relatively small size of the airway, and, possibly, psychological dependence or attachment to their tracheotomy tube. A more controlled process for decannulation is used in these children. A recent formal endoscopic examination of the airway, ideally within 1 month, is required before any attempt is made to try decannulation.[106] The most common causes of failed decannulation are significant suprastomal collapse and granulation, and this should be addressed at the time of surgery.

The child is admitted to hospital for a supervised trial of "ward decannulation." The tracheotomy tube is downsized in a stepwise manner, usually one to two sizes smaller each day until the smallest tube has been tolerated. The tracheotomy tube is then blocked for 24 hours and the child is kept on the ward for careful observation at night. If the trial of capping is uneventful, the tube is completely removed and the stoma covered with an occlusive dressing. A further 48-hour period of observation is recommended in that failure may occur at any stage. In the case of failed decannulation, the smallest tube is simply reinserted in the stoma and gradually upsized. Time may be required to allow the airway to grow; however, a repeat endoscopy should be performed before any further trials of decannulation to exclude concurrent pathology such as cord fixation or palsy, suprastomal granuloma or collapse, and tracheomalacia.[107]

Surgical Decannulation

If significant suprastomal collapse is identified that is not responsive to endoscopic measures, a "surgical decannulation" will be required. In principle, the stoma is formally closed, sometimes with additional support from a cartilage graft and period of intubation. At the begin-

ning of the operation, the child is intubated nasally with an age-appropriate tube. The tracheocutaneous fistula is excised, preserving the tracheal wall, unless a cartilage graft is required. If cartilage is not required (mild to moderate collapse only), the stoma is closed primarily and sutures are taken laterally to the sternomastoid to prevent collapse of the repair. If cartilage is required, it is harvested from a rib and carved to a boat shape as for laryngotracheal reconstruction (see open surgical techniques section). The malacic wall is excised until firmer cartilage is exposed. The cartilage graft is sutured to strengthen the anterior tracheal wall with minimal or no air leak. If the trachea is very malacic, an oversize graft can be supported on the sternomastoids, lifting the graft and anterior tracheal wall forward. Postoperatively, the patient remains nasally intubated for 5 to 7 days with the endotracheal tube acting as a stent for the reconstruction.

Endoscopic Treatment of the Larynx and Tracheobronchial Tree

The microsurgical techniques and equipment that are needed in pediatric laryngology are much closer to those of adult phonosurgery than general adult laryngology. Skill, patience and special instrumentation are required. Any damage to the delicate vocal fold may produce lifelong dysphonia that could prove difficult to correct. Optimal anesthetic conditions with the child breathing spontaneously without laryngeal intubation are crucial in this setting. Endoscopic treatment provides the opportunity for therapeutic intervention at the time of a diagnostic procedure, thus avoiding further general anesthesia and open surgery. Many techniques are minimally invasive with reduced trauma and risk to adjacent tissues than in open techniques. The opportunity for photo and video documentation is also extremely useful. Pledgets soaked in 1:10,000 adrenaline (epinephrine) help prepare the operative site before any procedure. Suspension laryngoscopy allows two-handed surgery; however, some may prefer the magnification, distal access, and range of movement afforded by newer generation telescopes and cameras. The surgeon's armamentarium includes the use of "cold steel" microinstrumentation, lasers (CO_2, KTP, thulium), balloons, microdébriders, indwelling stents, grafts, and sutures. Topical medical treatments such as steroids, cidofovir, and mitomycin C can also be administered endoscopically.

Microinstrumentation

Sharp dissection using cupped forceps and microscissors is precise and causes minimal damage to surrounding structures, and the mucosal injury is generally quick to heal. Cystic lesions and nodules may be successfully marsupialized or resected with less trauma than with a laser. Indeed, in inexperienced hands the laser probably has greater potential for damage. Aryepiglottic trimming for laryngomalacia[108] was originally described using sharp dissection. The aryepiglottic folds may simply be released or a small wedge of bulky arytenoid mucosa removed to prevent the forward prolapse of the posterior larynx and arytenoids, which is typical of the condition. Microinstrumentation with the sickle knife and sharp blades can be used to perform other procedures such as an endoscopic cricoid split (Fig. 205-17). In these cases, decompression of the cricoid ring followed by short-term stenting with an endotracheal tube may allow sufficient expansion of the subglottis to enable extubation and avert the need for a tracheostomy in early subglottic stenosis.[109]

Laser

The CO_2 laser for the larynx, and more recently the KTP laser for the trachea and bronchi, have been considered an essential part of the equipment needed to manage the pediatric airway. Other lasers such as the Nd:YAG and thulium laser have also been used in the respiratory tract. Newer techniques and instrumentation, however, may supersede use of the laser due to the delicate nature of the pediatric airway and its sensitivity to thermal injury. A number of improvements, including super pulsing, have reduced the collateral damage that occurs around the intended area of vaporization, making the laser relatively safe and effective in experienced hands. One should always err on the side of conservatism when using the laser in the pediatric airway (Fig. 205-18). Great care must be taken not to damage normal tissues and produce a

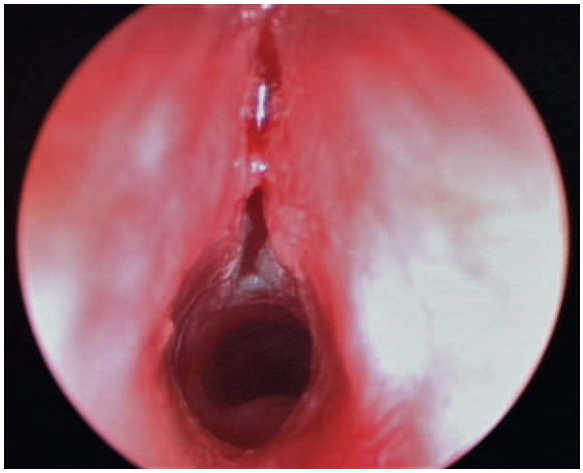

Figure 205-17. Endoscopic cricoid split performed in anterior midline using a sickle knife followed by balloon dilatation for subglottic stenosis.

Figure 205-18. Acquired complete glottic stenosis following excessive laser treatment for subglottic hemangioma.

secondary stenosis. A laser-safe tube must be used to provide anesthesia in all these cases; it is withdrawn into the pharynx and the inspired oxygen concentration is reduced to allow safe lasering of an unobstructed field.

The radiant energy produced by the CO_2 laser with a wavelength of 10.2 μm is strongly absorbed by tissues with a high water content with minimal penetration of surrounding tissues. It is useful for supraglottic and laryngeal pathology when attached to the operating microscope. CO_2 laser bronchoscopes have been developed, however, the optics are vastly inferior to normal telescopes, the technique is different, and its use is limited.

The KTP laser emits light at 532 nm (similar to the argon laser) that is preferentially absorbed by hemoglobin and has a greater penetration depth. It may be delivered via fiberoptic fibers to the lower airway, allowing precise access to distal lesions that cannot easily be reached with the CO_2 laser. The KTP laser fibers are sufficiently thin to be passed alongside a suction catheter of a conventional ventilating bronchoscope, providing an excellent view, hemostasis, and controlled vaporization.

The thulium laser is a continuous wave laser with a wavelength of 2013 nm. It has the advantage of being deliverable down a glass fiber with precise cutting and coagulation characteristics, and limited deep tissue penetration. Its use in the pediatric airway for laryngomalacia, laryngeal cysts, vocal cord palsy, tracheal hemangioma, and papillomatosis has recently been described.[110]

Techniques employed with the laser include excision of a wide variety of lesions,[111] vaporization of tissue, the encouragement of controlled scarring, and its use as a precise dissection tool. Postintubation granulomas can be accurately excised or vaporized, and cystic lesions marsupialized or debulked with good hemostasis and minimal postoperative edema. Subglottic hemangioma can be controlled with regular treatments, although the time to resolution is unchanged and there is a potential risk of subglottic scarring and stenosis especially with the CO_2 laser.[87-89] Propanolol is a recent therapy that can cause hemangiomas to regress.

Laser arytenoidectomy may be used for vocal cord palsy to remove the arytenoid and posterior vocal cord. This provides a posterior airway while preserving the function of the anterior vocal cord for phonation. Laryngeal papillomatosis responds well to vaporization with the laser, with potential reduction of viable viral particles that may seed down the trachea. Laser epiglottoplasty and supraglottoplasty for laryngomalacia is quick and bloodless,[112] and when used in the vallecula, scarring is promoted with elevation of a prolapsing epiglottis. Similarly, KTP laser to suprastomal granulomas secondary to tracheostomy tube placement may improve the airway lumen and stiffen up the anterior tracheal wall, facilitating subsequent decannulation.[113,114] Attempts to use the laser to divide anterior webs or subglottic stenosis, however, have generally been unsuccessful due to the tendency for recurrent and sometimes more severe stenoses.

Balloons

Endoscopic treatment of the pediatric airway using vascular-type balloons has become more popular in the last decade. They may be positioned under direct vision using the Hopkins rod or operating microscope and gradually inflated until the desired diameter and pressure are reached. The radial force generated is gentle and there is little mucosal injury. When using a spontaneous inhalational anesthetic technique, the anesthetist must be prepared for a period of total airway occlusion and apnea. One should avoid exceeding the burst pressure of the balloon or overstretching the airway, which potentially risks the development of cartilaginous injury and malacia. There are several situations in which endoscopic balloon dilatation is used for the stridulous child: in the case of early evolving stenosis following airway surgery or intubation, after division of posterior glottic scar bands, with endoscopic cricoid split, and to assist or maintain expansion of tracheal and bronchial stents.[96,115-117]

Microdébrider

The powered microdébrider was initially introduced to otolaryngologists as an additional tool in the treatment of nasal polyps and endoscopic sinus surgery. The development of longer blades with smaller angled cutting surfaces has seen its use migrate to the airway, including the pediatric airway. The concurrent suction attached to the handpiece allows abnormal tissue to be drawn into the blade and precise excision follows. This has been particularly suitable for cases of recurrent respiratory papillomatosis in which preservation of the submucosal tissues is crucial to avoid damage to the vocal ligament and scarring. In fact, a recent survey of members of the American Society of Pediatric Otolaryngology has noted that the microdébrider is now favored for the treatment of laryngeal papillomatosis over the CO_2 laser.[118] The technique is relatively fast, safe, and well tolerated. It has also been shown to cause equivalent immediate postoperative pain, greater improvement in voice quality and the overall procedure cost is lower in some centers.[119-121] The blade may be passed into the subglottis and upper trachea but access may be limited distally. The microdébrider has also been used to remove granulations and even subglottic hemangioma in some centers.[88,122]

Stents, Keels, and Grafts

Maintenance of the pediatric airway occasionally requires techniques of anatomic augmentation or the use of foreign materials to prevent collapse and to discourage stenosis. Many of these procedures can be performed endoscopically, thus avoiding an open operation and related potential morbidity. Glottic and subglottic stents may be positioned, secured, and later removed endoscopically. Expandable metallic stents used for tracheal and bronchial pathology can be placed endoscopically under radiologic guidance. Silastic sheeting used as a keel at the anterior commissure in cases of anterior webbing may be temporarily sutured into place through the neck. The use of the Montgomery T-tube in specialized circumstances of laryngotracheal disease can be inserted endoscopically using a heavy Prolene suture to guide the proximal limb toward the larynx. Recent reports of insertion of cartilage expansion grafts into the posterior larynx following endoscopic posterior cricoid split are also promising.[123]

Endoscopic Sutures

The development of endoscopic instrumentation such as the Lichtenberger needle holder has expanded the options available to the endoscopic airway surgeon. Type I and II laryngotracheoesophageal clefts may be sutured closed after endoscopic trimming of the common mucosal cleft wall. Interrupted sutures are used to close the defect on the tracheal and esophageal aspects with particular attention given to repairing the distal-most point where a fistula may persist. Two-layered repairs of type III laryngeal clefts have also been described, although the technique remains challenging.[124] In cases of vocal cord paralysis, endoscopic arytenoidopexy using a lateralizing suture has been performed with some success.[125,126] This may be temporizing or permanent.

Endoscopic Administration of Topical Treatments

Certain topical treatments can be applied endoscopically to the pediatric airway to assist in the management of the chronically stridulous child. Direct intralesional injection of papillomas with the antiviral cidofovir after debulking of the lesions is effective in reducing recurrence in approximately 60% of severe cases.[127] Its mechanism of action is via inhibition of the HPV viral DNA polymerization process; however, its use is reserved for those patients with aggressively progressing disease as the long-term side effects and potential for malignant transformation have yet to be documented.[128] Corticosteroids may be injected into evolving stenoses and into subglottic hemangiomas followed by a short period of postoperative intubation. The results have been encouraging so far.[87] Mitomycin C is an antineoplastic agent that has been used against solid tumors in the breast, lung, pancreas, and bladder. It was first used in the airway in 1998[129] and has since been applied topically to inhibit fibroblast growth, granulation tissue formation, and cicatricial scarring in many sites including the airway. The optimal dosage has yet to be agreed upon, although most centers tend to prefer 0.2 to 0.4 mg/mL applied on cotton pledgets for up to 5 minutes.[130]

Principles of Open Laryngeal Surgery

Open laryngeal framework surgery allows access to the upper respiratory tract from the supraglottis to the cervical trachea. These procedures are generally performed in the elective setting with careful consideration of the nature of the airway problem and its etiology, the patient's comorbidity and healing tendencies. As for tracheotomy, a meticulous dissection technique is essential, with attention paid to midline anatomic landmarks. The oblique fibers of the cricothyroid muscles are a useful guide to the cricoid cartilage. Anesthesia and ventilation may be maintained via endotracheal intubation or a temporary tracheotomy distal to the operative site depending on the circumstances. If a full laryngofissure is required, the position of the anterior commissure at the vertical midpoint of the thyroid cartilage is marked to allow accurate apposition on closure. Failure to do this may result in suboptimal voice outcomes. Placement of a surgical drain is strongly advised when postoperative air leak is likely to occur to reduce the chance of wound infection and surgical emphysema.

Open procedures may definitively address anatomic narrowing by allowing removal of tissue (stenoses, granulomas and other pathology), decompression of the lumen (cricoid split; Fig. 205-19), or expansion and augmentation with cartilage grafting (laryngotracheal reconstruction (Fig. 205-20), surgical decannulation and stomal reconstruction). Complete resection of a severe stenosis with end-to-end anastomosis is appropriate in some settings (cricotracheal resection). Subglottic hemangiomata may be definitively excised with a single stage open

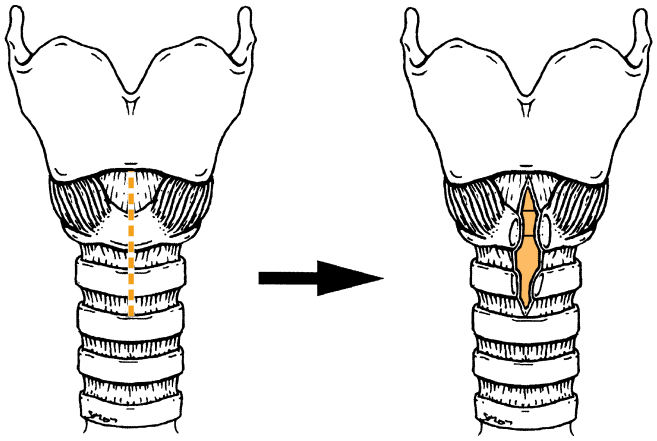

Figure 205-19. Principles of the anterior cricoid split operation: the cricoid and upper tracheal ring are opened in the midline to decompress the airway.

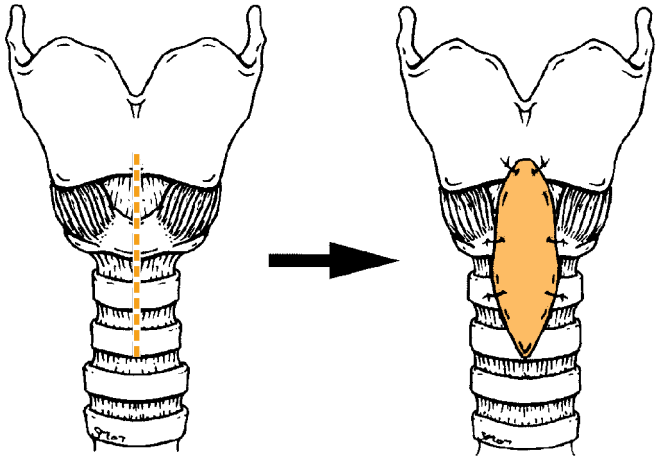

Figure 205-20. Principles of laryngotracheal reconstruction: an anterior cartilage graft is used to augment the subglottic lumen; this may be combined with a posterior cricoid split with or without posterior cartilage graft.

resection incorporating the techniques of cartilage augmentation into the repair. Laryngotracheoesophageal clefts can be repaired in two layers using a temporalis fascia or tibial periosteum graft as a reinforcing layer (Fig. 205-21). Maximal supportive medical therapy in the perioperative period with nutritional support, steroids, antibiotics, and antireflux treatment are important adjuncts to open surgery. Endoscopic follow-up is essential to monitor outcomes, granulations, and tendency to restenosis. This may need to be frequent in the early postoperative stages. (See Chapters 202 and 206 for further coverage of laryngeal surgery.)

The Future

The evaluation and management of the stridulous child can be a challenge for the general and pediatric otolaryngologist. Improved neonatal care and a greater understanding of the effects of intubation has led to a decline in iatrogenic airway disease in the last few decades. A systematic approach is essential with direct rigid endoscopic assessment remaining the gold standard investigation over other modalities. Medical management of the compromised airway is preferable if it can be achieved without jeopardizing patient safety. Minimally invasive therapeutic endoscopic measures are gaining popularity and may avert the need for a tracheotomy or open surgery in certain circumstances. The provision of optimal anesthetic conditions is pivotal to success of many pediatric airway procedures. Reconstructive airway techniques continue to be applied to a range of conditions with great success.

CHAPTER TWO HUNDRED AND SIX

Glottic and Subglottic Stenosis

George H. Zalzal

Robin T. Cotton

Key Points

Majority are caused by trauma:

- Iatrogenic
    - Prolonged intubation
    - Laryngeal surgery
- External neck trauma to a lesser extent
- Congenital (usually less severe and less frequent) even more infrequently
- Burns, ingestions
- Infection
- Inflammation (gastroesophageal reflux or Wegener's)
- Types:
- Anterior, posterior, circumferential, complete: all may be associated with movement disorders
- Prevention:
    - Repair of laryngeal fractures and lacerations
    - Proper tracheotomy techniques
    - Appropriate endolaryngeal surgery
    - Avoidance of intubation trauma
- Diagnosis:
- History and Physical
- Radiology
    - Soft tissue AP and lateral
    - CT
    - MRI
- Endoscopy (flexible and rigid)
- Others
- Pulmonary functions, voice assessment, pH probe, FEES, PFTs
- Management is through (1) expansion or (2) resection. Specifically:
- Endoscopic
- Anterior cricoid split
- Expansion surgery
    - Grafting and stenting
    - Single stage laryngotracheoplasty
- Resection
- Cricotracheal

Chronic laryngeal stenosis is a partial or complete cicatricial narrowing of the endolarynx and may be congenital or acquired. The condition is rare and presents multiple problems affecting soft tissue and cartilage. Iatrogenic injuries and external neck trauma account for most cases. Chronic laryngeal stenosis in pediatric patients may be managed differently from that in adult patients, but the principles of expansion versus resection surgery remain the same. Of all laryngeal stenoses, chronic subglottic stenosis is the most common and presents significant challenges in management (Fig. 206-1).

Etiology and Pathophysiology

Congenital Laryngeal Stenosis

Congenital stenosis is secondary to inadequate recanalization of the laryngeal lumen after completion of normal epithelial fusion at the end of the third month of gestation.[1] The final pathologic findings depend on the degree of recanalization. Thus if the laryngeal lumen is not recanalized and remains completely obliterated, it will result in complete laryngeal atresia; if it is partially recanalized, incomplete atresia,

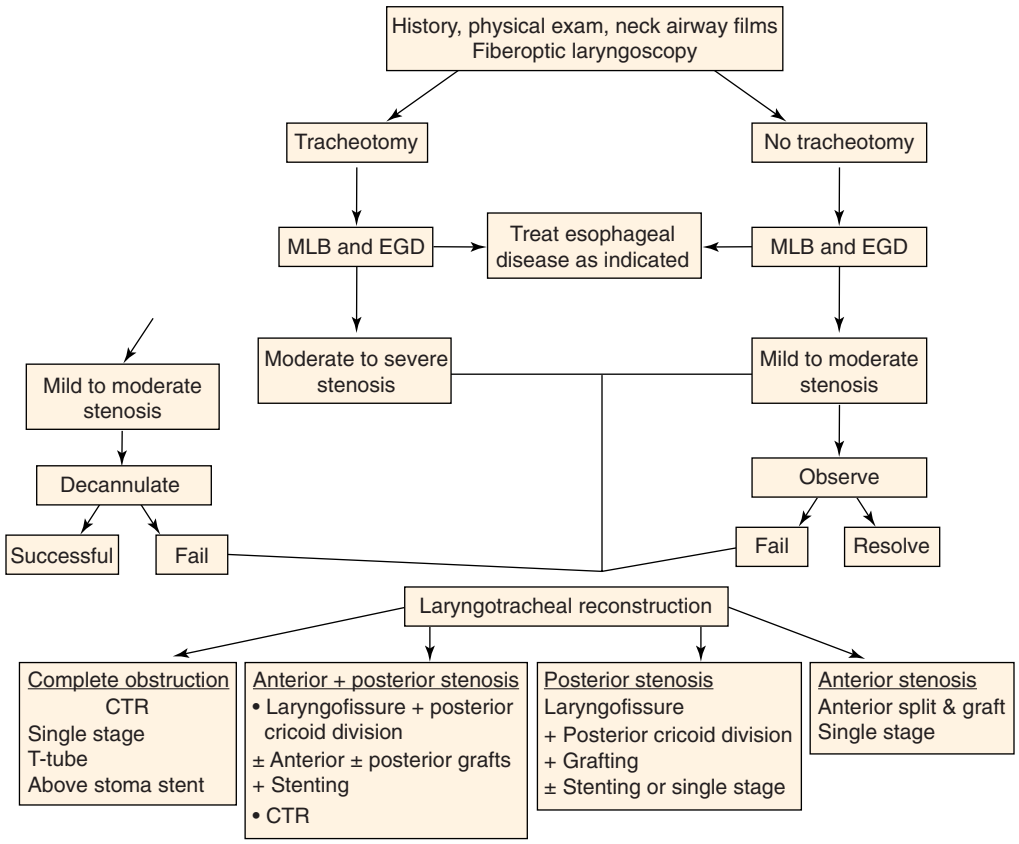

Figure 206-1. Algorithm for management of laryngeal stenosis.

stenosis, or webbing will occur. The cricoid cartilage is usually abnormally developed.

Congenital Laryngeal Atresia and Web

Laryngeal atresia can occur at any laryngeal level or combination of levels. The clinical picture depends on the severity of the lesion. In complete atresia, the glottis is closed at or above the vocal cords by a firm fibrous membrane. The neonate is aphonic, tries vigorously to breathe, undergoes rapid deterioration, becomes cyanotic despite continued respiratory efforts, and soon dies of asphyxia unless immediate tracheotomy is performed.[2,3] The condition is incompatible with life unless an emergency tracheotomy is performed or there is an associated tracheoesophageal or bronchoesophageal fistula. The most severe type of congenital laryngeal atresia presents as stillbirth and may not be recognized.

Congenital laryngeal webs account for about 5% of congenital anomalies of the larynx.[4] About 75% occur at the glottic level, and the rest are supraglottic or subglottic.[5] An association between anterior glottic web, the chromosome 22q11.2 deletion, and velocardiofacial syndrome has been established.[6-8] All patients with anterior glottic web should have their chromosome 22q11.2 deletion status determined by standard fluorescent in situ hybridization (FISH) analysis. Most webs present at birth or in the first few months of life. The severity of the web varies. Only a few are severe enough to require airway support by intubation or tracheotomy. A laryngeal web is often an abnormality of the glottis and the subglottic cricoid region (Fig. 206-2). The differential diagnosis includes bilateral vocal cord paralysis and congenital interarytenoid joint fixation. It is important to detect associated anomalies of the larynx, the respiratory tract, and other organ systems.

Treatment of congenital laryngeal atresia and web is presented later in this chapter under treatment of specific disorders.

Congenital Subglottic Stenosis

The normal subglottic lumen diameter in the full-term neonate is 4.5 to 5.5 mm and in premature babies is about 3.5 mm. A subglottic

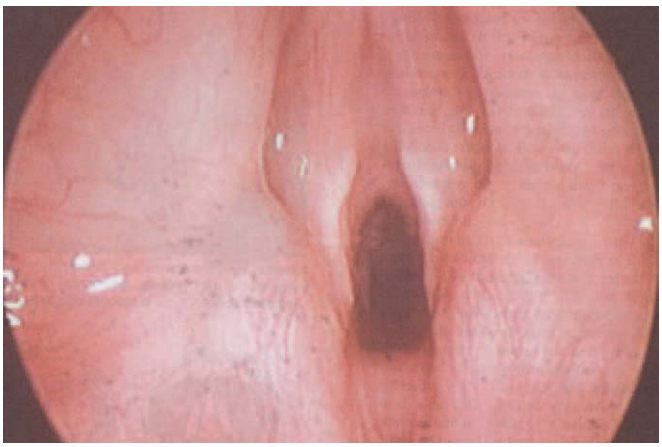

Figure 206-2. Endoscopic view of a congenital glottic web with subglottic extension.

diameter of 4 mm or less in a full-term neonate is considered to be narrowed.

Congenital subglottic stenosis (SGS) is considered to be congenital in the absence of a history of endotracheal intubation or other apparent acquired causes of stenosis. The diagnosis may be difficult to confirm, and it is unknown how many intubated premature infants who fail extubation have underlying congenital stenosis. Thus, by best approximation, congenital subglottic stenosis is the third most common congenital disorder of the larynx after laryngomalacia and recurrent laryngeal nerve paralysis. Acquired subglottic stenosis is more common than congenital stenosis because of the use of prolonged endotracheal intubation for respiratory support.

Congenital SGS is a clinical endoscopic diagnosis describing various histopathologic conditions that produce narrowing of the sub-

glottic airway. Congenital SGS can be divided into membranous and cartilaginous types.[9-11] The membranous type is a fibrous soft tissue thickening of the subglottic area caused by increased fibrous connective tissue or hyperplastic dilated mucous glands with no inflammatory reaction. It is usually circumferential, with the narrowest area 2 to 3 mm below the true vocal cords, sometimes extending upward to include the true vocal cords.[12]

The cartilaginous types are more variable, but the most common type is a thickening or deformity of the cricoid cartilage causing a shelf-like plate of cartilage, partially filling the concave inner surface of the cricoid ring and extending posteriorly as a solid rigid sheet, leaving only a small posterior opening.[13]

Symptoms depend on the degree of subglottic narrowing. In severe cases, respiratory distress and stridor are present at birth; in milder cases, the symptoms become evident during the first few weeks or months of life, presenting as prolonged or recurrent croup. Differential diagnosis includes subglottic hemangioma and subglottic cysts. Infants usually become symptomatic within 3 months of birth because of increased activity and increased ventilation requirements.[2,9]

Minimal laryngeal swelling secondary to infection or endoscopy may precipitate airway obstruction because the cricoid cartilage limits the swelling of tissue in any direction except toward the laryngeal lumen at the expense of the airway. Therefore great care is needed when endoscopy is performed on these children to prevent trauma to the subglottic mucosa.

Endoscopic diagnosis is essentially by means of flexible fiberoptic endoscopy to assess vocal cord function and rigid endoscopy to assess the degree of anatomic obstruction. Postendoscopic edema is avoided by operating on a quiet, relaxed infant who is well-oxygenated. Cooperation between the endoscopist and anesthesiologist is essential, as is gentle instrumentation, preferably with the rigid rod lens system telescope alone without the sheath. If postoperative edema occurs, aggressive management should be started with cool mist racemic epinephrine by aerosol or intermittent positive-pressure breathing, and a short course of high-dose intravenous corticosteroids.

Congenital subglottic stenosis is most often less severe than acquired stenosis and may therefore be managed more conservatively. Some patients outgrow the condition.[12-14] Management depends on the degree and severity of stenosis, shape (whether the cricoid cartilage is normal or abnormal), and whether there are associated congenital anomalies.

Mild cases of stenosis are managed conservatively by watchful waiting and regular follow-up because many children outgrow the problem. During observation, vigorous medical management of viral infection is recommended. More severe cases requiring airway support may be managed by tracheotomy and reconstructive repair, or by single-stage laryngotracheal reconstruction using costal cartilage grafting for expansion of the subglottic airway.

Acquired Laryngeal Stenosis

Trauma is the most common cause of acquired laryngeal stenosis in children and adults and may be external or internal.

External Laryngeal Trauma

Blunt trauma to the neck sustained during motor vehicle accidents injures the larynx when the anterior surface of the extended neck strikes the dashboard or steering wheel, causing a laryngeal framework fracture. This is more common in adults than in children, in whom the prominent mandible and relatively high position of the larynx protect the latter from injury. Fractures of the larynx occur secondary to in-home accidents when the neck is injured by striking furniture such as a coffee table. Chronic acquired laryngeal stenosis is a sequela of severe laryngeal trauma with fracture of the cricoid and thyroid cartilages with or without displacement, or of inadequately managed early stages of laryngeal trauma.

Another mechanism of blunt laryngeal trauma, the so-called clothesline injury, occurs when a person riding a bicycle hits the anterior neck on a branch or clothesline, sustaining laryngeal fracture, and thyrotracheal or cricotracheal separation. A patient may have a separation of the cricoid and trachea and still survive the injury. Penetrating wounds of the larynx are usually less common than blunt trauma and are more common in adults than in children.

Internal Laryngeal Trauma

Most cases of internal laryngeal injury are iatrogenic, secondary to prolonged endotracheal intubation, which is the most common cause of chronic laryngeal stenosis. Approximately 90% of cases of acquired chronic subglottic stenosis in infants and children occur secondary to endotracheal intubation.[12,14] The reported incidence of stenosis after intubation ranges from less than 1% to 8.3%.[15-19] This rate is much lower than the 12% to 20% reported in the late 1960s and early 1970s because of recognition of the problem and institution of preventive methods. Despite improvement in neonatal care, the incidence has stabilized at around 1% over the past 10 years.[19,20] These figures may underestimate the true incidence of the disease in the pediatric population because many infants who are intubated do not survive the primary illness. In addition, some acquired subglottic stenosis may not be recognized unless an infection of the upper respiratory tract develops or the patient requires reintubation later in life. The areas most commonly injured are the subglottic region in children and the posterior endolarynx in adults.[21]

In children, the subglottic region is especially prone to injury from endotracheal tube intubation for various reasons. First, the cricoid cartilage is the only area in the upper airway that has a complete circular cartilaginous ring, preventing the outward extension of traumatic edema. Second, the pseudostratified, ciliated, columnar respiratory epithelium lining this region is delicate and tends to deteriorate under the stress of an indwelling tube. Third, the subglottic submucosa is made up of loose areolar tissue that allows edema to develop easily and quickly. Fourth, the subglottic region is the narrowest portion of the pediatric airway.[12]

The pathophysiology of acquired subglottic stenosis is well described in the literature.[3,22-24] The endotracheal tube causes pressure necrosis at the point of interface with tissue, leading to mucosal edema and ulceration. As ulceration deepens, normal ciliary flow is interrupted, with mucociliary stasis leading to secondary infection and perichondritis. With further infection, chondritis and cartilaginous necrosis occur, especially with collapse of the airway during inspiration. Healing occurs by secondary intention with granulation tissue proliferation in the areas of ulceration and deposition of fibrous tissue in the submucosa. Primary healing of the laryngeal injury is hindered by the presence of loose and mobile subglottic mucosa, poor blood supply to the cartilage, and constant motion of the larynx associated with swallowing and head movement.[23,25] Study of intubated larynges from infants of 22 to 40 weeks' gestation who survived a few hours to 300 days showed acute injury was almost invariable and up to 100% of the subglottic epithelium was lost within a few hours of intubation, but progression of injury was relatively short lived. Ulcer healing started after a few days, rapidly progressed from day 10, and, in most cases, was complete after 30 days. This study suggests that longstanding acute injury of the subglottis is the exception rather than the rule, even with the endotracheal tube remaining in place.[23]

Duration of intubation and the size of the endotracheal tube are the most important factors in the development of laryngeal stenosis. No definite safe time limit for endotracheal intubation has been established. Severe injury has been reported after 17 hours of intubation in adults[22] and 1 week after intubation in neonates.[26] Several studies in adults have shown that a 7- to 10-day period is acceptable, after which prolongation of intubation is accompanied by an increased incidence of laryngotracheal complications.[21] Premature infants tolerate more prolonged intubation (weeks rather than days). Explanations include relative immaturity of the laryngeal cartilage in the neonates (more hypercellular with scant gel-like matrix) rendering it more pliable, thus yielding to pressure,[27] and the high location of the neonatal larynx in the neck with its posterior tilt and funnel shape.[25]

Insertion of an oversized endotracheal tube increases the risk of laryngeal injury. In children, the tube size should allow an air leak at 20 cm H_2O pressure if possible. Polymeric silicone and polyvinyl chloride are considered the safest materials for prolonged intubation.

Shearing motion of the tube causes abrasive traumatic action on the mucosa, especially in patients who are restless, those on respirators, and those with orotracheal intubation. Superimposed bacterial infec-

Figure 206-3. **A,** Endoscopic view of interarytenoid adhesion shows a posterior fistular tract resulting from a scar tissue band between the vocal process of the arytenoids cartilages. **B,** Endoscopic view of posterior glottic stenosis with vocal cord fixation. **C,** Same lesion as in **B,** after repair with posterior cartilage grafting and stenting, achieving full vocal cord mobility.

tion compounds the mechanical mucosal trauma by increasing the inflammatory response and scar tissue formation. Repeated intubations cause increased trauma and increase the risk of sequelae. Nasogastric tubes can cause pressure necrosis and cricoid chondritis if placed in the midline. Coexistence of endotracheal and nasogastric tubes may increase laryngeal complications.

When inexperienced personnel care for intubated patients, intubation complications may increase. Education of physician and nursing personnel caring for intubated patients markedly increases the expertise of that care. Systemic factors including chronic illness, general disability, immunosuppression, anemia, neutropenia, toxicity, dehydration, hypoxemia, poor perfusion, radiotherapy, and the presence of gastric acid reflux encourage the vulnerability of laryngeal mucosa to injury by decreasing tissue resistance and increasing infection rate.

Other Causes of Laryngeal Stenosis

Laryngeal stenosis may occur secondary to laryngeal injury resulting from laryngeal surgery. Emergency cricothyroidotomy through the cricothyroid membrane[28] and high tracheotomy can produce severe stenosis, particularly in children. Supraglottic stenosis and collapse may be related to prior laryngeal or tracheal injury. Acquired anterior glottic web can occur after excision of a laryngeal polyp or papilloma in the anterior commissure area if the anterior portions of both vocal cords are denuded simultaneously.[29] Laryngeal stenosis also is described after endoscopic microsurgery with modalities such as electrocautery or laser.[30]

Chondroradionecrosis can lead to scarring and stenosis shortly after radiotherapy or as long as 20 years later.[31] Intralaryngeal burns from fumes, smoke inhalation, or caustic lye ingestion can give rise to chronic laryngeal stenosis.[32]

Chronic Infection

Laryngeal stenosis secondary to chronic infection is rare except in isolated endemic geographic areas. It has been described in tuberculosis, syphilis, leprosy, glanders, typhoid fever, scarlet fever, diphtheria, mycosis, and laryngeal scleroma.

Chronic Inflammatory Disease

Laryngeal stenosis has been described secondary to sarcoidosis, lupus erythematosus, Behçet's syndrome, Wegener's granulomatosis, relapsing polychondritis, pemphigoid, epidermolysis bullosa, amyloidosis, and major aphthous ulceration. Management of laryngotracheal stenosis in Wegener's granulomatosis is complex, requiring individualized and often multimodality interventions to achieve satisfactory results.

Chronic inflammation secondary to gastroesophageal reflux (GER) may cause laryngeal stenosis. GER in children can be classified as physiologic, functional, pathologic, or secondary.[33] Many airway manifestations have been attributed to GER including stridor, recurrent croup, exacerbation of subglottic stenosis, and chronic cough. Diagnosis is difficult unless the index of suspicion is high.[34] The role of GER on the outcome of pediatric laryngotracheal reconstruction remains unknown.[35] Until this is clear, the authors recommend that GER is investigated and treated in patients undergoing laryngeal reconstruction during the perioperative period.

Laryngeal Neoplasm

Chondroma, fibroma, hemangioma, and carcinoma can cause laryngeal stenosis because of tumor infiltration or secondary to infective perichondritis, postradiation perichondritis, or postsurgical scarring and stenosis.

Types of Stenosis

Acquired glottic stenosis may be anterior, posterior, circumferential, or complete. Anterior glottic stenosis can be a thin glottic web, which is a bridge of scar tissue covered by epithelium located between the vocal cords involving the anterior commissure. This usually results from enthusiastic endoscopic surgery involving both true cords simultaneously. Thick, anterior glottic scarring is usually more extensive and results in true vocal cords, false cords, and laryngeal ventricles adhering to one another without any intervening web. The cause is often unmanaged severe external laryngeal trauma. Posterior glottic stenosis usually results from prolonged endotracheal tube intubation.

Pressure necrosis of the mucosa overlying the vocal process of the arytenoid occurs, followed by ulceration and granulation tissue formation on the medial surface of the body of the arytenoid cartilage. A similar process occurs to a variable degree in the interarytenoid area with involvement of the interarytenoid muscle, causing fibrous ankylosis of one or both cricoarytenoid joints.[36] Posterior glottic scar frequently extends downward to the subglottic region. It is important to differentiate between a complete posterior glottic stenosis, in which the scar is located in the interarytenoid space and posterior commissure, and an interarytenoid adhesion, in which the scar is between the vocal processes of the arytenoids with a small posterior, mucosally lined sinus tract in the posterior commissure area (Figs. 206-3 and 206-4A). The scarring of the posterior commissure may be confined to the submucosa (see Fig. 206-4B) or extend into one (see Fig. 206-4C) or both (see Fig. 206-4D) cricoarytenoid joints.

The voice is generally good because of the adducted position of the vocal cords. The major symptoms are referable to the airway. In mild or moderate cases, the patient may be able to ventilate without a tracheotomy and may experience only exercise intolerance. Patients who have a more severe stenosis may need a tracheotomy for adequate respiratory exchange. Diagnosis by indirect laryngoscopy is difficult and may be confused with bilateral vocal cord paralysis.[37] Diagnosis at direct laryngoscopy is made by careful observation of the posterior commissure. The true vocal cords are closely approximated because the vocal processes, and occasionally the arytenoid bodies, are tethered together by heavy scar. A posterior sinus tract should be carefully sought and is particularly difficult to see in the pediatric larynx. Unlike vocal cord paralysis, in posterior glottic stenosis the cricoarytenoid joints are partially or completely immobile on a passive motion test. Palpation of the arytenoids shows that they may be rocked in an anteroposterior direction but will not slide from side to side. Complete total glottic stenosis rarely occurs in isolation and is usually accompanied by supraglottic or subglottic stenosis. In children, it is a sequela of endotracheal intubation, lye ingestion, and thermal burn.

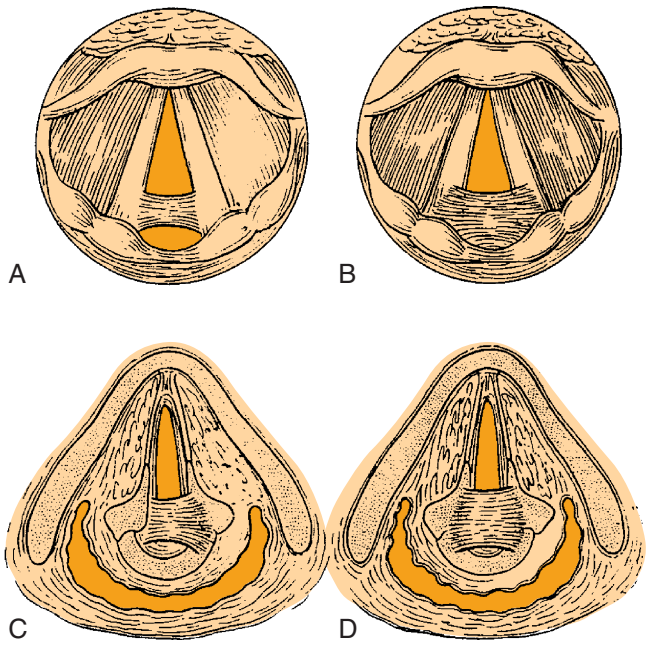

Figure 206-4. Posterior subglottic stenosis. **A,** Interarytenoid adhesion with a mucosally lined tract posteriorly. **B,** Posterior commissure and interarytenoid scar without a mucosally lined tract posteriorly. **C,** Posterior commissure scar extending into the right cricoarytenoid joint. **D,** Posterior commissure scar extending into both cricoarytenoid joints.

Prevention

Factors important in reducing the incidence of laryngotracheal stenosis include:

1. Early exploration of laryngeal fractures to minimize serious sequelae.

2. High tracheotomy and cricothyroidotomy should be avoided except in extreme emergencies. If it is suspected that a high tracheotomy or cricothyroidotomy has been performed, endoscopy is indicated. If the suspicion is confirmed, the neck should be explored, and the tracheotomy site should be relocated to a lower position to prevent chronic subglottic stenosis. However, if the repair of a cricotracheal resection is planned, a high tracheotomy rather than a lower one is advantageous because it reduces the length of the resection.

3. When performing a tracheotomy, the surgeon should avoid extensive resection of the tracheal wall and use the smallest size tracheotomy tube compatible with ventilation and suctioning.

4. Aggressive endoscopy for benign laryngeal lesions should be avoided, especially for those in the anterior commissure area, to prevent formation of an anterior glottic web. The procedures should be staged 2 weeks apart for each side. Different principles may be appropriate for malignant lesions.

5. Intubation and endoscopy should be performed gently on relaxed patients.

6. Circumstances contributing to laryngeal trauma secondary to prolonged intubation should be recognized and avoided whenever possible.

Diagnosis of Congenital and Acquired Laryngeal Stenosis

Laryngeal stenosis is diagnosed by a thorough history and physical examination, radiologic evaluation, and endoscopic examination of the airway and esophagus.[38] Other investigations such as pulmonary function tests also may be helpful.

History and Physical Examination

Mild to moderate laryngeal stenosis is usually asymptomatic until an infection of the upper respiratory tract causes additional narrowing of the airway, resulting in respiratory distress. These patients usually have a tendency toward prolonged courses of upper respiratory tract infections.

In acquired stenosis, there is a history of laryngeal insult. Symptoms usually occur 2 to 4 weeks after the original insult, although the latent period can occasionally be longer. In congenital stenosis, symptoms usually appear at or shortly after birth, suggesting the possibility of a laryngeal anomaly.

The main symptoms of laryngeal stenosis relate to airway, voice, and feeding. Progressive respiratory difficulty is the prime symptom of airway obstruction with biphasic stridor, dyspnea, air hunger, and vigorous efforts of breathing with suprasternal, intercostal, and diaphragmatic retraction. Abnormal cry, aphonia, or hoarseness occurs when the vocal cords are affected. Dysphagia and feeding abnormality with recurrent aspiration and pneumonia can occur.

Complete physical examination of the upper aerodigestive tract should be performed to rule out associated congenital anomalies or acquired injuries.

Radiologic Evaluation

Radiologic evaluation is performed after stabilization of the airway. Radiography helps assess the exact site and length of the stenotic segment, especially for totally obliterated airways. The soft tissue radiograph is the single most important view in children. The anteroposterior high-kilovoltage technique increases visibility of the upper airway by enhancing the tracheal air column while deemphasizing the bony cervical spine. In acquired stenosis, small areas of calcification may be seen, denoting the site of previous injury. Fluoroscopy is helpful in studying tracheal dynamics.

Computed tomography (CT) and magnetic resonance imaging (MRI) are useful. High-speed CT has reduced imaging time and is becoming more popular in the assessment of airway lesions. MRI still requires a significant amount of time, necessitating sedation in younger patients.

Evaluation of swallowing is important before airway reconstruction because dysfunctional feeding may complicate airway reconstruction by increasing the risk of aspiration postoperatively. Patients undergoing surgical correction of airway anomalies should have a historical screen for feeding problems. Patients with marginal feeding skills may be unable to compensate for the altered anatomy created by the reconstruction.

Videofluoroscopic swallowing studies (VSS) provide radiographic reviews of the bolus during swallowing. The presence of laryngeal penetration and aspiration can be documented and assessment of the ability of the child to protect the airway can be made. Many children with congenital anomalies of the airway, however, cannot tolerate the volume of contrast necessary to visualize the swallowing mechanism, and have significant oral aversion behaviors that preclude the introduction of any material into the mouth because of lack of exposure to nutritional stimuli at developmentally sensitive periods of their development. This makes the assessment of swallowing safety impossible by this method and an endoscopic evaluation of swallowing should be performed.

Endoscopic Examination

Indirect laryngoscopy alone is inadequate for diagnosis. Direct endoscopic visualization of the larynx is essential to study the stenosis carefully. Flexible fiberoptic endoscopy assesses the dynamics of vocal cord function and the upper airway, including the trachea.[39] In patients with severe burns with neck contractures, flexible endoscopy may be the only method to visualize the larynx. Flexible retrograde tracheoscopy through the tracheotomy site may provide useful information in some cases.

Rigid and flexible endoscopy of the airway and esophagus should be performed in the operating room with the patient under general

anesthesia. The rigid telescope is especially important in the examination of children because it better visualizes the small larynx. However, it is important to recognize that the airway lumen should be measured by passing bronchoscopes or endotracheal tubes of known sizes and cannot be gauged by the use of telescopes alone.[40]

Flexible endoscopy and spiral CT with mutiplanar resolutions have to be considered complementary techniques to rigid endoscopy in the preoperative evaluation and follow-up of children with laryngotracheal stenosis.[41]

Evaluation of Gastroesophageal and Gastrolaryngopharyngeal Reflux

GER is a common occurrence in children and adults. Many infants have no pathologic symptoms related to GER (the happy spitters). The current prevailing, although not universal, opinion is that GER and gastrolaryngopharyngeal reflux (GLPR) are likely to play a role in the development and exacerbation of SGS and may affect adversely the successful outcome of laryngotracheal reconstruction (LTR). GER and GLPR are defined as involuntary passage of gastric contents into the esophagus and pharynx, and are commonly occurring physiologic phenomena. It is not the presence of reflux that determines gastroesophageal reflux disease (GERD) or gastrolaryngopharyngeal reflux disease (GLPRD), but rather the frequency, intensity, and associated symptoms of reflux that distinguishes GERD and GLPRD from GER and LPR. Unfortunately, there is no gold standard for recognizing or excluding GERD and GLPRD, and differentiation between physiologic and pathologic reflux can be difficult. All diagnostic tests available for GER and GLPR have significant limitations. Generally, they tend to have high specificity but low sensitivity. Of the tests available today, 24-hour esophageal pH probe using a dual probe technique is believed to be the most reliable. This test, when used in conjunction with history, esophagoscopy, and esophageal biopsy, yields the best information in determining the likelihood of GERD and GLPRD.

Esophagogastroduodenoscopy with Biopsy

Esophagogastroduodenoscopy (EGD) allows direct visualization of the esophageal, gastric, and duodenal mucosa, as well as facilitating biopsy of any suspicious lesions. Any esophageal mucosal irritation, erosion, ulceration, epithelial metaplasia as in Barrett's esophagitis, or stricture should be noted and biopsied. Histologic findings of esophagitis are confirmed. EGD is a surgical procedure, with its own potential risks of bleeding, infection, intestinal perforation, mediastinitis, or peritonitis. This test is recommended when esophagitis is suspected, but not required for every patient undergoing reflux evaluation. When esophagitis is detected, EGD with biopsy may be repeated to determine treatment efficacy.

It is important to recognize eosinophilic esophagitis as a separate entity from GER. Control of this is important prior to surgical reconstruction of the airway.

Treatment of GER and GLPR starts with dietary and lifestyle modifications and can be supplemented by pharmacologic agents. If control of GER and GLPR is not achieved with maximum medical therapy, a surgical consultation should be obtained. Proper communication between the otolaryngologist, the gastroenterologist, and the surgeon based on the previous investigations leads to instituting the most appropriate therapeutic program for the individual patient.

Functional Endoscopic Evaluation of Swallowing

The functional endoscopic evaluation of the swallow (FEES) study requires the passage of a flexible endoscope transnasally into the hypopharynx. The hypopharynx can be visualized and parameters similar to those rated in VSS related to airway protection can be determined. In addition, secretions spilling from the oral cavity that pool in the hypopharynx may be visualized and their aspiration risk assessed. An assessment of hypopharyngeal sensation also can be made by demonstrating the laryngeal closure response elicited from a calibrated air stimulus to the larynx. Decreased sensation is correlated with an increased aspiration potential. If VSS is precluded because of oral aversion, then a FEES study is performed.

Table 206-1

Grading of Laryngeal Stenosis

Grade	Percentage of Laryngeal Lumen Obstruction
I	Less than 70%
II	70% to 90%
III	More than 90%; identifiable lumen is present (no matter how narrow)
IV	Complete obstruction; no lumen

Voice Assessment

Psychoacoustic evaluation and acoustic analysis of the voice may be used to establish the degree of vocal abnormality before surgery and compare it with voice analysis after surgery.[42,43]

Although assessment of pre- and postoperative vocal quality in young children may be frustrating, improvement in technology has made the task easier and several reports have been published regarding specific voice issues. In general, the voice results are unsatisfactory, with the vocal parameters suggesting a pattern of lower than optimum pitch and a restricted pitch range. Vocal quality appears to be disturbed in most patients; however, laryngeal reconstruction makes oral communication possible.[43-46]

Pulmonary Function Test

Pulmonary function tests with the spirometric maximum inspiration and expiration flow rates, flow volume loops, or pressure flow loops show characteristic changes in upper airway stenosis and can be used to compare the postoperative results with preoperative values.[47]

Management

Management should be individualized according to pathologic findings, patient age, degree and consistency of stenosis (hard or soft and percentage of stenosis), and general condition of the patient. Management of adults differs from that of children, and some operations useful in children are not applicable to adults.

All cases of moderate or severe laryngeal stenosis require a tracheotomy at or below the third tracheal ring to establish a safe airway. Stenosis that does not require a tracheotomy constitutes a mild case. A four-stage grading system has been widely adopted (Table 206-1).[40,48]

The first thing to do is to secure the airway if immediate repair cannot be performed. Severe cases of congenital subglottic stenosis or marked cartilaginous cricoid deformity need a tracheotomy to maintain an adequate airway. When a tracheotomy is performed, the smallest tube that permits adequate ventilation should be used. The tube should allow air leakage to occur to avoid injury to the tracheal mucosa and simultaneously preserve phonatory potential.

Tracheotomy was required in congenital subglottic stenosis in less than half of a large series of patients.[12] Once the airway is secured, two basic management modalities are considered: endoscopic or external. Endoscopic methods include traditional dilation including balloon dilation and techniques that use laser excision of stenotic areas. Open surgical methods include expansion and resection surgery. The morbidity of open reconstruction is higher, but this is balanced against the multiplicity and futility of endoscopic procedures when inappropriately used. In general, less severe cases respond to endoscopic methods, and more severe cases require external reconstruction. If the cartilaginous framework of the larynx is significantly deficient, endoscopy is unlikely to be successful.

The best chance for the patient lies in the first operation.[49] Endoscopic techniques for isolated subglottic stenosis may be successful in grade I and occasionally grade II subglottic stenosis. Expansion laryngotracheal surgery is very successful in grades II, III, and some grade IV. Partial cricotracheal resection is successful in some grade III and

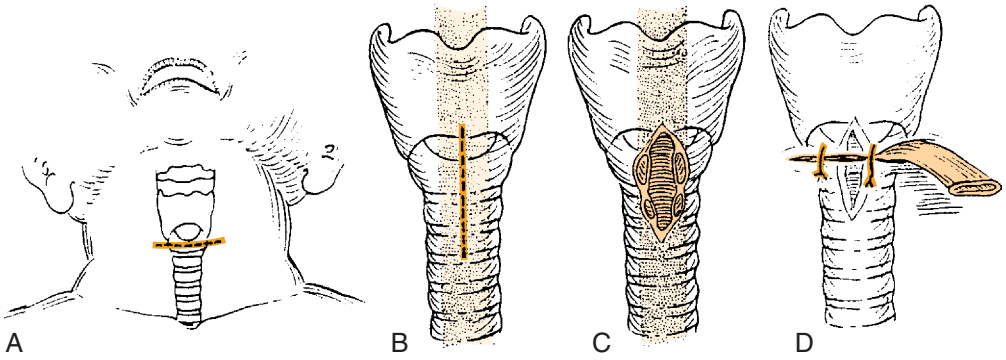

Figure 206-5. Anterior cricoid split. **A,** Skin incision. **B,** Midline laryngeal incision through cartilage and mucosa. **C,** With the cricoid cartilage decompressed, the endotracheal tube is ghosted in **B** and **C. D,** Loose skin closure with a drain inserted.

IV stenosis where there is a clear margin between the stenosis and the vocal cords.

Endoscopic Management

Dilation is sometimes useful early in the development of stenosis. It is not recommended for mature, firm stenosis or cartilaginous stenosis. Dilation is usually performed alone or supplemented with local or systemic corticosteroids or intralaryngeal stenting. The use of corticosteroids in all stages of acquired SGS is controversial. Corticosteroids tend to decrease scar formation by their anti-inflammatory action of delaying synthesis of collagen in early stages of wound healing and increasing collagen lysis in the later phases. Corticosteroids also delay wound healing by delaying the epithelial migration necessary to resurface the denuded area, thus increasing scar formation and predisposing to infection. Corticosteroids may be used systemically or locally. Local injection into subglottic scar is technically difficult and may be ineffective if a pressure injection system is not used. Resorption of cartilage secondary to the presence of local corticosteroids is a serious complication. Inhalation corticosteroids are believed to reduce granulation tissue formation after stent removal or early after endotracheal tube injury.

Mitomycin C is an antineoplastic antibiotic that acts as an alkylating agent by inhibiting deoxyribonucleic acid and protein synthesis. Experimental animal studies[50] and postendoscopic application[51,52] seem promising; however, there seems to be no advantage to its use after open surgical repair.[53] There is a risk of acute airway obstruction from excessive accumulation of fibrinous debris at the operative site in humans and animals after applying mitomycin to sites treated with CO_2 laser and dilatation.[54,55]

Endoscopic scar excision using the carbon dioxide (CO_2) laser is popular because it allows the surgeon to vaporize scar tissue with precision, producing minimal damage to healthy areas. Tissue destruction is directly related to the amount of energy delivered by the laser and the duration of exposure. If minimal energy of short duration is delivered, damage to the underlying and normal surrounding structures is minimal. However, if the laser is used at high energy levels for long times, it acts similar to any other uncontrolled method of tissue excision. The laser is useful for managing early stenosis with granulation tissue and may improve the airway without causing significant bleeding or edema, thus avoiding the need for a tracheotomy. Many authors have reported adequate results in managing early or mild SGS using the CO_2 laser,[56,57] generally with multiple procedures. CO_2 laser treatment was found to be effective in 92% of grade I subglottic stenosis but declined to 46% in grade II and to 13% in grade III. In order to avoid worsening of the airway it is recommended that CO_2 laser treatment be used only once if the airway lumen does not improve.[58] Endoscopic management has not been successful in the presence of the following conditions:

1. Circumferential cicatricial scarring
2. Abundant scar tissue greater than 1 cm in vertical dimension
3. Fibrotic scar tissue in the interarytenoid area of the posterior commissure
4. Severe bacterial infection of the trachea after tracheotomy
5. Exposure of perichondrium or cartilage during CO_2 excision, predisposing to perichondritis and chondritis
6. Combined laryngotracheal stenosis
7. Failure of previous endoscopic procedures
8. Significant loss of cartilaginous framework

Anterior Cricoid Split Operation

The anterior cricoid split operation (Fig. 206-5) was described in 1980 as an alternative to tracheotomy in the management of acquired SGS in premature infants.[59] The procedure has subsequently been used in the management of congenital SGS.[60] The concept is to split the cricoid and upper first and second tracheal rings in the midline anteriorly, thus allowing expansion of the cricoid ring. It is indicated in cases of congenital SGS caused by a small cricoid ring (i.e., not otherwise seriously deformed) or extensive submucosal fibrosis with healthy cricoid cartilage. It should be used only in patients whose condition is severe enough to require airway support and in whom lung function is adequate to permit decannulation. Use of auricular,[61] thyroid alar cartilage,[62] and hyoid[63] grafts has been reported to improve the success rate of the cricoid split operation. There are many factors that determine the success of the cricoid split procedure and hence the variability of its success from a low of 35% to a high of 88%.[64,65] Performing a cricoid split on a healthy infant with isolated subglottic stenosis yields the best results. Poor results occur when patients are generally sick and the airway lesion is not restricted to the subglottis.

With the patient under general endotracheal anesthesia, a horizontal skin incision is made over the cricoid to expose the cricoid and upper two tracheal rings. A single vertical incision is made through the anterior cartilaginous ring of the cricoid and through the mucosa to expose the endotracheal tube. The incision is extended inferiorly to divide the upper two tracheal rings in the midline. When the incision is made through the cricoid, the cricoid springs open, and the endotracheal tube is readily visible in the lumen. The incision in the larynx is extended superiorly in the midline to include the lower third of the thyroid cartilage to a level just inferior to the anterior commissure, but it can be extended to within 2 mm of the thyroid notch (Fig. 206-6).[66] Stay sutures of 3-0 Prolene are placed on each side of the incised cricoid. These can be used as retractors in the postoperative period if the endotracheal tube becomes dislodged and cannot be reinserted. The skin is loosely approximated around an elastic band drain. The endotracheal tube is left in place for about 7 days and acts as a stent while the mucosal swelling subsides and the split cricoid and tracheal rings heal.

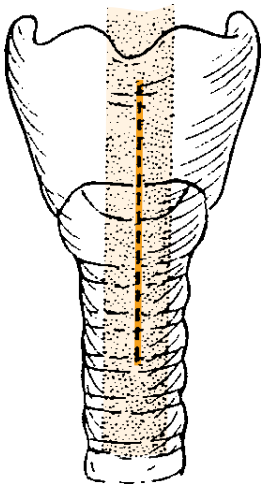

Figure 206-6. Incision for an anterior cricoid split in the management of SGS in infants (compare with Fig. 206-7.)

Endoscopy is not performed at extubation. Corticosteroids are administered before extubation and continued for 5 days.

External Expansion Surgery

Surgical reconstruction is recommended when conservative efforts to establish a satisfactory airway are inappropriate or have failed. In weighing the advantages of open reconstruction versus endoscopic management, the surgeon should consider his or her personal expertise and the severity of the lesion. In general, SGS grades III and IV lesions require external methods. Grade II may be amenable to either method. Occasionally, open surgery is required when the stenosis is of such a degree that tracheotomy has not been required.

Before surgery is performed, vocal cord paralysis should be ruled out. There should be no reason for the patient to continue to be tracheotomy-dependent despite adequate patency of the airway (e.g., presence of neurologic deficit or chronic pulmonary disease). The goal and rationale of open reconstructive surgery are to achieve early decannulation with minimal detrimental effect on the voice.

External surgical repair should be directed at the site and severity. Each case should be individualized. The two main methods of repair are resection and expansion surgery.[67-71] Expansion surgery is a collection of techniques that aim to widen the glottic and subglottic lumen. These techniques combine the use of laryngeal and cricoid splits, cartilage grafts, and stenting with success rates of higher than 90%.[72-75] Many techniques for correction of stenosis are available, but choosing the most appropriate procedure and achieving a successful outcome are problematic. Surgical repair at the youngest age possible is important for a child's speech and language development, as well as for eliminating the morbidity and mortality associated with a tracheotomy.

Combined Laryngofissure and Posterior Cricoid Division

Division of the posterior cricoid lamina through a partial laryngofissure is the method of choice for combined posterior glottic and SGS for grade II and moderate grade III. The operation is effective in patients of all ages. Cartilage grafts can augment the lumen. Scar removal is unnecessary in this procedure.

With the patient under general anesthesia administered via the tracheotomy, a horizontal skin incision is made incorporating the upper portion of the stoma (Fig. 206-7). Subplatysmal flaps are elevated superiorly and inferiorly, and the strap muscles are retracted laterally, exposing the thyroid, cricoid, and upper tracheal rings. A midline anterior incision is made in the larynx and upper trachea, extending from the superior thyroid notch to the tracheotomy site. After injection of 1% lidocaine with epinephrine 1 : 100,000 into the posterior larynx, the posterior scar and full length of the posterior lamina of the cricoid are divided, taking care to cut strictly in the midline, down to the level of the hypopharyngeal mucosa. The laryngeal scar should not be

Figure 206-7. excised. The incision is carried superiorly into the interarytenoid area through the interarytenoid muscle (when fibrosed) and inferiorly for about 1 cm into the membranous tracheoesophageal septum. The divided halves of the posterior cricoid lamina are distracted laterally and an autogenous costal cartilage (see Fig. 206-7) is used to maintain separation of the divided halves of the cricoid lamina. A stent is inserted suprastomally for 2 to 6 weeks. A variety of stents is advocated and each has its own specific application. The use of stents is being replaced more and more by the use of single stage laryngoplasty. It is also advisable to avoid a complete laryngofissure so as not to disrupt the anterior commissure, which could lead to deleterious voice results.

Grafts

In children, autogenous costal cartilage is the graft material of choice, especially when there is little identifiable cricoid cartilage remaining anteriorly.[12,76,77] Because of the abundance of available costal cartilage, any length of cartilage can be obtained to graft the subglottis and trachea. Ear cartilage[75] and free thyroid cartilage graft are alternatives in special circumstances. The use of vascularized hyoid interposition techniques should be discouraged in children because the hyoid is too small to augment effectively the subglottic lumen, the bone is too hard to sculpture, and the muscle pedicle tends to ossify, causing secondary compression of the larynx. Cartilage graft survival has been proven experimentally and clinically in children and adults.[78]

Thyroid alar cartilage is excellent for use in the anterior subglottic region but is limited to grade II and few grade III lesions[79] because of its limited thickness compared to costal cartilage and inability to use it in the posterior cricoid area. Removal of the alar cartilage does not seem to cause a laryngeal deformity but no long-term follow-up is available.[80,81]

Autogenous Costal Cartilage Reconstruction

The patient is positioned in an extended neck position. The tracheotomy tube is replaced with an endotracheal tube to allow easy access to

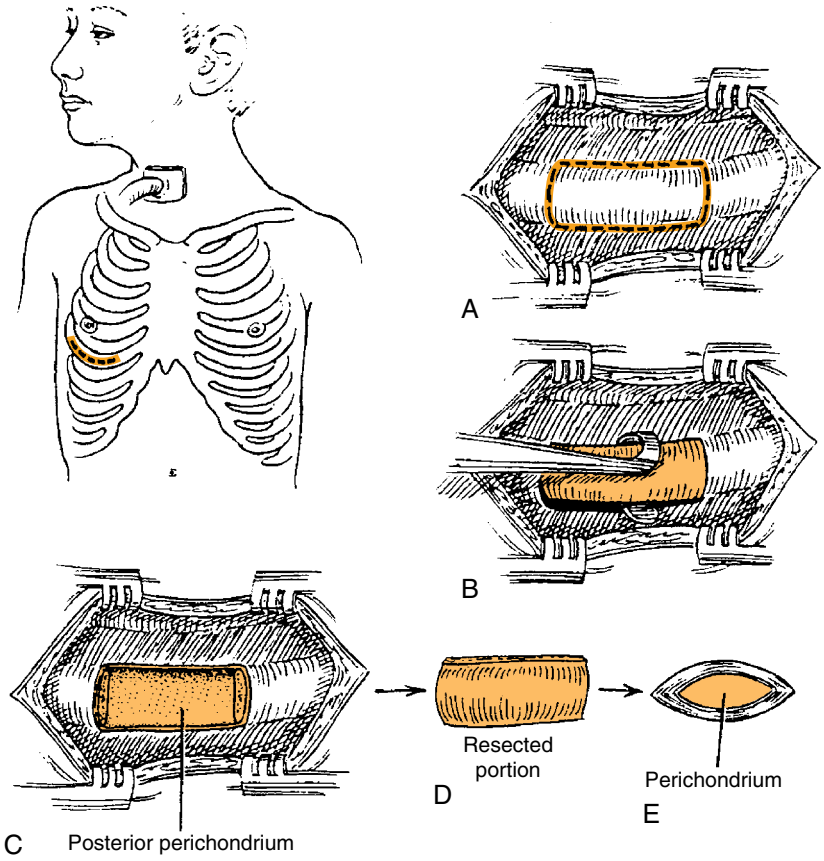

Figure 206-8. Donor site of a costal cartilage graft used for anterior augmentation of stenotic cricotracheal area. **A,** Incision over the fifth costal cartilage to obtain a costal cartilage graft. **B,** Perichondrial incisions are made along the inferior and superior borders of the rib, with care taken not to injure underlying cartilage. **C,** Dissection in the subperichondrial plane is accomplished so that the pericardium on the posterior part of the rib remains in situ on the chest wall of the patient. **D,** A 4-cm length of costal cartilage is removed and placed in physiologic saline solution. Lining perichondrium remains only on the anterior aspect of the graft. **E,** Costal cartilage graft is shaped into an ellipse and beveled to prevent the graft from settling into the lumen.

the neck and adequate anesthesia. The lower face, neck, and chest are scrubbed and draped. A 3-cm horizontal skin incision is made just inferior to the right mammary gland and is deepened to include the subcutaneous tissue and muscle. Costal cartilage is identified (Fig. 206-8), and the longest straight segment is removed with overlying lateral perichondrium, leaving the medial perichondrium in situ. The cartilage is fashioned to fit the intended site of transplantation. If the stenosis is anterior, cartilage is trimmed to a modified boat shape (see Fig. 206-8).[82] Flanges at the edges of the cartilage graft prevent prolapse into the lumen and allow maximum use of the width of the graft for distraction of the cricoid and upper trachea (Fig. 206-9). The regular boat-shaped graft is used for distraction of posteriorly cut cricoid segments in the management of posterior glottic and subglottic stenosis.[83] Indications for use of a cartilage graft in the posterior glottis and subglottis are: (1) posterior glottic or subglottic stenosis; (2) isolated subglottic shelves; and (3) circumferential SGS, when the posterior cricoid lamina has been divided. Despite suturing, creation of flanges, or both, the graft is not stable enough to remain in place and stenting is needed for several days.

A large series of posterior cartilage grafting with animal study documentation of survival of posteriorly placed cartilage grafts has been reported.[84] In cases of severe SGS, anterior and posterior grafts have yielded success rates greater than 90% after a single procedure within a short time after removal of the stent.[85,86]

Stents

Stents are used to counteract scar contractures and promote a scaffold for epithelium to cover the lumen of the airway. Stents also hold the reconstructed area in place and prevent mechanical disruption secondary to movement of the laryngotracheal complex during breathing, swallowing, and attempts at phonation. Stenting is necessary when using grafts to expand stenosed areas of the airway. Grafts provide rigidity and support and fill gaps in the incised and distracted segments to avoid the formation of fibrous tissue with subsequent contraction. If the grafts are dislodged, failure to correct the stenosis will follow.

When choosing stents, the physician should focus on the material, size, location, and duration of stenting. Many types of stents have been used and each has its own application. T-tubes continue to be used successfully in children and adults, special care is needed to avoid tube blockage.[87] Repair of laryngotracheal stenosis in almost all cases, except the anterior subglottis, requires brief stenting to keep the grafts in place and lend support to reconstructed areas. Long-term stenting is occasionally indicated.

Single-Stage Laryngotracheal Reconstruction

Single-stage laryngotracheal reconstruction (SSLTR) implies the use of cartilage grafts to obtain stability of the reconstructed airway and compress the prolonged stenting period of traditional LTR methods into a briefer period of endotracheal intubation. SSLTR may include an anterior cartilage graft, a posterior cartilage graft, or both, and often includes a cartilage graft of the former stoma site. The grafts are supported temporarily by a full-length endotracheal tube fixed in position through the nasal route. The optimal time for intubation has not been established definitively. In general, approximately 2 to 4 days of intubation are necessary for anterior cartilage grafts alone, and about 7 days are recommended if a posterior graft is used as well. A tendency exists to decrease the time of intubation with increasing age through childhood. SSLTR demands comprehensive knowledge of the principles of LTR

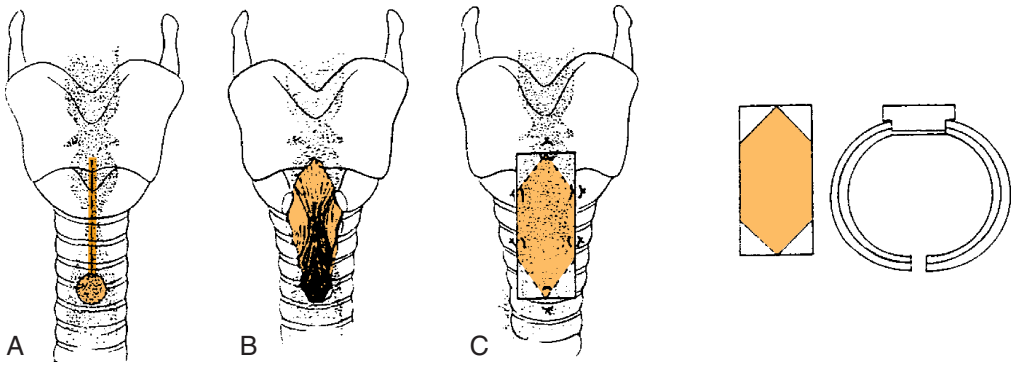

Figure 206-9. Anterior cartilage graft. **A,** Vertical incision is made into the thyroid cartilage from a point immediately below the anterior commissure through the upper tracheal rings, with care taken to remain in the midline. **B,** Intraluminal scar and lining mucosa are incised along the length of the stenotic segment. **C,** Costal cartilage is shaped into a modified boat (*inset*) and placed in position with the lining of the perichondrium facing internally.

and significant experience in the techniques. In addition, the otolaryngologist must have complete confidence in the nursing, anesthesia, and intensive care resources available at his or her institution.

SSLTR is indicated primarily in SGS without significant obstructions in the trachea or significant tracheomalacia. SSLTR may include all variations of the cricoid cartilage division and, in most cases, these divisions are stabilized by the use of a cartilage graft.

The concept of SSLTR is appealing because of the advantage of immediate decannulation or even the avoidance of tracheotomy altogether in a child who does not have a tracheotomy in place. Long-term stenting with its potential complications is also unnecessary. These advantages must be weighed against the potential for airway complications in the perioperative period, possible replacement of the tracheotomy, and complications that may arise during the intensive care required by these patients intubated for a prolonged period of time.

Certainly one requirement of SSLTR is meticulous management of the patient's condition in the ICU postoperatively. The nasotracheal airway must be maintained securely during the time of stenting without accidental extubation. Toddlers are prone to self-extubation unless carefully managed and sedated as appropriate. Older children and adults often can tolerate endotracheal intubation without any sedation.[88] Some centers use titration sedation to prevent agitation and accidental self-extubation, avoiding pharmacologic paralysis. One argument for using paralysis is that even if the patient is not accidentally extubated, motion of a nasotracheal tube in a surgical site results in poor healing. Although many variables determine success in the expansion of SGS, including preoperative grade, PR, underlying medical conditions, airway, and surgical technique, it has not been possible to quantify this particular effect. Further argument against the use of heavy sedation is the withdrawal symptoms that many children experience after cessation of the sedation drugs. The argument against pharmacologic paralysis is the necessity for immediate reintubation, should accidental extubation occur, and that postoperative pulmonary morbidity is high. These children develop migratory atelectasis, often with exacerbation of reactive airway disease or pulmonary infiltrates despite intensive pulmonary toilet, bronchodilator therapy, broad-spectrum antibiotics, and chest physiotherapy. The success of SSLTR is dependent on not only the surgical technique but also on intensive careful postoperative management.

Most surgeons exclude patients with notable craniofacial or vertebral anomalies from SSLTR to avoid a potentially difficult emergent reintubation.

SSLTR remains an excellent treatment modality for the repair of SGS in infants. It is reported that infants weighing more than 4 kg and those with a gestational age greater than 30 weeks have a greater chance for successful extubation and eventual airway patency. It appears that infants weighing fewer than 4 kg have more complications surrounding extubation. This may be because of the other underlying disease states often present in these neonates.

Cricoid Resection with Thyrotracheal Anastomosis

Surgical resection of the anterior arch of the cricoid cartilage, together with a portion of the posterior cricoid lamina below the cricothyroid articulation with thyrotracheal anastomosis, was first suggested in 1953[89] and resurgence of this procedure in adults[90-93] encouraged use in children. Several authors report good results.[60,88,109] In children with isolated tracheal stenosis, repair with resection and end-to-end anastomosis yields excellent results.[94] When the stenosis involves the subglottis, the resection becomes technically difficult, but excellent results have been reported by several authors.[67,95-100] The procedure is applicable to the few patients in grades III and IV SGS. Arytenoid prolapse has been described as a complication in children[101] but not in adults.[102] Several reports favor CTR over LTR for grade 4 stenosis.[68,69] The current recommended strategy is to perform partial cricotracheal resection (PCTR) as a primary or salvage procedure in patients with grades III and grade IV stenosis.[102] Risk factors for failure are presence of unilateral or bilateral vocal cord paralysis.[103] Cricotracheal resection has been reported in children weighing less than 10 kg with excellent results.[104] No deleterious effects on laryngeal growth or function have been observed in humans.[105] In cases where the margins for resection are close to the vocal cords especially posteriorly, PCTR with grafting is indicated. It is very important not to resect a significant portion of the posterior cricoid plate, since animal studies have shown airway impairment in such cases. Vertical posterior cricoid laminotomy is safe.[106] The partial cricotracheal resection procedure has eliminated the need for four-quadrant cricoid division which still is an excellent procedure with good results in some cases.[107]

With the patient under general anesthesia through the tracheotomy, the larynx and upper airway are dissected and identified. The dissection is performed on the cricoid in a subperichondrial plane to avoid injury to the recurrent laryngeal nerve. The superior resection line starts at the inferior border of the thyroid cartilage and passes obliquely posteroinferiorly to cross the lower margin of the cricoid plate below the level of the cricothyroid joints (Fig. 206-10). The distal resection line is made immediately below the inferior border of the stenosis. To compensate for the disparity in the diameters between the tracheal and subglottic lumen, the superior cut of the tracheal lumen is beveled, and the membranous trachea may need to be plicated. Primary thyrotracheal anastomosis is accomplished by advancement of the distal segment superanteriorly to the residual posterior shell of the cricoid cartilage and suturing a tongue of mucosa from the posterior trachea to the remaining laryngeal mucosa. Cartilage sutures are then placed at the anastomosis, which should be kept free of tension. This is best accomplished by suprahyoid laryngeal mobilization and tension-relieving sutures in the cartilage. After surgery, extension of the neck is to be avoided for 10 days by placing three sutures from the chin to the upper chest area. Stenting is generally used either with an endotracheal tube (single-stage technique), a T-tube, or a suprastomal stent.

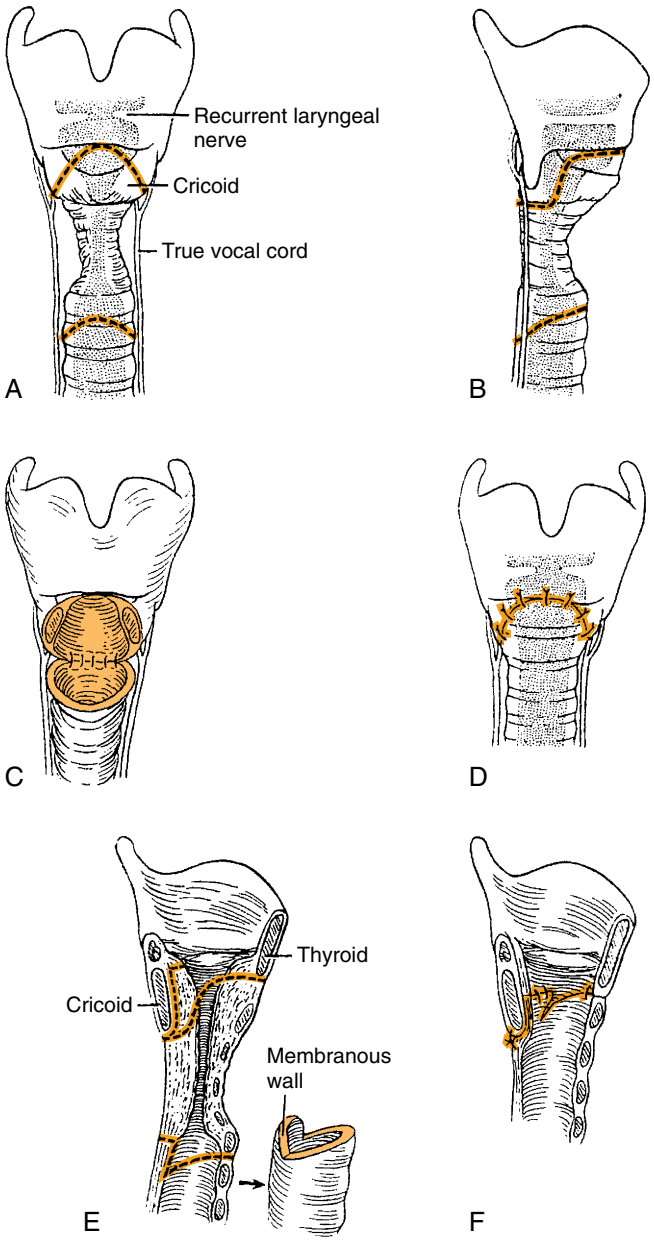

Figure 206-10. Partial cricoid resection with thyrotracheal anastomosis. **A,** Anterior view of the stenotic area to be resected, including the anterior cricoid lamina. **B,** Lateral view of the same area. Note the preservation of the posterior cricoid lamina and the location of the recurrent laryngeal nerve. **C,** After resection. The trachea is beveled and approximated to the subglottis. **D,** Suturing is completed (3-0 polyglactin 910). **E,** If a posterior subglottic thick scar is present, it is resected with preservation of the posterior cricoid cartilage, and a mucosal flap is developed from the posterior tracheal wall. **F,** Suturing of the mucosal flap is performed, and coverage of raw areas is achieved.

Management of Specific Disorders

Congenital

Atresia and Webs

The immediate management of laryngeal atresia is by establishing an airway at birth through an emergency tracheotomy. Rarely, it may be possible to pass a small bronchoscope through an incomplete atresia into the trachea, followed by a tracheotomy. It is extremely difficult to insert a large-bore needle into the highly mobile trachea of infants, and a neck incision with tracheotomy is the preferable method of establishing an emergency airway. Occasionally, tracheal agenesis coexists. After adequate airway is maintained, the elective surgical correction of laryngeal atresia generally restores respiratory function, but the phonatory and protective functions may remain significantly impaired after surgery.

Treatment of laryngeal webs depends on the thickness of the web.[3] A thin web may be broken down by passage of the bronchoscope or incised with a surgical knife, scissors, or the CO_2 laser. An attempt should be made to incise the web along one vocal cord, followed 2 weeks later by incision along the opposite side (to prevent further web formation). However, the smaller the larynx, the more difficult this is to achieve.

The less common thick glottic webs are more difficult to manage, and may be difficult or impossible to incise or dilate because of the associated subglottic-cricoid abnormality.

Tracheotomy may be required to establish the airway. Surgical excision of the glottic web and cartilaginous abnormality via a laryngofissure approach, followed by stenting and placement of an anterior autogenous costal cartilage graft, can be performed in a single or double stage.[108,109] The optimum age for surgery is unknown, and the possibility of aggravating the situation with an ill-judged operation should be considered. However, infants with severe obstruction above the tracheotomy are at greater risk of dying of cannula obstruction because of their decreased reserve airway above the tracheotomy. In such cases, earlier reconstruction should be considered. Endoscopic placement of a keel in children is difficult, and the external approach is recommended for best results.

Anterior Glottic Stenosis

Small anterior webs less than 2- to 3-mm wide produce minimal or no symptoms, and surgery is usually unnecessary. Thin anterior webs can be managed by microendoscopic incision of the web with a microsurgical knife or CO_2 laser. A keel may be placed endoscopically[110]; however, if this technique fails or if longer, thick anterior glottic scars are present, an external approach is needed. Tracheotomy is performed, followed by laryngofissure and incision of the stenotic area or web with the surgical knife. Resection of scar tissue should be minimized because this creates further mucosal loss. The umbrella keel gives reliable results and should be inserted for 2 weeks. The keel prevents restenosis in the anterior commissure during reepithelialization. If the keel is used for 2 weeks or fewer, granulation tissue formation is minimal. The design of the keel is such that contact with the posterior glottis is avoided, thus minimizing scarring secondary to the keel itself.

Stenosis and Vocal Cord Paralysis

Vocal cord paralysis can accompany anterior, posterior, or complete glottic stenosis. Bilateral vocal cord paralysis, associated with acquired glottic stenosis, needs a partial arytenoidectomy with lateralization of the true cord in addition to the operation discussed earlier in this chapter for correction of glottic stenosis. This is generally required unilaterally and occasionally bilaterally. Arytenoidectomy is reliably performed through the anterior thyrotomy approach. If done as a separate and later operation, an endoscopic laser arytenoidectomy is a valid alternative.[111] Arytenoid separation has been reported to be helpful.[112]

Posterior Glottic Stenosis

Management of posterior glottic stenosis varies with the degree of pathologic findings.[113] A simple interarytenoid adhesion requires a different approach from scarring involving both cricoarytenoid joints (see Fig. 206-4). It is a major challenge because the voice is generally excellent. Children with Down syndrome have a higher rate of posterior glottic stenosis than the general population.[114] Endoscopic division of the adhesion is sufficient if a mucosally lined sinus tract is present posteriorly. This is easily accomplished with a microsurgical knife while the posterior surface of the mucosally lined sinus is protected by insert-

ing a microsuction tip. In the absence of a mucosally lined sinus tract, simple endoscopic incision of the scar results in restenosis. Partial laryngofissure, however, is the most common approach for such cases and is required for more advanced cases with cricoarytenoid joint fixation. Endoscopic posterior cricoid split with grafting is another approach for repair.[115]

In children with severe posterior glottic scarring with cricoarytenoid joint fixation or subglottic extension, a division of the posterior cricoid lamina in the midline with insertion of a free autogenous costal cartilage graft (see Fig. 206-7) is recommended.[83,116] Complete glottic stenosis is difficult to manage, and voice results are usually poor because of severe scarring involving the vocal cords. Also, it may be associated with a decrease in the anteroposterior diameter of the larynx secondary to external trauma. Management involves incising the scar in an anteroposterior manner, posterior cartilage grafting, and placing a stent. Cartilage grafts should not be used in the anterior commissure area.

Anterior Subglottic Stenosis

Anterior subglottic stenosis is managed by incising the scar anteriorly and placing a modified boat-shaped cartilage graft[82] (see Fig. 206-9) to keep the segments of the cricoid distracted. The perichondrium of the graft should be at the level of the mucosa. At the end of the procedure, endoscopic examination of the subglottic airway is recommended to check for possible poor placement or partial collapse of the graft. The cartilage graft can usually be extended inferiorly to cover the tracheostomy if a single stage is planned.

Endotracheal intubation after a single-stage laryngotracheoplasty can range from 2 days for simple anterior cartilage[117] grafting to 2 weeks for moderately severe stenosis repaired with anterior and posterior grafts.[118]

Postoperative Management

Postoperative management[119] is affected by whether a stent was used. In patients in whom stents were not used, antibiotics for 2 weeks after the surgery are recommended and endoscopy is indicated once the patient is ready for decannulation. When stenting has been used, long-term, low-dose antibiotics are recommended for the duration of stenting to prevent infection. Appropriate tracheotomy care is extremely important. The caregiver should be proficient and knowledgeable about routine and emergency care because the control of GER is important.

Decannulation

The tracheotomy tube is gradually downsized and eventually plugged. Children should always be under adult supervision.[120] Once a child is ready for decannulation, endoscopy should be performed to ensure the airway is clear and the factors that influence successful decannulation after surgery have been well described. Occasionally suprastomal granulomas are seen. If the child is being considered for decannulation, these granulomas should be removed; however, if the child is not ready for decannulation, removal of suprastomal granulomas is not indicated unless they are completely obstructing the airway.[121]

The presence of suprastomal collapse can prevent decannulation, and further management may be needed.[122] When the child can tolerate the tracheotomy plugging for as long as he or she is awake, the decision for decannulation is made and the child is admitted to the hospital where the tracheotomy is plugged overnight with continuous monitoring. If there is no oxygen desaturation or apnea, the tracheotomy tube is removed the following morning, the stoma is covered with an occlusive dressing, and the child is kept for an additional night, again with continuous monitoring. Tracheotomy tube fenestration is not performed. A residual tracheocutaneous fistula may need to be surgically closed.

Summary

Glottic and subglottic stenosis, although rare, are difficult to manage. Surgical goals are to produce as early as possible[123] an adequate airway, an acceptable voice, and a competent larynx to avoid aspiration. The keys to successful outcome depend on (1) accurate preoperative and intraoperative assessment; (2) correct choice of surgical procedure; (3) meticulous surgery directed at the site of the lesion; and (4) close postoperative care and monitoring.

CHAPTER TWO HUNDRED AND SEVEN

Diagnosis and Management of Tracheal Anomalies and Tracheal Stenosis

Greg R. Licameli

Mark A. Richardson

Key Points

- The management and diagnosis of tracheomalacia and tracheal stenosis is complex and has evolved over the last two decades as experience grows with this condition.
- This chapter addresses tracheomalacia, congenital tracheal stenosis, and the management of tracheal stenosis with various surgical techniques.

The diagnosis and surgical management of tracheal stenosis, whether acquired or congenital, remains a challenge. In infants and children, tracheal stenosis has a high morbidity and mortality, particularly for those with severe disease, and is often associated with other congenital anomalies that require concomitant repair. Over the past 2 decades, certain principles of management have been developed that have improved patient outcomes. The evaluation and development of a logical management plan for these complex cases often requires the involvement of multiple medical specialties.

Embryology

The trachea develops as an evagination of foregut mesenchyme in the fourth week of gestation. This gradually expands caudally to form the developing lungs and joins together posteriorly to form the common membranous wall of the esophagus and trachea. Initially, this evagination has an extensive communication with the ventrocaudal part of the pharynx. From this primordial outgrowth, the trachea extends caudad ventral to and roughly parallel with the esophagus. Only the epithelial lining and the glands of the trachea are derived from the original entodermal outgrowth from the pharynx. The cartilage, connective tissue, and muscle of its wall are formed by mesenchymal cells that migrate to become massed around the growing entodermal tube. Usually by the ninth week, developing cartilaginous rings can be identified.

Tracheomalacia

Tracheomalacia, which is the absence or deformity of the tracheal cartilage, can present with inspiratory and expiratory stridor, wheezing (which may be mistaken for asthma), chronic cough, and recurrent respiratory infections. It may be subdivided into two categories: primary tracheomalacia, which is an intrinsic deformity of the tracheal cartilage in the absence of any other pathology, and secondary tracheomalacia, which is due to extrinsic compression, most commonly related to cardiac or vascular anomalies, as well as tracheoesophageal fistula.[1,2]

The symptoms of primary tracheomalacia tend to improve as the child's tracheobronchial tree grows in caliber, and surgical intervention is often not required. This condition occurs in both premature and mature infants. In contrast, the causes of secondary tracheomalacia usually require surgical correction to remove the cause of the compression and subsequently to assess the residual tracheal wall integrity.

Vascular Anomalies—Vascular Rings

Vascular rings are the result of abnormal development of the aortic arch complex. The most common complete vascular ring is a double aortic arch, in which the ascending aorta bifurcates to encase both the trachea and esophagus as it joins the descending aorta. Symptoms begin early in childhood and are related to both respiration and feeding. A barium swallow study shows a posterior compression of the esophagus.

A second but less common vascular ring arises from the persistence of the right aortic arch, with a left ligamentum arteriosum usually associated with a retroesophageal left subclavian artery, or less commonly, mirror branching of the right and left subclavian and common carotid arteries, and may present with similar symptoms as a double aortic arch.[3]

Surgical division of the ring immediately improves symptoms related to swallowing; however, symptoms related to the associated tracheal deformity may take some time to resolve as the patient grows.

Vascular Anomalies—Arterial Compression

The most common cause of vascular compression of the trachea is from an anomalous innominate artery compression. A more distal origin of the innominate artery from the aorta causes compression of the right anterior trachea that endoscopically demonstrates a triangular-shaped

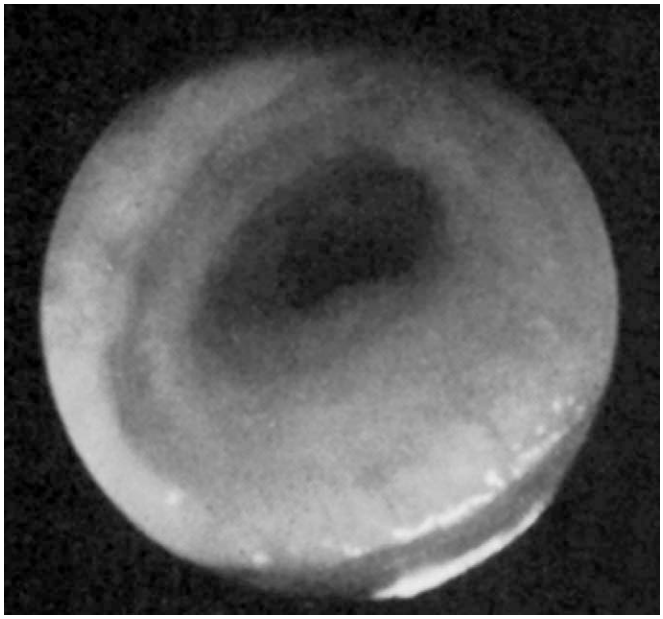

Figure 207-1. Long-segment tracheal stenosis (complete rings).

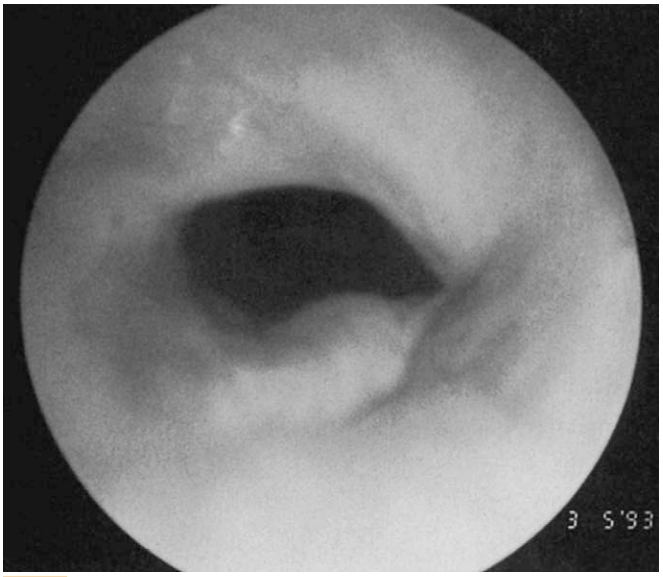

Figure 207-2. Short-segment tracheal stenosis.

deformity. Lifting the tip of the bronchoscope against the artery diminishes the right brachial pulse. Chest radiographs show anterior tracheal compression but no esophageal deformity.[3] Often these patients present with inspiratory or biphasic stridor, cough, recurrent respiratory infections and reflex apnea, with the latter often referred to as "dying spells."[4]

Pulmonary artery anomalies can also cause tracheal compression. In this situation, the aberrant left pulmonary artery arises on the right and passes between the esophagus and trachea, causing compression of the trachea and right bronchus, which is seen on endoscopy. Division of the artery with reanastomosis improves symptoms of stridor and wheezing.[5]

Other tracheal pathologies (e.g., congenital tracheal enlargement, cysts, abnormal tracheal bifurcation) are also in the differential diagnosis for congenital anomalies of the tracheobronchial tree.

Tracheoesophageal Fistula

Tracheoesophageal fistula is a common congenital abnormality, presenting at birth with respiratory distress, excessive mucus, feeding difficulties, and aspiration. It is often associated with tracheomalacia.[6] Five types have been described, with the most common abnormality occurring with the proximal esophagus ending in a blind pouch and the lower esophagus connected to the trachea via a fistula. The majority of cases are diagnosed by the inability to pass a catheter orally into the stomach.[7] Severe aspiration can occur with the use of radiologic contrast studies; therefore its use is controversial. Endoscopic examination is critical in the evaluation and planning of surgical intervention.[8] One half of all patients have congenital anomalies of other organ systems, including cardiac, genitourinary, and gastrointestinal abnormalities. A small percentage of patients have an intact esophageal lumen with a small connection to the trachea, known as an *H-type fistula*. These patients are usually less dramatically affected and diagnosis may be defied for months. Careful investigation with both contrast radiography and endoscopy is required to identify the small connection from the upper posterior trachea to the esophagus.[9]

Diagnosis

The severity of tracheal stenosis usually determines the age of presentation, which can be quite variable, ranging from days to weeks or even months. A long-segment stenosis with a markedly limited tracheal diameter would ordinarily present in early infancy with evidence of respiratory obstruction, especially when the airway may be compromised by secretions or infection, which produce additional incremental difficulties in adequate respiration (Fig. 207-1). Shorter segments, with a more moderate degree of obstruction in terms of tracheal diameter, may appear later in infancy or early childhood when the increasing respiratory demands of growing infants outstrip the capacity of the narrow airway to provide adequate levels of air and gas exchange (Fig. 207-2).

Any child who is being considered for bronchoscopy and who has atypical asthma, inspiratory and expiratory stridor, and recurrent respiratory disease should also have a potential diagnosis of tracheal stenosis. Poor weight gain and sometimes poor feeding are also associated with tracheal stenosis. Chest radiography may be helpful but is often nondiagnostic due to the dynamic aspects of the pediatric trachea. In some cases, however, a suggestion of the stenosis can be evident on close examination of the radiograph. A minority of patients with congenital tracheal stenosis present without any associated malformations and a careful assessment of particularly the cardiac vasculature is required.[10]

Endoscopy

Endoscopic evaluation with a rigid bronchoscope is clearly the most accurate means of diagnosing tracheal stenosis and assessing its length, degree, and character. Due to the limited diameter of the trachea, however, endoscopy must be approached expertly and with full availability of the smallest equipment possible. In some cases, placement of an endotracheal tube through the larynx to the level of the stenosis may cause a loss of ventilatory capability as a result of obstruction of the tube at the site of the stenosis. Additionally, even the smallest bronchoscope (4-mm outer diameter) might not pass through the stenosis and, in some cases, placement of a rigid bronchoscope for ventilation and the use of the longer rigid telescope (2.5-mm outer diameter) or ultra-thin flexible bronchoscope (2-mm outer diameter) might be the only means of visualization of the length of the stenosis and identification of any distal abnormalities in the tracheobronchial tree.

Endoscopic evaluation of the airway performed with rigid instrumentation and with the patient under general anesthesia is, however, accompanied by the greatest risk and requires skill in performing anesthesia, expert endoscopic skills, and a full complement of pediatric endoscopic instruments and photographic documentation capability. Minor trauma to the mucosa could precipitate an obstructive event. Once the patient has been given general anesthesia, additional anesthesia can be administered by applying lidocaine topically to the tracheal mucosa. Ideally the patient can maintain spontaneous ventilation, so that the adequacy of neuromuscular movement in the larynx can be assessed. It is generally wise to use the telescope as an initial form of evaluation without the accompanying bronchoscope for tracheoscopy to determine whether there is a significant stenosis and to identify its

approximate location and the nature of the tracheal rings (i.e., whether they are complete or incomplete). In some cases, even the smallest 2.5-mm pediatric bronchoscope (4-mm outer diameter) will not pass through the stricture, and again, the bronchoscopic telescope might be the only instrument able to pass through the stenosis to visualize the carina and distal bronchi. The patient must be hyperventilated for such an examination to be possible, but in so doing the length of the trachea affected can be gauged and a potential surgical procedure designed.

The length of the stenotic segment should always be estimated during the course of endoscopy as well as the degree of involvement of the trachea and the main bronchi, and is frequently underestimated. The determination whether a tracheal stenosis is congenital or acquired is an important one. Commonly, the congenital stenotic tracheal segment is associated with a somewhat longer trachea than the native and normal trachea of newborns. Congenital problems are often associated with other abnormalities of vascular structure and genetic defects. Acquired stenoses are accompanied by irregular scarring, perichondritis, and loss of cartilaginous support, which complicate surgical resection and reanastomosis.

Radiology

Computed tomography (CT) and magnetic resonance imaging (MRI) provide accurate evaluations of the airway, with MR images having a slight edge in depicting finer detail and the actual nature of the stenosis. There is an inherent risk for infants and children, who may require sedation or general anesthesia before examination.

Because some cases of congenital tracheal stenosis are often associated with a vascular ring or pulmonary artery sling, some means of determining whether there are abnormalities in the great vessels of the heart should be performed. Echocardiography or MRI might be satisfactory in some cases, although arteriography or heart catheterization may be necessary to fully identify or rule out the possibility of aberrant vasculature.

If additional information must be obtained, contrast bronchography can be performed with a thin solution of contrast material to outline the tracheal dimensions and bronchial branchings. This contrast material must be thinned because the secretions themselves and inflammation—which is sometimes stimulated by the contrast—can cause significant problems in ventilation for the patient. Despite the inherent danger in contrast bronchography, it does provide a measurable evaluation of long-segment tracheal stenosis and any accompanying bronchial abnormalities, which are often seen in congenital stenoses. There is increasing evidence that bronchography and angiography is being supplanted by spiral CT with multiplanar reconstruction and MRI.[11]

Advances in CT/MRI have allowed for fine detail three-dimensional reconstructions to provide a virtual endoscopy of the airway. It is limited by not being able to provide a dynamic assessment of either tracheomalacia or bronchomalacia, may not provide enough resolution to define subtle anatomic abnormalities, and can underestimate the degree and extent of the narrowing.[12] It has the advantages of being able to evaluate the airway distal to a stenosis that cannot be traversed by bronchoscopy and can be used in the measurement of the airway caliber over time. It should be considered as a complementary technique to formal rigid or flexible endoscopy in selected patients.[13]

Associated Anomalies

Congenital tracheal stenosis is often associated with other developmental anomalies. Cardiovascular anomalies are the most common, occurring in up to one half of cases, and include patent ductus arteriosus, ventricular septal defects, left pulmonary artery sling, aberrant subclavian artery, and double aortic arch.[10] Anomalies of the bronchopulmonary, gastrointestinal, renal, or skeletal systems should also be sought. Several authors believe that the simultaneous repair of both tracheal and cardiac defects provides better postoperative management and long-term outcomes.[14,15]

Louksnov and colleagues thought that a key element to achieving a 97% survival rate in 37 patients who underwent surgical repair was the use of cardiopulmonary bypass, which allowed them extensive mobilization of the tracheobronchial tree and a tension-free anastomosis,[14] as well as better exposure of the operative field.[16]

Table 207-2

Anton-Pacheco Functional Classification

Type: Mild	None or occasional symptoms
Type: Moderate	Respiratory symptoms without respiratory compromise
Type: Severe	Respiratory compromise
Subtype A	No other associated malformations
Subtype B	Associated malformations

Data from Anton-Pacheco J, et al. Patterns of management of congenital tracheal stenosis. *J Pediatr Surg.* 2003;38:1452-1458.

Classification

Congenital tracheal stenosis was originally classified based on anatomic morphologies as described by Cantrell and Guild,[17] and was augmented by the development of a clinical symptom classification by Anton-Pacheco.[11] These complementary approaches allow better correlation of anatomic findings with patient symptoms, important for surgical planning and outcome (Tables 207-1 and 207-2).

Surgery

Surgery for tracheal stenosis can be categorized generally in the following ways: (1) conservative management; (2) endoscopic, using laser or dilation; (3) resection and reanastomosis, including slide tracheoplasty; or (4) augmentative procedures using cartilage, perichondrium, or vascularized tissue.

Conservative Management

The role of conservative or nonsurgical management of congenital tracheal stenosis has recently been better defined. Historically, patients were treated conservatively because of poor surgical outcomes. There is increasing evidence that a carefully selected group of patients with congenital tracheal stenosis will resolve their difficulties with growth of the airway. This is largely due to the fact that tracheal airflow is proportional to the fourth power of the radius of the trachea. Patients with mild stenosis and occasional symptoms can be managed with respiratory physiotherapy, antibiotics in case of infection, supplemental oxygen, and close observation.[11,18] Rutter and colleagues described seven patients with complete tracheal rings who did not require surgical intervention.[19]

Cheng and colleagues reported their experience with 22 consecutive patients, 11 who underwent surgery and 11 who were followed nonsurgically. Initial diagnosis was made with bronchoscopy and supported by radiologic and clinical findings. The patients who were observed later (1.5 vs 0.4 years), were less symptomatic, had less severe tracheal narrowing (58% vs 30% of normal tracheal diameter), and had a lower mortality than the surgical group. Six of the 11 patients in the

observation group underwent serial CT measurements of the tracheal diameter. These data showed that five of six patients experienced an increased rate of tracheal growth compared with normal pediatric tracheal growth until approximately 7.5 years of age, when it then grew at a normal rate. The researchers suggested conservative management if the stenosis was not long segment and if the most stenotic segment was less than 60% of the normal trachea.[18]

Surgical management broadly involves two modalities: endoscopic tracheoplasty and open tracheal reconstruction. Endoscopic options include tracheal dilation, intraluminal stent placement, and laser ablation. Biopsies can be performed if there is suspicion of systemic disease such as amyloidosis or sarcoidosis. Open tracheal reconstruction can include the use of autologous, homologous, or inert stenting material to enlarge the airway diameter or to remove stenotic segments. The morbidity of an endoscopic approach is less than that of an open procedure but often involves repeated surgery. Selection of a therapeutic approach depends on the type of airway anomaly and can involve a variety of endoscopic modalities either alone or combined with an open approach to the trachea.

Dilation

Dilation of strictures has traditionally been performed with Jackson or Maloney rigid dilators. This method involves serial dilation with progressively larger-diameter bougies but has a tendency to shear tissue, which may create more scarring and further stricture formation.[20] In comparison, balloon tracheoplasty imparts only radial forces to the lesion and is less traumatic to the surrounding tissues. Balloon devices range from catheters developed for percutaneous transluminal angioplasty to specially designed balloons that fit over the tip of a rigid bronchoscope. Balloon-tipped catheters are connected to an inline pressure gauge and a water-filled syringe that delivers a steady, constant dilation. Serial dilation is performed with increasingly larger balloons. Balloon-tipped catheters can also be placed under radiologic guidance to confirm placement (Fig. 207-3).[21]

A 15-year experience of balloon tracheoplasty in 37 patients was reported by Hebra and associates.[20] Short-term improvement for both congenital and acquired lesions was seen in 90% of patients, with long-term improvement in 54%. Complications were infrequent and included tracheitis, atelectasis, and pneumomediastinum. This method appears to be most useful in the management of soft granulation tissue or to aid in delaying open reconstruction in premature or medically unstable infants.

Messino and colleagues[22] and Bag and associates[23] have described aggressive balloon dilation of complete tracheal rings with endotracheal stenting in children younger than 2 years of age. The posterior wall of a complete ring is the weakest point, as demonstrated by their postmortem studies, and allows disruption of the trachea with subsequent fibrotic healing. This method should be reserved for critically ill patients because complications can be life threatening.

Laser Therapy

Laser therapy is often combined with dilation procedures in the endoscopic management of tracheal strictures or obstructing masses. Use of the laser allows precise tissue ablation with less trauma to the surrounding tissue compared with cryosurgery and electrocautery.[24] Early reports described the use of the carbon dioxide laser with a bronchoscopic coupler and a rigid bronchoscope to manage tracheal lesions.[25] With the development of improved optics and laser micromanipulators mounted directly to the microscope, visualization and precision have improved. Lesions most amenable to this technique are soft granulation and short segments of mature fibrosis. Simpson and others[24] and Ossoff and associates[26,27] listed the following factors as contributing to laser therapy failure: circumferential scarring, fibrosis greater than 1 cm in vertical length, tracheomalacia, and severe bacterial infection in the presence of a tracheostomy.

A method using radial incisions and dilation with a rigid bronchoscope for moderate to severe subglottic and tracheal stenosis was described by Shapshay and coworkers.[28] Success was attributed to the preservation of islands of epithelium between the radial incisions. Results were good at 1-year follow-up (Fig. 207-4). Mucosal preservation was also advocated by Dedo and Sooy,[29] who described the use of the carbon dioxide laser in the elevation of mucosal flaps. An incision is made into the superior surface of the scar, creating a trapdoor flap, and the underlying fibrous tissue is ablated with the laser with replacement of the mucosal flap (Fig. 207-5). Success with these techniques appears to be dependent on reepithelialization before scar formation, avoidance of extensive tissue damage, preservation of mucosa, and careful patient selection.

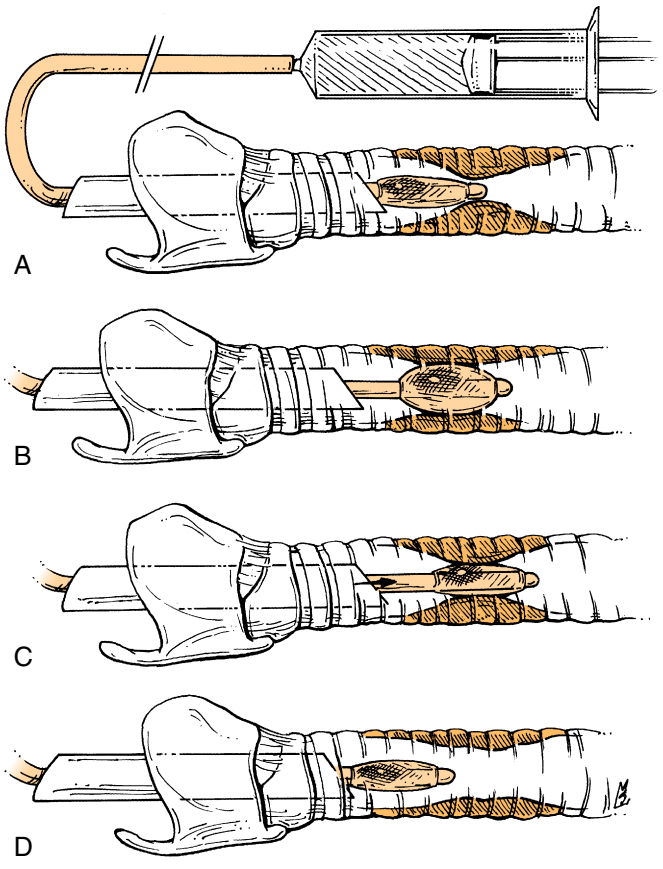

Figure 207-3. Pneumatic dilation of short-segment, acquired stenosis. Balloon insertion **(A)** and inflation **(B)**, reduction of stenosis **(C)**, and balloon deflation and removal **(D)**.

Intralesional and systemic corticosteroids have been suggested by some authors to aid in the prevention of scar formation and stenosis at the site of mucosal injury. However, corticosteroids may reduce epithelial migration, increase scar formation, or weaken existing cartilaginous support.[30] Other adjunctive measures include the use of antibiotics and antireflux medications. Mitomycin C is an antitumor antibiotic that inhibits fibroblastic proliferation and has been used in airway reconstruction to help prevent scar formation, with varied success.[31-33]

The combination of endoscopic laser division of tracheal stenosis or complete tracheal rings with balloon dilatation has been successfully reported.[34-36] Advantages purported by Andrew and associates include the ability to perform this technique with spontaneous respiration in a patient with a suboptimal airway, and the avoidance of endotracheal intubation after the procedure, which could incite further stenosis.[36]

Stents

Stents are important in the management of tracheal stenosis and can be used in either endoscopic or open approaches. Montgomery[37] first described the use of a polymeric silicone (Silastic T tube; Boston Medical Products) in 1965. This type of stent allows ventilation, support for soft tissue grafts and cartilage, and tracheal lumen suctioning. This tube is used in conjunction with a tracheostomy and is placed under endoscopic guidance. Maniglia[38] reported on the use of the T-tube stent in 53 adult patients with tracheal stenosis, subglottic stenosis, or both, with good results in 85%. Problems associated with

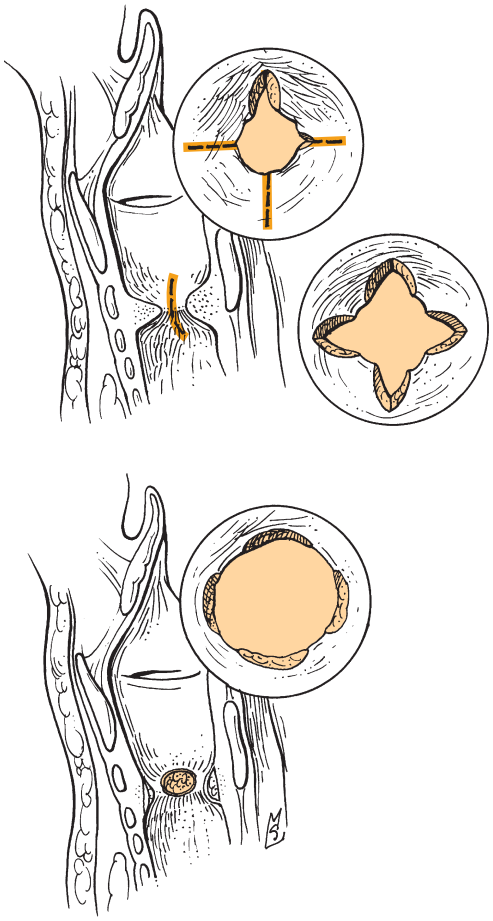

Figure 207-4. Star-shaped laser incision and dilation (Shapshay).

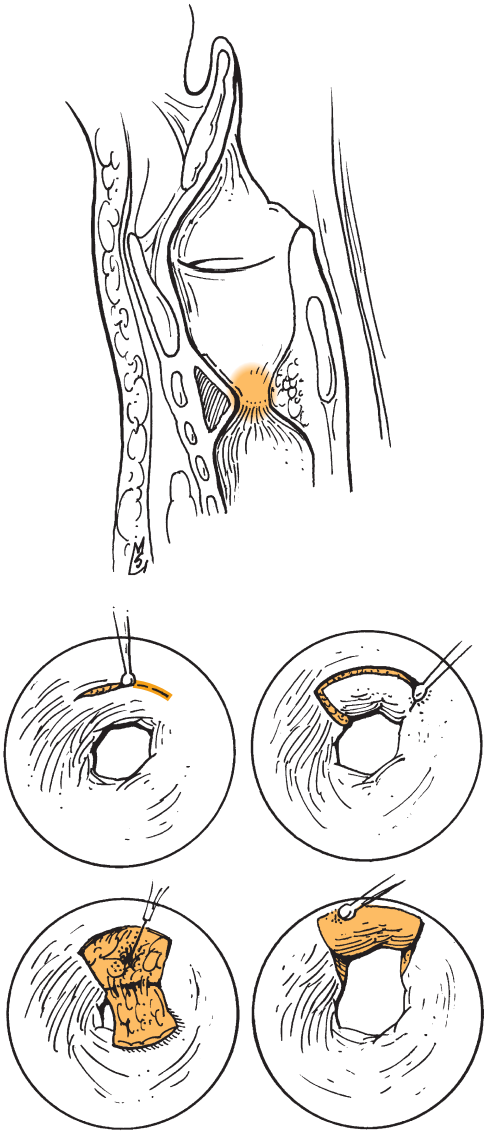

Figure 207-5. Laser trapdoor flap.

stents include obstruction, granulation tissue formation, infection, and malposition. Phillips reported use of this tube in 10 children with complex airway stenosis, the majority requiring stenting due to difficulties with severe granulation and stenosis of the subglottis after laryngotracheal reconstruction. This author and others emphasized the need for meticulous postoperative care to prevent luminal obstruction with secretions.[39]

The use of solid stents in children is limited. One version is the Dumon stent, modified from the Montgomery T-tube stent. It is a cylindrical solid silicone stent with external studs to hold it in place. Its main advantage is ease of removal, but its use in children has been limited because wall thickness itself can cause luminal obstruction in relatively small-caliber airways. Migration and occlusion from secretions, due to impairment of mucociliary clearance, are more problematic than expandable stents.

Experience with indwelling expandable stents in children has been limited, and initially these devices were used primarily in adults with advanced tracheobronchial malignancies.[40] Materials currently in use include self-expanding woven polymers and stainless steel wire, which are placed bronchoscopically. Mair and colleagues[41] demonstrated faster mucosalization and improved tracheal patency with polymer stents versus stainless steel stents both in a piglet model and in children. Bugmann and associates[42] reported on the successful use of an expandable Z-shaped wire stent in a 6-month-old patient with severe tracheomalacia. No complications were reported at 2-year follow-up. In adults, Nashef and colleagues,[43] among others,[23] found that the most common complication of stent placement was the formation of granulation tissue. Concerns raised by the authors regarding their use in children include the uncertainty of long-term tolerance of these stents, mucosal hypersecretion, and the risk of perforation and migration (Fig. 207-6).

Over the past decade, experience with expandable metal stents has increased. Filler and colleagues[44] reported on 16 children who required 30 balloon expandable metallic stents (Palmaz) over a 5-year period. All patients had improvement of their respiratory status, and three died of underlying cardiac disease. Obstruction in these patients was due to tracheomalacia, bronchomalacia, prior surgery, or vascular compression. Vinograd outlined his experience with metallic stents in 32 pediatric patients retrospectively reviewed. Initial stent insertion was uncomplicated, but the degree to which the stent needed to be expanded within the airway was much more difficult to gauge. Underexpansion could potentially cause stent displacement and overexpansion could cause mucosal injury and excessive granulation tissue formation. Although most patients had immediate relief of their airway obstruction, repeated endoscopies for removal of granulation tissue was required in 20 patients, and excessive granulation tissue occurred in another six patients who subsequently required stent removal. The authors also raised the question of the optimal period of time to leave the stent in place. Periodic expansion of the stent with patient growth needs to be balanced with the unknown effects on tracheal growth. In addition, stent removal was considered difficult with the potential development of life-threatening airway obstruction during extraction.[45]

A potential advantage to this type of stent is the ability to reexpand the stent as the child grows to accommodate a larger airway caliber.

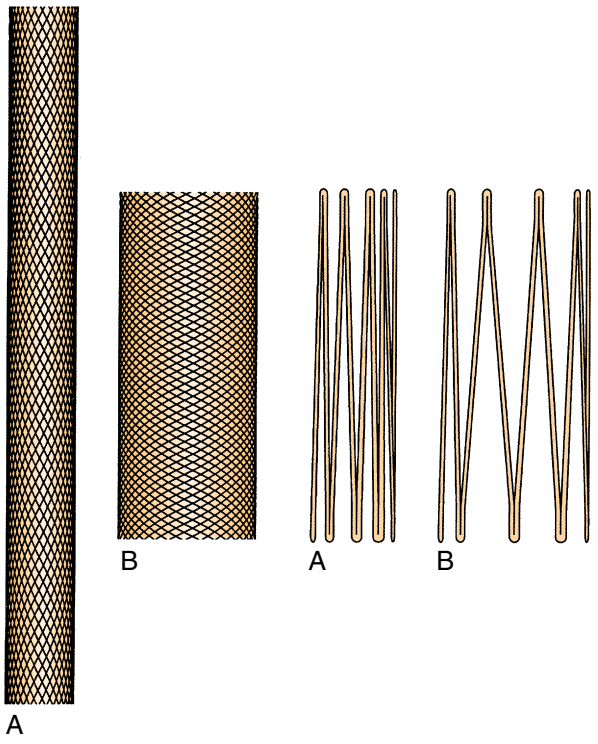

Figure 207-6. Polymer and wire stents in unexpanded **(A)** and expanded **(B)** forms.

Another advantage is that the stent is balloon expandable and can be removed more easily than a self-expanding stent such as the Gianturco stent, which is primarily used in adults. Furthermore, the wire mesh design preserves mucociliary clearance and hinders migration of the stent, unlike solid silicone stents.

The most common complication with the Palmaz stent was development of obstructing granulation tissue that necessitated early removal of the stent in three patients in the Filler[22] series. Because of the inability to remove the stent in a patient who underwent laser resection of stent granulation tissue, the authors advocate balloon compression or endoscopic scraping to address this problem. Furman and colleagues[46] reported on six patients requiring 12 Palmaz stents over a 3-year period with similar results and believed that stenting should be used in patients for whom conventional therapy had failed.

In a group of five infants ranging in age from 7 days to 12 months, Maeda and colleagues[47] reported on their success in treating congenital tracheal stenosis with stenting over a 3-year period. At follow-up bronchoscopy, the stents were found to be covered with respiratory mucosa. Granulation tissue developed at the site of the stent in all children, and one child died of intractable pneumonia related to recurrent granulation tissue.

A multicenter review by Jacobs and colleagues discussed the use of stenting in 33 children and highlighted the need to adapt the various stents available to the patient and their particular pathology, as evidenced by their use of custom carinal stents fashioned from cardiopulmonary bypass venous cannulas. They emphasized the need for accurate diagnosis before the surgical treatment of any extrinsic and intrinsic airway obstruction. In this series, stents were used as a primary modality to stabilize the airway or to support reconstruction after a variety of reconstructive procedures, with complications similar to earlier published reports.[48]

Experience with Nitinol stents in two children with tracheal stenosis was favorable.[49] Nitinol stents are formed from the metal alloy of nickel and titanium and are less reactive in the airway than stainless steel stents, potentially avoiding difficulties with granulation tissue formation. Another property of this alloy is its ability to reduce in size with temperature cooling, potentially facilitating its removal from the airway. Another promising area is the use of extraluminal microplates to support tracheal expansion[50] and the use of stainless steel wire to act as a scaffolding for pericardial patch tracheoplasty.[51]

In summary, stents can be useful as a primary modality for treatment, allowing time for very small children or children in unstable condition to grow and tolerate more complex open repairs if necessary. They can also be used in the postoperative period to support the repair or to salvage the airway in the case of stenosis. Experience in this area continues to grow in this small group of complex patients.

Open Repair

Acquired stenoses are often further complicated by scarring, poor vascular supply, and chronic infection. Tracheal resection and reanastomosis have been widely used in hundreds of adult patients for tracheal stenosis since the 1960s; however, Halsband[52] found only 26 reports of these procedures in children between 1969 and 1984. In general, surgical therapy should be pursued when conservative or nonsurgical therapy fails or is deemed inappropriate. A variety of techniques are available for the surgical management of tracheal stenosis, including tracheoplasty with autologous material, wedge resection, slide tracheoplasty, total resection with end-to-end anastomosis, tracheal homograft reconstruction, and stenting with bioinert materials. Often, multiple techniques must be used.

Tracheoplasty can be performed with rib cartilage as described by Kimura and others.[53] Cartilage is a rigid autologous tissue that derives its nutritional support through diffusion and can survive without a direct vascular supply. Because of this, cartilage has been widely used as a tracheal graft material. The surgical technique involves securing the airway either by a previously placed tracheostomy or by endotracheal intubation, which is performed orally and then converted to a transtracheal site once the trachea is exposed. The area of stenosis is exposed anteriorly and the extent of the stenosis is outlined bronchoscopically, either by palpation with the bronchoscope or using the light of the telescope. The external appearance of the trachea can underestimate the extent of the stenosis.[54] Intraluminal granulation tissue is removed and the scar is incised. A rib graft is harvested (usually a fifth or sixth rib on the right is used) and fashioned as described previously. Perichondrium is preserved on the anterior surface of the rib graft and becomes the luminal surface of the airway. The graft is held in place by interrupted suture material and, depending on the extent of the stenosis, is supported with an endotracheal tube for 5 to 7 days (Fig. 207-7). For longer-term stenting, an Aboulker or T-tube stent can be used. The decision of whether to use cardiopulmonary bypass, extracorporeal membrane oxygenation, or distal tracheal intubation during the procedure is controversial and depends on the site of the lesion and the surgeon's personal preference. Pericardium is the most commonly used alternative to rib augmentation and also has good long-term survival rates (Fig. 207-8).[55-58] Other autologous materials that can be used include periosteum,[59] pedicled muscle flaps,[60,61] composite grafts,[62] the esophagus,[63,64] omentum,[65] and solvent-preserved dura.[66]

Kimura and others[53] were the first to report successful repair of a 1-year-old with complete stenosis of the trachea using costal cartilage. Their experience was updated with an additional four patients in 1988.[67] Long-term survival was 80%, with one death due to respiratory distress 10 months after repair. Complications related to this procedure include anastomotic breakdown, stenosis, and granulation tissue formation at the suture line. Jaquiss and colleagues,[54] among others,[68] described six patients who underwent rib tracheoplasty (mean age, 14 weeks) with an average stenosis of 70% of the total length of the trachea. All patients had survived at a follow-up of 6 months to 7.6 years. Bronchoscopy was performed three times or fewer postoperatively in all but one patient. These authors advocated cardiopulmonary bypass to obtain an unobstructed view of the airway during repair. Lobe and others[66] reported on seven infants with congenital tracheal stenosis, four of whom underwent repair with costal cartilage.[69] One death caused by pneumonia occurred 5 weeks postoperatively.

The experience with costal cartilage tracheoplasty continues to grow. Forsen and colleagues[70] reported on 10 patients with congenital long-segment tracheal stenosis repaired at an average age of 18 weeks with costal cartilage tracheoplasty. They were followed up for an

average of 8 years, and 70% of patients were active without tracheostomy. Kamata and colleagues[71] detailed their experience with 11 infants who underwent tracheobronchial reconstruction with costal cartilage grafts. Similar to other studies, frequent postoperative bronchoscopies were needed, and the use of extracorporeal membrane oxygenation

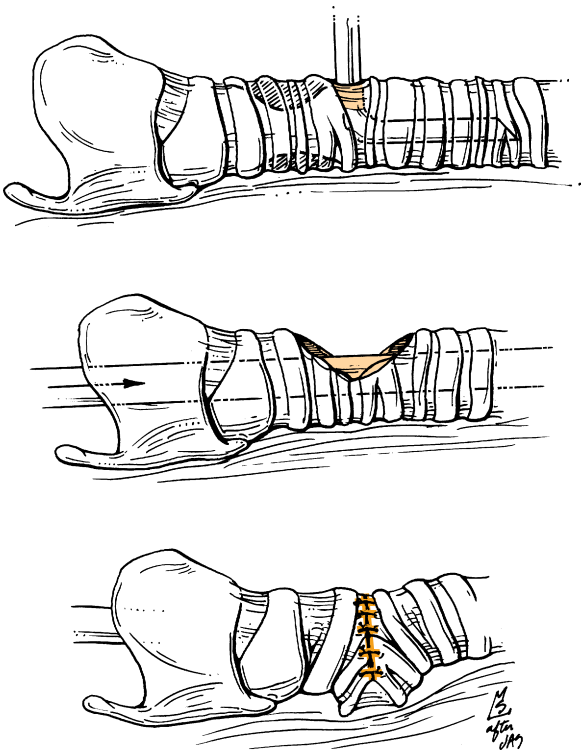

Figure 207-9. Wedge section and closure.

(ECMO) facilitated repair. A common finding in all these series was a high incidence of associated cardiovascular and pulmonary anomalies.

Troublesome to repair is the formation of granulation tissue at the graft site. One advantage of rib graft in contrast to pericardial grafts is that the endotracheal tube does not need to be beyond the proximal edge of the graft for stenting purposes and subsequently decreases granulation tissue formation.[54] DeLorimier and others[72] have suggested that the formation of granulation tissue is more likely if the graft involves 30% or more of the luminal surface. Epithelialization of costal cartilage grafts in the trachea has been demonstrated in both animals and humans.[73] Grillo and colleagues[74] have stated that the use of absorbable (polyglycolic acid polymer) versus nonabsorbable suture material reduces the amount of granulation seen at the anastomotic site.

The technique of wedge resection is most useful for a localized stenosis involving one or two tracheal rings. This method may be useful in small infants in whom the recurrent laryngeal nerve can be difficult to identify. After oral intubation, the lesion is defined and an anterior wedge of trachea is removed. The defect is closed primarily with interrupted sutures. Weber and colleagues[75] used this procedure successfully in four patients with localized stenosis (Fig. 207-9).

Segmental resection is successful for repair of long-segment tracheal stenosis comprising less than 50% of the tracheal length. In children, this operation uses the principles of tracheal repair that were developed for adults.[76] Following endoscopy to outline the extent of the lesion, the stenotic segment is excised. Dissection beyond the stenosis is kept to a minimum to preserve the vascular supply to the trachea. Sutures are placed submucosally and tied extraluminally. Important to the success of the repair is the ability to achieve a tension-free anastomotic suture line. Various techniques can be applied, including suprahyoid release, infrahyoid release, peritracheal mobilization, intercartilaginous incisions, perihilar release, dissection of the pulmonary vasculature, transplantation of the left mainstem bronchus, and neck flexion with chin-to-chest suturing (Fig. 207-10).[77-79]

The results of several authors have been encouraging.[75,78,80,81] Nakayama and others[82] reported on 10 patients, four of whom underwent tracheal resection. They emphasized the association of multiple tracheobronchial and vascular anomalies in these patients and the need for a detailed preoperative evaluation. Healy[69] reported on three chil-

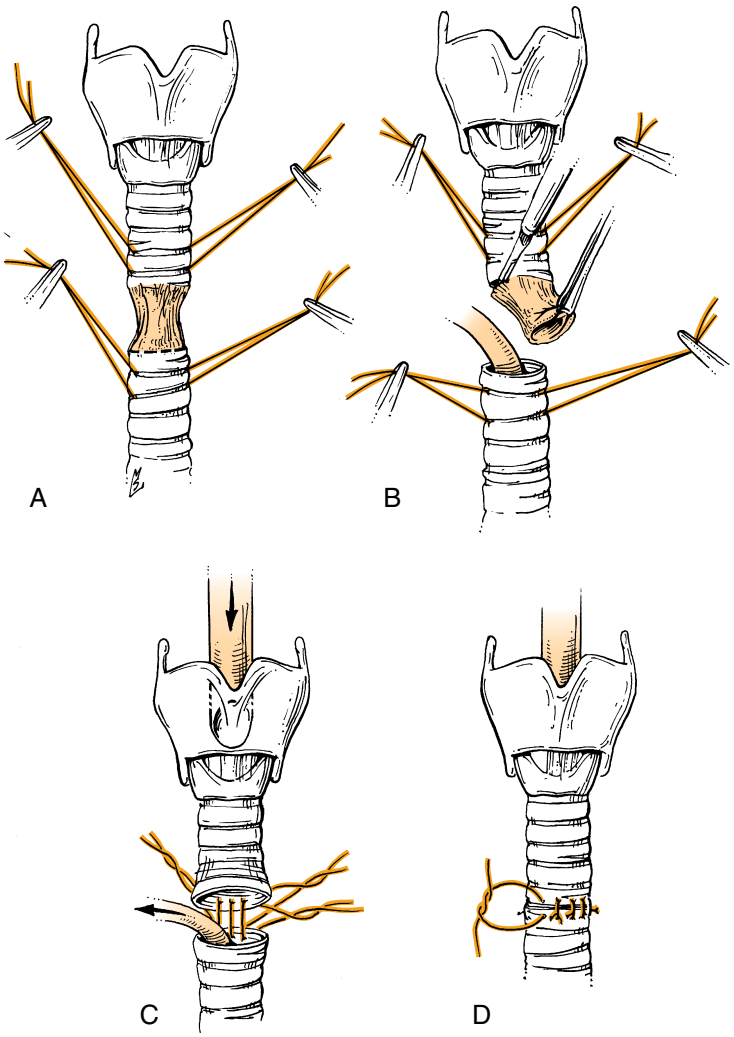

Figure 207-10. **A**, Area of stenosis. **B**, Resection of stenosis with intubation of trachea distally. **C**, Interrupted absorbable sutures placed circumferentially and reintubated from above **(D)**.

dren, ages 4 weeks to 3 years, who were successfully resected. The author thought that three to five tracheal rings could be resected in children without a laryngeal release. He also commented that postoperative endotracheal intubation can often be avoided in adults, but in children the cartilage is still very pliable and may not offer sufficient resistance to tracheal collapse at the anastomotic site. Two patients who required postoperative nasotracheal intubation were not mechanically ventilated but were allowed to breathe spontaneously in an intensive care unit setting and were successfully extubated several days later. DeLorimier and others[72] detailed their experience with 45 patients with tracheobronchial stenoses. Seventeen patients underwent segmental resection, with three anastomotic strictures developing postoperatively. These strictures were resected with success in two patients. In their series of 52 patients ranging in age from 7 weeks to 15 years, Grillo and Zannini[83] undertook segmental resection in 20. Good results were obtained in 17 patients. The remaining 32 patients were treated conservatively, with 24 requiring either a T tube or tracheotomy. In their series of 21 patients with congenital tracheal stenosis, Benjamin and colleagues[84] also treated 12 patients without surgery. This experience lends support to the individualized treatment options and the nonsurgical management of selected patients.

Segmental resection is often not possible due to the length of trachea to be resected. First described by Tsang and others,[85] slide tracheoplasty involves dividing the stenosis transversely in the midportion and then incising the upper segment vertically posteriorly and the lower segment vertically anteriorly. The two ends are then placed over each other, effectively halving the stenotic segment while doubling the circumference. The distance that the tracheal ends need to move is half that of a resection and primary reanastomosis. This fact aids in reducing tension along the suture line, which may be more critical in children than in adults.[51] Grillo[86] described two children (ages 3 months and 3 years) and two young adults, all of whom had complete cartilaginous rings. The stenotic areas were 36% and 50% of the total tracheal length for each group, respectively. Short-term results were deemed good. An advantage to this technique is decreased granulation tissue that is often seen at the site of the cartilage graft reconstruction. Other advantages to this procedure are the avoidance of graft materials, decreased tracheal mobilization, and a good success rate (Fig. 207-11).

Cotter and colleagues[87] reported on 17 patients with congenital tracheal stenosis who underwent tracheoplasty over a 10-year period; 11 underwent augmentation with pericardial grafts or costal cartilage. Five of six patients who had resection and reanastomosis did well for 2 to 9 years after surgery, seven of eight patients with tracheoplasty did well for 2 to 4 years after surgery. This study found that the former group had fewer postoperative bronchoscopies and fewer difficulties with the development of granulation tissue at the suture line. Important in the management of these patients was frequent postoperative bronchoscopy, and the use of cardiopulmonary bypass for some made the operation technically easier. No complications were related to the use of cardiopulmonary bypass. The authors advised segmental resection, when possible, with early extubation to reduce mucosal injury.

Recent reports favor the use of slide tracheoplasty over augmentation with cartilage or pericardial patch grafts for long-segment tracheal

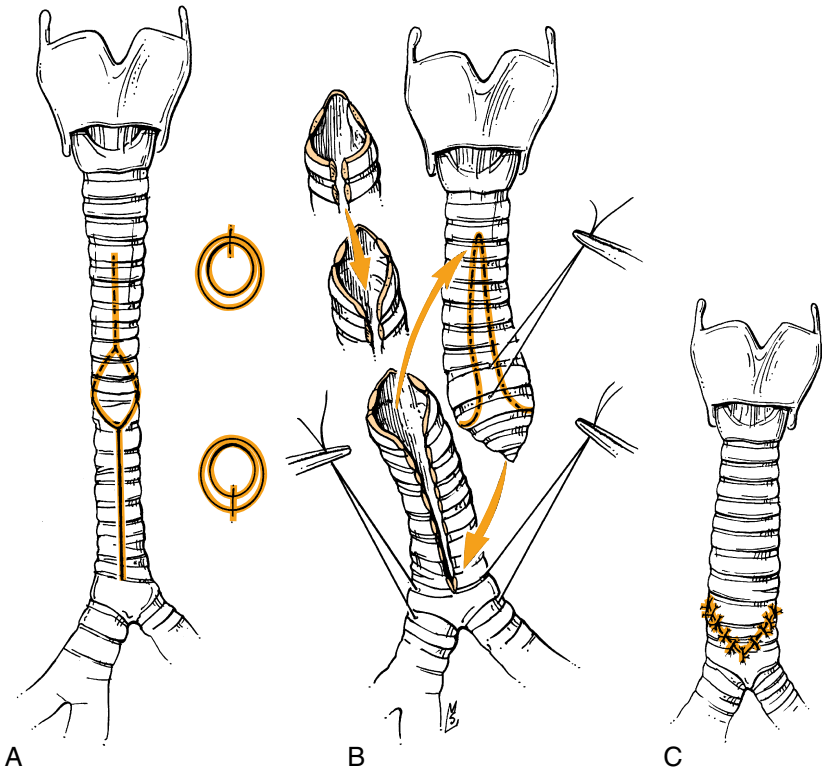

Figure 207-11. Slide tracheoplasty. **A**, Area of stenosis. **B**, The trachea is divided on an angle and then vertically anteriorly and posteriorly. **C**, Surgical result.

stenosis. According to Grillo and colleagues,[88] "Patch tracheoplasty met a previously urgent need but should perhaps be largely reserved for unusual problems." In all juvenile patients, the repaired tracheal segment continues to grow, with complications related to suture line granulomas (two of seven slide tracheoplasty patients) that resolve with a single bronchoscopy without recurrence. Others have reported similar experience with long-term growth of the reconstructed airway and few complications.[88-92]

In the series by Acosta,[93] six patients were treated with resection and reanastomosis and three with slide tracheoplasty. The latter group had favorable outcomes with regard to anastomosis complications such as leaks, mediastinitis, fibrosis, or stenosis. Kim compared eight patients between 12 days and 6 months with congenital tracheal stenosis, four who underwent slide tracheoplasty, three had pericardial patch, and one had resection and end-to-end reanastomosis. Bothersome granulation tissue formation was seen in the pericardial patch subset. Tsugawa compared 17 pediatric patients who underwent slide tracheoplasty with 12 pediatric patients who underwent costal cartilage tracheoplasty and concluded that slide tracheoplasty was the preferred method[94] with similar findings in a group of 10 patients described by Matute.[95] These findings have prompted these authors to recommend slide tracheoplasty as the procedure of choice.

Tracheal homograft transplantation with cadaveric human tracheal homograft is an exciting new modality for the repair of severe long-segment tracheal stenosis in children. Initially described in 1980 in adult patients,[96] 24 children were recently reported by Jacobs and others.[97] An 83% survival rate was achieved, with follow-up ranging from 5 months to 10 years. Tracheal homograft banks exist in Europe, and specimens are fixed in formalin, washed in thimerosal (sodium ethylmercurithiosalicylate), and stored in acetone. The trachea is exposed through a neck incision, a median sternotomy, or both. Cardiopulmonary bypass is used to facilitate the operative field. The anterior part of the trachea is removed, leaving only a posterior tracheal wall intact. Dumon stents are then sutured into the native trachea to provide support for the homograft for 10 to 12 weeks until the graft hardens and reepithelialization occurs. The endotracheal tube is positioned to lie within the lumen of the Dumon stent. The homograft is fashioned to the defect and sutured in place with interrupted sutures (Fig. 207-12).

Postoperative care includes 2 weeks of intravenous antibiotics followed by 4 weeks of oral trimethoprim as well as inhaled albuterol and corticosteroids. No immunosuppression is needed because the thimerosal used in the preparation of the homograft destroys antigenicity. Frequent bronchoscopy is required to remove granulation tissue at the site of the stents.

Advantages to the tracheal homograft include an adequate supply of tissue, which can be placed without suture-line tension, and the presence of a carina, which is needed for distal reconstruction. Ciliated columnar epithelium has been shown to coat the homograft. Tracheal homograft reconstruction is an exciting new approach to severe or recurrent tracheal stenosis.

In 1999, Jacobs and colleagues[98] updated the worldwide experience with tracheal autografts in 31 children. Twenty-one of these patients underwent previous surgical attempts at airway reconstruction, and results were encouraging for both the short and medium terms. Mortality overall was 16%; however, three of the five patients who died had functional airways. Twenty-six patients survived, with 22 patients deemed asymptomatic on follow-up bronchoscopy that showed epithelialization of the grafts. Continued follow-up of these patients is planned in an established database.

Backer and colleagues[99] described six patients with tracheal stenosis resulting from complete tracheal rings that were constructed with partial tracheal resection, posterior end-to-end anastomosis, and anterior repair with the patients' own resected trachea. In four patients, the anterior repair was augmented with pericardial patch. The use of a free tracheal autograft was based on the senior author's observation that the trachea in children with complete tracheal rings was usually longer than average. This technique is more appealing than performing tracheal homografts because the autograft is lined with respiratory epithelium, will not reject from its donor, and has the potential to grow. Intermediate-term results were reported with an additional four patients added to the study in 2000.[100] Nine of ten children were reported on 2 to 44 months postoperatively. One child had dehiscence of the autograft requiring repair within the aortic homograft, and two patients were

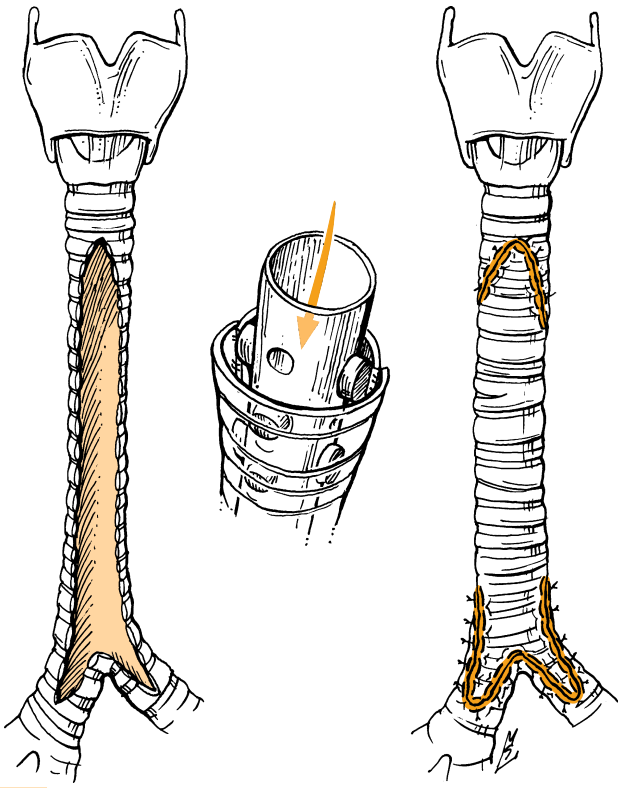

Figure 207-12. Homograft transplant with a Dumon stent.

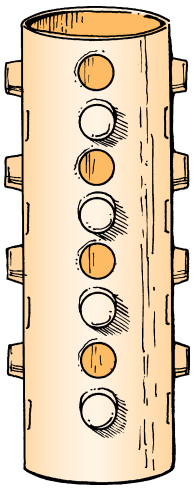

Figure 207-13. Silastic Dumon stent.

trachea dependent. One child died of sepsis and multisystem organ failure, and subsequent autopsy showed that the autograft was well healed. Autografts on serial bronchoscopy appeared to grow with the patient and are difficult to distinguish from the surrounding trachea.

Synthetic tracheal prostheses have not enjoyed the same success as prosthetic devices used elsewhere in the head and neck because the trachea is much more susceptible to infection. Synthetic devices that have been used include ceramic rings, Marlex mesh, and silicone stents.[101] These are complicated by dense granulation tissue reaction, migration of the prosthesis, recurrent stenosis, and the risk of vascular erosion (Fig. 207-13).

Fortunately, over the last few years, several papers have been published looking at these multiple surgical techniques. In a study by Anton-Pacheco and colleagues involving 19 patients from 3 days to 7 years, 14 underwent surgery over a 13-year period. For symptomatic cases with short segment stenosis, defined as less than 30% of total tracheal length, tracheal resection with anastomosis was preferred, and in long-segment stenosis (greater than 70%), slide tracheoplasty was recommended.[102] Backer reviewed a single institution's experience with four surgical techniques over 18 years involving 50 patients. Current management included resection/anastomosis for short stenosis (up to eight rings), and for long-segment stenosis, a tracheal autograft technique later supplanted by the pericardial tracheoplasty procedure in use until 1996.[103] Chui performed a retrospective analysis of 68 patients treated at six centers to determine prognostic factors that influence mortality after repair with either cartilage patch or slide tracheoplasty. No difference was seen between the two techniques, but a higher mortality was seen in two groups of patients: those younger than 1 month of age and those with intracardiac anomalies.[104] These findings were also corroborated by Herrera in 2007 in an excellent review of the literature. In reviewing the literature over a 42-year period, the researcher concluded that short segment stenosis was best treated with resection and long-segment stenosis was best treated with tracheoplasty, with cardiopulmonary bypass as part of the standard of care for these operations.[105]

Complications related to open surgical resection have been addressed by several authors.[52,67,74,106] The most common complication of tracheal reconstruction is the formation of granulation tissue at the anastomotic site or around the stent. This problem is usually managed with bronchoscopic-guided laser removal and with intravenous or intralesional injection of corticosteroid. Anastomotic leak or separation is often caused by excessive tension at the site of resection. Several techniques have been described to lessen the tension, including the supralaryngeal-, tracheal-, and hilar-releasing maneuvers mentioned earlier. Recurrent laryngeal nerve injury is rare and is usually managed conservatively if it is unilateral. Aspiration can also complicate recurrent laryngeal nerve injury and may be seen after thyrohyoid or suprahyoid release.

Complications can be avoided by ensuring several factors before surgery.[107] Ideally, the surgical resection candidate should not be mechanically ventilated, should not be taking steroids, and should not have prior radiotherapy to the area. Muscle flaps between the esophagus and trachea can reduce the incidence of fistula formation. Glottic competence should be evaluated, especially in neurologically compromised patients.

Conclusion

Evaluation and management of tracheal stenosis is a complex undertaking, as evidenced by the numerous methods available for reconstruction. In general, limited tracheal stenoses can be managed endoscopically, whereas longer stenoses are better corrected through an open approach. The trend over the last decade is for segmental resection and reanastomosis for short-segment stenosis and use of slide tracheoplasty or augmentation of long-segment stenosis. The experience with both tracheal homografts and autografts continues to grow. No one surgical method is appropriate for every setting, and often the surgeon must use several therapeutic options. Furthermore, the surgeon must recognize the limitations and complications of each of the various management options to ensure a successful outcome.

CHAPTER TWO HUNDRED AND EIGHT

Foreign Bodies of the Airway and Esophagus

Lauren D. Holinger

Sheri A. Poznanovic

Key Points

- The highest incidence occurs in children 1 to 3 years old.
- Most airway foreign bodies are located in the bronchi.
- Most esophageal foreign body impactions occur in the cervical esophagus, just below the cricopharyngeus muscle.
- An aerodigestive tract foreign body frequently mimics other conditions and is often the result of an unwitnessed episode; the diagnosis must be considered in any patient with prolonged or unusual pulmonary symptoms.
- Complete airway obstruction resulting from a foreign body and esophageal impaction with a battery are emergencies. Delayed diagnosis may lead to complications.
- Esophageal foreign body impaction is frequently associated with vomiting and dysphagia, but may also manifest with respiratory distress.
- There is a high rate of spontaneous passage of esophageal coins into the stomach.
- Negative radiographic findings do not rule out the presence of a foreign body. Generally, chest radiography is an adjunctive procedure to a thorough history and physical examination.
- Communication with the anesthesiologist regarding the anesthetic and endoscopy plan is essential before any surgical intervention.
- Endoscopic instrumentation revolutionized the field of bronchoesophagography, and reduced the mortality associated with aerodigestive tract foreign bodies.
- Careful endoscopic removal of foreign objects under direct vision is the safest management for patients with foreign bodies of the airway and esophagus.
- Stricter industry standards for toy part sizes and increased public awareness have helped to decrease fatalities from choking.

Foreign bodies in the airway, pharynx, and esophagus continue to be a diagnostic and therapeutic challenge for practicing otolaryngologists. Despite improvement in public awareness and emergency care, foreign bodies result in approximately 150 deaths per year in children secondary to asphyxiation.[1] Most deaths occur before hospital intervention.

Although the role of the otolaryngologist begins after the child is evaluated initially by emergency department or primary care physicians, otolaryngologists and primary care physicians should have a high index of suspicion for foreign body aspiration or ingestion. Because a foreign body can mimic other conditions, particularly without a witnessed event, there can be a delay in management that may lead to complications.

Before the 20th century, bronchotomy was the method of choice for airway foreign body removal. Most patients with foreign body aspiration died from the initial event, the attempt at removal, or complications thereof. Although intubation of the airway was suggested at the time of Hippocrates, Killian in 1895 was the first to use a hollow tube to evaluate the tracheobronchial airway.[2] He used this technique to remove a bone from the right main bronchus in 1897, becoming the first to perform endoscopic removal of an airway foreign body.

Endoscopic illumination was initially used in esophagoscopy and was incorporated into a bronchoscope by Jackson,[2] who revolutionized the field of bronchoesophagography with the development of instruments and techniques for foreign body removal. The principles he and his son developed[3] were paramount in reducing the mortality associated with airway foreign bodies and are still the basis of foreign body removal today.

The introduction of the rod-lens telescope in the 1970s greatly improved the visualization of bronchoscopic removal of foreign bodies. Foreign body removal has been performed with topical anesthesia and sedation. With new, safer anesthetic agents and improved anesthesia techniques and monitoring, however, general anesthesia is now routine.

Children frequently swallow objects that pass through the gastrointestinal tract without problems. This also may occur in adults. Foreign bodies occasionally become lodged in the esophagus because of the object's size or shape, narrowing of the esophageal lumen, extrinsic compression, or anatomic abnormalities.

Before the mid-1850s, the most common management for suspected esophageal foreign body impaction was to attempt to push the object into the stomach. Various instruments, including curved hooks, forceps, and even a walking cane, were used. Dupuytren was reported to pinch the neck of patients vigorously to crush a food impaction in the cervical esophagus, allowing it to pass to the stomach.[2] The first esophagoscope used in 1890 by Mackenzie was later improved by Jackson, Ingals, and Mosher. The earliest rigid esophagoscopies for foreign body extraction by Jackson and Ingals were performed on awake patients in a sitting position. Because anesthesia risks have decreased, and instrumentation for endoscopic removal of esophageal foreign bodies has improved, these procedures are now performed with the patient supine and under general endotracheal anesthesia.

Epidemiology

The incidence of airway and esophageal foreign bodies has not changed significantly, but the safety in removal has increased dramatically. Most aerodigestive foreign bodies are esophageal—85% as reported by Hsu and colleagues.[4] Most airway foreign body aspirations occur in patients younger than 15 years old. In this age group, choking-related episodes treated in the emergency department number approximately 29.9 per 100,000 population.[1] The highest incidence occurs between 1 and 3 years of age; 25% of patients are younger than 1 year.[5-9] The reasons toddlers are most susceptible are (1) they lack molars necessary for proper grinding of food; (2) they have less-controlled coordination of swallowing, and immaturity in laryngeal elevation and glottic closure; (3) there is an age-related tendency to explore the environment by placing objects in the mouth; and (4) they are often running or playing at the time of ingestion.[10] Older children and adolescents may have an anatomic abnormality[11] or a neurologic impairment.[12] Accidental aspiration or ingestion of objects tends to be twice as common in boys. Vegetable matter is seen in approximately 70% to 80% of airway foreign body ingestions; the most common are peanuts in the United States, watermelon seeds in Egypt,[13] and pumpkin seeds in Greece.[14] The percentage of aspirated and ingested metallic foreign bodies, especially safety pins, has decreased, primarily because of the widespread use of disposable diapers. Plastic pieces constitute approximately 5% to 15% of airway foreign bodies; plastic pieces tend to remain longer because they are inert and radiolucent.

The most common esophageal foreign bodies are coins (75% of cases).[5-9] Meat and vegetable matter impactions are less common in children. Round objects, trinkets, disk batteries, and sharp objects constitute less than 20% of impacted esophageal foreign bodies. The duration of impaction before endoscopic removal is less than 24 hours in most patients, more than 1 week in 6%, and of unknown duration in 10%.[6,7]

Of patients with multiple esophageal foreign body impactions, 80% have an esophageal anomaly on further evaluation.[6] Of patients with recurrent esophageal foreign bodies, 19% have esophageal anomalies that previously required surgical repair.

Location

Most airway foreign bodies become lodged in the bronchi because their size and configuration allow passage through the larynx and trachea (Fig. 208-1). Larger objects become impacted in the larynx or trachea, sometimes causing complete obstruction, which is an acute emergency. Bronchial foreign bodies are more common in the right main bronchus in adults, which is thought to be caused by the position of the carina to the left of the midline and its lesser angle of divergence from the tracheal axis.[15] Several authors report airway foreign bodies in children with equal frequency in the right and left main bronchi, with no clear explanation for this occurrence.[2,16,17]

Most esophageal foreign body impactions occur in the cervical esophagus just below the cricopharyngeus muscle (Fig. 208-2).[5,6,8] Another 4% to 5% of esophageal foreign bodies become lodged at the midesophagus or distal esophagus, often caused by extraluminal compression by the aortic arch or left main bronchus (Fig. 208-3). Esophageal foreign body impactions also can occur above an esophageal stricture.[6]

Acute Airway Obstruction

Complete airway obstruction resulting from a foreign body is an absolute emergency. Food (e.g., hot dogs, candies) and nonfood objects (e.g., toys, balloons) commonly become lodged in the larynx and trachea. Increased public awareness, availability of emergency personnel, and the widespread use of the Heimlich maneuver have greatly reduced the mortality of acute obstruction.[18] The most important factor in reducing mortality is recognition of the person in acute airway distress. Coughing and gagging indicate partial obstruction. Older children and adults may signal choking by grasping the neck.

The Committee on Accident and Poison Prevention of the American Academy of Pediatrics developed guidelines in accord with the American Red Cross and the American Heart Association for manage-

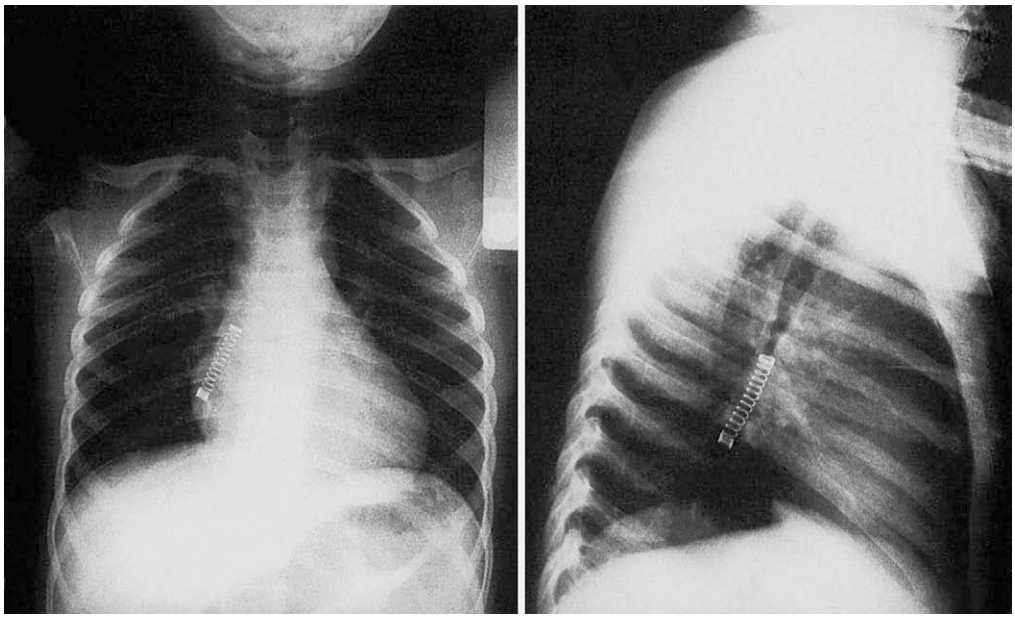

Figure 208-1. Posteroanterior and lateral views of a pen spring in right main bronchus.

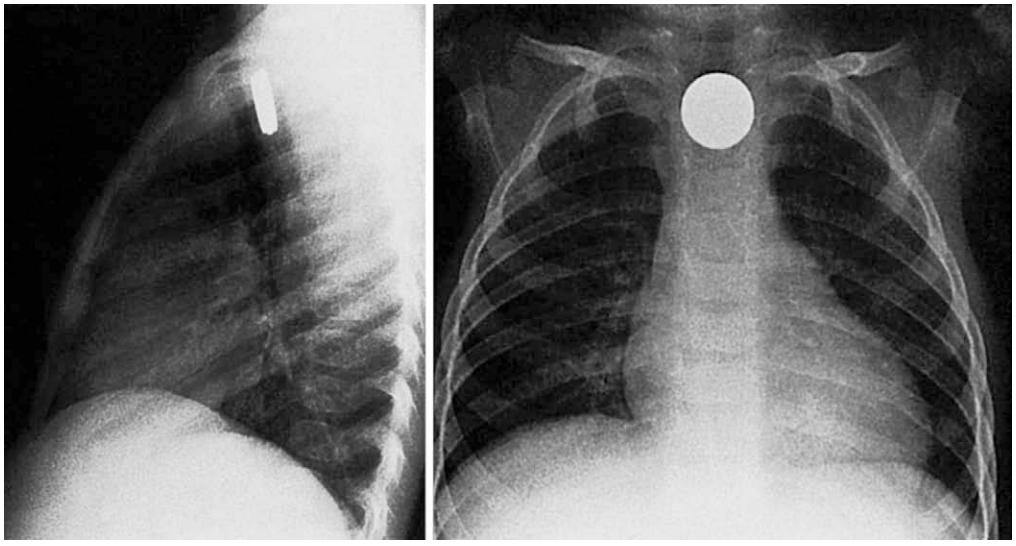

Figure 208-2. Posteroanterior and lateral films of two pennies and a nickel in a typical esophageal location immediately below the cricopharyngeus.

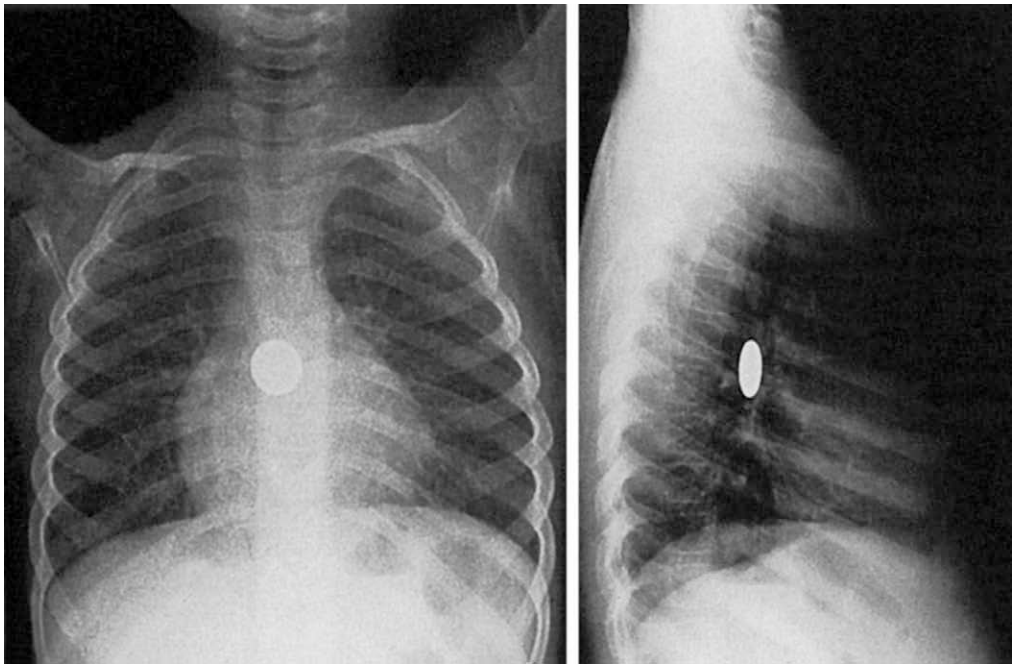

Figure 208-3. Posteroanterior and lateral chest films of a coin in the midesophagus.

ment of choking victims.[19] For infants, rescue breaths and chest compressions are recommended. Children older than 1 year require gentle abdominal thrusts while supine. Older children and adults are positioned standing, sitting, or recumbent for the Heimlich maneuver. Back blows or abdominal thrusts in individuals with only partial obstructions could lead to complete obstruction and are not recommended.

Symptoms

Foreign body aspiration is suspected when a victim has acute choking or severe coughing with respiratory distress. The diagnosis sometimes is obscured if the event is unwitnessed in a young child. Some children do not admit to aspiration because of fear of punishment. Symptoms of foreign body aspiration can mimic conditions such as asthma, croup, and pneumonia. Onset of wheezing in an otherwise healthy child should prompt suspicion of foreign body aspiration.

There are three clinical phases of foreign body aspiration.[15] The initial phase consists of choking, gagging, and paroxysms of coughing or airway obstruction that occur at the moment of aspiration. The choking, gagging, and coughing subside during the asymptomatic phase when the foreign body becomes lodged, and the reflexes fatigue. The asymptomatic phase can last hours to weeks. Complications occur in the third phase, when obstruction, erosion, or infection causes hemoptysis, pneumonia, atelectasis, abscess, or fever.

A careful history and physical examination are most important in diagnosing foreign body aspiration. Determining the site of the obstruction is important in the management of the problem.

Laryngeal Foreign Bodies

A foreign body in the larynx may constitute an airway emergency that requires lifesaving first aid before transport to the hospital. Irregular foreign bodies or orientation in the sagittal plane may produce only

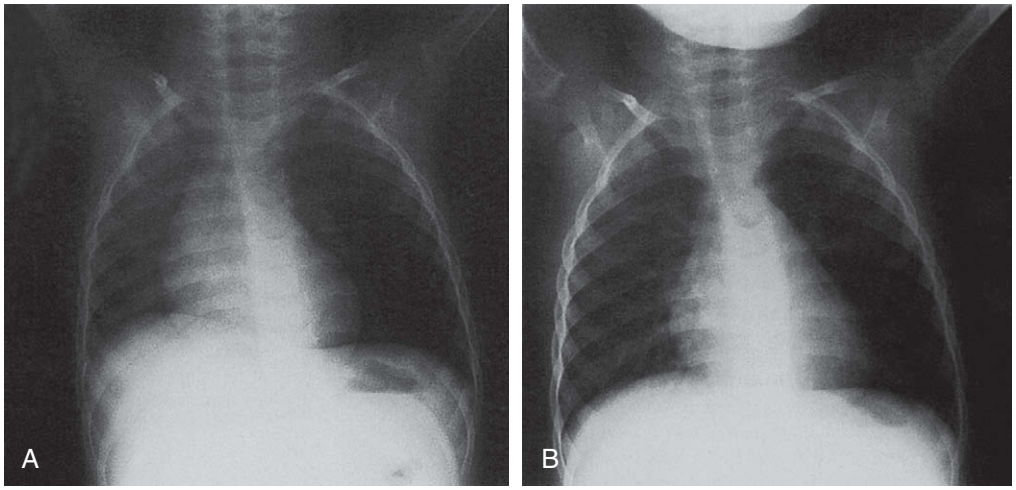

Figure 208-4. **A** and **B,** Expiratory **(A)** and inspiratory **(B)** chest films show hyperinflation on side of left bronchial foreign body (a peanut fragment). This is a typical early finding.

partial obstruction, allowing adequate air movement around the obstruction. Resulting laryngeal edema can lead to complete obstruction. Typically, these patients have symptoms of obstruction and hoarseness. Some symptoms can mimic croup.[3] Delayed diagnosis may lead to complications.

Tracheal Foreign Bodies

Patients with tracheal foreign bodies are seen in similar fashion, but typically do not have hoarseness. Jackson and Jackson[3] described three signs associated with tracheal foreign bodies: the "asthmatoid wheeze," the "audible slap" produced from foreign body contact with the trachea, and the "palpable thud" over the trachea. As with laryngeal foreign bodies, edema can progress to complete obstruction.

Bronchial Foreign Bodies

Of airway foreign bodies, 80% to 90% are found in the bronchi.[20] These patients typically have a triad of cough, wheezing, and decreased breath sounds. One large series reported that 65% have the classic triad,[17] but 95% have at least one finding.[16]

The asymptomatic phase may give a false sense of security that the problem has resolved and lead to a delay in diagnosis. Chest auscultation may reveal decreased breath sounds or wheezing. Sudden onset of wheezing is particularly suggestive of a bronchial foreign body, especially if unilateral, but may be a subtle finding.[21] Occasionally, bronchial foreign bodies can cause respiratory compromise as a result of swelling of dried vegetable matter (e.g., dried beans and peas) or edema around the object, producing complete obstruction and lobar collapse. Movement of the foreign body from one main bronchus to the other produces respiratory distress, resulting from obstruction of the previously normally ventilating lung.

Esophageal foreign body impaction is most frequently associated with vomiting, odynophagia, dysphagia, and ptyalism.[5-8] If the ingestion is witnessed, gagging or choking may be reported. A large foreign body may cause symptoms of airway obstruction and cough caused by compression or irritation of the upper airway. In long-standing esophageal foreign body impaction, fever and other symptoms of respiratory infection may be present.[6]

A careful history and physical examination are the first steps necessary to diagnose esophageal foreign body impaction. Appropriate radiographic evaluation further aids diagnosis and management.

Radiographic Evaluation

Laryngotracheal Foreign Bodies

Airway films—high-kilovolt posteroanterior and lateral soft tissue radiographs of the neck—are the radiographic examination of choice to identify laryngeal and tracheal foreign bodies. Chest radiographs are ordered before intervention. Neck films may show subglottic narrowing. Esclamado and Richardson[20] reported that 92% of patients with tracheal foreign bodies had abnormal neck radiographs, whereas 50% had normal chest films. When such children do not respond rapidly to medical management, foreign body aspiration must be ruled out.

Bronchial Foreign Bodies

Children with bronchial foreign bodies can be radiographically normal or may show obstructive emphysema (air trapping or hyperinflation—an early finding) and atelectasis or consolidation (late findings). Even if the diagnosis is strongly suspected by history and physical examination, posteroanterior and lateral chest radiographs are performed. Chest radiography generally is an adjunctive procedure because the history and physical examination are sufficient to suspect a bronchial foreign body.

During normal respiration, the airway dilates with inspiration and contracts on expiration. This respiratory cycle can be altered by the presence of bronchial foreign bodies.[22] Small objects may cause no radiographic abnormalities. Foreign bodies that obstruct mainly on expiration generate a check-valve effect, resulting in hyperinflation of the affected side and mediastinal shift to the opposite side (Fig. 208-4). This is a typical early finding. A ball-valve effect is produced later when foreign bodies obstruct on inspiration and open on expiration, producing atelectasis on the affected side and a mediastinal shift toward the affected side (Fig. 208-5). When the object completely obstructs the bronchus, a stop-valve effect occurs, leading to consolidation of the lobe involved.

Inspiratory and expiratory chest films can aid in the diagnosis, showing hyperinflation on expiratory films or atelectasis on inspiratory films. In younger children who cannot cooperate, lateral decubitus films may help. The dependent lung should collapse normally, but remains inflated in bronchial obstruction. Fluoroscopic evaluation is of little benefit; decreased diaphragmatic movement on the side of the obstruction is helpful in only 50% of cases.[16] Simultaneous biplane fluoroscopy is used for extraction of radiopaque foreign bodies in the lung periphery.

Radiographic findings often suggest but do not diagnose foreign body aspiration. Asthma and mucous plugging can simulate foreign body aspiration. Mu and associates[23] reported that 35% of patients having normal radiographic studies were later found to have bronchial foreign bodies. Other studies show the lack of sensitivity or specificity of radiographs in diagnosing airway foreign bodies.[24,25] In cases of suspected foreign bodies, endoscopic evaluation is important because negative radiographs are not enough to rule out the presence of a foreign body.[24]

Esophageal Foreign Bodies

When an esophageal foreign body is suspected by history and physical examination, a radiologic evaluation is performed to assess its location and size, and to anticipate the possibility of multiple foreign bodies. Posteroanterior and lateral airway films and posteroanterior and lateral chest films, including the abdomen, are performed. Foreign bodies rotate to the greatest diameter of the lumen; flat objects in the esophagus usually are oriented in the coronal plane.[26] It is imperative to obtain a lateral airway and chest film to evaluate for possible battery ingestion because a battery can easily mimic a coin on posteroanterior view.

There is a high rate of spontaneous passage of esophageal coins into the stomach.[27] Predictors for a high rate of spontaneous passage include location in the distal esophagus, male gender, and age older than 5 years.[28] An observation period of 8 to 16 hours is considered appropriate management in otherwise healthy children with asymptomatic esophageal coins.[29] A repeat radiograph is warranted before attempted removal to confirm the location of the coin. A handheld metal detector may improve the timing and ease of confirming the location of blunt metallic foreign objects within the esophagus just before administration of general anesthesia.[30]

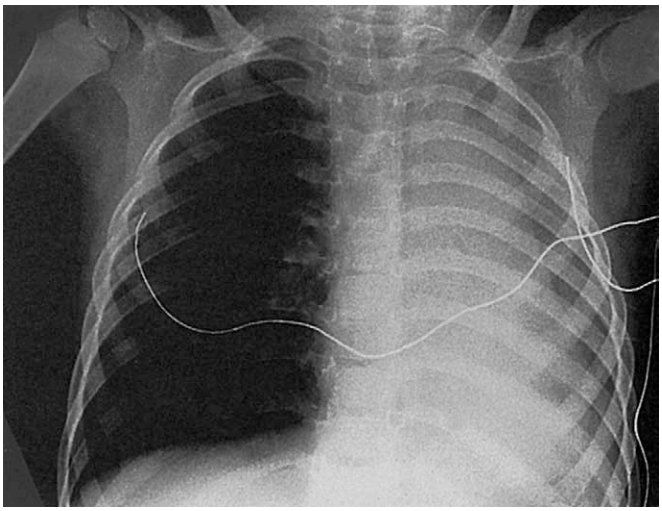

Figure 208-5. Anteroposterior chest film of left lobar collapse secondary to candy corn in the left main bronchus.

In rare cases in which an esophageal foreign body was not found on initial endoscopy and migrated extraluminally, fluoroscopy with contrast material may aid in preoperative location of the object. Open surgical exploration is rarely required to retrieve a foreign body.[26]

Management

Most patients who arrive at the hospital with airway foreign bodies have passed the acute phase and are no longer in respiratory distress. Patients in respiratory distress are given support until the endoscopy team can safely attempt removal. This support may include oxygen, heliox,[31] or intubation. With rare exceptions, esophageal foreign body impactions are not dire emergencies. There is time to obtain a history regarding the ingestion and a pertinent medical history. An inadequate diagnostic workup and hasty preparation of the operating suite likely lead to a poor outcome. Other associated conditions, such as tetanus immunization status or blood lead levels,[32] should be appropriately ascertained and treated.

The standard radiographic posteroanterior and lateral airway and chest films may give adequate information for foreign body removal. If the foreign body is sharp or irregularly shaped, a radiograph in the plane of the greatest dimension of the foreign body may help plan removal. If a suspected esophageal foreign body is radiolucent, a barium contrast study should be avoided because it would delay endoscopy in that the patient can no longer take anything by mouth, and the foreign object may be obscured by the material swallowed. Generally, the patient should take nothing by mouth for 6 hours, and then be adequately hydrated.

The basic principles of endoscopic foreign body removal have not changed since Jackson's time.[3,8] The type and size of endoscope depend on the age of the patient and the location of the object. Foreign body forceps are selected on the basis of practice with a similar object, preferably a duplicate brought in by the patient's family. It is important that the operating room personnel be familiar with the planned procedure, and that communication with the anesthesiologist regarding the anesthetic and endoscopy plan has occurred.

Equipment

Age-appropriate equipment for endoscopic foreign body removal is carefully selected before the patient is brought to the operating room (Table 208-1). Equipment should be in good working order and checked before the procedure. All members of the endoscopy team should be familiar with the location, setup, and use of the instrumentation. If there is inadequate equipment or a lack of trained personnel, transfer of the patient to an adequately equipped center with an experienced endoscopy team should be considered.

Table 208-1

Guidelines for Selection of Bronchoscope, Esophagoscope, and Laryngoscope for Diagnostic Endoscopy by Age

Mean Age (Range)	Bronchoscope Size*	mm*	Laryngoscope Size*	Esophagoscope Size*
Premature infant	2.5	3.7	8	4
Term newborn (newborn to 3 mo)	3	5.8	8	4-5
6 mo (3-18 mo)	3.5	5.7	9	5-6
18 mo (1-3 yr)	3.7	6.3	10.5	6

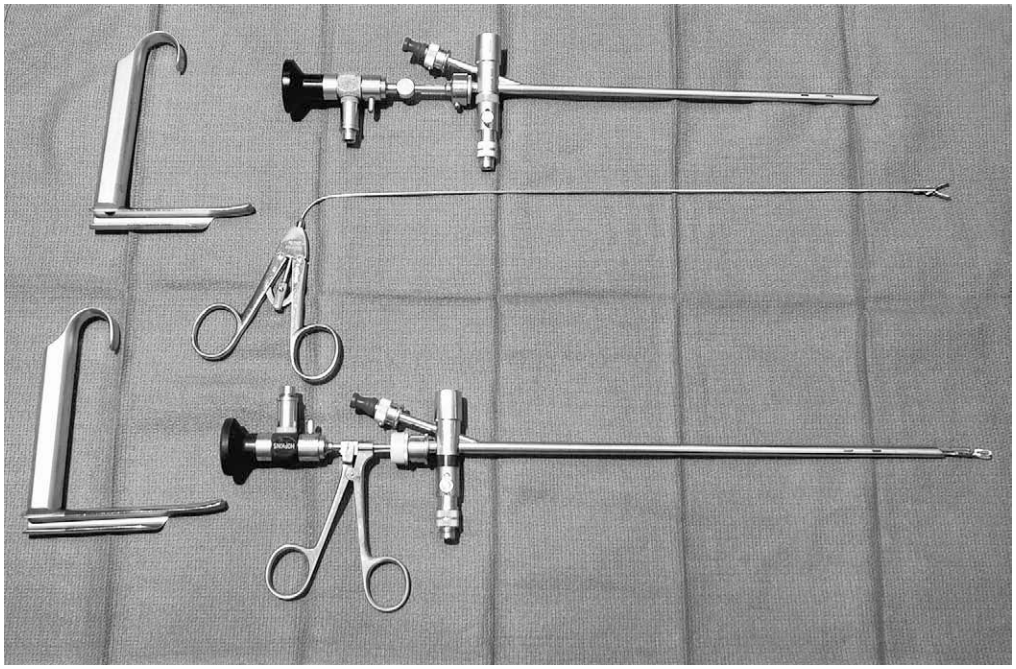

Figure 208-6. Instruments for endoscopic removal of an airway foreign body.

Laryngoscopy visualizes laryngeal foreign bodies and facilitates passage of a bronchoscope. Preferred bronchoscopes with a rod-lens telescope are the Doesel-Huzly bronchoscopes (Karl Storz) (Fig. 208-6). Age-appropriate sizes minimize laryngeal edema. For airway foreign bodies, two bronchoscopes are prepared so that if one fails, another is immediately available. For esophageal foreign bodies, an esophageal speculum and appropriate-sized esophagoscope for the patient's age and size are chosen. Suctions and forceps should be checked to ensure they are of adequate length to be used with the endoscopy equipment. Active or passive action forceps may be used; in most situations, the improved visualization achieved with optical forceps is preferable. Because of their size, optical forceps may impair the ability to ventilate a patient adequately through the bronchoscope; alternate forceps should be readily available.[3,7,8] With all endoscopic foreign body procedures, safety glasses should be worn by the endoscopy team, and a dental guard should be placed before introduction of the endoscope.

Anesthesia

Unless the patient is in extremis, foreign body removal is performed under general anesthesia to provide optimal airway control and patient comfort. The plan for induction and maintenance of anesthesia, and the method of evaluation and removal of the foreign body should be communicated preoperatively between the anesthesiologist and endoscopist. Patients are given nothing by mouth for an adequate time to reduce the risk of aspiration. Patients are placed supine for mask induction using volatile inhalational agents for children. Eye protection prevents corneal abrasions. Spontaneous respiration is maintained. The larynx is topically anesthetized with 1% to 4% lidocaine to inhibit laryngeal reflexes and to reduce the incidence of laryngospasm.

For a suspected laryngeal foreign body, patients are preoxygenated. After mask induction, anesthesia is maintained with an insufflation catheter through the nares into the hypopharynx. For tracheobronchial foreign body removal, the laryngoscope tip is placed in the vallecula to expose the larynx for passage of the bronchoscope. The patient breathes through the bronchoscope until the conclusion of the procedure. For esophageal foreign bodies, the patient undergoes endotracheal intubation. The endotracheal tube prevents inadvertent aspiration of the foreign body into the airway during attempted removal, and minimizes any tracheal compression caused by a rigid esophagoscope.

Technique

For bronchial foreign bodies, the healthy bronchus is examined first. The bronchoscope is positioned above the foreign body, and secretions are gently suctioned to expose the object fully. Before and during the attempt at removal, 100% oxygen is given. The forceps are placed through the bronchoscope, and the foreign body is engaged. The bronchoscope, forceps, and foreign body are removed as a unit, and the bronchoscope is returned immediately to the airway for ventilation and assessment for other foreign bodies. As previously mentioned, simultaneous biplane fluoroscopy can be used for extraction of radiopaque foreign bodies in the lung periphery.[33]

Occasionally, attempts at endoscopic retrieval fail, and thoracotomy is required. If the foreign body is too large to be extracted through the larynx, the foreign body may be broken into small fragments and removed through the bronchoscope. Alternatively, a tracheotomy is performed, and the foreign body is removed through the neck, maintaining the airway and delivering the object with bronchoscopic guidance.[34,35]

For esophageal foreign body removal, an esophageal speculum or esophagoscope is passed through the right side of the mouth and directed toward the pyriform sinus. The scope is angled toward the sternal notch. The esophageal lumen is kept in view at all times while the esophagoscope is gently advanced until the foreign body is visualized. The foreign body is engaged with the forceps; the esophagoscope is advanced toward the object; and the foreign body, forceps, and esophagoscope are removed as a single unit. If multiple foreign bodies are suspected, the esophagoscope is reinserted to assess the condition of the esophageal mucosa, and to identify additional foreign bodies below the primary one. Multiple foreign bodies are found in 5% of patients (Fig. 208-7).[6]

Removal of Sharp Objects

Extraction of sharp, pointed, or unusually shaped objects can be extremely challenging.[7,36] Locating the point is crucial. Usually, the tip of a pointed object engages the mucosa, causing the object to tumble and proceed with the point trailing. Pointed objects may be bendable or breakable; analysis of a duplicate may aid in this determination. The endoscope is aligned parallel to the long axis of the airway or esophagus to minimize the likelihood of damage to the surrounding mucosa. During the extraction, the object first is moved distally to disengage the point.

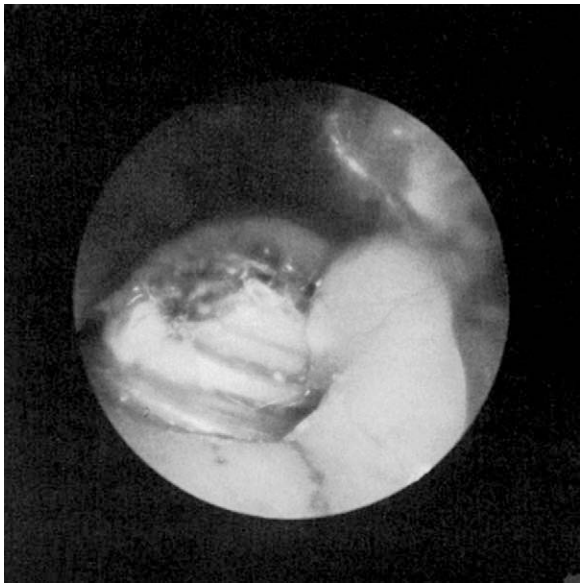

Figure 208-7. Multiple coins in the esophagus of a patient with a history of tracheoesophageal fistula.

Pin-bending forceps may be used for bendable objects; this reconfigures the object's point to trail on removal. Safety pins are uniquely challenging; pins that become lodged are invariably open. The incidence of safety pins as foreign bodies has decreased with the introduction of disposable diapers. Two methods of removal are suggested: (1) sheathing the point within the endoscope while locking the forceps closed to hold the keeper against the outside of the tube particularly during extraction through the larynx, and (2) gastric version (under fluoroscopic guidance) of esophageal safety pins, using rotation forceps to flip the safety pin point down within the stomach. The Clerf-Arrowsmith pin-closing forceps risk entanglement with the safety pin, which becomes virtually impossible to remove. This dangerous tool is not recommended. If a sharp object is severely impacted or embedded, an open surgical approach may be the safest method of foreign body removal.[5,7]

Long or large objects in children younger than 2 years may not pass through the duodenum. It is preferable to remove these objects from the stomach endoscopically before they migrate further or perforate a bowel wall. If a disk battery traverses beyond the esophagus, and the patient remains asymptomatic, parents are advised to check the patient's stools for passage and to return immediately to the hospital if fever or abdominal pain occurs.[7,37] An abdominal film should be obtained for delayed passage. Children younger than 6 years who have swallowed a battery 15 mm in diameter or larger that has not passed out of the stomach within 48 hours should undergo endoscopic removal. Many batteries 15 mm or greater do not pass out of the stomach and cause corrosive injury in an acidic environment.

Disk Battery Ingestions

Disk batteries are commonly used in hearing aids, calculators, watches, and other portable electronic devices. The peak incidence of ingestion occurs at age 1 to 2 years. In 33% of cases, the ingested battery is from the child's hearing aid.[38] A patient with a history of ingestion and esophageal lodging of disk batteries (also known as button batteries) requires immediate action.[7,37,38] In 1 hour, the esophageal mucosa may be damaged; in 4 hours, leakage of caustic battery contents may cause erosion through the muscular wall of the esophagus; and within 6 or more hours, an esophageal perforation leading to mediastinitis, tracheoesophageal fistula, or death may occur.[7,37,38] If esophageal lodging of a disk battery is suspected, radiography localizes the battery. An immediate esophagoscopy is performed to remove the battery and assess the patient's esophageal mucosa. Most batteries of this type are of a smaller diameter (<15 mm) and usually traverse the gastrointestinal tract with only minor injury. Larger button batteries (≥15 mm in diameter) are more likely to lodge in the esophagus or stomach, causing serious corrosive injury. Mercuric oxide–containing batteries can cause systemic mercury poisoning if they open in the gastrointestinal tract. The imprint code of a duplicate battery should be conveyed to a Poison Control Center or Button Battery Ingestion Hotline for specific information.[38]

Pill Ingestions

Medications in pill form may lodge within the esophagus because of delayed esophageal transit, dry swallow (i.e., swallowing without liquids), adherent tablets, or a supine swallow. The pill may cause caustic injury through various mechanisms because of prolonged contact with the esophageal mucosa.[39] More than 70 different medications in pill form have been reported to cause caustic injury. Antibiotics and antivirals account for 60% of cases. Most heal without significant injury. Anti-inflammatory medications have been reported in fewer cases, but a third of these patients have had significant hemorrhage or had strictures develop.[39]

Most injured patients have no predisposing factor other than improper swallowing of pills; however, any functional or anatomic abnormality of the esophagus may give rise to this condition. Patients usually are seen with sudden onset of retrosternal pain, dysphagia, and odynophagia.[39] Fever, hematemesis, and dehydration are less common presenting symptoms. Often, patients recall the sensation of a pill sticking in the esophagus before the onset of symptoms, or have swallowed a pill without water or at bedtime.[39] Most symptoms resolve over days to weeks.

Endoscopy should be considered if the symptoms are severe, persistent, or atypical, or if hematemesis or a stricture is suspected.[39] Esophagoscopy can differentiate other potential causes, such as infection, malignancy, or gastroesophageal reflux disease. In addition, any pill remnants may be removed, and an accurate assessment may be made of the degree of mucosal injury. The most common findings on esophagoscopy are small, shallow, discrete ulcers that may be single or multiple. Large, circumferential lesions several centimeters in length have been reported.[39] Most shallow ulcers heal spontaneously. Deep injuries may lead to stricture formation and perforation. Education of the public and health care personnel in methods of proper pill swallowing is important to prevent pill-induced esophageal injuries.

Esophageal Perforation

Perforation of the esophagus in a patient with an impacted esophageal foreign body may be caused by the object itself, by the length of time that the object has been lodged, or by attempts to retrieve the object.[8,26,38,40-42] If perforation is suspected preoperatively, esophageal perforation may be diagnosed on preoperative radiographic evaluation. Cervical subcutaneous emphysema, retroesophageal abscess, or an obvious extraluminal portion of the esophageal foreign body may be apparent.[5] Fever with tachycardia, tachypnea, and increased pain all may be early signs of a perforation.[5,43] With early recognition and management, the mortality rate for esophageal perforation has decreased from 60% to 9%.[42] After esophagography has been performed to locate and evaluate the extent of the injury, early institution of nothing by mouth and broad-spectrum antibiotics may be all that is necessary in pharyngoesophageal perforations,[41,43] the most common area injured in endoscopic removal of esophageal foreign bodies. In more severe injuries, drainage, closure, or more complex surgical repairs may be necessary.

Postoperative Management

After esophagoscopy for foreign body extraction, children are observed and given nothing by mouth for 4 hours. Patients are monitored for fever, tachycardia, and tachypnea, all signs of possible perforation. Antibiotics are not routinely given unless significant esophageal injury is evident.

When appropriate-sized bronchoscopes are used for brief procedures, racemic epinephrine or corticosteroids are not given. Chest physiotherapy may help to clear inspissated secretions. A routine postoperative radiograph is unnecessary unless the patient's symptoms

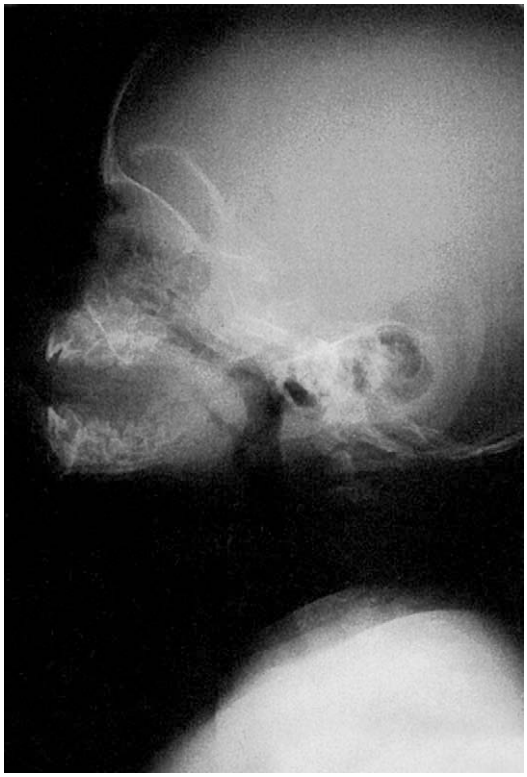

Figure 208-8. Lateral neck film reveals retroesophageal abscess.

persist or progress. When extraction attempts fail or are incomplete, patients are rested for several days, and then returned to the operating room for repeat endoscopy. One more recent study examined factors associated with increased pulmonary recovery time after foreign body removal. A recovery time of more than 1 week was associated with preoperative inflammatory findings by radiologic study, procedure time greater than 50 minutes, and worsening postoperative radiologic findings.[44]

Complications

Before the 20th century, the mortality rate caused by foreign body aspiration was high, with most patients dying of complications. In 1882, Weiss reported 937 cases for which bronchotomy was performed, with a 27% mortality rate; however, 23% died without management.[2] Jackson's techniques reduced the mortality rate to about 2%.[22] The present rate is 2% or less.[4,11,16,17,45,46]

Most complications are the result of delayed diagnosis and treatment.[17,21,47,48] Earlier diagnosis correlates with fewer complications.[48] Of laryngotracheal foreign bodies, 45% were associated with major complications, and 67% were associated with major complications when the delay was longer than 24 hours.[20] The introduction of rod-lens telescopes has reduced the incidence of missed or incomplete removal of foreign bodies, reducing complications further.

Pneumonia and atelectasis are the most common complications after bronchial foreign body removal. Patients usually respond to intravenous antibiotics and chest physiotherapy. Bleeding can occur because of granulation tissue or erosion into a major vessel. Pneumothorax and pneumomediastinum can result from an airway tear. Small perforations typically heal spontaneously, and do not require specific management. Impaction of the foreign body can cause airway obstruction, converting a controlled situation into an emergency. Laryngeal inflammation and edema have decreased significantly with the use of appropriate-sized endoscopic equipment.

Long-term complications (e.g., granulation tissue, stricture formation) can occur at the site where the foreign body is lodged. Certain foreign bodies are more likely to cause more complications.[48] The oils of nuts may contribute to edema and granulation tissue.[3]

The most frequent complications of endoscopic esophageal foreign body removal are categorized as those occurring before endoscopy, during endoscopy, and after endoscopy.[39] Vomiting and respiratory distress are most common preoperatively. During esophagoscopy, the endotracheal tube may be dislodged, and the patient may have cricopharyngeal spasm, esophageal mucosal injury, or perforation. After esophagoscopy, vomiting, aspiration, a second missed foreign body, and fever are the most common complications. Esophageal perforation, retroesophageal abscess, mediastinitis, and death are rare (Fig. 208-8). In several large series of endoscopic esophageal foreign body removal, there were no life-threatening complications.[5,6,41,42]

Controversies in Management

Nonendoscopic means of foreign body extraction have been suggested. These methods have been detrimental in some cases, causing emergent situations and even death. Although chest physiotherapy and bronchodilators have been suggested as a management for airway foreign bodies, this proposal has been retracted.[49]

Flexible bronchoscopic removal of airway foreign bodies seems attractive, with more recent literature advocating its use in adults and increasing experience in pediatrics as a diagnostic tool.[9] Unless the endoscopist also is skilled at rigid bronchoscopy, flexible bronchoscopic foreign body removal in children is not recommended,[25] especially in small children. The main problems are poor control of the airway and of the foreign body itself.[9,25]

For impacted esophageal foreign bodies, bougienage with esophageal dilators or a nasogastric tube has been proposed to push foreign bodies into the stomach.[2,49] This blind technique may cause esophageal injury and is not universally accepted. Foley catheter removal with fluoroscopic control of blunt radiopaque esophageal foreign bodies has been recommended for a single object lodged below the cricopharyngeus for a short duration.[23,42,50] Advantages include reduced cost and avoidance of general anesthesia. Few serious complications have been reported when this technique was used in healthy children. Other authors[6,26,49] point out that the risks of general anesthesia in these patients are small. This technique does not allow a postretrieval assessment of the esophageal mucosa or identification of a nonradiopaque second foreign body. Because the coin is not grasped using this technique, loss of control of the coin at the level of the posterior pharynx can result in an airway emergency. In addition, there is a risk of vomiting and aspiration with an unprotected airway, and young patients who have this procedure while awake and restrained in a steep head-down position may experience emotional trauma.

Use of various pharmacologic agents in the management of esophageal foreign bodies has also been proposed. Papain (meat tenderizer) has been used in patients with impacted esophageal meat boluses.[49] Papain was given as a 5% solution to adult patients, with the meat passing in most instances. However, there were at least two cases of mediastinitis and death in these patients caused by necrosis of the esophagus and perforation. Glucagon produces relaxation of the smooth muscle of the esophagus, promoting passage into the stomach. One open-label study in pediatric patients failed to show a higher incidence of passage in patients who received glucagon versus placebo.[51] Sumatriptan prolongs fundic relaxation and delays gastric emptying. Studies conducted so far have revealed an increase in the rate of gastroesophageal reflux and the number of esophageal mother waves.[52,53]

Flexible esophagoscopy has been used for removal of blunt objects or meat impaction. Sharp objects pose a greater risk, however, because of the inability to sheath the object as with a rigid esophagoscope.[36]

Careful endoscopic removal of foreign objects under direct vision is the safest management for patients with foreign bodies of the airway and esophagus. Prevention is ideal, with increased education of the public, especially individuals who supervise children—parents, teachers, and other care providers—on age-appropriate foods and household objects. Stricter government and industry standards for toy part sizes and appropriately sized containers have helped to decrease fatalities from choking, but have come about only through the cooperation of physicians, consumer advocacy groups, and governmental public health agencies.[54,55]

CHAPTER TWO HUNDRED AND NINE

Gastroesophageal Reflux and Laryngeal Disease

Philippe Contencin

Thierry Van den Abbeele

Natacha Teissier

Key Points

- Other than gastroesophageal reflux (GER) disease, with its digestive and general signs and symptoms and valid tests, the definition of GER-related laryngeal disorders remains unclear.
- No true specific features of GER-related laryngeal disorders have been found, and the role of refluxed acid (or nonacid) gastric content in their occurrence is still unknown.
- Only a statistical correlation between GER and some inflammatory processes of the pediatric larynx has been found.
- Several possible mechanisms have been described, including direct epithelial injury, and indirect harm via vague mediated reflexes with or without vocal misuse.
- In addition to classic signs and symptoms of GER, the diagnosis is based on therapeutic trials, esophageal pH, and, for the future, impedance monitoring.
- Although most controlled studies (in adults) show no efficacy, anti-GER treatment or proton pump inhibitors or both are advised in selected cases of apnea with laryngospasm, associations with regional neuromuscular disorders (including laryngomalacia), recurrent croup, and laryngeal surgery.

First reported in the 19th century for bronchitis, the involvement of gastroesophageal reflux (GER) in the respiratory tract is still a controversial topic. Most pulmonologists consider GER as a possible aggravating factor for asthma. The involved mechanism of it is unknown, however.

The pediatric larynx is a sensitive organ subject to spasm and edema in case of minor harm. Evidence of the association of GER and laryngeal disorders in newborns to adults has been found. Data suggesting a cause-and-effect relationship are still missing, however.

History

Internists and otolaryngologists have reported possible airway involvement in adult patients with upper digestive disorders. By the end of the 19th century, Osler mentioned the occurrence of dyspnea in the postprandial period when the gastric cavity is full. From the early 1970s, with the description of "hiatal hernia" in adults, to more recent pediatric studies, it has become obvious that some laryngeal inflammatory processes develop in conjunction with upper digestive malfunctions, including GER.

The first modern clinical demonstration of GER-related laryngeal harm was made by Ward and colleagues[1] in glottic granulomas and contact ulcers in adults, and by Little and colleagues[2] in subglottic stenosis in an animal model. In infants and children, GER was initially shown through barium studies to be responsible for recurrent croup.[3] Similarly, apnea in premature newborns and various forms of laryngitis were linked to GER by means of esophageal and pharyngeal pH monitoring.[4,5] Finding decreases in pharyngeal pH to 2 at the laryngeal inlet or above in cases of pediatric chronic rhinitis/laryngitis raises a high index of suspicion of the role of acid reflux in these disorders of the airway. There was a statistically significant difference in upper and lower pH monitoring data between these patients and controls.[6] Some control patients and even gastroenterology patients might have pH variations that were close to each other, however, without any rhinolaryngologic symptoms. Since those studies were performed, control infants and children could not ethically be tested. Many studies focused on in vitro tests and on the efficacy of anti-GER treatments in patients.

Definition

GER is an abnormal and repeated ascent of gastric content into the esophagus (and possibly above it). There is a physiologic GER that occurs mainly in the postprandial period. Small amounts of refluxed material may cause burping at any age and a small degree of emesis in the infant. Sometimes it is also called "functional" GER because esophageal pH monitoring may show a few acid periods (<5% of recorded time at pH less than 4 on a 20-hour basis) that are considered unharmful to the esophagus. In this case, no other digestive symptom is noted, and upper digestive endoscopy is normal.

GER disease (GERD) is believed to have gastrointestinal or extragastrointestinal signs. Gastrointestinal signs include emesis, dysphagia,

choking, gagging, and failure to thrive in children. Extragastrointestinal signs include chronic coughing, wheezing, hoarseness, sore throat, stridor, recurrent croup, and obstructive apnea. Heartburn is extremely rare.

GERD was defined using gastrointestinal criteria; normal values for GER tests were established according to this definition. These criteria are not entirely appropriate in cases of a laryngeal disorder (also improperly called "laryngopharyngeal reflux" in adults). An extensive assessment for GER with "normal" results may be associated with chronic laryngeal inflammation; however, abnormal results indicating GERD may be found in cases of asymptomatic and endoscopically normal larynges. Many authors emphasized the particular pH profile of "airway-linked" GER. In a cohort of 90 children with pH monitoring, Zalesska-Krecicka and coworkers[7] found a high prevalence of daytime refluxes when patients with laryngeal disorders were in the upright position.

Physiopathology

The anatomic proximity and the neurofunctional collusion of the human larynx to the hypopharynx and upper esophagus lead to its unique vulnerability.[8] In no other mammal species is the larynx so caudal compared with the digestive tract organs. This positioning can explain the diffusion of the gastric juice up to the laryngeal mucosa.[9] Although many patients have GER, why do so few have true laryngeal disorders? It seems that a mechanism peculiar to the larynx is involved, and this can be due to direct contact with the gastric juice or to a vague mediated reflex.

Studies by Willging and Thompson[10] emphasized the role of laryngeal sensitivity in the development of pediatric anomalies such as laryngomalacia and GER-induced laryngeal reflexes. Paradoxical vocal cord motion, laryngospasm, and saliva and food aspiration are associated with abnormal thresholds of local chemoreceptors and mechanoreceptors. It has been shown that premature infants develop progressive swallowing ability and control of the lower esophageal sphincter postnatally, depending on the status of their respiratory and neurologic systems. GER and laryngeal sensitivity are intimately related and involved in cases of prematurity.[11]

Lipan and associates[9] discussed possible mechanisms of potential harm of the larynx by GER. They stated that, compared with classic intraesophageal reflux, cranial involvement by GER may be the result of four failing "barriers" including upper esophageal sphincter and pharyngolaryngeal mucosal resistance. These two domains warrant specialized interest and involvement of gastroenterologists, pathologists, and immunologists to know what exactly differentiates patients with gastrointestinal symptoms from patients with head and neck symptoms affected by GER. In 1998, an experimental rabbit model–based study emphasized the role of hydrogen chloride and pepsin inducing a chemical trauma and the individual laryngeal chemosensitivity.[12] In 2003, Altman and colleagues[13] found expression of a proton pump in the laryngeal mucosa. These mechanisms are held responsible for inflammatory laryngeal pediatric processes and for adult laryngeal carcinomas.[14] Eventually, in an "in vitro" model of laryngeal cultures, Ylitalo and Thibeault[15] showed more changes in gene expression of postcricoidal fibroblasts after 60 seconds of exposure to pepsin at low pH. Some authors denied the role of acid secretions in this domain, however, considering the inefficacy of gastric acid suppressors (i.e., proton pump inhibitors) in healing chronic laryngitis in adults.[16]

Diagnosis

A patient history of combined digestive and respiratory symptoms may help suggest the diagnosis of GERD. In infants, feeding difficulties with tears, apparent life-threatening events with hypotonia, and rise of refluxed food while supine are useful signs that may lead to empirical treatment. Radiographic studies with barium swallow, a search for lipid-laden macrophages at bronchial lavage, and a thoracic scintiscan with ingestion of nuclide elements are not routinely performed. Esophagoscopy with a flexible fiberscope may show esophagitis and large hiatal hernia. These abnormalities are rare, however, in cases with no gastrointestinal symptoms. It is unclear whether laryngoscopy and bronchoscopy can point to marks of GER because no specific features are described other than cobblestoning of the posterior supraglottic or subglottic area.[17,18]

Esophageal pH monitoring is considered by gastroenterologists to be the gold standard for diagnosing GER. Acid periods recorded over 18 to 24 hours can be correlated with airway manifestations (e.g., cough, stridor). An abnormal percentage of the recorded time at a pH less than 4 allows the physician to manage the GER. The question is what percentage should be considered abnormal in the absence of gastrointestinal signs and symptoms. It is unknown whether nonacid or weakly acid reflux may also play a role in the pathogenesis of GER-related laryngeal disorders.[19,20] A negative test does not rule out GER without esophageal lesion, however. Combined pharyngeal and esophageal pH records showed that brief refluxes can reach the laryngeal inlet and cause problems, whereas classic standards for this pH test are considered normal with a poor total acid time. Pharyngeal pH recordings are subject to drifts by dryness, however, and are not used routinely. Many studies have shown that brief diurnal refluxes are usual features of airway-disordered GER. Brief, pharyngeal and nonacid refluxes may be diagnosed easily by a promising test: esophageal impedance recording. This technique, which includes pH monitoring, allows recording of any refluxate, and is expected to enter routine practice.[21]

In adults with laryngeal symptoms and suspicion of GER, a therapeutic trial with a proton pump inhibitor is sometimes recommended, although more recent studies denied any efficacy of these treatments compared with placebo.[16,22] A therapeutic trial with a proton pump inhibitor would not be recommended as a diagnostic test in infants and children.

McMurray and coworkers[23] summarized the optimal assessment in cases of suspected esophagopharyngolaryngeal reflux: endoscopy with mucosal biopsy and dual probe pH monitoring are advocated.[23] This assessment underlies the principle of a mandatory abnormal GER (under gastrointestinal specifications) to start a specific treatment that is still subject of doubt.[9,24]

Disorders

The most frequent GER-related disorders in the airway of children of any age are classically the laryngeal diseases listed in Box 209-1. In older children and adults, dysphonia is the most frequently reported pathologic sign, along with pharyngeal symptoms (e.g., pain, globus sensation). Recurrent subglottic laryngitis with dyspnea (croup) is the most common consequence of GER on the airway in children. A statistically significant correlation with GER was found in patients with recurrent croup using two-channel pH monitoring.[5] Successful anti-GER therapeutic trials and recurrences after stopping management also were noted in patients with recurrent croup.[25]

GER has been shown to have an important role in the development of subglottic stenosis. Long-term endotracheal intubation leads to increased acid pharyngeal reflux. Animal studies have shown that acid placed on the subglottic mucosa after local trauma leads to granulation tissue and fibrous scarring with subsequent stenosis.[2] Some authors believe that successful surgical management of subglottic stenoses in children depends on the control of GER.[26]

Box 209-1

Gastroesophageal Reflux–Related Laryngeal Disorders in Infants and Children

Apnea, laryngospasm
Paradoxical vocal cord motion
Laryngomalacia
Recurrent croup
Laryngeal granulations
Acquired glottic web
Hoarseness, chronic cough
Aspiration
Subglottic stenosis (and laryngeal surgery)

The most important GER-associated laryngeal phenomena in infants are motor disorders. GER is found in more than 90% of cases of laryngomalacia.[27] GER may cause edema at the laryngeal inlet. GER also may be induced by the negative endothoracic pressure resulting from the airway obstruction. GER is probably associated only with pharyngoesophageal motor anomalies that are caused by the neurologic dysfunction that determines laryngomalacia.[27] Glottic and pharyngoesophageal dysfunctions that occur simultaneously with GER lead to aspiration. In return, laryngeal adductor responses seem to coincide with reflux in premature newborns, with subsequent obstructive reflex apnea.[4]

Apnea in neonates and obstructive sleep apnea in adults have been reported as linked to GER. The concomitant time with GER episodes has been shown in premature infants by Orenstein and colleagues.[4] Senior and associates[28] described a decline of obstructive sleep apnea scores at polysomnography with anti-GER treatment. Dyce and coworkers[29] stated that GER is associated with many congenital disorders, including Pierre Robin sequence and 22q11 deletion syndrome.

Hoarseness and vocal fold nodules are sometimes described as a result of GER. Mandell and colleagues[30] compared the results of esophageal biopsy with endoscopic findings and bronchioalveolar lavage in a series of 127 hoarse children including 104 with nodules. There was no correlation between biopsy and bronchioalveolar lavage results, and endoscopy was more contributory than any other test. In a study of 254 pediatric patients, Shah and associates[31] found only one quarter of GER-positive cases. It seems that the incidence of GER in hoarse children may vary depending on the criteria used and the type of assessment made. Vocal cord dysfunction or laryngeal dyskinesia are strongly associated with psychiatric illness and GER.[32]

A link between GER and recurrent respiratory papillomatosis has been suggested by McKenna and Brodsky[33] from a series of four children whose noncompliance with anti-GER treatment determined occurrence of laryngeal symptoms and reappearance of papillomas at endoscopy. All these studies widely favor the close relationship between GER and inflammatory features of the larynx. They do not carry any direct evidence of the role of GER, however, owing to nonspecific aspects of the described features (except for contact ulcers, which are very rare in children).

Possible Role of Gastroesophageal Reflux

Because no direct role of GER has been shown by GER tests, endoscopy, and biopsy, therapeutic trials were used to search for indirect evidence. Besides acid and pepsin, many other components of refluxed material may be harmful, according to experimental animal or in vitro studies. Even powerful antagonists of gastric H^+ ion secretion may be useless in cases of documented GER with laryngeal involvement without esophagitis.

A retrospective study examined the impact of anti-GER treatments on the development of subglottic stenosis after surgery, and found there were fewer tracheostomies remaining in the treated group.[34] This study's method may be biased, however, and the same suspicion arose in other small series.[26,35] Of five published randomized controlled trials on the efficacy of GER treatments versus placebo in adult laryngeal disorders, four were negative, and the positive trial was considered weak because it included only 11 patients in each group.[16]

The implication of GER in laryngeal pathologies remains a controversial topic. It is still unclear how refluxed material ascending from the stomach may be harmful to the laryngeal mucosa, and which mechanisms, common muscular or immune or both, lead to GER and laryngeal inflammation. In the first hypothesis, we may wonder why many patients with GERD have no laryngeal disorder (even while vomiting and aspirating). In the latter, is the common digestive mechanism the cause or the consequence of laryngeal diseases? If it is not the consequence, further studies are necessary to find out if different types of reflux exist, or, more likely, if different types of laryngeal sensitivity could explain the controversial results in the described series. This laryngeal sensitivity may be related to other particular laryngeal descriptions, such as apnea encountered in preterm infants,[36] and laryngeal dysfunctions such as laryngomalacia[10,37] and paradoxical vocal fold motion.[38]

Management

The first step in antireflux management is to ensure that the patient has an age-appropriate diet and lifestyle. Foods that relax the lower esophageal sphincter should be avoided. Small meals at regular times and avoidance of any food or drink 1 hour before bedtime are common recommendations. Infants should be given milk thickened with rice, and fruit juice should be avoided. The posture of the patient at rest also is extremely important. Gravity reduces the frequency and strength of reflux episodes. Raising the head of the bed by 10 to 15 degrees is recommended for children, whereas infants who weigh up to 10 kg can be placed on a special mattress with a 30- to 45-degree slope. Pillows should be avoided. When not in bed, infants should be as upright as possible, even when physiotherapy is applied.

Recommended antireflux drugs (prokinetics) stimulate esophageal and gastric motility, while reinforcing the tonicity of the lower esophageal sphincter. Domperidone and metoclopramide can be prescribed despite their risk of adverse side effects (extrapyramidal syndrome with high dosage). Alginates coat the gastric contents and prevent its reascension. H_2 blockers inhibit gastric acid secretion and have been successfully used in some difficult cases, but some pediatric patients are nonresponders. Proton pump inhibitors (e.g., omeprazole, lansoprazole, esomeprazole) are now widely used in adult and pediatric patients. They prevent the release of hydrogen ions and are useful in severe forms resistant to other management. Management usually continues for years. Drugs can be limited to 2- to 3-month cycles, however, because the spontaneous course of the disease is typically episodic except in infants, in whom management may be continued for longer periods. Surgery (mainly Nissen fundoplication) is appropriate in cases in which severe disorders recur as soon as drugs are withdrawn, or in which medical control is impossible to achieve.

Conclusion

GER is strongly associated with many laryngeal disorders in infants and children, although evidence of a causal relationship is still lacking. This phenomenon is probably explained by different local sensitivities among subjects. The significant association is a strong argument, however, in favor of an anti-GER treatment in the absence of another obvious cause, or when critical surgery involving the airway is planned. Based on their experience, most laryngologists recommend that GER should be sought and managed in cases of recurrent laryngitis and of surgery for subglottic stenosis and other laryngeal abnormalities, such as nodules, cysts, and posterior cleft.[39] Whether prokinetic or anti-H^+ agents are most efficacious is still unknown.

CHAPTER TWO HUNDRED AND TEN

Aspiration and Swallowing Disorders

David J. Brown

Maureen A. Lefton-Greif

Stacey L. Ishman

Key Points

- In evaluating children with aerodigestive disorders, the first priority is securing a safe airway.
- The coordination of breathing and swallowing is crucial to survival because both functions share the pharynx as a common conduit.
- The four phases of swallowing are the oral preparatory, oral, pharyngeal, and esophageal phases.
- The characteristics of dysphagia are defined by the anatomic site of impairment: nose and nasopharynx, oral cavity and oral pharynx, hypopharynx and larynx, and trachea and esophagus.
- Swallowing must provide sufficient nutrition and fluid for optimal growth and development.
- Videofluoroscopic swallow studies and flexible endoscopic evaluation of swallowing are commonly used evaluation tools to assess the pharyngeal phase of swallowing deficits.
- Dysphagia management may include feeding modifications, supplemental nutrition, oral motor and swallowing therapies, and alternative feeding routes.

Swallowing involves multiple, highly integrated, and partially overlapping actions; however, for discussion purposes, it is frequently separated into three phases—*oral, pharyngeal,* and *esophageal*. During the *oral phase,* food is processed into a "swallow-ready ball" (bolus), and then transported to the back of the mouth. This phase is limited to sucking fluid from a nipple during infancy. After approximately 6 months of age, this phase is sometimes subdivided to include the *oral preparatory phase,* which conditions solid foods requiring chewing. The *pharyngeal phase* comprises a series of complex and interrelated events that direct and propel boluses through the pharynx into the esophagus while the airway is protected. During this phase of swallowing, the velum rises and approximates the pharyngeal walls, breathing stops, the larynx rises, the vocal folds adduct, and the base of tongue and pharyngeal muscles propel the bolus through a relaxed upper esophageal sphincter. The act of swallowing results in mechanical closure of the airway and cessation of breathing. The *esophageal phase* begins when the bolus enters the esophagus and ends when it passes into the stomach.

Typical swallowing maturation involves transformation from the primitive sucking and swallowing reflexes used during infancy into the mature and volitional functions of biting, chewing, and bolus formation necessary for the safe and adequate delivery of nutrients in older children and adults. Appropriate adjustments to growth and developmental changes of the aerodigestive system and changes in airway protective responses are essential to competent postnatal maturation processes. Changes in the anatomic relationships of the oral cavity, pharynx, and larynx occur throughout the first few years of life and are well described. In addition, neurodevelopmental, cognitive, and sensory inputs modulate deglutitive function, and consequently may influence the maturation process.

Competent deglutition (the act of swallowing) is crucial to survival. Two primary functions of swallowing are to direct oral secretions, liquids, and food from the mouth to the stomach while protecting the airway, and to provide sufficient amounts of nutrients and fluids for children to grow and develop optimally. Appropriate adjustments to growth and increases in nutritional needs are crucial to successful postnatal deglutition. Because breathing and swallowing share common conduits, such as the oral cavity and pharynx, their functions are intertwined.

Dysphagia (swallowing dysfunction) may be caused by any condition that interferes with structural integrity of the structures comprising the aerodigestive tract or their coordination. Congenital or acquired structural or anatomic anomalies may cause airway and swallowing defects. This chapter focuses on the evaluation of infants and children with suspected dysphagia and the associated primary aerodigestive tract anomalies. Management approaches to swallowing and airway-related problems are reviewed.

Evaluation of Infants and Young Children with Suspected Dysphagia

Clinical or Bedside Evaluation

Evaluation of all children with feeding and swallowing difficulties begins with taking a thorough history and performing a physical exam-

ination. Children with anatomic anomalies are at increased risk for dysphagia when the underlying conditions interfere with the structural integrity of the oropharynx or the complex coordination of neuromuscular and airway processes involved in deglutition; consequently, the focus of the clinical evaluation is the identification of diagnostic tests that determine the nature and extent of the swallowing impairments, and assist with management decisions. Children who present with structural anomalies as one component of a complex medical history or syndrome (e.g., bronchopulmonary dysplasia or Smith-Lemli-Opitz syndrome) may require other specialized evaluations (e.g., direct laryngoscopy and bronchoscopy) to determine the impact of the associated comorbidities on swallowing.

Instrumental Evaluation

When the clinical evaluation identifies problems that may be caused by or reflect problems that are invisible, an instrumental evaluation is typically recommended. Common examinations that allow for direct visualization of the structures involved in swallowing include radiologic (e.g., upper gastrointestinal series [UGI] and videofluoroscopic swallow studies [VFSS]) and endoscopic (e.g., flexible endoscopic evaluation of swallowing [FEES]) procedures. Clinicians need to be cautious about the interpretation of negative findings of aspiration during UGI, VFSS, and FEES. Each of these evaluations may establish a diagnosis of dysphagia by identifying specific aspects of the pathophysiology of the dysfunction; however, they may fail to detect aspiration even in children who aspirate, particularly when aspiration is episodic.

Upper Gastrointestinal Series

UGI may provide important information for children with anatomic anomalies, particularly when the anomaly is distal to the oropharynx. UGI provides information that allows for assessment of the anatomy and physiology of the esophagus, stomach, and duodenum; defines gastrointestinal obstructions; and identifies malrotation. In addition, it serves as a screen of the oropharyngeal structures and their functions. Decisions about whether liquid barium should be administered orally or by nasogastric tube are determined by the specific diagnostic questions, and whether children are at risk for aspiration secondary to swallowing dysfunction.

Videofluoroscopic Swallow Study

VFSS, sometimes referred to as a modified barium swallow study, may be useful in children suspected to have oropharyngeal dysphagia because it images the structures of the oral cavity, pharynx, and cervical esophagus during deglutition.[1] VFSS may screen gastrointestinal structures distal to the cervical esophagus. The goals of VFSS are to provide information that helps determine whether anatomic or structural abnormalities are present; ascertain if coordination of the structures and functions of the upper aerodigestive tract supports safe and efficient bolus passage; and identify strategies that enhance the safety and efficiency of feeding, while minimizing the dysphagic problems. During VFSS, children ingest liquids or foods or both impregnated with barium contrast material to simulate functional feeding as closely as possible. Consequently, children must be ready, willing, and able to cooperate with VFSS.[2,3]

Flexible Endoscopic Evaluation of Swallowing

FEES is an extension of the routine flexible fiberoptic nasopharyngolaryngoscopy examination, and may be used to evaluate the structures and functions of the nasopharynx, oropharynx, and larynx during phonation, spontaneous swallows, and swallows of liquids and foods.[4,5] FEES may be particularly useful in children who are nonoral feeders, who are unable to cooperate with VFSS, who have vocal fold dysfunction, or in whom their ability to handle their secretions is questionable.

FEES may provide sensory information when the endoscope touches adjacent mucosa or structures. To standardize evaluations of responses to sensory input, calibrated air pulses have been administered endoscopically.[6] The utility of FEES plus sensory air pulse testing (FEES-ST) has been shown during the evaluation and treatment of children with specific diagnostic conditions (e.g., type I laryngeal clefts) and during preoperative evaluations for pediatric airway reconstruction.[7,8] Elevated laryngopharyngeal sensory thresholds have been documented in children with clinical diagnoses of recurrent pneumonia, neurologic disorders, and gastroesophageal reflux disease (GERD).[6] Table 210-1 outlines the utility of using VFSS and FEES based on the anatomic or structural condition.

Other Diagnostic Evaluations

Other diagnostic tests may be needed to determine the cause of the swallowing dysfunction. Imaging of the brainstem may be needed to diagnose abnormalities of the skull base or spine as potential underlying conditions. Specialized evaluations may be needed for children with refractory respiratory conditions. Chest radiographs, pulmonary function tests, high-resolution computed tomography (CT), and bronchoscopy provide information regarding the extent of lung injury. Endoscopy of the gastrointestinal tract may be beneficial for patients with histories or presentations suggestive of gastrointestinal conditions.

Four Anatomic Sites of Dysphagia

The four primary anatomic sites with anomalies of the aerodigestive tract that may adversely affect swallowing and contribute to dysphagia are the nose and nasopharynx, oral cavity and oral pharynx, hypopharynx and larynx, and trachea and esophagus (Fig. 210-1).

Nose and Nasopharynx

Anomalies of the nose and nasopharynx affect the oral and pharyngeal phases of swallowing. Dysphagia from anomalies of the nose and nasopharynx is secondary to upper airway obstruction and the caliber of the upper airway and the child's ability to compensate while swallowing (Fig. 210-2). Bilateral disease has a more significant impact on airway patency and swallowing than unilateral disease.

Any cause of nasal airway obstruction can lead to feeding difficulties, particularly during infancy when nasal airflow is an important component of breathing and feeding. Nasal obstruction can result from myriad conditions, including midface hypoplasia, congenital nasal pyriform aperture stenosis, septal deviation or hematoma, chronic or acute rhinitis, congenital midline nasal masses (including dermoids, encephaloceles, and gliomas), nasal or nasopharyngeal tumors, choanal atresia, and adenoidal hypertrophy. These children frequently have difficulty coordinating feeding and breathing, and may have failure to thrive or recurrent aspiration.[9]

Unilateral nasal disease may not be detected for years and is often associated with unilateral nasal congestion or rhinorrhea. Bilateral disease has a more significant impact on airway patency and swallowing than unilateral disease and is usually recognized soon after birth because the child commonly has severe respiratory difficulties with cyclical cyanosis relieved by crying.[10] These children are also unable to feed effectively, and may have coughing and choking with cyanotic spells when attempting to eat. Diagnostic evaluation often starts with attempted passage of a 6F feeding tube through the nares. A thorough evaluation with flexible fiberoptic endoscopy and imaging should be carried out if nasal obstruction is suspected. Figure 210-2 outlines the evaluation for children with dysphagia that is suspected to originate from the nose and nasopharynx.

Oral Cavity and Oral Pharynx

Anomalies of the oral cavity and oral pharynx may affect the oral and pharyngeal phases of swallowing, and many have the potential for upper airway obstruction. The respiratory issues should be evaluated and stabilized before initiating the feeding efforts or evaluations for suspected dysphagia (Fig. 210-3).

Functional swallowing depends on efficient bolus formation and movement of the bolus from the mouth to the stomach, and coordination of breathing with bolus passage to protect the airway. Successful bottle-feeding and breastfeeding requires compression of the nipple and the generation of sufficient negative intraoral pressure for suction. Anatomic abnormalities that compromise either the compression or the suction actions of nipple feeding may create feeding difficulties by decreasing the efficiency of feeding. Although abnormalities of the oral

cavity and oropharynx may occur in isolation, they frequently co-occur with defects in other portions of the aerodigestive tract, and may also compromise airway function. As always, airway concerns are the first priority and are addressed before attention is focused on feeding and swallowing. This section reviews common conditions affecting the oral cavity and oropharynx, including cleft lip and palate, micrognathia or retrognathia, and macroglossia.

Cleft lip may affect infant feeding by interfering with the lips and tongue creating a seal around the nipple. This interference may compromise the compression phase of sucking and cause excessive fluid loss. Palatal clefts may compromise the suction phase of nipple feeding by interfering with the generation of the negative intraoral pressure needed to extrude fluid from the nipple. The extent of the impact of any anatomic defect depends on multiple factors (e.g., location and extent of impairment, the presence of other anomalies or comorbidities). Some children with isolated small cleft lips or submucous clefts feed without problems or have mild problems that are amenable to feeding routine adaptations.[11] Special feeders, such as the Haberman feeder or Mead-Johnson nurser, allow infants to compensate when there are problems with the compression phase of nipple feeding. Caregivers squeeze the bottles to deliver fluids. Additionally, a cross-cut nipple can be used to facilitate fluid flow. These adaptations are often used before surgical repair of the cleft lip or palate. Clinicians must be cautious about airway protective mechanisms (i.e., aspiration potential) before recommending any feeding routine adaptation that increases the rate of fluid flow.

Common craniofacial syndromes associated with cleft lip and palate are Apert's, Stickler's, and Treacher Collins syndromes; Pierre Robin sequence; CHARGE (coloboma, heart disease, atresia choanae, retardation, genital hypoplasia, and ear anomalies) association; and 22q11 deletion syndromes including velocardiofacial syndrome and DiGeorge syndrome.[12] These conditions may interfere with aspects of feeding and swallowing beyond those localized to the oral cavity or oropharyngeal structures.

Micrognathia and retrognathia can occur in isolation; however, they also occur in association with Pierre Robin sequence and genetic syndromes such as Goldenhar's, Treacher Collins, Smith-Lemli-Opitz, and cri du chat syndromes. Retrognathia and micrognathia may compromise airway patency and feeding secondary to retrodisplacement of the tongue. In Pierre Robin sequence, airway obstructive patterns are caused by pharyngeal collapse and velum elongation leading to palatal and base of tongue obstruction.[13] In addition to the interference with the compression and suction phases of nipple feeding, the combination of a relatively small oropharynx and nasopharyngeal reflux secondary to a cleft palate may compromise breathing and swallowing coordination. The diagnosis is made by clinical evaluation and confirmed by instrumental assessment, if warranted. The prognosis for successful oral feeding depends on the degree of respiratory distress and the presence

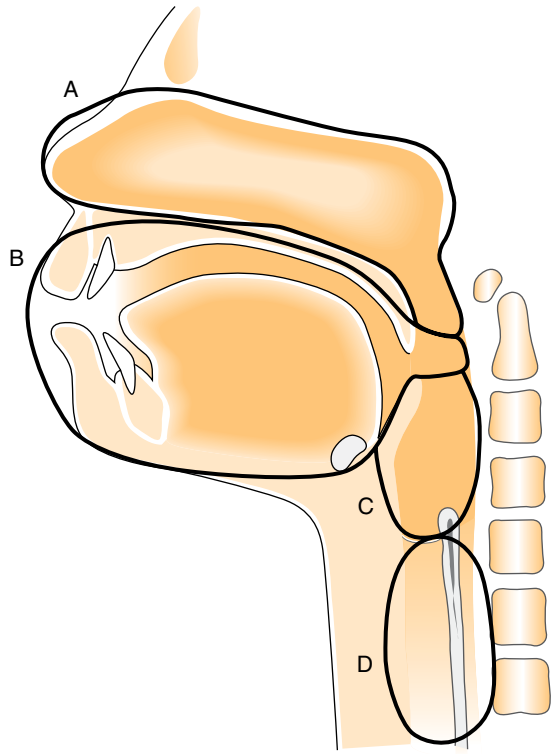

Figure 210-1. Four anatomic sites of dysphagia. **A,** Nose and nasopharynx. **B,** Oral cavity and oral pharynx. **C,** Hypopharynx and larynx. **D,** Trachea and esophagus. *(© 2008 by Johns Hopkins University, Art as*

of associated issues or diagnoses. Patients with Pierre Robin sequence–associated syndromes generally require gastrostomy tube placement despite successful airway intervention.[14]

Macroglossia often leads to feeding difficulty because tongue enlargement may interfere with the creation and maintenance of an adequate lip-tongue and nipple seal. Additionally, tongue movement may be restricted, leading to difficulty controlling food in the oral cavity. Macroglossia is associated with Down syndrome and Beckwith-Wiedemann syndrome. Feeding problems are reported in 50% to 80% of children with Down syndrome; specific dysphagia characteristics include delayed and aberrant oral-motor function, abnormal tongue and mandibular function, and delayed initiation with difficulty of the oral phase of swallowing.[15,16] Hypotonia may also compound feeding and swallowing problems in children with Down syndrome.

Pharyngeal diverticula or tumors are less commonly seen in children. The effects of these conditions depend on the size and location of the defect, and there may be no impact on feeding unless these are significantly enlarged.

Hypopharynx and Larynx

Anomalies of the hypopharynx and larynx may affect the pharyngeal and esophageal phases of swallowing. Initial evaluation usually involves performing a flexible fiberoptic laryngoscopy (Fig. 210-4).

Vallecular cysts are rare mucous retention cysts that manifest with stridor, respiratory distress, dysphagia, and failure to thrive. These cysts sit in the vallecular space and can cause significant retroflexion of the epiglottis, which leads to respiratory distress and dysphagia. Dysphagia can result from interference with base of tongue and epiglottic movement and from obstruction of the natural lateral flow of food around the epiglottis during swallowing. Vallecular cysts can be diagnosed by flexible fiberoptic laryngoscopy, direct laryngoscopy, or a swallow study. They can be seen on CT and magnetic resonance imaging (MRI), but are difficult to see on plain films of the neck.

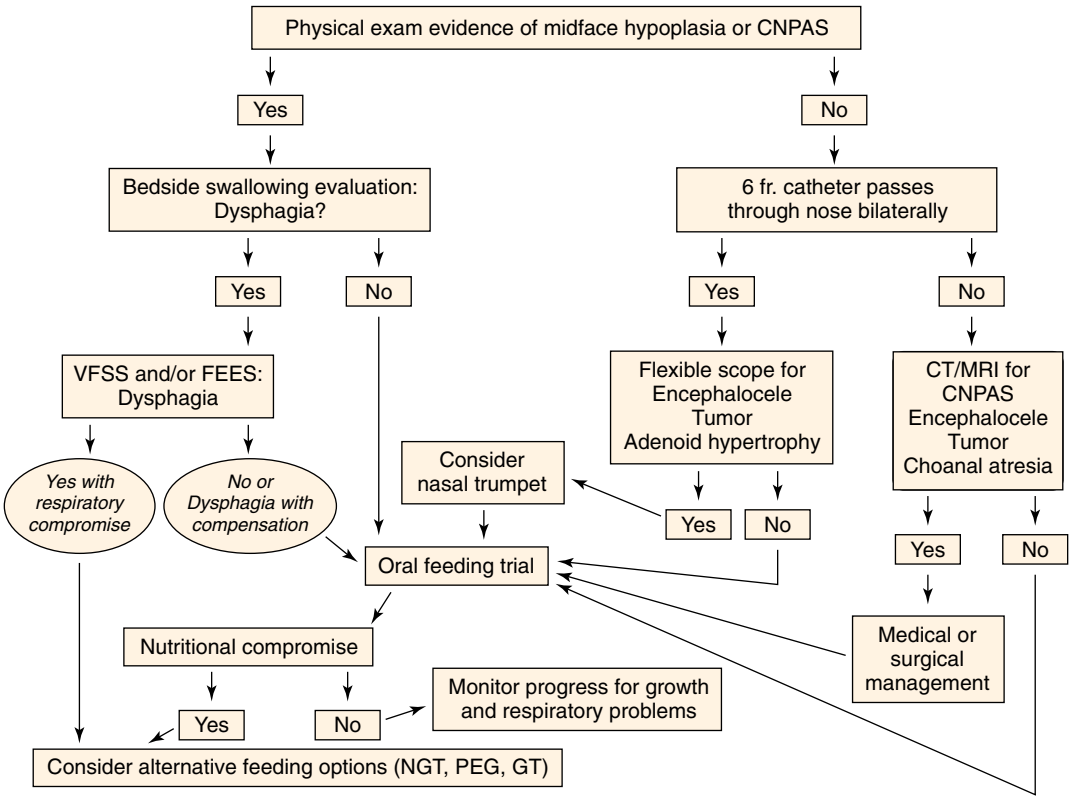

Figure 210-2. Evaluation and management of dysphagia with suspected nose and nasopharynx anomaly. CNPAS, congenital nasal pyriform aperture stenosis; FEES, flexible endoscopic evaluation of swallowing; GT, gastrostomy tube; NGT, nasogastric tube; PEG, percutaneous endoscopic gastrostomy; VFSS, videofluoroscopic swallow studies.

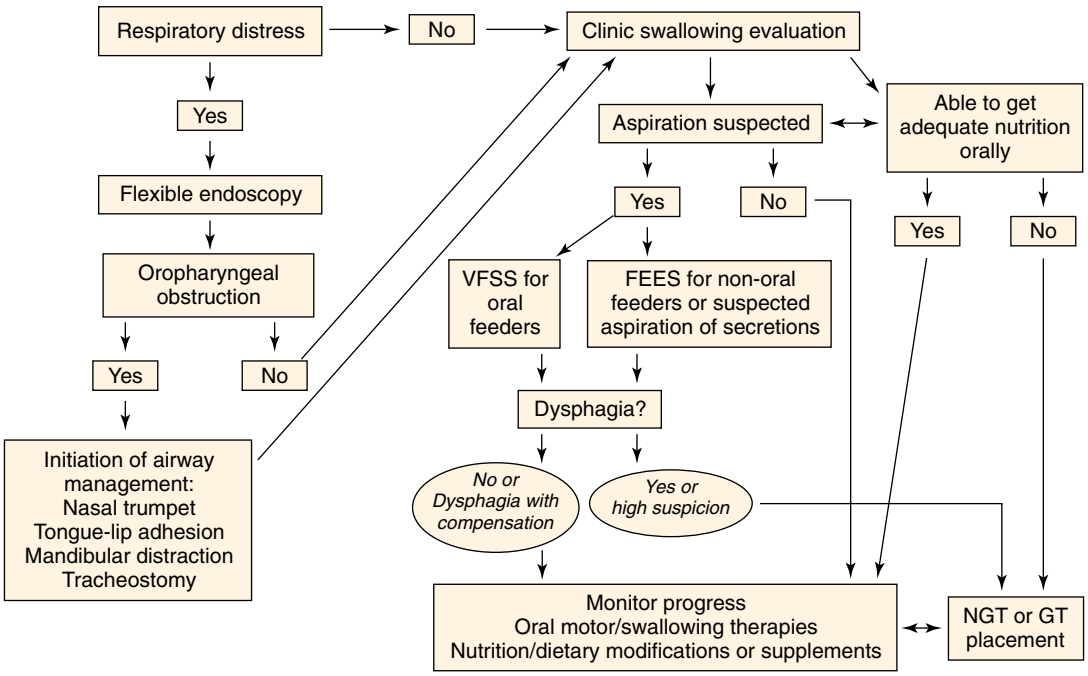

Figure 210-3. Evaluation and management of dysphagia with suspected oral cavity and oropharynx anomaly. FEES, flexible endoscopic evaluation of swallowing; GT, gastrostomy tube; NGT, nasogastric tube; VFSS, videofluoroscopic swallow studies.

Surgical management of vallecular cysts is recommended by marsupialization of the cyst and removal of the mucosal lining, which can be performed with a carbon-dioxide laser, cold knife, or a microdébrider. Yao and colleagues[17] described an 11-week-old infant with a vallecular cyst, choking with feeds, failure to thrive, stridor, laryngomalacia, and gastroesophageal reflux.[17] After surgical removal of the cyst, the aerodigestive symptoms resolved within days, as is often the case. This patient showed improvement in weight percentiles from less than 10th percentile at the time of surgery to the 50th percentile 12 weeks later.

Laryngomalacia is the most common cause of stridor in infants, representing more than 70% of cases. These children present with inspiratory stridor secondary to collapse of the epiglottis or arytenoids or both during inspiration. Many studies have found that laryngomalacia is associated with gastroesophageal reflux and underlying neurologic conditions.[18-20] Respiratory distress can be seen in more severe cases with cyanosis, obstructive sleep apnea, supraclavicular retractions, and subcostal retractions. Severe laryngomalacia can also contribute to feeding difficulties heralded by choking while feeding, failure to thrive, and emesis.

Laryngomalacia is diagnosed by flexible fiberoptic laryngoscopy with the infant awake and upright. Infants with presentations suggestive of dysphagia should have a swallowing evaluation. More than 90% of patients with laryngomalacia are treated nonsurgically with close clinical follow-up. Matthews and coworkers[21] found that of 24 infants diagnosed with laryngomalacia who had 24-hour double-probe pH monitoring, all had at least one episode of pharyngeal refluxate, and greater than 90% had three episodes. Because GERD and laryngomalacia seem to coexist, many clinicians manage laryngomalacia patients with antacids or proton pump inhibitors. For patients with respiratory distress or failure to thrive, a supraglottoplasty is recommended. Lee and associates[22] showed that carbon-dioxide laser supraglottoplasty can improve substernal and suprasternal retractions, but that many patients continued to have choking and feeding problems postoperatively. This condition warrants a postoperative swallowing evaluation and close clinical follow-up.

Vocal fold paralysis represents 10% of congenital laryngeal anomalies. Infants may have unilateral or bilateral vocal fold paralysis, and can present with stridor, recurrent aspiration, and dysphagia from the inability to protect the airway. The diagnosis is best made by flexible fiberoptic laryngoscopy in an awake patient. Management of vocal fold paralysis in children should focus first on establishing a safe airway. After the airway is stable, the nutritional needs should be assessed.

Swallowing difficulties can be evaluated by VFSS or FEES or both. These evaluations can identify penetration, aspiration, the patient's ability to protect the airway adequately, and the effect of changes in feeding utensils (e.g., fast vs. slow flow nipples) or different liquid viscosities (e.g., thin vs. thick liquids). Some infants benefit from a slower swallowing transit time, which can be accomplished by decreasing the flow from the bottle's nipple or by thickening the formula or breast milk. Other infants require a feeding tube to obtain adequate nutrition and hydration.

Laryngeal webs can be congenital, secondary to incomplete resorption of the laryngeal lumen epithelium during embryologic development, or acquired from vocal fold trauma secondary to laryngeal surgery or endotracheal intubation. Infants may present with stridor, a weak cry, hoarseness, respiratory distress, and aphonia, and some may have dysphagia. Laryngeal webs are associated with cardiac and 22q11 anomalies. The diagnosis is made by flexible fiberoptic laryngoscopy or direct laryngoscopy. Thin webs can be managed by endoscopic lysis, whereas thicker webs require an open laryngeal fissure and placement of a laryngeal keel or stent. For patients with preoperative dysphagia, a follow-up swallowing evaluation should be performed postoperatively.

Posterior laryngeal clefts are uncommon congenital anomalies caused by incomplete formation of the septum between the esophagus and the airway. This laryngeal anomaly is associated with tracheoesophageal fistulas in one third of cases. The Benjamin-Inglis classification system describes four types of posterior laryngeal clefts: Type 1 clefts are interarytenoid and lie above the level of the true vocal folds, type 2 clefts extend below the true vocal folds and partially through the cricoid cartilage, type 3 clefts extend into the extrathoracic trachea, and type 4 clefts extend into the intrathoracic trachea.[23] Common presentations are stridor, choking, aspiration, chronic cough, and failure to thrive. Direct laryngoscopy and bronchoscopy should be performed with bimanual palpation and probing of the interarytenoid area to confirm the diagnosis. Microaspiration and penetration can be seen on FEES or VFSS.

The management of posterior laryngeal clefts depends on the extent of the cleft. Chien and colleagues[7] found type 1 posterior

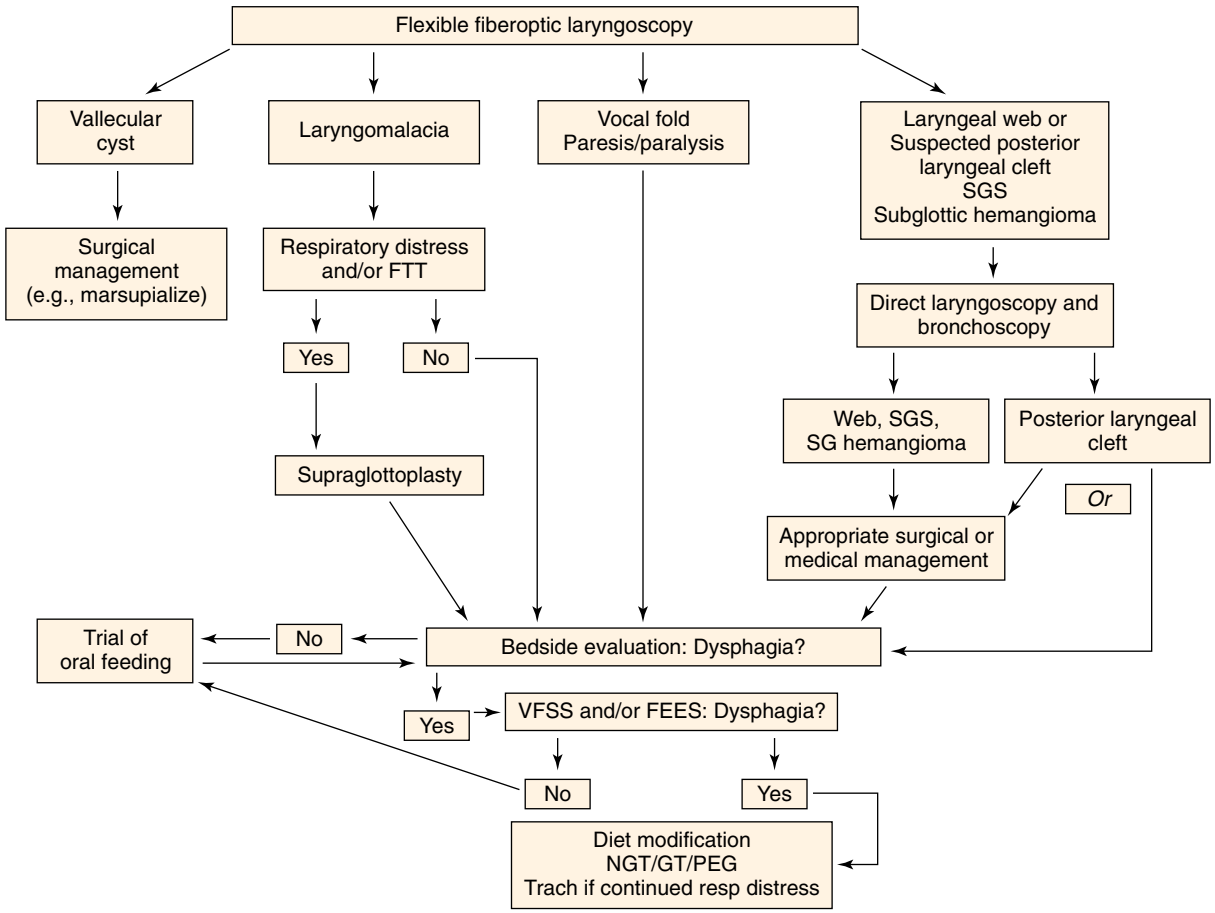

Figure 210-4. Evaluation and management of dysphagia with suspected hypopharynx and larynx anomaly. FEES, flexible endoscopic evaluation of swallowing; FTT, failure to thrive; GT, gastrostomy tube; NGT, nasogastric tube; PEG, percutaneous endoscopic gastrostomy; SG, subglottic; SGS, subglottic stenosis; VFSS, videofluoroscopic swallow studies.

laryngeal clefts in 1 of 13 patients presenting to their institution with symptoms of chronic cough or aspiration over a 3-year period. They recommend that type 1 clefts have a trial of nonsurgical management first with a proton pump inhibitor to treat GERD, upright feedings, and thickened feedings. Children who fail conservative treatment should have surgical repair. Types 1 and 2 posterior laryngeal clefts can be repaired endoscopically, whereas type 3 and 4 clefts require an open surgical repair. A postoperative swallowing study should be performed.

Subglottic pathologies such as stenosis and hemangiomas affect swallowing in similar ways. Subglottic anomalies manifest with inspiratory or biphasic stridor, and the best evaluation method is by direct laryngoscopy and bronchoscopy. MRI or three-dimensional CT may be useful in delineating the extent of subglottic narrowing. The increased work of breathing can lead to increased laryngeal refluxate, penetration, and aspiration. The acidic refluxate into the subglottis can lead to further airway edema and narrowing. The first priority for these patients is to ensure a stable airway. When that has been achieved, swallowing function can be assessed by a bedside swallowing evaluation, and VFSS or FEES if indicated.

Trachea and Esophagus

Dysphagia of the trachea and esophagus may affect the pharyngeal and esophageal phases of swallowing. In addition to structural anomalies, inflammatory conditions such as GERD and eosinophilic esophagitis can affect these areas. The initial evaluation depends on the specific condition suspected. Figure 210-5 outlines a working algorithm for evaluating these patients.

GERD symptoms such as regurgitation and emesis occur in 50% to 67% of normal children, with most having symptom resolution by 1 to 2 years of age.[24,25] Children younger than 2 years old present with airway symptoms (stertor, stridor, or cyanosis) and feeding abnormalities (vomiting, dysphagia, and failure to thrive).[26] GERD can affect all of the major aerodigestive anatomic areas (see Fig. 210-1), and has been implicated in stertor, lingual tonsil hypertrophy, arytenoid edema, vocal fold edema, subglottic edema, cobblestoning of the trachea, and blunting of the carina.[27,28]

GERD is also associated with other known conditions that affect the aerodigestive tract. Giannoni and colleagues[20] prospectively evaluated 33 consecutive infants diagnosed with laryngomalacia and noted that 64% had GERD. Additionally, GERD was associated with more severe cases of laryngomalacia and cases with complicated clinical courses. Animal studies have linked gastric acid and pepsin to subglottic stenosis and vocal fold granulomas.[29,30]

When GERD affects the upper aerodigestive tract, it is referred to as *laryngopharyngeal reflux*. The diagnostic workup for LPR in infants lacks consensus and includes symptom assessment questionnaires, flexible fiberoptic laryngopharyngoscopy, single-lumen or double-lumen pH probe, barium esophagogram, scintigraphy, impedance, and laryngeal biopsy. Often a trial of antireflux medication is given to see if symptoms resolve.

GERD can affect the sensation of the larynx and blunt protective reflex mechanisms. Suskind and coworkers[31] retrospectively reviewed 28 infants with GERD and found altered laryngeal sensation by FEES and FEES-ST and dysphagia by VFSS and FEES. GERD was managed medically or surgically, and repeat VFSS and FEES-ST testing showed improved laryngeal sensation and swallowing function. These authors hypothesize that the refluxate causes laryngeal edema and decreased sensation, which alters the laryngeal adductor reflex, and then disrupts the suck-swallow-breathe sequence and causes dysphagia.

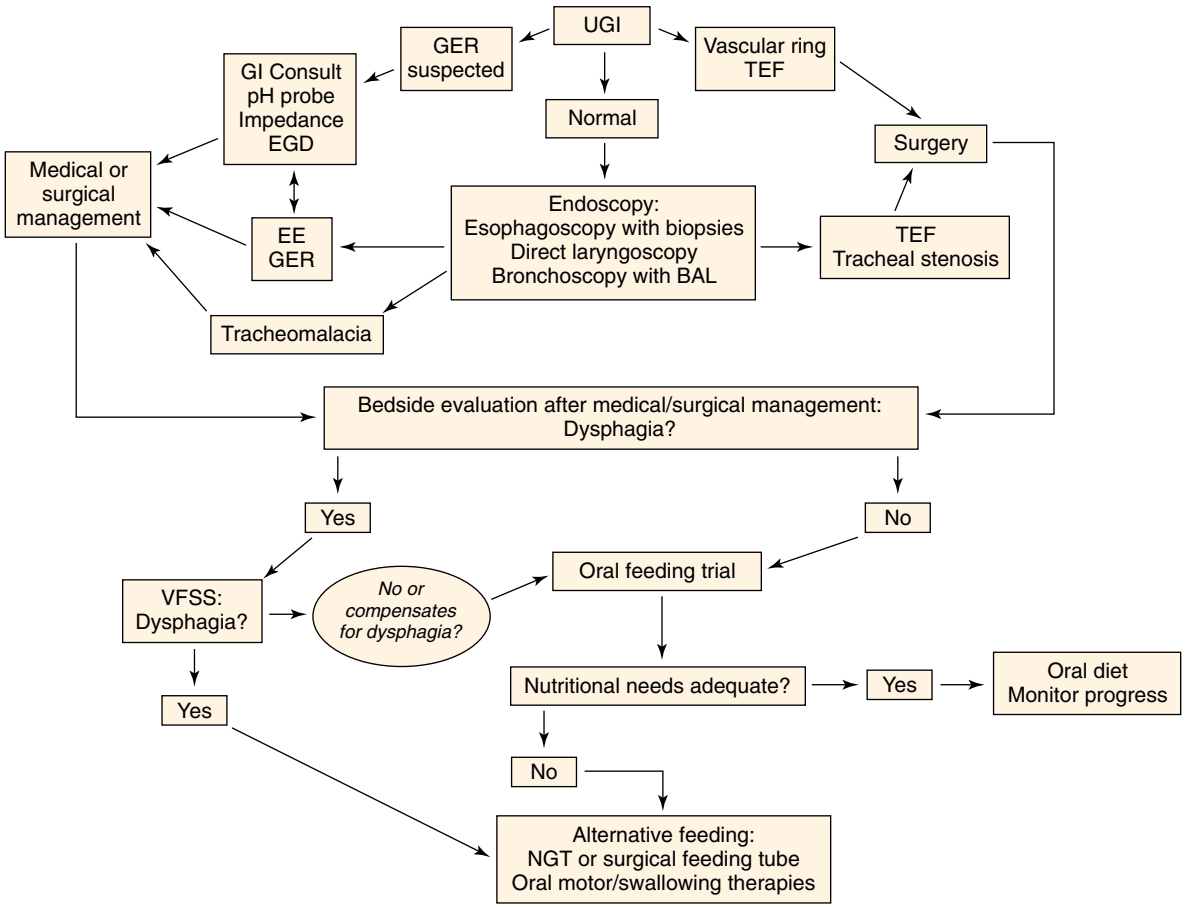

Figure 210-5. Evaluation and management of dysphagia with suspected trachea and esophagus anomaly. BAL, bronchoalveolar lavage; EE, eosinophilic esophagitis; EGD, esophagogastroduodenoscopy; GER, gastroesophageal reflux; GI, gastrointestinal; NGT, nasogastric tube; TEF, tracheoesophageal fistula; UGI, upper gastrointestinal series; VFSS, videofluoroscopic swallow studies.

Eosinophilic esophagitis is an inflammatory process of the mucosal and submucosal layers of the esophagus.[32] Symptoms often mimic the symptoms of GERD with feeding difficulties predominating in infants and toddlers; vomiting and abdominal pain are common in school-age children, and dysphagia is evident in preadolescents.[33] Food impaction may occur in older children and adults. Diagnosis of eosinophilic esophagitis is made by a combination of the clinical symptoms listed previously and histologic confirmation of 15 eosinophils or more per high-powered field along with normal gastric and duodenal biopsy specimens. In addition, biopsies must be performed after 6 to 8 weeks of regular proton pump inhibitor therapy or have a documented negative pH probe study.[34,35] Eosinophilic esophagitis may be patchy, and the diagnosis requires multiple biopsies; often four or five are recommended.

In contrast to GERD, treatment with acid-blocking therapies is ineffective in alleviating symptoms. Dietary changes, such as implementation of an elemental diet, suggest that food allergies play an important part in the pathogenesis of this disease.[36] Elemental diets have been shown to be effective greater than 95% of the time; other approaches include directed elimination diets (>75% effective) and empirical elimination diets (>70% effective).[37] Systemic steroids have also been advocated. Histologic remission has been documented after 4 weeks of corticosteroid use, although recurrence is common within 6 months of the cessation of treatment.[38] Topical corticosteroids, swallowed instead of inhaled, have also been advocated to treat acute eosinophilic esophagitis, and are known to reverse the associated clinical symptoms and histologic changes.[37]

Congenital tracheal stenosis is a rare congenital anomaly consisting of complete, circular tracheal rings. More than one third are associated with pulmonary slings or other cardiovascular anomalies. The dysphagia can be secondary to increased work of breathing or the associated vascular anomalies. CT, three-dimensional CT, and MRI are useful in determining the stenotic length and the presence of associated vascular anomalies. Bronchoscopy confirms the presence of complete tracheal rings and the length of the stenosis. Although many of these children require surgical correction, Rutter and associates[39] estimated 10% can be managed without surgery. Adequate nutrition and growth are crucial for these children. Oral feeders should have evaluation by FEES or VFSS or both because aspiration can result in significant respiratory compromise in these children with small airway caliber.

Tracheomalacia is anterior-to-posterior collapse of the trachea. Children with tracheomalacia present with expiratory stridor, wheezing, coughing, and sometimes dysphagia. Conditions that affect the structural integrity of the trachea such as tracheoesophageal fistulas, esophageal anomalies, vascular rings and slings, and innominate artery anomalies can cause tracheomalacia. The dysphagia can be a result of increased work of breathing, from the associated esophageal anomaly, or from vascular anomalies compressing the esophagus.

The diagnosis can be made by either airway fluoroscopy or bronchoscopy. Esophagograms are useful to identify esophageal anomalies and vascular anomalies compressing the esophagus. MRI can evaluate the extent of vascular anomalies further.

Tracheomalacia related to weak tracheal cartilage often resolves spontaneously in 2 to 3 years, as the child and the tracheal airway grow. Infants who are symptomatic with respiratory distress may require continuous positive airway pressure. Infants with tracheal collapse from esophageal or vascular anomalies benefit from surgical correction of the offending anomaly. Assessment of swallowing function may include VFSS and UGI after surgical correction.

Conclusion

Functional swallowing involves a complex orchestration of events throughout the aerodigestive tract. We have outlined four anatomic areas of the aerodigestive tract that contribute to dysphagia if anomalies are present: nose and nasopharynx, oral cavity and oral pharynx, hypopharynx and larynx, and trachea and esophagus. These four anatomic areas provide a framework for the evaluation and management of dysphagia. When managing children with dysphagia, the first priority is to provide a safe airway for breathing. After the airway is stabilized, swallowing function should be assessed and managed with the ultimate goal of providing sufficient nutrition and fluid for optimal growth and development. The care for children with dysphagia is complex, and a team approach including members from speech-language pathology, nutrition, gastroenterology, and otolaryngology is ideal.

CHAPTER TWO HUNDRED AND ELEVEN

Caustic Ingestion

Glenn B. Williams

Rose Mary S. Stocks

J. Dale Browne

James N. Thompson

Key Points

- Injuries from caustic ingestion are rare in the United States; 5000 to 15,000 occur per year.
- The current strict public policy on solution labeling and concentration was spearheaded by Jackson in the early 20th century.
- In developing nations without such policies, caustic injuries are more common.
- Acid ingestion leads to coagulative necrosis; alkali ingestion leads to liquefactive necrosis.
- The antrum of the stomach is the most vulnerable to acid ingestion; areas of anatomic narrowing are at greatest risk after alkali ingestion.
- Because of their resemblance to disk-shaped batteries, all coin-shaped foreign bodies should be removed expeditiously.
- Endoscopy is the most useful tool in assessing injury to the upper gastrointestinal tract.
- Typically, infant and toddler caustic ingestions are accidental, whereas adolescent and adult ingestions are suicide attempts.

"Those who cannot remember the past are condemned to repeat it."

—George Santayana

The preceding quote comes to mind when reviewing more recent caustic ingestion literature, most of which is from developing countries. Over the last decade, numerous articles have been published from various institutions in the developing world.[1-10] The fundamental problem is "uncontrolled and cheaper domestic cleaners have been introduced through common informal or open markets."[6] More recent reports estimate the incidence of caustic injuries in the United States to be 5000 to 15,000 per year; this low incidence has not always been the case.[5] During the early 1900s, in concert with the ready availability of cleaning solutions composed of strong alkalis or acids, reports of caustic ingestions filled the medical literature. These early cleaning solutions were packaged in inconspicuous containers that concealed the potential danger of the content. This public health issue was highlighted in a landmark article in 1921 by Jackson,[10] developer of the first distal lighted esophagoscope. Supported by extensive lobbying efforts by Jackson, the U.S. Congress passed legislation that controlled the sale of these potential toxins in 1927. Legislation led to the 1953 creation of the first National Poison Control Center in Chicago. In 1971, the U.S. Federal Hazardous Substance and Poison Prevention Packaging Act passed, mandating childproof container caps and banning excessively hazardous products and concentrations.

Despite these measures, extensive medical literature, and a century's experience, serious injuries secondary to caustic ingestion persist in the United States and abroad. Pediatric caustic ingestions are typically accidental and involve common household items. In adolescents and adults, ingestions are more likely intentional and represent suicide attempts.

Pathophysiology

Acid and alkali solutions are the two main categories of caustic products. Commonly ingested substances include cleaning agents, bleach, concentrated laundry detergent, concentrated ammonia, dishwashing detergent, alkali hair straighteners, nail-decorating liquids, sodium hydroxide–containing glucose testing tablets, and disk batteries.[11-15] Extensive local damage can occur after ingestion of sodium hydroxide–containing glucose test tablets and disk-shaped batteries if they lodge in the esophagus. Disk-shaped batteries are easily swallowed, and if they become lodged cause injury by several mechanisms: leakage of alkali causing direct caustic injury; absorption of toxic substances; pressure necrosis; and electrical discharge, which can cause mucosal burns.[16] Subsequently, the following types of esophageal injuries may occur: esophageal burn with or without perforation, tracheoesophageal fistula, and aortoesophageal fistula. Caustic substances present in farming homes used as disinfectants, pipeline clearance, and cattle horn removal are not subject to U.S. protective packaging legislation.[17]

Acid ingestion leads to coagulative necrosis with eschar formation that subsequently prevents further tissue penetration. Esophageal damage secondary to acid ingestion is less likely because of the protection afforded by the slightly alkaline pH of the esophagus, and because of the resistance of the squamous epithelium to acids. The antrum of the stomach is the most vulnerable region of the upper digestive tract to acidic substances owing to pooling and prolonged contact with the compound.[18]

Alkalis are responsible for more severe caustic ingestion sequelae; multiple factors contribute to the extensive damage. Direct contact with cell membranes leads to their disruption secondary to saponification and proteinate formation as the alkali reacts with membrane components. Solubility of alkalis allows for deeper penetration of the caustic agents typically in areas of anatomic narrowing (e.g., cricopharyngeus,

Hematemesis

aortic arch, left main stem bronchus, and diaphragmatic hiatus).[18] Damage ceases only when the alkali is neutralized by its reaction with tissue. The histopathologic events that occur after a 10% sodium hydroxide burn of esophageal mucosa include edema of the submucosa, inflammation of the submucosa with thrombosis, sloughing of the superficial layers, necrosis of the muscular layer, fibrosis of the deep layers, and delayed re-epithelialization.[19]

Initial Assessment and Diagnosis

Patients with caustic ingestion present with many symptoms, ranging from asymptomatic to overt stridor with severe dysphagia secondary to laryngeal edema and hypopharyngeal or esophageal injury (Box 211-1). As with all injured patients, the primary survey focuses on airway, breathing, and circulation (ABCs). A rapid assessment of the patient's airway and determination of the need for intervention is of primary importance. Simultaneously, patients suspected to have a severe injury should have large-bore intravenous catheters for early fluid resuscitation and medication. Patients with significant oral mucosal burns, tongue edema, hoarseness, stridor, and dyspnea should be monitored closely for possible airway obstruction.

Fiberoptic laryngoscopy is an invaluable tool in the assessment of hypopharyngeal damage and the risk of airway compromise. In a patient with an injured but stable airway, dexamethasone (20 to 30 mg intravenous bolus in adults; 0.5 to 1 mg/kg in children) can help prevent further deterioration. Direct visualization of the larynx is necessary for a successful and safe intubation; blind nasotracheal intubation should be avoided for fear of destabilizing a tenuous airway. If orotracheal intubation cannot be performed safely because of edema or exudate or both, a surgical airway (cricothyrotomy or tracheotomy) is the safer choice. Dyspnea associated with rales and rhonchi may indicate aspiration of caustic material or pulmonary edema. Chest and abdominal radiography should be obtained to rule out pulmonary infiltrates or free air. Patient complaints of epigastric pain and examination findings of peritonitis (e.g., abdominal wall rigidity, tenderness) are highly correlated with gastric injury.[20]

Vital information necessary for appropriate care of a patient with a caustic ingestion includes identification of the ingested agent and its characteristics (pH, concentration, physical form [i.e., granular, liquid]), time and setting of ingestion, and volume swallowed. The social setting of the ingestion may provide clues to the amount of caustic involved in the injury and should be explored in the history. Children ingest caustic substances accidentally while exploring their surroundings or because of lack of parental education or parental neglect.[9,21] Adult ingestions are generally suicide attempts, and large volumes are ingested. In the laboratory, the amount of titratable base is a more accurate predictor of a strong alkaline substance.[22] Vancura and colleagues[23] showed esophageal ulceration at a pH 12.5 or greater and significant mucosal damage with sodium hydroxide concentrations of 0.4% in mongrel cats. pH is clinically a more practical, rapid method of estimating the risk of mucosal injury.

Large volumes of strong acids are generally required to create esophageal injury, whereas a few milliliters of strong alkali can cause extensive damage instantaneously. Injury to the upper gastrointestinal mucosa after acid ingestion is more prolonged and is aided by reflex pylorospasm. Entry of acid into the stomach and contact with the pylorus results in a reflex spasm, leading to increased length of exposure and a predominance of gastric mucosal injuries in these patients. Measures such as emetics or buffering attempts are not recommended because they do not lessen the injury, and they increase the risk of aspiration. Conservative measures are encouraged, such as cleaning oral mucosa burns with water to dilute any remaining caustic, and manually removing any visible lye granules to lessen continuing injury.

Although the acute crises of esophageal perforation and upper airway obstruction are more dramatic, the most common complications from strong alkaline burns result from the more protracted courses of fibrosis and delayed epithelialization. Superficial burns generally heal without sequelae; however, deeper injuries involving the muscular layer and submucosa are associated with a more extensive loss of mucosa with subsequent fibrosis. A characteristic esophageal stricture develops in four stages: (1) An intense inflammatory response with associated dysmotility occurs in the area of the burned mucosa and deeper layers. (2) Granulation tissue with fibroblasts brings a matrix of collagen fibers to the newly formed connective tissue. (3) These collagen fibers begin to contract 3 or 4 weeks after the initial injury, with irregular formation of this collagen matrix, which enables the formation of adhesive bands. (4) Pseudodiverticula form between these adhesions as the contracting process continues until a dense inflexible fibrous scar replaces the destroyed submucosa and muscular layers. Circumferential burns are much more likely to lead to a symptomatic stricture than are noncircumferential injuries.[24]

Endoscopy

The clinician's principal diagnostic challenge lies in accurately predicting which ingestion injuries are prone to rapid, inconsequential healing, and which are prone to stricture formation or perforation. Endoscopy is the most useful method of assessing whether esophageal injury has occurred. Traditional adjunctive studies, such as barium esophagogram, are inadequate because of the reliance on motility disturbance and mucosal irregularities to detect injury[25] and significant false-negative rates (30% to 60%).[26,27] The usefulness of technetium 99m–labeled sucralfate has been shown; it has high sensitivity and specificity in determining the presence of an esophageal injury after pediatric caustic ingestion.[28] The high sensitivity and specificity allow this nuclear medicine study to serve as a screen for injury; however, it does not determine severity of injury or enable intervention. Depending on radiography alone for guidance may lead the clinician to underestimate the degree of injury in some patients.

The timing and necessity of endoscopy remains a topic of debate. Proponents of endoscopy within 24 hours in all cases of caustic ingestions are supported by retrospective reviews detailing instances of significant esophageal injury despite the absence of symptoms or signs of mucosal burns.[3,4,6,29-32] In citing the poor correlation of signs, symptoms, and esophageal injury, such studies frequently do not differentiate the form of the ingested substance (liquid vs. granular), and whether the asymptomatic burns were from more potent liquid alkalis. This association may lead to the conclusion that any form of an ingested caustic may cause significant distal injury even in the absence of signs or symptoms of mucosal burns. Although conservative and cautious, this approach may subject patients (and parents) occasionally to unneeded procedures, worry, and expense. In a retrospective study of 41 ingestions that noted the type of lye ingested, the granular form did not cause significant mucosal injury, whereas all strictures resulted from liquid alkalis.[30]

An alternative view of when to perform endoscopy considers several factors, including form and strength of the caustic, presence or absence of multiple signs and symptoms, and age of the patient. Most adult patients ingest caustic agents as a suicide attempt—this is a more straightforward diagnostic assessment. The volume of agent swallowed is usually great, commonly causing dysphagia, stridor, or oropharyngeal burns. Suicidal adults may be unreliable historians, which forces the

clinician to rely on physical findings to direct therapy, especially because oral mucosal injury may be absent when a strong alkali is quickly swallowed. Consequently, endoscopy is advisable for any adult having ingested a strong alkali or acid (e.g., sodium hydroxide, potassium hydroxide, hydrochloric acid, sulfuric acid), regardless of the lack of presenting symptoms or signs. In suicidal ingestions, the physician should examine the stomach for necrosis with endoscopy, laparoscopy, or laparotomy because a large volume of caustic may have been swallowed.

In contrast, toxic agents are accidentally swallowed in children as a result of innocent curiosity and confusion with food and drink. Just as children do not swallow a great deal of any distasteful food or medicine, they would not swallow any noxious, bitter acid or unpalatable granular lye. These compounds are rarely associated with significant esophageal burns because the volume ingested is generally very small.[30,33,34] Exceptions have been reported, but these cases are associated with presenting combinations of oral burns, drooling, and dysphagia that easily raise suspicion that a significant amount of the compound has been swallowed. In cases of pediatric ingestion of acids or granular lye, endoscopy can be reserved for children with significant oral burns, dysphagia, or stridor. A glucose test tablet or disk-shaped watch battery needs to be endoscopically removed as quickly as possible because these items cause localized transmural necrosis and esophageal perforation. This recommendation can be extended to any coin-shaped object lodged in a child's esophagus because some disk batteries may resemble a coin on chest radiographs (Fig. 211-1).

Most severe pediatric esophageal injuries are the result of just a few milliliters of a strong liquid alkali, usually sodium hydroxide. Some investigators have found that the presence of two or more signs and symptoms (e.g., oral burns, drooling, dysphagia, vomiting, stridor) reliably indicates esophageal injury significant enough to lead to stricture formation or perforation, requiring endoscopy.[33-35] Based on evidence from a retrospective study, one series concluded that unless a pediatric patient is symptomatic (e.g., vomiting, drooling, oral lesions, respiratory distress, hemostasis), endoscopy is unnecessary because asymptomatic children were not found to develop sequelae. The authors of the series confined this recommendation to developed countries with a more controlled, lower concentration of alkalis and acids.[36]

Although such criteria can be helpful in evaluating a child with a questionable history of liquid alkali ingestion, prudent evaluation of a pediatric patient with known ingestion of a strong liquid alkali should consider reported cases of an otherwise silent, significant injury appreciated only through endoscopy. In cases of known pediatric liquid alkali ingestion, endoscopy offers a direct assessment with low morbidity for the presence or absence of significant injury. In borderline patients, a technetium 99m–labeled sucralfate study can be useful. In children without a strong history and with only one presenting sign or symptom, the risk of significant injury is low, and endoscopy can be deferred or held, pending the results of a nuclear medicine study. Otherwise, it is safer to perform endoscopy in all children with known ingestion of a strong liquid alkali or who have positive findings on a technetium 99m–labeled sucralfate study.

Note its resemblance to a coin. **B,** Lateral view of battery within the chest. **C,** Endoscopic view of mucosal injury caused by the battery; lines mark circular burn at battery edge. **D,** Visual size comparison of a similar battery, a penny, and a nickel.

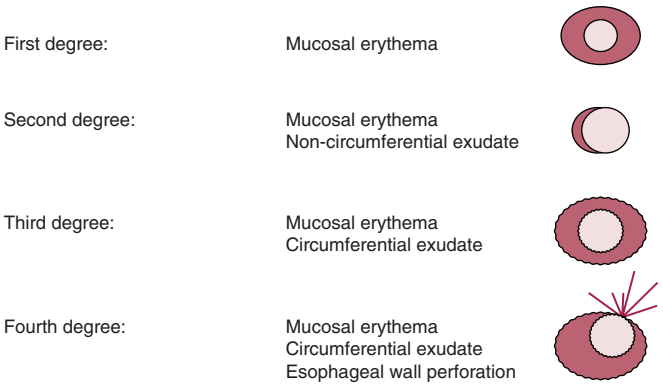

Figure 211-2. Four stages of esophageal burns.

Although any portion of the esophageal wall may be involved with the burn, the areas with the greatest extrinsic compression are most prone to injury. These are the cricopharyngeus, the aortic arch and left main stem bronchus compression sites, and the distal esophagus at the esophagogastric junction. As for other foreign bodies, this site is where solid caustics or batteries may lodge, causing severe localized injuries. When evaluating a significant burn of the esophagus, the endoscopist should be aware of the potential for a tracheoesophageal fistula resulting from the injury, especially at the upper esophageal and midesophageal narrowings. Tracheoscopy should be included when extensive burns are seen in these areas to examine the posterior tracheal wall for injury.

Staging

Methods of endoscopically staging and reporting esophageal burns vary. Historically, a classification borrowed from thermal burns has been used with references to first-degree, second-degree, and third-degree injuries that range from mild mucosal edema, to partial-thickness necrosis, to transmural necrosis.[37] Variations on this method have noted whether the lesion was circumferential. Recurrent difficulties in accurately and consistently applying this method include a failure to appreciate the true burn depth through the endoscope because of a necrotic exudate. Further contributing to endoscopic inaccuracy is difficulty in assessing the true amount of surface area burned because of mucosal edema. Such edema can prevent a complete, circumferential examination and obscure the sometimes subtle changes of an evolving submucosal necrosis, leading to an underestimation of injury in marginally burned areas.

Using modified classifications, four stages can provide the endoscopist with a consistent format for describing caustic injury to the esophageal lumen: first degree, mucosal erythema; second degree, erythema plus noncircumferential exudate; third degree, circumferential exudate; and fourth degree, circumferential exudate with esophageal wall perforation (Fig. 211-2).[38] Additional references to the site and length of the burn can be documented. In this staging system, only first-degree burns consistently heal uneventfully. Second-degree injuries occasionally form strictures, and all third-degree burns generally form strictures. Fourth-degree burns carry the additional risk of sepsis and mediastinitis. Because it is difficult to predict the true depth accurately, there is the potential for a third-degree burn eventually to extend into a fourth-degree burn—hence the need for close follow-up.

Several days after a caustic esophageal injury, any necrotic mucosa, submucosa, and muscular layer will have sloughed. At this point, the esophageal wall is at its weakest and may be prone to perforation, either spontaneously or secondary to an endoscope or nasogastric tube. The same is true for a transmural injury to the gastric wall. Close observation in all patients with third-degree esophageal burns is mandatory in a hospital for several days. Although antibiotics have not been shown to prevent strictures, broad-spectrum antibiotics are prudent in extensive third-degree burns that may lead to perforation.[30]

Additionally, endoscopy in the first 24 hours is safer to minimize the risk of perforation and for early identification of patients at risk for a fourth-degree injury. Although traditionally endoscopy has been aborted at the first significant burn,[10,17] the value and safety of full-length, careful esophagoscopy has been shown, especially in identifying patients with significant distal injury extending into the stomach.[30,37,39-42] With this in mind, endoscopy should be aborted when there is no definable lumen, rather than ceasing at the first severe burn. Although rigid and flexible endoscopes have been used to examine the full length of the esophagus successfully, the flexible model is necessary for adequate visualization of the stomach. If necrosis is identified extending into the gastric mucosa, direct visualization of the outer gastric wall should be strongly considered to rule out a transmural necrosis. Visualization may be by laparoscopy or laparotomy, depending on the surgeon's preference.

Therapy

When esophagogastric mucosal injury is diagnosed, the choice of therapy depends on the degree of injury. Injuries limited to first-degree burns of the esophageal mucosa require no further therapy. Blunt esophagectomy after identification of fourth-degree and selected extensive third-degree esophageal burns reduces the expected mortality from leaving a necrotic esophagus in place.[39,43] Identifying a perforation makes the decision for esophagectomy straightforward. For extensive third-degree burns, a thoracotomy or thoracoscopy for direct examination of the esophageal wall may be indicated to assess for transmural necrosis. Such decisions may be difficult, and may require the judgment and experience of the endoscopist. Débridement at the time of laparotomy or laparoscopy is dictated by the injury. In cases of gastric perforation, débridement of omentum, small bowel, and other intra-abdominal structures may be necessary.

The major controversy in therapeutic choices involves intermediate esophageal burns (i.e., second-degree and localized third-degree injuries). The goals of therapy are to maintain the esophageal lumen by the pharmacologic reduction or prevention of stricture formation and to maintain a conduit from the hypopharynx to the stomach by esophageal dilation, stenting, or reconstruction.

Pharmacologic Therapy

In 1950, Howes[44] and Spain[45] documented the retarding effect of corticosteroids on wound healing in separate laboratory studies. The following year, Rosenberg and coworkers[27] noted decreased stricture formation with corticosteroid therapy after alkali burns of rabbit esophageal mucosa. Although infection led to a high mortality rate, the supposed benefit from corticosteroids seemed clear. The addition of antibiotics reduced mortality, and the subsequent regimen of corticosteroids and antibiotics reduced esophageal strictures in the laboratory setting.[46-48] These findings led to the empirical therapeutic combination of corticosteroids and broad-spectrum antibiotics for significant second-degree and third-degree esophageal injuries. Retrospective analyses produce conflicting results. Some studies have shown benefit in reducing strictures, whereas others have not.[49,50]

In an attempt to resolve this controversy, Anderson and associates[51] reported on a prospective analysis through 18 years of 60 children with esophageal burns secondary to strong caustics (80% alkali). Patients were randomly assigned to receive 21 days of corticosteroids or no therapy, with the degrees of injury stratified equally in both groups. Of 21 patients identified as having circumferential burns, 20 developed strictures. Only 1 of 20 patients with a noncircumferential burn developed a stricture. Corticosteroids had no effect in the patients with circumferential burns. Ironically, the only stricture in the noncircumferential injury occurred in a child who received corticosteroids.

Lathyrogenic drugs that reduce collagen cross bonding have been used in attempts to decrease stricture formation.[52] Compounds such as β-aminopropionitrile, *N*-acetylcysteine, and penicillamine decrease stricture formation in laboratory settings, but their benefit in humans is unproven. Of these medications, penicillamine is the least toxic, and potentially may play a limited role.

Contact with acid and pepsin retards the healing of lye-induced esophageal burns in rabbits.[53] Clinically, the increase of gastroesophageal reflux has been documented in pediatric caustic strictures and subsequent loss of lower esophageal sphincter integrity.[54] With this

information, it follows that efforts to decrease the effects of stomach acid on injured esophageal mucosa may be useful clinically. Sucralfate therapy for caustic esophageal burns has shown promise in the healing of ulcers without stricture formation.[55,56] Although unproven clinically in prospective caustic injury series, the low toxicity of pharmacologically reducing gastroesophageal reflux provides an attractive adjunctive measure in controlling strictures that is worthy of such a study.

Experience has been positive in the use of topical mitomycin in the management of pediatric tracheoesophageal strictures.[57-59] Mitomycin is an antibiotic used as an antineoplastic agent. Its usefulness stems from its behavior as an alkylating agent that inhibits deoxyribonucleic acid and protein synthesis, and fibroblast formation. Although experience in the use of this medication in caustic esophageal injuries is minimal, the successful use of this agent in selected aerodigestive tract lesions may herald some usefulness in caustic injuries.

Mechanical Therapy

The simplest mechanical method for maintaining a lumen in a third-degree esophageal burn is to place a nasogastric tube at the time of initial endoscopy. The true benefit of nasogastric tube stenting varies, with results ranging from spectacular to no benefit.[60,61] In a patient with a third-degree burn and dysphagia, a nasogastric tube provides a convenient stent and a means of nutritional support. Other types of stents have used polymeric silicone tubes in the esophagus with mixed success. Any clear benefit over serial dilations has not been shown.[62] Ideally, if this philosophy is used in guiding therapy, stents should remain in place long enough to allow re-epithelialization (2 to 3 weeks) with some reporting use for 9 to 14 months.[2]

Mild strictures can be serially dilated in a prograde fashion through an esophagoscope with filiform dilators. Cooperative patients (generally adults) may tolerate the periodic swallowing of weighted dilators in the office. Fluoroscopic guided balloon catheter dilation for acquired strictures has shown little success.[63] When identified, multiple strictures are managed most safely with retrograde dilators, popularized by Tucker[64] in the 1920s. A gastrostomy is necessary for the passage of an endless loop of silk exiting the mouth to allow slow, serial increases in caliber, while maintaining a secure position within the narrowed lumen and minimizing the risks of perforation (Fig. 211-3). If a significant, lengthy third-degree burn is identified at initial endoscopy, strong consideration should be given to the placement of a gastrostomy tube and

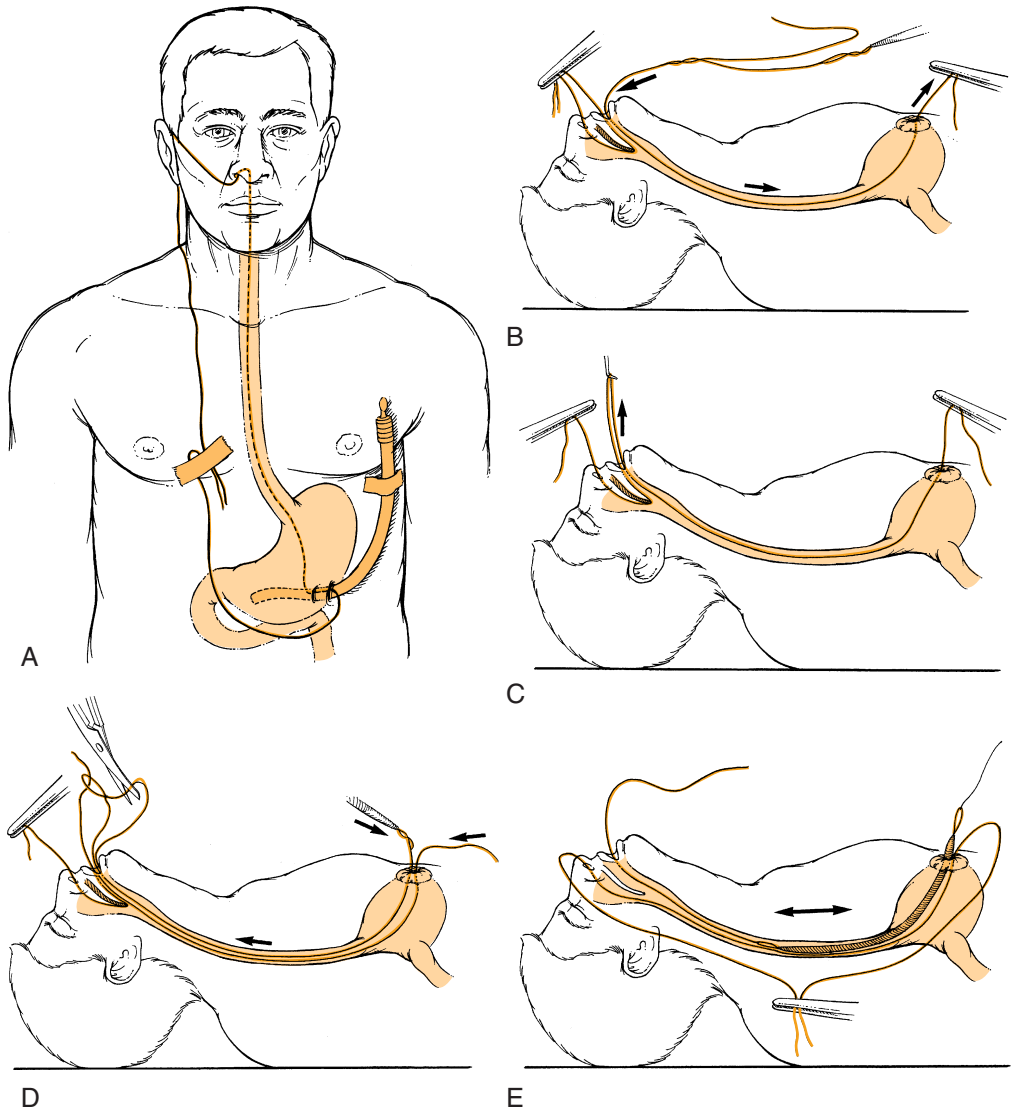

Figure 211-3. **A,** Appearance of a typical patient undergoing chronic retrograde dilations via gastrostomy. A guide string enters the nasal cavity, loops behind the ear, and enters alongside the gastrostomy tube. **B,** String (heavy silk) is retrieved from the posterior pharynx. **C,** A dilator is secured to silk exiting the mouth for gentle progressive prograde dilation. Care is taken to clamp the loop exiting the mouth and nose. **D,** A dilator is secured to silk exiting the gastrostomy tube for gentle progressive retrograde dilations. **E,** When dilator is within the lumen of the strictures, a gentle to-and-fro prograde or retrograde dilation may be accomplished. For security, a second heavy silk loop can be passed before any dilation in case the dilator string breaks.[64]

retrograde silk during the same anesthesia or before discharge to avoid a delay in safe dilation in the outpatient setting.

The timing of stricture dilation depends on the severity of the injury. In second-degree injuries, prophylactic dilation is not recommended, although periodic follow-up is important. Stricture formation may occur 6 weeks from the time of injury, and may become evident only when obstructed with food. Generally, a barium swallow at 3 weeks serves as a baseline in asymptomatic patients and as an initial study before prophylactic dilations in patients with lengthy third-degree injuries that are at high risk for stricture development. Routine barium esophagography is useful for 1 year to monitor progress of a managed stricture, and to rule out the development of an occult stricture. For symptomatic patients, the frequency of dilations depends on patient response. Weekly dilations may be necessary to maintain a viable lumen in severe injuries (Fig. 211-4).

When repetitive dilations fail to relieve symptoms, or when severe esophageal strictures render dilation impossible or fruitless, more aggressive techniques are indicated to reconstruct the conduit from hypopharynx to stomach. Esophageal replacement with gastric tubes, right colon, transverse colon, or descending colon has been described. The right colon has been reported to be the most useful conduit (Fig. 211-5).[65,66] When possible, blunt esophagectomy is preferable to thoracotomy. For isolated strictures, local resection with end-to-end reanastomosis, colon patch esophagoplasty, and esophageal stricture bypass with a colonic conduit have been reported in successful attempts to preserve an injured esophagus.[67-69]

Gastric outlet obstruction as a complication of acid ingestion is well known but uncommon, with an incidence 3.8% to 8.2% in pediatric series.[7,70] Less common is outlet obstruction secondary to alkali ingestion, with 5.3% (9 of 168) of patients developing gastric outlet obstruction in addition to esophageal strictures in the series reported by Ciftci and colleagues.[70] Presenting symptoms include frequent nonbilious emesis and secondary marked weight loss.[7] Treatment is surgical and includes gastrojejunostomy[7] or Billroth I[70] for complete obstruction and the Finney or Heineke-Mikulicz pyloroplasty for patients with partial obstruction.[70]

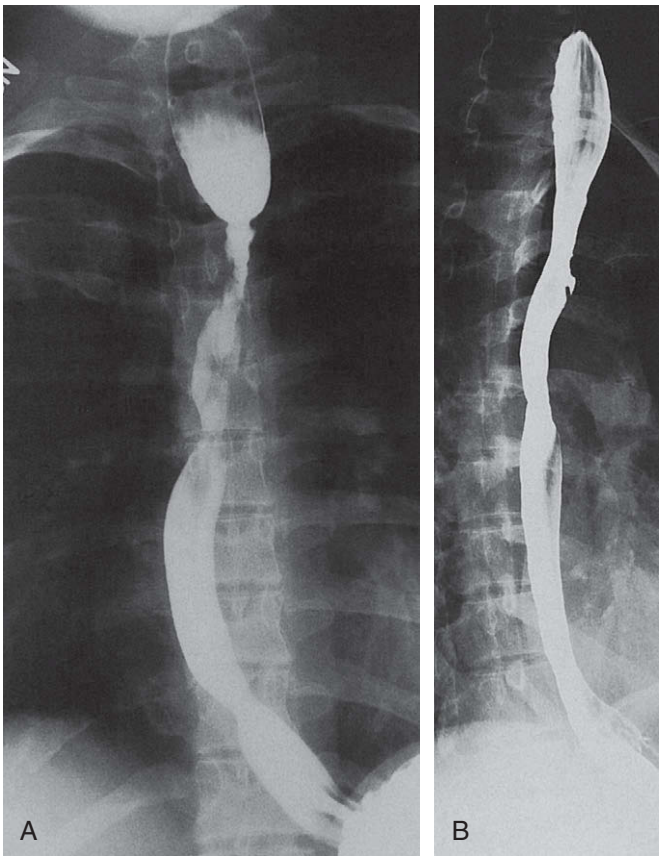

Figure 211-4. **A,** Barium swallow shows midesophageal stricture after lye ingestion in an adolescent 4 weeks after ingestion and at the beginning of retrograde dilations. **B,** Same patient 5 years later, after 4 years of repetitive dilations; the patient has a stable stricture and is generally nonsymptomatic.

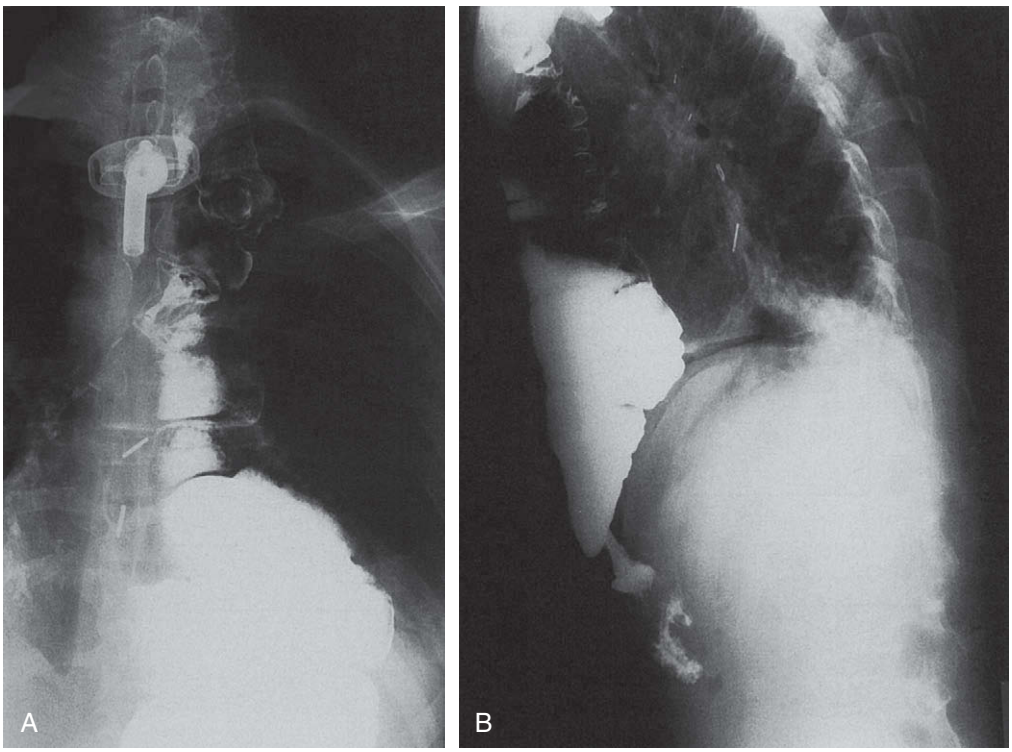

Figure 211-5. **A,** Anterior view of a barium swallow of a patient with a fourth-degree burn necessitating a total blunt esophagectomy with subsequent reconstruction using the right descending colon. The tracheotomy was originally placed emergently because of laryngeal obstruction secondary to supraglottic necrosis or edema. **B,** Lateral view of the same patient. Note the position of colon transfer in the anterior mediastinum.

The benefits from esophagectomy are not limited to the reconstruction of a swallowing conduit. In large series of esophageal carcinomas, a 1% to 4% incidence of caustic ingestion is typical. Although the true increased risk of carcinoma is unknown, it has been estimated at 1000-fold. The tendency for local extension of these malignancies is lower than expected with a higher potential rate of cure because they develop in the fibrotic, stenotic scar.[71] With this in mind, long-term follow-up is essential in any patient with a caustic esophageal stricture. The redevelopment of dysphagia after years of minimal difficulties should prompt an investigation with at least barium esophagography and, if abnormal, esophagoscopy with appropriate biopsy specimens.

In selected patients with a severely strictured esophagus requiring a lifetime of repetitive dilations necessary to maintain any useful lumen, elective esophagectomy with subsequent reconstruction may be reasonable. Additionally, a hiatal hernia, esophagitis, and peptic stricture may develop decades after a severe caustic injury, with resultant progressive fibrosis and dysfunction of the gastroesophageal sphincter. In this setting, the use of traditional dilation techniques as primary long-term therapy actually worsens the situation and the reflux.[72] Aggressive prophylactic antireflux measures with proton pump inhibitors may improve the outlook for these patients by increasing the long-term success of dilation, avoiding the need for aggressive surgery.

Conclusion

Caustic ingestion is an uncommon injury in the United States that varies widely in severity, ranging from minimal mucosal erythema to frank transmural necrosis of the esophagus and stomach with viscous perforation (Fig. 211-6). After appropriate identification of concentra-

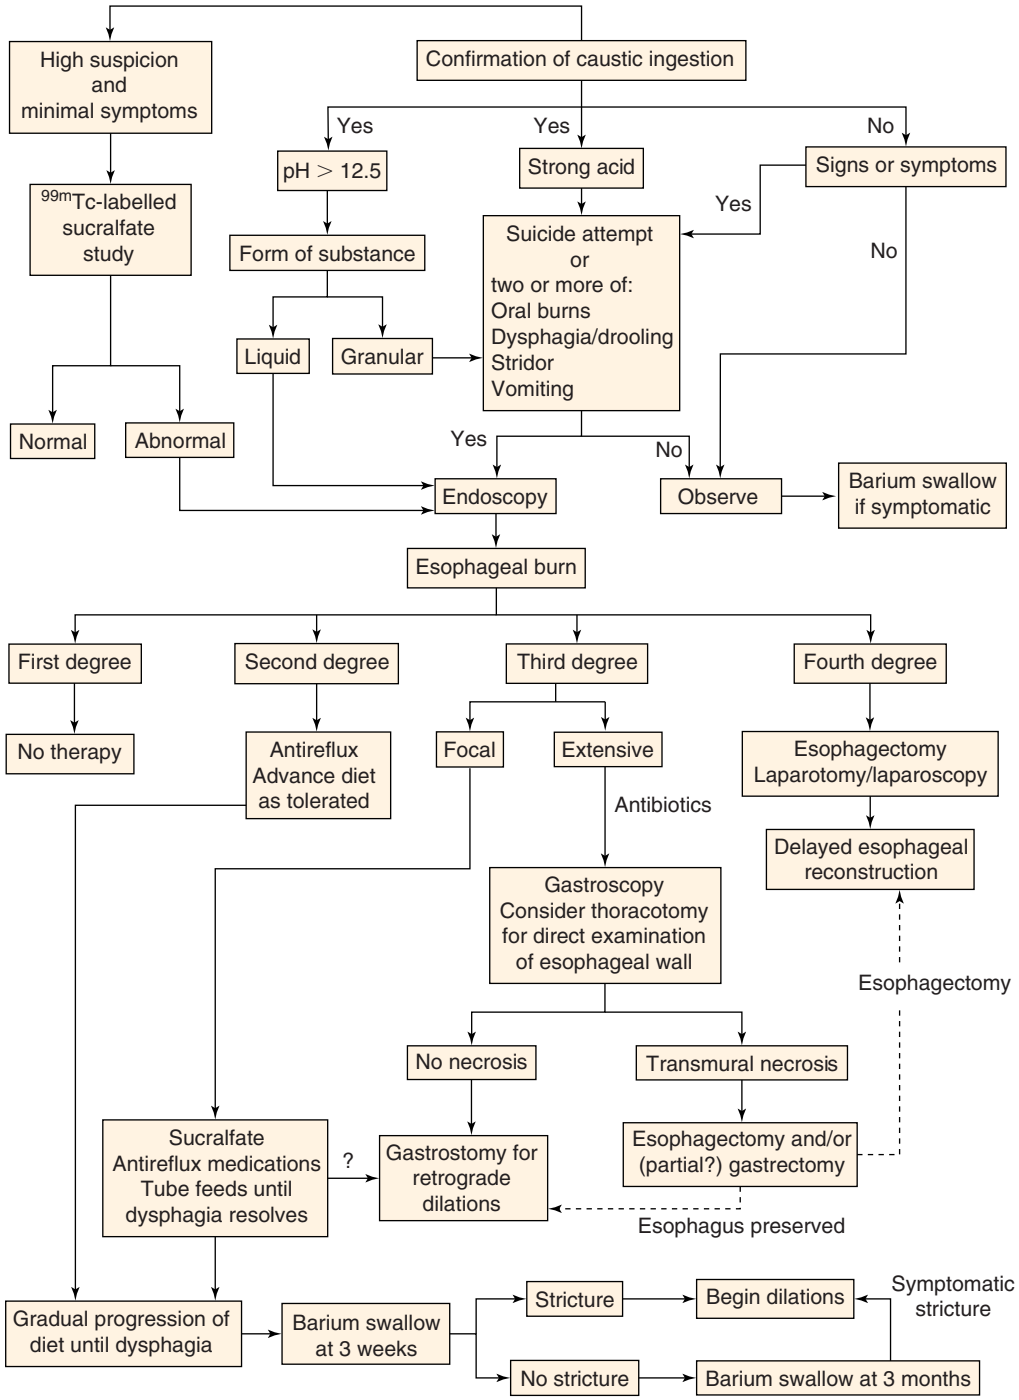

Figure 211-6. Evaluation and treatment of caustic ingestion.

tion, pH, and form of the ingested substance, the clinician should decide whether to evaluate the upper aerodigestive tract further. Full-length esophageal endoscopy is the most accurate initial method of examination, and is indicated after any ingestion of a strong liquid alkali. The need for endoscopy in other settings depends on the strength, volume, and form of the ingested caustic and associated signs and symptoms. Esophageal stricture formation is the chief long-term complication with a potential devastating impact on quality of life. Although repetitive stricture dilations are the mainstay of management, prevention or reduction in the severity of this complication is promising. Extensive necrotic esophageal injuries are doomed to fibrosis, but protocols emphasizing mucosal protectants with aggressive antireflux management may provide a means to minimize stricture formation in second-degree and localized third-degree injuries.

      natural history of, 721
      origin of, 721, 721f
      postoperative surveillance for, 722
      preoperative embolization for, 721-722
      surgical approach for, 718t, 722, 722f-723f, 763
      transnasal endoscopic-assisted surgery for, 2483, 2483f
Angiogenesis
  in acutely raised skin flaps, 1069, 1069f
  in formation of granulation tissue, 1077-1078
Angiography
  prior to anterior and middle cranial base surgery, 2444-2445
  of anterior skull base, 2475
  catheters for, 1932-1933
  computed tomography
    of anterior skull base, 2475, 2475f
    of neck masses, 1637, 1637t
  equipment for, 1932
  of glomus jugulare/vagale tumor, 1935f
  magnetic resonance, 137
    of anterior skull base, 2475
    of neck masses, 1637, 1637t
    of petrous apicitis, 1989f
  of multiple chemodectomas, 1935f
  of neck masses, 1637, 1637t
  of paranasal sinus tumors, 1124
  for penetrating neck trauma, 1630-1632, 1631t, 1632f-1633f
Angiokeratoma corporis diffusum universale, oral manifestations of, 1257
Angioma(s)
  cherry (senile), 290-291
  spider, 291
  strawberry, 290
  tufted, 2824-2825
    Kasabach-Merritt phenomenon with, 2825
Angiopathy, diabetic, presbycusis due to, 232
Angiosarcoma, of neck, 1668
Angiosomes, 1064
  in acutely raised skin flaps, 1069, 1069f
Angular cheilitis, 1230, 1230f
  in HIV, 225, 226f
Angular gyrus, in central auditory pathway, 1837
Angular vestibuloocular reflex (aVOR), 2306, 2307f
  after labyrinthectomy, 2291-2292, 2291f-2293f
Ankle strategy, 2308
Ankylosis, of temporomandibular joint, 1281t, 1282
Ann Arbor staging system, for lymphoma, 1676, 1677t
Annular ligament, of stylomastoid foramen, 1826f
Annulus of Zinn, 440
Anosmia, 633
  congenital, 636
  specific, 636
Anotia, 2742
ANOVA (analysis of variance), 71
Ansa cervicalis
  anatomy of, 2579f-2580f, 2581
  characteristics of, 918-919
  in neuromuscular pedicle procedure, 920, 921f
Ansa cervicalis–recurrent laryngeal nerve anastomosis, for laryngeal reinnervation, 922-923
  advantages of, 922
  clinical results of, 923
  disadvantage of, 922
  history of, 917-918
  surgical indications and contraindications for, 922
  surgical technique for, 922-923, 923f
Ansa hypoglossi nerve, for facial nerve paralysis, 2426-2427
Antacids
  for extraesophageal reflux, 901
  for GERD, 970
Anterior ampullary nerve, 1854f, 2278f
Anterior cerebral artery, 2351f
Anterior cervical lymph nodes, 2582
Anterior cervical space, imaging of, 158, 160f, 162f
Anterior cervical trauma, laryngeal injury due to, 933-934, 934f

Anterior clinoid process
  in surgical anatomy of anterior cranial base, 2442-2443, 2443f, 2472f
  in surgical anatomy of lateral skull base, 2435f
Anterior commissure
  anatomy of, 1486
  laryngeal carcinoma of, 1486
    anatomic basis for, 1486
    imaging of, 161, 1474, 1474f
    treatment of, 1496-1497, 1523
      transoral laser microsurgery for, 1531
Anterior commissure tendon, surgical anatomy of, 1541-1542
Anterior communicating artery, 2351f
Anterior compartment lymph nodes, in neck dissection, 1704, 1704f, 1706t
Anterior cranial base
  anatomy of, 1697
  boundaries of, 2442, 2443f
    anterior, 2442, 2443f
    superior, 2442-2443, 2443f
  surgical anatomy of, 741, 2442-2444
    craniofacial junction in, 2442, 2443f
    extracranial structures related to, 2443, 2444f
    and surgical landmarks of orbital skeleton, 2443-2444, 2444f
    for transnasal endoscopic-assisted surgery, 2471-2475
      anterior cranial fossa in, 2471, 2472f
      clivus in, 2474, 2474f
      nasal cavity in, 2471-2473, 2472f-2473f
      nasopharynx in, 2474
      paranasal sinuses in, 2473-2474, 2473f
      retroclival region in, 2474-2475, 2474f-2475f
Anterior cranial base irradiation, 1697-1699
Anterior cranial base surgery
  anesthesia for, 2447-2448
  bicoronal incision in, 2450-2451, 2450f
  complications of, 2468-2469, 2469t
  electrophysiologic monitoring during, 2450
  flap elevation in, 2450-2451, 2451f
  goals of, 2448, 2448b
  intraoperative imaging during, 2449
  operative approaches for, 2450-2454
    anterior craniofacial resection as, 2451-2453, 2452f-2453f
    basal subfrontal, 2453-2454, 2454f
    endoscopic, 2448-2450
    functional and aesthetic considerations in choice of, 2450
    general considerations with, 2448-2450
    image-guided computer-assisted, 2448-2449, 2449f
    overview of, 2448
    planning of, 2448-2450
    robotic, 2450
    subcranial, 2454, 2454f
  outcomes of, 2469-2470
  pathology and management planning for, 2446-2447, 2447b
  postoperative care after, 2468
  preoperative embolization for, 2446
  preoperative evaluation for, 2444-2448
    angiography in, 2444-2445
    of cerebral blood flow, 2445-2446, 2446f
    other evaluations in, 2446-2447
  reconstruction after, 2467-2468
  transnasal endoscopic-assisted, 2471-2486
    anesthesia for, 2476
    combined approaches for, 2484
    complications of, 2485
    craniocervical junction–odontoid approach for, 2483-2484, 2484f
    instrumentation for, 2476
    patient preparation for, 2475-2476
    pedicled septal flap in, 2476-2477
    postoperative care after, 2484-2485
Anterior cranial base surgery *(Continued)*
    preoperative assessment for, 2475, 2475f
    reconstruction after, 2484
    surgical anatomy for, 2471-2475
      anterior cranial fossa in, 2471, 2472f
      clivus in, 2474, 2474f
      nasal cavity in, 2471-2473, 2472f-2473f
      nasopharynx in, 2474
      paranasal sinuses in, 2473-2474, 2473f
      retroclival region in, 2474-2475, 2474f-2475f
    surgical team setup for, 2476f
    transcribriform approach for, 2482
      with bilateral access, 2482, 2482f
      with unilateral access, 2482
    transmaxillary-transpterygoidal-infratemporal approach for, 2482-2483, 2483f
    transsellar and parasellar approaches for, 2479, 2480f
    transsphenoidal approach for, 2477-2481
      with direct transnasal access, 2477, 2477f
      with petrous apex access, 2481
      with transclival approach, 2479-2481, 2480f-2481f
      with transethmoidal access, 2478-2479, 2479f-2480f
      with transseptal access, 2477-2478, 2477f-2478f
      with transseptal-transnasal access, 2478, 2479f
    transtuberculum-transplanum approach for, 2482
Anterior cranial base tumors
  benign, 2446, 2447b
  fibrous dysplasia as, 2647f
  malignant, 1697-1699, 2446, 2447b
    esthesioneuroblastoma as, 1697-1698, 1698f, 1698t
    sinonasal undifferentiated carcinoma as, 1698-1699
  preoperative planning for, 2446-2447
Anterior cranial fossa
  in surgical anatomy of anterior skull base, 2471, 2472f
  in surgical anatomy of lateral skull base, 2435f
Anterior cranial fossa floor, in surgical anatomy of anterior cranial base, 2442-2443, 2443f-2444f
Anterior craniofacial resection, 2451-2453, 2452f-2453f
Anterior cricoid split operation, 2910f, 2918-2919, 2918f-2919f
Anterior cutaneous nerve, anatomy of, 2578, 2580f
Anterior disk displacement, of temporomandibular joint
  with reduction, 1280, 1282f
  without reduction, 1279-1280, 1282f
Anterior ethmoidal air cells, in frontal sinusitis, 776
Anterior ethmoidal artery
  anatomy of, 682, 684f, 1124f
  bleeding from, 690-691, 691f-692f
  prior to endoscopic sinus surgery, 764, 765f
  septal branch of, 483f
  in surgical anatomy of anterior cranial base, 2471-2473, 2472f
Anterior ethmoidal foramen, 322f, 439
Anterior ethmoidal nerve, 483f
  external branch of, 497, 497f
Anterior ethmoidectomy, in endoscopic sinus surgery, 747, 748f
Anterior fontanelle, 2618f
Anterior glottic gap, laryngeal videostroboscopy of, 819, 820f
Anterior glottic web, 2869, 2869f
  stridor due to, 2899, 2900f
  and velocardiofacial syndrome, 2899, 2900f, 2913
Anterior inferior cerebellar artery (AICA)
  anatomy of, 1856f, 2351f
    surgical, 2403-2404, 2404f
  in posterior fossa surgery, 2540
  in surgical anatomy of anterior skull base, 2481f
  in surgical anatomy of lateral skull base, 2437f, 2439f
Anterior inferior cerebellar artery (AICA) occlusion, sensorineural hearing loss due to, 2123
Anterior lacrimal crest, 439
Anterior lamella, of eyelid, 442-443, 443f
Anterior laryngeal wall stenosis, 951
Anterior laryngofissure, with posterior cricoid division, for laryngeal stenosis, 2919, 2919f
Anterior mallear fold, anatomy of, 1825f
Anterior malleolar fold, anatomy of, 1827f
Anterior malleolar ligament, anatomy of, 1827f
Anterior meningoencephaloceles, surgical management of, 742
Anterior nasal aperture, 320f
Anterior nasal depth, 2617t
Anterior nasal spine, 320f, 509f
Anterior neck dissection, 1719
  defined, 1719, 1719f
  technique for, 1719, 1720f
Anterior neuropore, congenital malformations of nose due to developmental errors of, 2686-2690, 2687f
Anterior ostiomeatal channels, 666f
Anterior ostiomeatal unit, 664, 665f
Anterior palatal artery, 483f
Anterior partial laryngectomy, for glottic cancer, 1517t
Anterior petrous apex (APA), 1975-1976, 1976f
  pneumatic, 1976, 1977f
Anterior rhinoscopy, 100, 484
Anterior scalene muscle, anatomy of, 2579f
Anterior scalp flap, 2450-2451
Anterior semicircular duct, anatomy of, 1851f
Anterior septal angle, 509f
Anterior skull base. *See* Anterior cranial base.
Anterior spinal artery, 2351f
Anterior spiral vein, 1856f
Anterior tonsillar pillar, 1297-1298
Anterior tracheal wall stenosis, 951
Anterior transhyoid pharyngotomy, for hypopharyngeal cancer, 1427-1429, 1428f
Anterior triangle, of neck, 96, 96f, 2578f, 2579-2581
  ansa cervicalis in, 2580f, 2581
  carotid triangle in, 2578f, 2579-2580, 2580f
Anterior triangle dissection, 1709-1710
Anterior tympanic artery, 1828f
Anterior vestibular artery, 1854, 1856f
Anterior visceral space, anatomy of, 203
Anterolateral fontanelle, 2618f
Anterolateral thigh flap, 1082t, 1083
  for hypopharyngeal and esophageal reconstruction, 1455
  for oropharyngeal reconstruction, 1379
    of tongue base, 1390-1391
    of tonsils and pharyngeal wall, 1386
Anthropometry, 269
Antiaging products, 403
Antiangiogenesis, in gene therapy, 22
Antiangiogenic compounds, for head and neck squamous cell carcinoma, 1060
Antiarrhythmics, oral sequelae of, 1247t-1248t
Antiarthritics, oral sequelae of, 1247t-1248t
Antibacterial activity, of saliva, 1141
Antibiotic(s)
  for deep neck space infections, 205-206, 206t
  for odontogenic infections, 178, 188
  oral sequelae of, 1247t-1248t
  for otitis media
    acute, 2770
    with effusion, 2771-2772

Antibiotic(s) *(Continued)*
ototopical, 1959t-1960t
for acute bacterial otitis externa, 1951-1953
evidence-based data on, 1952
hypersensitivity reaction to, 1954
mechanism of action of, 1951
ototoxicity of, 1953-1954
resistance to, 1953
for pediatric chronic sinusitis, 2779
for rhinosinusitis, 733-735
intravenous, 733-734, 735t
issues with, 736
long-term macrolide, 733, 734t
oral, 733
short-term, 734t
topical, 734-735, 735t
for stridulous child, 2906
for vocal professionals, 855
Antibiotic prophylaxis
for acute otitis media, 2771
for burns, 315
for orthopedic joint patients, 1253, 1253t
for sinus surgery, 743, 773
for temporal bone fractures, 2044-2045
Antibody-dependent cellular cytotoxicity (ADCC), 603-604, 606
Antibody-mediated hypersensitivity reactions, 608-612
Anticholinergics
for allergic rhinitis, 620
for nonallergic rhinitis, 701
Anticoagulants
dizziness due to, 2310t
oral sequelae of, 1247t-1248t, 1248, 1250
preoperative evaluation of, 105
Anticonvulsants
for chronic pain, 243-244, 244t
dizziness due to, 2310t
oral sequelae of, 1247t-1248t
Antidepressants
for chronic pain, 244-245, 245t
for migraine, 2350
in palliative care, 1104
for tinnitus, 2137
Antidiarrheal agents, oral sequelae of, 1247t-1248t
Antidromic potentials, to assess facial nerve function, 2388
Antiemetics, for postoperative nausea and vomiting, in children, 2593
Antiepileptics
for chronic pain, 243-244, 244t
dizziness due to, 2310t
oral sequelae of, 1247t-1248t
Antifungal agents
for rhinosinusitis
nonallergic eosinophilic fungal, 715-716
systemic, 735, 735t
topical, 735-736, 735t
topical, 1959t-1960t
for fungal otitis externa, 1954-1955
ototoxicity of, 1955
for rhinosinusitis, 735-736, 735t
Antigen presentation, 602f, 606, 606f
Antigen-presenting cells (APCs), 602f, 606, 606f
Antihelix, of ear, 476-477, 476f, 1824f, 2742f
Antihistamines
oral sequelae of, 1247t-1248t
for otitis media
acute, 2770
with effusion, 2771
for rhinitis
allergic, 620
nonallergic, 700-701, 701t
for rhinosinusitis, 734t, 737
for vocal professionals, 854
Antihypertensives
dizziness due to, 2310t
intraoperative, 112
oral sequelae of, 1247t-1248t, 1248
Anti–immunoglobulin E (anti-IgE)
for allergic rhinitis, 622
for rhinosinusitis, 735t, 737
Anti-inflammatory medications
oral sequelae of, 1247t-1248t
ototopical
classes of, 1956, 1956t
for eczematoid otitis externa, 1956-1957
hypersensitivity reaction to, 1954
mechanism of action of, 1951
ototoxicity of, 1956
Antilipidemics, oral sequelae of, 1247t-1248t
Antimalarials, sensorineural hearing loss due to, 2120
Antimicrobial peptides (AMPs), 598-599
cathelicidins as, 599
defensins as, 599
tissue distribution of, 599
Antimicrobial substances, in saliva, 1140
Antimicrosomal antibodies (AMAs), 1740-1741
Antimycotics, oral sequelae of, 1247t-1248t
Antineoplastic agent(s)
oral sequelae of, 1247t-1248t
ototoxicity of, 2171-2174
carboplatin as, 2173-2174
cisplatin as, 2171-2173
clinical studies on, 2171-2172
delayed, 2171-2172
experimental studies on, 2172
genetic predisposition to, 2172
histopathology of, 2172
mechanics of, 2172-2173
pharmacokinetics of, 2171
risk factors for, 2172
vestibular, 2172
difluoromethylornithine as, 2174
animal studies on, 2174
clinical studies on, 2174
conclusions on, 2174
Antineutrophil cytoplasmic antibodies (ANCAs), in Wegener's granulomatosis, 658, 2103
Antioxidants
for cisplatin ototoxicity, 2173
for noise-induced hearing loss, 2145
oral sequelae of, 1247t-1248t
Anti-Parkinsonian medications, oral sequelae of, 1247t-1248t
Antiphospholipid antibody syndrome, inner ear disease in, 2166
Antiproliferatives, oral sequelae of, 1247t-1248t
Antipyretics, oral sequelae of, 1247t-1248t
Antireflux agents
for extraesophageal reflux in children, 2946
oral sequelae of, 1247t-1248t
for recurrent respiratory papillomatosis, 2893
for rhinosinusitis, 735t, 737
Antireflux surgery, for GERD, 970
Antiretroviral therapy, highly active, 211
Antiseptics, ototopical, 1959t-1960t
for fungal otitis externa, 1955
Antithyroglobulin antibodies (ATAs), 1740
Antithyroid agents, 1739, 1739t
adverse reactions to, 1742
for Graves' disease, 1742
for Graves' ophthalmopathy, 1810
oral sequelae of, 1247t-1248t
for thyroid storm, 1745
Antithyroid antibodies, 1740-1741
Anti-thyroperoxidase (anti-TPO), 1740
Antitragus, 476-477, 476f, 1824f, 2742f
Antitumoral immune response, direct in vivo stimulation of, 21
Antiviral agents
for Bell's palsy, 2395
for rhinosinusitis, 731, 734t
Antrostomy, in endoscopic sinus surgery, 747, 747f
failure of, 764-766, 766f
Antrum, in mastoidectomy, 2011-2012
Anxiety
palliative care for, 1103-1104
professional voice disorders due to, 853
Anxiolytics, oral sequelae of, 1247t-1248t
AOM. *See* Acute otitis media (AOM).
AP (action potential), in electrocochleography, 1892-1894, 1907
in Meniere's disease, 2337
APA (anterior petrous apex), 1975-1976, 1976f
pneumatic, 1976, 1977f
APCs (antigen-presenting cells), 602f, 606, 606f
Apert's syndrome, craniofacial anomalies in, 2641t, 2645-2646
APHAB (Abbreviated Profile of Hearing Aid Benefit), 57
Aphthous stomatitis, 1289, 1289f
in HIV, 227, 227f
recurrent, 1236-1239
clinical features of, 1237-1238
defined, 1236-1237
differential diagnosis of, 1238, 1238t
etiology and pathogenesis of, 1237, 1237t
herpetiform-type, 1238, 1238f
histopathologic features of, 1239
major, 1237-1238, 1238f
minor, 1237, 1238f
treatment of, 1239
Apnea
defined, 251b
obstructive
in children, 2607
sleep (*See* Obstructive sleep apnea (OSA))
Apnea index (AI), 251b, 252
Apnea technique, for pediatric anesthesia, 2600

efficacy of, 2253-2254
Auditory signal, mechanoelectrical transduction of, 1840, 1841f
Auditory steady-state response (ASSR), 1911-1912
clinical applications of, 1910f, 1912
for cochlear implants in children, 2234-2235
Auditory symptoms, of migraine, 2348-2349
distortion as, 2349
hearing loss as, 2348-2349
phonophobia as, 2349
tinnitus as, 2349
Auditory training, after cochlear implantation, 2253-2257
in adults, 2254-2255
in children, 2254-2255
efficacy of, 2253-2254
Auditory tube. *See* Eustachian tube.
Auerbach's plexus, 953, 954f
Aura
migraine with, 247, 2347, 2347b
migraine without, 2347b
Aural atresia, congenital. *See* Congenital aural atresia (CAA).
Aural cholesteatoma. *See* Cholesteatoma.
Aural fullness, 2198
Aural papillomatosis, 1957, 1957f
management options for, 1957
Aural polyp, 1965
Auricle(s), 476-477, 476f
anatomy of, 1823, 1824f, 1944, 2742
physical examination of, 97
Auricular branch block, 242
Auricular cartilage, 476-477
burns of, 316
Auricular defects, prosthetic management of, 1345-1346, 1345t, 1346f
Auricular hematomas, 97, 310, 2038
Auricular muscle group, 442f
Auricular nerve injury, due to otoplasty, 479
Auricular prosthesis, 1345-1346, 1345t, 1346f
Auricular reconstruction. *See* Atresiaplasty.
Auriculocephalic angle, 477
Autofluorescence
in early glottic carcinoma, 1516
in premalignant lesions of larynx, 1488-1489
Autofluorescence bronchoscopy, 1009
Autogenous cartilage grafts
for nasal reconstruction, 368-369, 369f-370f
in noncaucasian rhinoplasty, 569, 570f
complications of, 578, 579f
Autogenous cartilage struts, for nasal tip projection, 535-536, 536f
Autogenous costal cartilage grafts, for laryngeal stenosis, 2919-2920, 2920f
Autogenous costochondral reconstruction, for microtia, 2744, 2744t
Autografts
for craniofacial defect repair, 2657
for ossiculoplasty, 2006, 2025
Autoimmune disorders
laryngeal involvement in, 887, 887f
otologic manifestations of, 2114
of salivary glands, 2858-2863
sensorineural hearing loss due to, 2123-2124
sudden, 2128
Autoimmune inner ear disease (AIED), 2164-2168
clinical presentation of, 2165-2166
cochlear implant for, 2221
defined, 2164
diagnosis of, 2166, 2167t
differential diagnosis of, 2166
epidemiology of, 2165
future directions for, 2167-2168
pathology and pathogenesis of, 2165
animal studies of, 2165
human temporal bone studies of, 2165
sensorineural hearing loss due to, 2124, 2165
fluctuating, 2199
rapidly progressive, 2199-2200
treatment of, 2166-2167
Autoimmune thyroiditis, 1747
oral manifestations of, 1251
ultrasound of, 1644
Autoinflation, for otitis media with effusion, 2772
Autologous fat, for vocal fold medialization, 905-906
Autologous temporalis fascia grafts, for medialization thyroplasty, 910
Autologous whole-cell vaccine, for head and neck squamous cell carcinoma, 1024
Automated auditory brainstem response (AABR), 2721
Automated endoscopic system for optimal positioning (AESOP), 39, 40f
Automatic speaking valve (ASV), 1599-1600
Autonomic control, in salivary gland secretion, 1136
Autonomic dysfunction, preoperative evaluation of, 106
Autonomic reflexes, of oral cavity, 1205-1206
Autoregulation, of capillary blood flow, 1066
Autosomal dominant disorder, 6, 6f, 2088, 2088f
Autosomal dominant sensorineural hearing loss (ADSNHL)
genetic testing for, 2098
nonsyndromic, 2090-2093, 2092t
syndromic, 2093-2096, 2094t
Autosomal recessive inheritance, 2088-2089, 2089f
Autosomal recessive sensorineural hearing loss
nonsyndromic, 2089-2090, 2090f, 2091t
syndromic, 2094t, 2096
Avita (tretinoin)
for aging skin, 403-404
with chemical peels, 392-393
for chemoprevention of oral cancer, 1315
Avitene (microfibrillar collagen), for embolization, 1933
AVM. *See* Arteriovenous malformation (AVM).
Avoidance
for allergic rhinitis, 619-620
for nonallergic rhinitis, 699-700
aVOR (angular vestibulo-ocular reflex), 2306, 2307f
after labyrinthectomy, 2291-2292, 2291f-2293f
Avulsions, soft tissue, 307, 308f
Awake fiberoptic nasotracheal intubation, 122-123
advantages of, 123
avoiding failure in, 125, 126b
bronchoscopy cart for, 123, 123f
conscious sedation for, 124
fiberoptic bronchoscope in, 123-125, 125f
historical perspective on, 122-123
indications for, 123, 123b
keys to successful, 124b
monitoring during, 124
nasal trumpet placement for, 124, 125f
optimal setup for, 125f
patient preparation for, 123-124
technique of, 124-125
topical anesthesia for, 124
Axial pattern flaps, 1067, 1067f
Axonotmesis, 2384-2385
of facial nerve, 2040
Azelastine (Astelin)
for allergic rhinitis, 620
for nonallergic rhinitis, 701t
for rhinosinusitis, 734t, 737
Azithromycin
for endocarditis prophylaxis, 1249t
ototoxicity of, 2176
for pediatric surgery prophylaxis, 2597t

epidermoid inclusion, 868f-869f, 869
mucus retention (ductal), 869, 869f-870f
open, 869, 870f
pathophysiology and pathology of, 869
treatment of, 869-870
behavioral, 869-870
medical, 869
surgical, 870, 870f
intubation granuloma as, 875-876, 875f
diagnosis of, 875-876
history in, 875
vocal capability battery in, 875-876
epidemiology of, 875
management of, 876
pathophysiology and pathology of, 875
postoperative dysphonia as, 873-874, 873f
diagnosis of, 873-874
history in, 873
laryngeal examination in, 874
vocal capability battery in, 873-874
epidemiology of, 873
management of, 874
behavioral, 874
medical, 874
pathophysiology and pathology of, 873, 874f
surgery for, 863-865, 864f
symptoms of
in nonsingers, 859, 861
in singers, 859, 861
vocal fold hemorrhage and unilateral (hemorrhagic) vocal fold polyp as, 867-869
with capillary ectasia, 868f
diagnosis of, 868
history in, 868
laryngeal examination in, 868
vocal capability battery in, 868
epidemiology of, 867
pathophysiology and pathology of, 867-868

Benign vocal fold mucosal disorder(s) *(Continued)*
treatment of, 868-869
behavioral, 868
medical, 868
surgical, 868-869
vocal nodules as, 865-866
with capillary ectasia, 867f
defined, 865
diagnosis of, 865
history in, 865
laryngeal examination in, 865
vocal capability battery in, 865
epidemiology of, 865
management of, 865-866
behavioral, 865
medical, 865
surgical, 865-866, 866f, 867t
pathophysiology and pathology of, 865
voice therapy for, 863, 864f
Benzodiazepines, as adjuncts to induction of anesthesia, 111
Benzydamine hydrochloride, for mucositis, 1102
Bernoulli effect, in voice production, 846
Bernstein test, 962-963
Berry's ligament, anatomy of, 1751
Beta decay, 1032
Beta defensins, in middle ear protection, 1871
Beta error, 65, 66t
Beta particles, 1031-1032
Beta-adrenergic agents, for migraine, 2350
β_2-transferrin test, for CSF rhinorrhea, 789, 2044
β-all-*trans* retinoic acid, for cancer chemoprevention, 1061
β-blockers
for Graves' disease, 1743
intraoperative, 112
β-carotene
for cancer chemoprevention, 1061-1062
for chemoprevention of oral cancer, 1315
β-defensins, 599
β-lactamase inhibitors, for streptococcal pharyngitis, 2787
Betadine (povidone-iodine), for embolization, 1933
Betahistine, for Meniere's disease, 2337-2338
Beta-hydroxy acids, for aging skin, 404
Betamethasone valerate cream, for eczematoid otitis externa, 1955-1956
Beta-trace protein (βTP), in CSF rhinorrhea, 790
Betel nuts, and oral cancer, 1294, 1365
Bethanechol, for extraesophageal reflux, 901
Bevacizumab, for nasopharyngeal carcinoma, 1700
Bezold abscess, 1985-1986, 1986f-1987f
due to temporal bone infection, 1980t
BFU-E (burst-forming units–erythroid), 605
BFU-MEG (burst-forming units–megakaryocytes), 605
Bias, 53
allocation, 62t
ascertainment, 62t
detection, 62t
vs. efficacy of treatment, 62t
in outcomes research, 53
selection, 53, 68t
susceptibility, 62t
treatment, 53
Bias velocity, in rotatory chair testing, 2322
Bicarbonate (HCO_3)
in saliva, 1139
in salivary gland secretion, 1135
Bicellular reserve cell theory, of salivary gland tumorigenesis, 1163
Bicklemann, A. G., 251
Bicoronal incision, 2450-2451, 2450f
for nasal fracture repair, 505, 505f
for pediatric facial fracture, 2701-2702, 2703f
Bidirectional sensitivity, of vestibular system, 2278-2279
BIH (benign intracranial hypertension)
CSF rhinorrhea due to, 787
facial paralysis due to, 2400-2401
sensorineural hearing loss due to, 2123
Bilateral advancement flap, 345, 346f
Bilateral cochlear implantation, 2241
for adults, 2224
for children, 2226
results of, 2247-2251
Bilateral hockey stick incision, for neck dissection
radical, 1709, 1710f
selective, 1717-1718, 1717f
Bile, in reflux laryngitis, 886
Bile monitoring, ambulatory 24-hour, 960-961, 961f
Bilevel positive airway pressure (BiPAP), for obstructive sleep apnea
in children, 2610-2611
Bilitec 2000, 960-961, 961f
Bill's bar
anatomy of, 1822, 1823f
in surgical anatomy of lateral skull base, 2437-2439
Bilobed flap
for cheek defects, 357, 359f
for nasal defects, 365-366, 365f
Binaural cochlear implantation, 2241
for adults, 2224
for children, 2226
results of, 2247-2251
Binaural processing, 2248
Binaural squelch, 1846, 2248
Bing-Siebenmann dysplasia, 2727
Binostril approach, for transnasal endoscopic-assisted anterior skull base surgery, 2478, 2479f
Biochemical defects, in recessive disorders, 7
Biocompatibility, in skeletal or cartilaginous defect repair, 2657
Biofilms
on adenoid pads, and pediatric chronic sinusitis, 2779-2780
for chemoprevention of oral cancer, 1315
in chronic rhinosinusitis, 706, 732
disruption of, 735
in chronic suppurative otitis media, 2221
in otitis media and cholesteatoma, 1974, 2764
Bioinformatics, in head and neck squamous cell carcinoma, 1028-1029
Biologic agents, with radiotherapy, 1054, 1055f
Biomarkers
for head and neck squamous cell carcinoma, 1026-1027
epidermal growth factor receptor as, 1026
human papillomavirus as, 1026
loss of heterozygosity as, 1026
margin analysis for, 1027
in oral rinses and saliva, 1026
other, 1026-1027
polymorphisms in DNA repair enzymes as, 1027
serum analysis for, 1026-1027
for laryngeal squamous cell carcinoma, 1493, 1505
for oral cancer, 1295
for salivary gland neoplasms, 1163, 1194
Biomaterials, in skeletal or cartilaginous defect repair, 2657-2658
Biomimetic materials, for craniofacial defect repair, 2658
Bionx plating system, for pediatric facial fractures, 2701t
Biopsy
endobronchial and transbronchial, flexible fiberoptic bronchoscopy for, 1004-1005, 1004f-1005f
fine-needle aspiration
in children, 2574
of salivary glands, 2854
of lymphoma, 1675-1676
of neck masses, 1638
of oropharyngeal cancer, 1366
of salivary glands, 1149, 1149f, 1165-1166, 1180-1181
in children, 2854
of thyroid nodule, 1756-1758
repeat, 1759
ultrasound-guided, 1655f
ultrasound-guided, 1653-1654, 1655f
of glottic cancer, 1518
laryngeal, for benign vocal fold mucosal disorders, 862
of lymphoma
core-needle, 1676
corticosteroids prior to, 1676
fine-needle aspiration, 1675-1676
open, 1676
of melanoma, 1109
of neck masses, 1638
in children, 2814
of oropharyngeal cancer, 1366
fine-needle aspiration, 1366
of paranasal sinus tumors, 1124
of salivary glands, 1149, 1149f, 1165-1166, 1180-1181
in children, 2854-2855
sentinel lymph node (*See* Sentinel lymph node biopsy (SLNB))
of thyroid nodule, 1756-1758
repeat, 1759
ultrasound-guided, 1655f
Biotinidase deficiency, sensorineural hearing loss in, 2094t, 2096
BiPAP (bilevel positive airway pressure), for obstructive sleep apnea
in children, 2610-2611
Bipedicle flap, for nasal reconstruction, 371
Bipedicle mucosal advancement flap, for nasal defects, 347, 347f
Bipolaris, rhinosinusitis due to, 732-733
Birdshots, 1626, 1628t
Birth order, and otitis media, 2767
Bisphosphonates, for hyperparathyroidism, 1804
Bitter taste
individual differences in, 1211-1212
peripheral sensitivity to, 1211
transduction of, 1209
Bizygomatic width, 2617t
BK channel defects, and hearing, 2079
B-K mole syndrome, 288, 288f, 1107
BKB (Bamford-Koval-Bench) Sentences, for cochlear implants, 2223
Blair incision, modified, for parotidectomy, 1172, 1173f, 1195, 1195f
Blast trauma, peripheral vestibular disorders due to, 2343
Blastomycosis, laryngeal and tracheal manifestations of, 885, 892
BLEC (benign lymphoepithelial cyst), in HIV infection, 217-218, 218f
Bleeding
due to neck dissection, 1723
due to thyroid surgery, 1770
Bleeding disorders, oral manifestations of, 1256
Bleomycin, for induction chemotherapy, 1056-1057

Blepharoplasty, 439-451
adjunctive procedure(s) to, 451
Botox for, 451
injectable filler for, 451
skin resurfacing as, 451
aesthetic considerations and ideals and, 444-447
for brow position, 445, 445f
for eyelids, 445-447, 446f
and upper eyelid ptosis, 446-447, 447f
for midface, 447
complications of, 449-451
for facial paralysis, 2430
preoperative planning for, 447
surgical techniques for, 447-451
lid shortening procedure as, 449
of lower eyelid, 448-449
subciliary approach to, 449, 450f-451f
transconjunctival approach to, 448-449, 450f
with ptosis repair, 447-448
of upper eyelid, 447-448, 447f-449f
Blepharospasm, 2401
Blind nasal technique, for difficult airway, 114t
Blindness, due to neck dissection, 1723
Blink reflex, to assess facial nerve function, 2388
intraoperatively, 2555, 2555f
Blom-Singer duckbill prosthesis, 1598f
Blood clot, in wound healing, 1076
Blood dyscrasias, sensorineural hearing loss due to, 2123
Blood supply, to brain, 2351, 2351f
Blood viscosity, decreased, and skin flap viability, 1073-1074
Blood volume, in children, 2571
Blowout fracture, 170f, 321
Blue nevus, 286-287, 287f
Blunt neck trauma, 1634-1635
B-lymphocyte–activating factor belonging to the TNF family (BAFF), 609t-610t
BM. *See* Basilar membrane (BM).
B-mode sonography, 1643
BMPs (bone morphogenetic proteins), in mandibular reconstruction, 1327-1328, 1328f
Board certification, 79-80, 80b
Bode plot, in vestibular tests, 2302, 2303f
Body-cover concept, of phonation, 811
Body-worn (BW) external speech processors, 2229, 2232, 2232f
Boilermaker's deafness, 2121
Bolus fabrication, by maxillofacial prosthodontist, 1331, 1332f
Bone, primary *vs.* secondary, 2614
Bone conduction process, and orbital wall fractures, 2712
Bone disease
due to hyperparathyroidism, 1781
otologic manifestations of, 2108-2112
in fibrous dysplasia, 2110-2111, 2111f
in osteitis fibrosa cystica, 2112
in osteogenesis imperfecta, 2109-2110, 2110f
in osteopetroses, 2111-2112, 2112f-2113f
in Paget's disease, 2108-2109, 2109f
sensorineural hearing loss due to, 2124
Bone erosion
in cholesteatoma and chronic otitis media, 1971-1974, 1972f-1973f
of paranasal sinus walls, 672
Bone formation, 2614
endochondral, 2614, 2615f
intramembranous, 2614
Bone grafts
in cleft-lip nose repair, 559, 564f
for nasal fractures, 505, 505f
for nasal reconstruction, 369, 370f
Bone growth
osteogenesis in, 2614
endochondral, 2614, 2615f
intramembranous, 2614
Bone growth *(Continued)*
remodeling and displacement in, 2614-2615, 2639
of mandible, 2639f
of nasomaxillary complex, 2619, 2621f
Bone healing, 330-331
Bone morphogenetic proteins (BMPs), in mandibular reconstruction, 1327-1328, 1328f
Bone remodeling, 2614-2615, 2639
of mandible, 2639f
of nasomaxillary complex, 2619, 2621f
Bone resorption
in cholesteatoma and chronic otitis media, 1971-1974, 1972f-1973f
with vascular tumors, 2826
Bone sarcomas, of neck, 1666, 1667t
Bone scans, for nasopharyngeal carcinoma, 1354
Bone Source (hydroxyapatite), for chin implants, 465t
Bone-anchored hearing aid (BAHA), 2212-2216
background of, 2213
biology and histology of, 2213
biophysical principles of, 2213
comparison of features of, 2206t
complications of, 2215
components of, 2213f
for conductive hearing loss, 2027
for congenital aural atresia, 2759
design of, 2213
indications and contraindications for, 2212-2213, 2216t
location of, 2204f
materials for, 2213
operative technique for, 2213-2215, 2214f
radiologic implications of, 2213
results of, 2215-2216
sound transduction and coupling to auditory system with, 2205f
for unilateral sensorineural hearing loss, 2216
in young children, 2215
Bone-conduction implantable hearing aids, 2212-2216
background of, 2213
biology and histology of, 2213
biophysical principles of, 2213
comparison of features of, 2206t
complications of, 2215
components of, 2213f
design of, 2213
indications for and contraindications to, 2212-2213, 2216t
in infants, 2723-2724
location of, 2204f
materials for, 2213
operative technique for, 2213-2215, 2214f
radiologic implications of, 2213
results of, 2215-2216, 2216t
sound transduction and coupling to auditory system with, 2205f
for unilateral sensorineural hearing loss, 2216
in young children, 2215
Bone-conduction testing, in pure-tone audiometry, 1888, 1888f-1889f
Bony labyrinth
anatomy of, 1831, 1852, 1853f
embryogenesis of, 1852
Bony vault, rhinoplasty of, 540-542
for bony profile reduction, 540-541, 540f
for narrowing of nose, 541-542
double osteotomies in, 542, 542f-543f
lateral osteotomies in, 541, 542f
medial-oblique osteotomies in, 541, 541f
Boomerang incision, for neck dissection
radical, 1709, 1710f
selective, 1713-1714
BOR (branchio-oto-renal) syndrome
deafness in, 2051t-2058t, 2093-2095, 2094t
inheritance pattern of, 6, 2093-2095
inner ear anomalies in, 2735
Border cells of Held, 1832f
Bordetella pertussis, laryngeal and tracheal manifestations of, 892
Boric acid solution, for fungal otitis externa, 1954
Borrelia burgdorferi. See Lyme disease.
Borrelia vincentii, Vincent's angina due to, 2786
Boston-type craniosynostosis, 2641t
BOT (balloon occlusion test), for embolization, 1934, 1934f
Botryoid odontogenic cyst, 1265-1266
radiographic features of, 1266
treatment of, 1266
Bottle feeding, and otitis media, 2767
Bottom-up approach, for pediatric facial fracture repair, 2706f
Botulinum toxin (Botox)
for achalasia, 965
for alaryngeal speech, 1459
with blepharoplasty, 451
for depressor muscles, 432, 433f
for laryngeal hyperfunction, 839, 840f-841f
for synkinesis, 2432
Bouton vestibular afferent nerve fibers, 2283, 2283f
Bowen's disease, 286
Bowman-Bird protease inhibitor, for chemoprevention of oral cancer, 1315
Boyce's sign, 986-987
BPPV. *See* Benign paroxysmal positional vertigo (BPPV).
Brachiocephalic trunk, in root of neck, 2581f
Brachycephaly
in Down syndrome, 2632
synostotic, 2643f, 2644, 2645f
fronto-orbital advancement for, 2652-2653
Brachytherapy, 1036, 1047
interventional bronchoscopy with endobronchial, 1010t
maxillofacial prosthodontics in, 1332, 1335f
for oral cancer, 1314, 1314f
for unresectable tracheal tumor, 1621
Bradykinin, in skin blood flow, 1066
BRAF gene, in thyroid carcinoma, 1753
Bragg peak, 1034
Brain
blood supply to, 2351, 2351f
effects of radiotherapy on, 2626t
Brain abscess, 1994
due to cranial base surgery, 2468
epidemiology of, 1980t-1981t, 1994
imaging of, 1994f-1995f
otitis media and, 2777
pathogenesis of, 1994
symptoms of, 1994
treatment of, 1994
Brain fungus, due to otitis media, 1992-1993, 1993f
Brain growth, postnatal, 2617t
Brain hernia, due to otitis media, 1992-1993, 1993f
Brain injury, due to cranial base surgery, 2468
Brain size, 2617t
Brain weight, 2617t
Brain-derived neurotrophic factor (BDNF)
for facial nerve paralysis, 2427
in gene therapy, 2192
for prevention of ototoxicity, 2189-2191
Brain-evoked potentials, for olfaction, 632
Brainstem
efferent pathways from vestibular nuclei to, 1865
in surgical anatomy of anterior cranial base, 2475f, 2481f
in surgical anatomy of lateral skull base, 2439f
in vestibular function, 2308

Brainstem *(Continued)*
vestibular nerve terminations in, 1858f, 1859-1860
in vestibulo-ocular reflex, 2296-2297
anatomic and physiologic basis for, 2296

indications for, 999, 999b
innovations and future developments in, 1009-1011
autofluorescence bronchoscopy as, 1009
endobronchial ultrasonography as, 1011
endoscopic/bronchoscopic lung volume reduction as, 1011
interventional, 999b, 1007-1009
for balloon bronchoplasty, 1009
for endobronchial stent placement, 1009
for foreign body removal, 1008
in children, 2939t, 2940
general principles of, 1007-1008
patient preparation and instrument selection for, 1008
for tissue débridement, 1008-1009, 1010t
for laryngomalacia, 2867
patient discussion and informed consent for, 1000
patient positioning and route of entry for, 1000
for penetrating neck trauma, 1631t, 1634
rigid, 1000-1001
sedation and airway management for, 1000
for tracheal neoplasms
diagnostic, 1616-1617
therapeutic, 1619-1622
Bronchoscopy cart, for awake fiberoptic nasotracheal intubation, 123, 123f
Bronchospasm, during anesthesia, in children, 2595
Bronchus(i), anatomy and terminology for, 998-999, 999f
Brooke-Spiegler syndrome, 292
Brow
aesthetic proportions of, 428, 429f, 445, 445f
aging, 428-432, 429f, 445, 445f
Brow depressor muscles
botulinum toxin for, 432, 433f
release of, 434, 434f
Brow lift, 2430
direct, 430, 431t
endoscopic, 431, 431t
midforehead, 430, 431t
Brow muscles, 431, 433f
Brow position, ideal, 445, 445f
Brow ptosis, 445, 445f, 2430
Brow rejuvenation, 428-438
aesthetic proportions for, 428, 429f
brow muscles in, 431, 433f
and characteristics of aging brow, 428-432, 429f
patient selection for, 428-430
anatomic considerations in, 429-430
psychological considerations in, 428
postoperative care after, 434
results of, 434-438, 436f-438f
surgical goals of, 430
surgical technique for, 432-434
brow elevation and fixation in, 434, 435f
frontal and parietal bone dissection in, 432-433
incisions in, 432, 433f
local anesthesia in, 432
release of brow depressor muscles in, 434, 434f
temporal dissection in, 433-434, 433f-434f
technique(s) for, 430-432, 431t
browpexy for, 430, 431t, 432f
coronal forehead lift for, 430, 431t
direct brow lift for, 430, 431t
endoscopic brow lift for, 431, 431t
midforehead brow lift for, 430, 431t
midforehead lift for, 430, 431t
pretrichial forehead lift for, 430, 431t
temporal lift for, 431-432, 431t
treatment of depressor muscles with botulinum toxin for, 432, 433f
Brown-Guss provocation maneuvers, 500
Browpexy, 430, 431t, 432f
Brute force sample, 68, 69t
Bruxism, 262t
BSCC (basaloid squamous cell carcinoma)
of hypopharynx and cervical esophagus, 1425
of larynx, 1506
Bsn (bassoon) gene, in murine deafness, 2058t-2060t, 2080
BSND, in deafness, 2051t-2058t
BTE (Bridges to Excellence), 84t-87t
BTE (behind-the-ear). *See* Behind-the-ear (BTE).
BTO (balloon test occlusion), for cerebral blood flow evaluation, 2491
βTP (beta-trace protein), in CSF rhinorrhea, 790
Buccal bifurcation cysts, infected, 1264-1265
Buccal branch, of facial nerve, 1194f, 2418-2419, 2419f
Buccal carcinoma, 1308-1309
clinical appearance of, 1308f
epidemiology of, 1308
radiation and chemoradiation for, 1309
reconstruction for, 1308-1309, 1309f
squamous cell, 1308, 1308f
surgical treatment of, 1308-1309, 1309f
survival with, 1309
verrucous, 1308
Buccal fatpad, 321f
Buccal lymph nodes, 2582
Buccal membranes, physical examination of, 99
Buccal mucosa, 1295f, 1298
Buccal nerve, 321f
Buccal space involvement, in odontogenic infections, 181, 181f
Buccinator lymph nodes, 1360f
Buccinator musculomucosal flap, for soft palate reconstruction, 1381-1382, 1381f
Buckshots, 1626-1627, 1628t

Bud stage, of enamel organ development, 1259
Budesonide, for eczematoid otitis externa, 1955
Budesonide nasal spray (Rhinocort)
  for nonallergic rhinitis, 700t
  for rhinosinusitis, 734t, 736
Buffalo III voice profile, 2878
Buffering, saliva in, 1141
Buflomedil, and skin flap viability, 1073
Buildup region, in radiation, 1033
Bulb insufflator, for ear hygiene or chronic ear drainage, 1958, 1961f
Bulbar conjunctiva, 444
Bulbopontine sulcus, in surgical anatomy of lateral skull base, 2439f
Bulk flow, across interstitial space, 1066
Bulla frontalis, in frontal sinusitis, 776
Bullet(s)
  expanding, 1626, 1627f
  fragmenting, 1627f
  high-velocity, 1626, 1626f
  low-velocity, 1625
  self-exploding, 1627f
  tumbling, 1625-1626, 1627f
  yaw of, 1625
Bullet injuries, of neck
  due to handgun, 1625
  due to rifle, 1626, 1626f-1627f
  due to shotguns, 1626-1627, 1628t
Bullous myringitis, 1948, 1948f
Bullous oral mucosal lesions, 1231-1240
  erythema multiforme as, 1239-1240, 1254
    clinical features of, 1239, 1239f-1240f
    defined, 1239
    differential diagnosis of, 1239
    etiology and pathogenesis of, 1239
    histopathologic features of, 1239-1240
    treatment of, 1240
  herpes simplex infection as
    primary, 1235, 1252
      clinical features of, 1235, 1235f
      defined, 1235
      diagnosis of, 1235
      differential diagnosis of, 1235
      etiology and pathogenesis of, 1235
      treatment of, 1235, 1252
    recurrent, 1235-1236, 1252
      clinical features of, 1236, 1236f
      defined, 1235
      differential diagnosis of, 1236
      etiology and pathogenesis of, 1235-1236
      histopathology of, 1236, 1237f
      vs. recurrent aphthous stomatitis, 1238, 1238t
      treatment of, 1236
  mucous membrane (cicatricial) pemphigoid as, 1233-1235, 1254
    clinical differential diagnosis of, 1234, 1234t
    clinical features of, 1233-1234, 1233f-1234f
    defined, 1233
    etiology and pathogenesis of, 1233
    histopathologic features of, 1234-1235, 1234f
    treatment of, 1235
  pemphigus vulgaris as, 1231-1233, 1254
    clinical differential diagnosis of, 1232
    clinical presentation of, 1232, 1232f
    defined, 1231-1232
    etiology/pathogenesis of, 1232
    histopathologic features of, 1232-1233, 1232f-1233f
    treatment of, 1233
  recurrent aphthous stomatitis as, 1236-1239
    clinical features of, 1237-1238
    defined, 1236-1237
    differential diagnosis of, 1238, 1238t
    etiology and pathogenesis of, 1237, 1237t
    herpetiform-type, 1238, 1238f
    histopathologic features of, 1239
    major, 1237-1238, 1238f
Bullous oral mucosal lesions *(Continued)*
    minor, 1237, 1238f
    treatment of, 1239
  traumatic (eosinophilic) granuloma as, 1240
    clinical features of, 1240, 1240f
    defined, 1240
    differential diagnosis of, 1240
    etiology of, 1240
    histopathologic features of, 1240, 1240f
    treatment of, 1240
Bullous pemphigoid, esophageal manifestations of, 980
Bumetanide, sensorineural hearing loss due to, 2120, 2175
Bupivacaine, intraoperative, 112
Bupivacaine block, for neuropathic pain, 245
Bupropion, for neuropathic pain, 245, 245t
Burden, in psychometric validation, 55
Burkitt's lymphoma, 1679
  in children, 2838, 2839f
  clinical presentation of, 1674
  treatment and prognosis for, 1679
Burns, 314-316
  assessment and treatment of, 315-316
  classification of, 314-315, 315f
  of eyelids, 316
  of lips and oral commissure, 316
  of nasal and utricular cartilage, 316
Burow's solution (aluminum acetate otic drops), 1959t-1960t
  for fungal otitis externa, 1954
Burow's triangles, with advancement flaps, 345, 346f
"Burst" activity, in facial nerve monitoring, 2387, 2547, 2547f
Burst-forming units–erythroid (BFU-E), 605
Burst-forming units–megakaryocytes (BFU-MEG), 605
Burstone analysis, for mentoplasty, 463, 463f
Burwell, C. S., 251
Bushy cells, in cochlear nucleus, 1835, 1845
Buttress(es), of facial skeleton, 331, 331f
  repair of, 336
Buttress graft
  in nasal tip refinement, 576
  in revision rhinoplasty, 589
BW (body-worn) external speech processors, 2229, 2232, 2232f

C

C chemokines, 611t-612t
C fibers
  in dental pain, 1202
  in nonallergic rhinitis, 695
C trains, in electromyography, 2547
Ca^{++}. *See* Calcium (Ca^{++}).
CA (cochlear aqueduct). *See* Cochlear aqueduct (CA).
CA (compressed analog), for cochlear implants, 2230
CAA. *See* Congenital aural atresia (CAA).
Cachexia, palliative care for, 1104
Cacna1D, in murine deafness, 2058t-2060t, 2080
Cadherin 23 (CDH23), in tip links, 2074
Cadherin 23 *(CDH23)* gene, in deafness, 2051t-2058t, 2074
Cadherin expression, in oral cancer, 1301
CAHPS (Consumer Assessment of Health Providers and Services), 82, 84t-87t
Calcifications, tonsillar, 1411, 1412f
Calcifying epithelial odontogenic tumor, 1276
  microscopic findings in, 1276
  radiographic findings in, 1276, 1276f
Calcifying odontogenic cyst (COC), 1268-1269
  microscopic features of, 1269, 1269f
  radiographic features of, 1269
  treatment of, 1269
Calcimimetic agents, for hyperparathyroidism, 1804
Calcitonin
  in calcium homeostasis, 1775
  serum levels of, with thyroid nodule, 1756
Calcitonin gene–related peptide (CGRP)
  in salivary gland secretion, 1137
  and skin flap viability, 1073
Calcitriol, in parathyroid hormone regulation, 1776
Calcium (Ca^{++})
  in saliva, 1139
  serum, 1782
Calcium (Ca^{++})-activated chloride (Cl^{-}) channels, in salivary gland secretion, 1135
Calcium (Ca^{++})-activated potassium (K^{+}) channels, in salivary gland secretion, 1135
Calcium channel blockers
  for achalasia, 965
  for migraine, 2350
Calcium channel defects, and hearing, 2080
Calcium deficiency, oral manifestations of, 1254
Calcium homeostasis, 1775-1777
Calcium hydroxyapatite (Radiesse dermal filler), for vocal fold medialization, 906
Calcium (Ca^{2+})-mediated adaptation, of mechanoelectrical transduction currents, 2078-2079, 2079f
Calcium phosphate cement, for nasal reconstruction, 368
Calcium (Ca^{2+})-transporting plasma membrane 2, in deafness, 2051t-2058t
Calcium–adenosine triphosphatase 2 (Ca^{2+}-ATPase 2), in deafness, 2051t-2058t, 2080
Calcium-sending receptor gene, in parathyroid neoplasm(s), 1775
Calculi, of parotid gland, 150
Calculous lesions, of salivary glands, 1647
Caldwell, George, 756
Caldwell view, 662, 663f
  of facial bones and sinuses, 130
Caldwell-Luc procedure, 756, 756f
Calgary Sleep Apnea Quality of Life Index (SAQLI), 57
Caliber, of handgun, 1625
Caloric testing, 2319-2320
  anatomic and physiologic basis for nystagmus during, 2290
  convective component of, 2319, 2320f-2321f
  nonconvective component of, 2319-2320
  normative values for, 2320
  protocol for, 2320
  recording of eye movements in, 2320, 2321f
Calvaria, growth and development of, 2615-2617, 2617t, 2618f
Calyceal vestibular afferent nerve fibers, 2283, 2283f
Calyx ending, of hair cells, 1857, 1859f
CAMP (Clinical Assessment of Musical Perception), 57
cAMP (cyclic adenosine monophosphate)
  in olfactory transduction, 629
  in salivary gland secretion, 1137
Camper's fascia, 2577
Canal wall down mastoidectomy, 2010-2011
  for chronic otitis media with cholesteatoma, 1969, 1970t
  intact canal wall *vs.,* 2014
    indications for, 2014-2015, 2015f
  operative procedure for, 2013-2014, 2014f
Canal wall up mastoidectomy, 2010
  vs. canal wall down procedure, 2014
  for chronic otitis media with cholesteatoma, 1969, 1970t
  indications for, 2014-2015
Canalicular cell adenomas, of salivary glands, 1170
Canalith repositioning, for benign paroxysmal positional vertigo, 2331-2332, 2332f

Canalithiasis, 2329-2330
  of lateral semicircular canal, 2331
  of posterior semicircular canal, 2331
Canalplasty, in tympanoplasty, 2002
  with lateral graft technique, 2002-2003, 2002f
c-ANCAs (cytoplasmic antineutrophil cytoplasmic antibodies), in Wegener's granulomatosis, 658, 2103
Cancer, gene therapy for, 20-22, 21f
  antiangiogenesis in, 22
  conditionally replicating adenovirus therapy in, 22
  cytotoxic or suicide gene strategies in, 21
  direct in vivo stimulation of antitumor immune response in, 21
  genetic modification of tumor-infiltrating lymphocytes in, 20-21
  modifying oncogenes and tumor suppressor genes in, 21-22
Cancer pain, palliative care for, 1103
Cancer stem cell hypothesis, in head and neck squamous cell carcinoma, 1028
Candida albicans, otitis externa due to, 2195
Candida esophagitis, 976, 976f
  imaging of, 1404, 1405f
Candida spp
  otitis external due to, 1944-1945
  pharyngitis due to, 199-200
Candida superinfections, in chronic suppurative otitis media, 2221
Candidal leukoplakia, 1231, 1231f
Candidiasis
  laryngeal and tracheal, 884-885, 884f, 893
  oropharyngeal, 199-200, 1229-1231, 1252
    acute, 1230, 1230f, 1230t
    angular cheilitis due to, 1230, 1230f
    in children, 2786
    chronic, 1230, 1230t
    clinical features of, 1230-1231
    defined, 1229
    differential diagnosis of, 1231
    erythematous, 1230, 1230f
    etiology and pathogenesis of, 1229-1230
    histopathologic/diagnostic features of, 1231, 1231f
    in HIV, 225, 226f
    hyperplastic, 1231, 1231f
    pseudomembranous, 1230, 1230f
    risk factors for, 1229, 1230t
    treatment of, 1231
Canine smile, 2417-2418
Canine space involvement, in odontogenic infections, 180-181, 180f
Caninus, 321f
Cannulas, for liposuction, 453, 455f
Canthoplasty, 2420-2421
Cantilever bone graft, for nasal fractures, 505, 505f
CAP (compound action potential)
  in Bell's palsy, 2394
  electrically evoked, 1912-1913
    with cochlear implants, 1913f, 1914
Cap graft
  for nasal tip enhancement, 576, 577f
  in revision rhinoplasty, 589
Cap stage, of enamel organ development, 1259
Capek, Joseph, 38
Capek, Karel, 38
CAPE-V (Consensus Auditory Perceptual Evaluation for Voice), 819, 826
Caphosol, for mucositis, 1102
Capillary ectasia, of larynx, 817, 866-867
  diagnosis of, 866-867
    history in, 866
    laryngeal examination in, 866-867
    vocal capability battery in, 866
  epidemiology of, 866
  epidermoid inclusion cyst with, 868f
Capillary ectasia, of larynx *(Continued)*
  hemorrhagic polyp with, 868f
  management of, 867
    behavioral, 867
    medical, 867
    surgical, 867
  pathophysiology and pathology of, 866
  vocal nodules with, 867f
Capillary hemangioma, sinonasal lobular, 718t, 725, 725f
Capillary lake, 866-867
Capillary malformations, 2832-2833, 2834f
Capillary obstruction, in acutely raised skin flaps, 1070-1071
Capillary system, and skin flaps, 1065-1066, 1065f
  acutely raised, 1068-1069
Capsaicin provocation test, in nonallergic rhinitis, 696
Capsid, in Epstein-Barr virus, 1352
Capsulopalpebral fascia, 444
Carbamathione, for noise-induced hearing loss, 2145
Carbamazepine, for neuropathic pain, 243, 244t
Carbamide peroxide (Debrox, Murine removal kit), for cerumen removal, 1958t
Carbogen, with radiotherapy, 1041
Carbon dioxide (CO_2) laser, 31t, 32-33
  for airway stenosis, 945, 2918
  for benign vocal fold mucosal disorders, 864
  for glottic cancer, 1517t, 1519t
  for laryngeal hemangiomas, 881
  optical resonating chamber of, 26, 27f
  for premalignant lesions of larynx, 1490
  for recurrent respiratory papillomatosis, 879, 2889-2891
  for stridulous child, 2908
  for transoral laser microsurgery, 1528
Carbon dioxide (CO_2) laser endoscopic resection, for hypopharyngeal cancer, 1429-1430, 1442
  outcomes of, 1436-1438
Carbon dioxide (CO_2) laser resurfacing
  complications of, 402
  equipment for, 400, 400f
  postoperative care after, 401-402
  results of, 401f-402f
  technique of, 400, 400f
Carbon ion therapy, 1046
Carbon monoxide, in noise-induced hearing loss, 2147-2148
Carbonated apatite (Norian CRS), for chin implants, 465t
Carbonic anhydrase inhibitors, for Meniere's disease, 2337
Carboplatin
  in combination chemotherapy, 1059-1060
  ototoxicity of, 2173-2174
  sensorineural hearing loss due to, 2120, 2173-2174
Carcinoembryonic antigen (CEA)-targeted vaccine, for head and neck squamous cell carcinoma, 1024
Carcinoid tumors
  of larynx
    atypical, 1507
    typical, 1507
  of trachea, 1615, 1615f
Carcinoma ex pleomorphic adenoma, of salivary glands, 1187-1189, 1188f
Carcinoma in situ (CIS)
  of larynx, 1486-1491, 1489f-1490f, 1515
    treatment of, 1489-1490, 1520-1521
  oropharyngeal, 1361
Carcinosarcoma
  of larynx, 1506
  of salivary glands, 1187, 1188f
Cardiac bulge, 2661f, 2691f
Cardiac disease, oral manifestations of, 1246-1249, 1249t
Cardiac output, of newborn, 2571
Cardiac transplantation, oral sequelae of, 1248
Cardiopulmonary bypass, sensorineural hearing loss due to, 2120
Cardiopulmonary complications
  of obstructive sleep apnea, in children, 2604, 2604f
  of sleep-disordered breathing, in children, 2792, 2792f
Cardiovascular disease, oral manifestations of, 1246-1249, 1249t
Cardiovascular manifestations, of hyperparathyroidism, 1781
Cardiovascular system
  in children, 2571-2572
    and blood volume, 2571
    and newborn heart and cardiac output, 2571, 2571t
    and oxygen transport, 2571-2572
    and response to hypoxia, 2571
  preoperative evaluation of, 102
Caregiver Impact Questionnaire, 57
Carina fully implantable hearing system, 2210-2211
  clinical results with, 2210-2211
  components of, 2210, 2210f
  history of, 2210
  placement of, 2210, 2211f
Carinal resections, 1619, 1621f-1622f
  reconstruction after, 1619, 1623f
Caroticotympanic arteries, 1870
Caroticotympanic canaliculus, 1824f
Carotid arteriography, cross-compression, for cerebral blood flow evaluation, 2490
Carotid artery
  in surgical anatomy of lateral skull base, 2436f, 2438
    preoperative management of, 2489
      algorithm for, 2490f, 2491-2492
      cerebral blood flow assessment in, 2490-2491, 2490f
      four-vessel arteriography in, 2489-2490, 2491f
  tinnitus-producing fibromuscular dysplasia of, endovascular treatment for, 1943
Carotid artery aneurysms
  of petrous apex, 2525, 2527f
  upper cervical and petrous, 2504, 2504f-2505f
Carotid artery canal
  anatomy of, 1824f
  inferior foramen of, 1822-1823
  in surgical anatomy of lateral skull base, 2435f-2436f, 2438
  in surgical anatomy of middle cranial base, 2445f
Carotid artery hemorrhage, due to neck surgery, 1728
Carotid artery injury, due to temporal bone trauma, 2039, 2040f, 2047
Carotid artery invasion, imaging of, 166-167
Carotid artery pseudoaneurysm, due to deep neck space infections, 207
Carotid artery rupture, 1479
  due to cranial base surgery, 2468-2469
  due to deep neck space infections, 207
  due to neck dissection, 1723-1724
  due to neck surgery, 1728
  due to radiotherapy, 1048
Carotid artery stenosis, due to neck irradiation, 1695
Carotid blowout syndrome, 1479
  due to neck surgery, 1728
  due to radiotherapy, 1048
Carotid body, 1658-1659
Carotid body tumors, 1657-1658, 1934-1935, 1935f
  endovascular treatment of, 1937, 1937f

Carotid cavernous fistula, due to temporal bone trauma, 2047
Carotid gland, 1657-1658
Carotid groove
  in surgical anatomy of anterior cranial base, 2443f
  in surgical anatomy of middle cranial base, 2445f
Carotid ligation, in extended neck dissection, 1719-1721, 1720f
Carotid paragangliomas, 1657-1658, 2506f
  anatomy and physiology of, 1658-1659
  classification of, 1660
  clinical presentation and diagnosis of, 1659-1660
  etiology of, 1659, 1659t
  history of, 1657-1658
  imaging of, 1658f, 1660-1661
  malignancy of, 1660
  multicentricity of, 1660-1661
  observation for, 1661-1662
  radiation therapy for, 1661
  surgical management of, 1660-1661
Carotid prominence, in surgical anatomy of anterior cranial base, 2473
Carotid sheath, anatomy of, 202
  in children, 2578-2579, 2578f
Carotid sinus syndrome syncope, due to carotid paraganglioma, 1659
Carotid space (CS)
  anatomy of, 203
  imaging of, 150-151, 151f-152f
  schwannoma of, 1663f
Carotid stump pressure, for cerebral blood flow evaluation, 2490
Carotid triangle, 96, 96f, 2578f, 2579-2580
  arterial branches of, 2579-2580, 2580f
Carpenter's syndrome, craniofacial anomalies in, 2646
Cartilage grafts
  for nasal reconstruction, 368-369, 369f-370f
  for nasal tip projection, 535-536, 537f, 549-550, 550f-551f
  for revision rhinoplasty, 583, 584f
  for saddle nose deformity, 555, 556f
Cartilage plumping grafts, for nasal tip projection, 535-536, 536f
Cartilage struts, autogenous, for nasal tip projection, 535-536, 536f
Cartilage tympanoplasty, 2004-2005
Cartilage-mediated growth, in craniofacial growth and development, 2614
Cartilage-splitting approaches, for nasal tip refinement, 522, 523f-526f
Cartilaginous defect repair, biomaterials in, 2657-2658
Cartilaginous glottis, 849
Cartilaginous neoplasms, of larynx, 881-882
Cartilaginous vault rhinoplasty, 536-540
  access to nasal skeleton in, 537-539, 539f
  aesthetic improvement after, 537, 538f
  factors to consider in, 537
  incremental cartilaginous profile alignment in, 539
  mucoperichondrium in, 539-540
  pollybeak deformity due to, 512, 512f, 539, 539f
  for reduction of overlong caudal quadrangular cartilage, 513f
  with traumatic or iatrogenic avulsion of upper lateral cartilage, 539-540, 540f
Carved polymeric silicone (Silastic) implants, for medialization thyroplasty, 908-910, 910f
Carving template, in microtia reconstruction, 2744-2745, 2745f
Case series, 54-55, 54t
  data interpretation with, 59-61
Case-control study, 54, 54t
Caspases, in cisplatin ototoxicity, 2173
Casts, for prosthetic maxillary obturation, 1338-1339, 1338f
Cat scratch disease (CSD)
  in children, 2818
  deep neck space infections due to, 201
  salivary gland involvement in, 1159
Catagen phase, 374, 374f
CATCH-22, 2869
Catenary lever, 2018
Cathelicidins, 599
Catheters, angiographic, 1932-1933
Cauda-conchal sutures, 476f
Caudal extension graft
  in noncaucasian rhinoplasty, 576, 576f
  in revision rhinoplasty, 593
Caudal helix, 476f
Caudal septal deviation, revision rhinoplasty for persistence of, 593
Caudal septal excision, excessive, revision rhinoplasty for, 591f, 593
Caudal septum
  repositioning of, 547, 547f
  in septoplasty, 491-492, 491f-492f
    overaggressive resection of, 492, 492f
  shortening of, 547-548, 547f-548f
"Cauliflower deformity," 310
Caustic esophageal injury, 942, 977-978
  in children, 2956-2964
    algorithm for, 2962f
    endoscopy for, 2957-2959, 2958f
    epidemiology of, 2956
    initial assessment and diagnosis of, 2957
    pathophysiology of, 2956-2957
    signs and symptoms of, 2957b
    staging of, 2959, 2959f
    therapy for, 2959
      mechanical, 2960-2962, 2960f-2961f
      pharmacologic, 2959-2960
  clinical features of, 977
  etiology of, 977
  grading of, 977, 978t
  imaging of, 1404-1405, 1405f
  prognosis for, 977-978
  squamous cell carcinoma due to, 978
  strictures due to, 977-978, 978f-979f
    imaging of, 1405, 1405f
Caustic laryngeal trauma, 939-941
  etiology of, 940-941
  incidence of, 939-940
  management of, 941
Cautery, for epistaxis, 687-688, 687f
$Ca_v1.3$, in murine deafness, 2058t-2060t, 2080
$Ca_v1.3$ channels, 2080-2081
Caval mucosa, in sensation of nasal obstruction, 641-642
Cavernous hemangioma, 290
  epistaxis due to, 684f
Cavernous sinus meningiomas, embolization of, 1938
Cavernous sinus thrombosis
  due to deep neck space infections, 207
  due to odontogenic infections, 181, 182f
  preseptal orbital, 676
Cavernous sinus tumors, surgical approach for, 2509-2510
Cavernous venous sinus, 1699
Cavity dumped lasers, 34
Cavum conchae, 476-477, 1824f
CBF evaluation. *See* Cerebral blood flow (CBF) evaluation.
CBT (cognitive-behavioral therapy), for tinnitus, 2135
CC chemokines, 611t-612t
CCDC50 (coiled-coil domain–containing protein 50/Ymer) gene, in deafness, 2051t-2058t
CCL chemokines, 611t-612t
CCR (cervicocollic reflex), 2307-2308
$CD4^+$ cells, 601
$CD8^+$ cells, 601
CDH23 (cadherin 23), in tip links, 2074
CDH23 (cadherin 23) gene, in deafness, 2051t-2058t, 2074
Cdkn2d (cyclin-dependent kinase inhibitor 2D) gene, in murine deafness, 2058t-2060t
CDP. *See* Computerized dynamic posturography (CDP).
CEA (carcinoembryonic antigen)-targeted vaccine, for head and neck squamous cell carcinoma, 1024
CECT. *See* Contrast-enhanced computed tomography (CECT).
Cefazolin
  for endocarditis prophylaxis, 1249t
  for pediatric surgery prophylaxis, 2597t
Ceftazidime, for rhinosinusitis, 734
Ceftriaxone
  for endocarditis prophylaxis, 1249t
  for pediatric surgery prophylaxis, 2597t
Cefuroxime, for rhinosinusitis, 734t-735t
Celecoxib (Celebrex), for recurrent respiratory papillomatosis, 2892
Celiac disease, oral manifestations of, 1254
Cell cycle, 12, 13f
Cell cycle arrest, due to radiation, 1037, 1037f
Cell division, 12, 13f
Cell membrane, 1066-1067
Cell surface receptors, in salivary gland secretion, 1136-1137, 1136f, 1137t
Cell survival curve, with radiation therapy, 1037-1039, 1038f
Cell-mediated immune response, 602f
Cellular immunodeficiency disorders, 2114
  otologic manifestations of, 2114
Cellular recruitment, in allergic rhinitis, 616, 617f
Cellular systems, and skin flaps, 1065-1067, 1065f
Cellulitis
  of external ear, 1946, 1948
  orbital, due to odontogenic infections, 181, 182f
  retropharyngeal, 2810-2811, 2810f

Cervical lymph node(s)
anatomy of, 1683, 1683f, 1684t
classification of, 1683, 1683f, 1684t, 2582-2583
deep, 2582
superficial, 2582
Cervical lymph node groups, in neck dissection, 1703-1705
levels of, 1703-1705, 1704f, 1706t
radiologic anatomic markers in, 1705, 1707t-1708t
sublevels of, 1704-1705, 1705f, 1706t
Cervical lymph node metastasis(es), 1682-1695
anatomic basis for, 1683, 1683f, 1684t
of cervical esophageal cancer, 1434-1439
chemoradiation therapy for
postoperative, 1693-1694, 1694t
primary, 1693, 1693t
classification of, 1684t
in contralateral neck, 1688, 1690
of hypopharyngeal cancer, 1434-1439
incidence and distribution of, 1686f, 1688t
radiation therapy for, 1689t
imaging of
contrast-enhanced CT for, 164-165, 167f
of laryngeal carcinoma, 1476, 1479f
MRI for, 165-166, 168f
incidence and distribution of, 1684-1688
from clinical and radiologic assessment, 1684-1687, 1685f-1686f
in contralateral neck, 1688
from hypopharyngeal tumors, 1686f, 1688t
from nasopharyngeal tumors, 1687f
from oral cavity tumors, 1685f, 1688t
from oropharyngeal tumors, 1685f, 1688t
pathologic, 1687, 1688t
from supraglottic laryngeal tumors, 1686f, 1688t
of laryngeal carcinoma, 1493-1494, 1493f
embryology and, 1482-1483
glottic, 1497-1498
imaging of, 1476, 1479f
radiation therapy for, 1690t
subglottic, 1501, 1501f
supraglottic, 1500-1501
incidence and distribution of, 1686f, 1688t
of nasopharyngeal carcinoma, 1352-1353, 1353f
incidence and distribution of, 1687f
radiation therapy for, 1690, 1690t
neck control for
with N0 status, 1688, 1690, 1692, 1692t
with N1-N3 status, 1692-1695
postoperative irradiation or chemo-irradiation for, 1693-1694, 1694t
after primary radiotherapy, 1692-1693, 1693t
neck dissection for (*See* Neck dissection)
of oral cavity tumors
incidence and distribution of, 1685f, 1688t
radiation therapy for, 1689t
Cervical lymph node metastasis(es) *(Continued)*
of oropharyngeal cancer, 1360f, 1361t
incidence and distribution of, 1685f, 1688t
radiation therapy for, 1689t
of paranasal sinus tumors, 1130
radiation therapy for
indications for neck node dissection after, 1694
late complications of, 1694-1695
with N0 status, 1688, 1690, 1692, 1692t
with N1-N3 status, 1692-1695
neck control after, 1692-1693, 1693t
postoperative, 1693-1694, 1694t
of retropharyngeal nodes, 1688
target volumes for, 1688-1690
delineation of, 1690-1691, 1691f
for hypopharyngeal tumors, 1689t
for laryngeal tumors, 1690t
for nasopharyngeal tumors, 1690, 1690t
for oral cavity tumors, 1689t
for oropharyngeal tumors, 1689t
techniques for, 1691, 1692f
recurrent, 1695
postoperative, 1693-1694, 1694t
after primary radiation therapy, 1695
retropharyngeal, 1687-1688
of salivary gland tumors, 1196-1197
staging of, 1683-1684, 1684t
of thyroid cancer, 1766
Cervical lymphadenectomy. *See* Neck dissection.
Cervical lymphadenopathy
in children
bacterial, 2818, 2818f-2819f
drug-induced, 2819
fungal, 2818-2819
reactive, 2818
suppurative, 2818, 2818f
viral, 2817-2818
imaging of, 1414-1415, 1415f
CT of, 139
with extracapsular spread, 164-166, 167f
inflammatory (reactive), 164
with invasion of carotid artery, 166-167
metastatic
contrast-enhanced CT of, 164-165, 167f
MRI of, 165-166, 168f
MRI of, 142
with non-Hodgkin's lymphoma, 165-166, 167f
ultrasound of, 143
in immunosuppressed patients, 218-219, 219t
neck masses due to, 1638
in children
bacterial, 2818, 2818f-2819f
fungal, 2818-2819
viral, 2817-2818
Cervical lymphatics, 1312-1313, 1313f
Cervical plexus, 2581
ansa cervicalis of (*See* Ansa cervicalis)
anterior division of, 2579f
cutaneous branches of, 2578, 2580f
for facial nerve grafting, 2422
Cervical plexus block, superficial, 242
Cervical sensory nerve injuries, due to neck surgery, 1731-1732
Cervical skin flaps, for hypopharyngeal and esophageal reconstruction, 1450-1451
Cervical space infections. *See* Deep neck space infections.
Cervical vertigo, 2354
Cervicocollic reflex (CCR), 2307-2308
Cervicofacial advancement flap, for buccal carcinoma, 1309f
Cervital, for ossiculoplasty, 2026t
Cetirizine (Zyrtec)
for nonallergic rhinitis, 701t
for rhinosinusitis, 734t

Cetuximab (Erbitux)
for metastatic squamous cell carcinoma, 1061
with radiotherapy, 1052, 1054
for laryngeal cancer, 1585
CF. *See* Cystic fibrosis (CF).
CFD (computational fluid dynamics), CT with, 643
CFU. *See* Colony-forming unit (CFU).
CGH (comparative genomic hybridization), for head and neck squamous cell carcinoma, 1019
CGRP (calcitonin gene–related peptide)
in salivary gland secretion, 1137
and skin flap viability, 1073
Chalasia, cricopharyngeal, 1399
CHAMP procedure, auditory brainstem response in, 1911
Chance, *vs.* efficacy of treatment, 62t
CHAOS (congenital high airway obstruction syndrome), 2869, 2870f, 2904-2905
Characteristic frequency, 1844-1845, 1845f
Charcot-Leyden crystal (CLC) protein, 604
Charcot-Marie-Tooth syndrome, deafness in, 2051t-2058t
CHARGE association
facial paralysis in, 2397
inner ear anomalies in, 2735
Charged particle beams, in radiotherapy, 1034-1035
Check ligament, 321f
Cheek advancement flap, for nasal defects, 348, 349f
Cheek defects, 355-359
advancement flaps for, 358
V-Y, 358, 361f
rotation flaps for, 357-358, 359f
sub-superficial musculoaponeurotic system dissection for, 357-358, 360f
transposition flaps for, 358-359, 361f
bilobed, 357, 359f
rhombus shaped, 355
Cheek pedicle transposition flap, for nasal defects, 348, 349f
Cheilitis
angular, 1230, 1230f
in HIV, 225, 226f
solar (actinic), 283
Cheiloplasty, 2431, 2431f
Chelating agents, oral sequelae of, 1247t-1248t
Chemesthesis, of oral cavity, 1202
Chemical labyrinthectomy, for Meniere's disease, 2185-2189, 2338-2339, 2338f
Chemical markers, for CSF rhinorrhea, 789-790
Chemical peels, 391-397
agents for, 392-394
complications of, 396-397
contraindications to, 391, 392t
in dark-skinned individuals, 392
deep, 394-395
equipment tray for, 393f
histologic changes with, 390-391
indications for, 391, 392t
medium-depth, 393-394, 393f-394f
patient selection and education for, 391-392
and phenol toxicity, 395
postoperative care after, 396, 396f
prepeel preparations for, 392
superficial, 392-393, 403
Chemical shift artifact, on MRI, 134
Chemical shift selective presaturation, for MRI, 135-136, 136f
Chemical surgery, for skin lesions, 294
Chemodectomas, 1657. *See also* Paragangliomas (PGLs).
multiple, 1934-1935, 1935f
Chemokine(s)
in humoral immune response, 608, 611t-612t
in wound healing, 1076
Chemokine connective tissue–activating peptide-III (CTAP-III), in wound healing, 1076
Chemokine receptor 2 (CXCR2), in wound healing, 1076
Chemokine receptor 4 (CXCR4), in head and neck squamous cell carcinoma, 1060
Chemoprevention
of head and neck squamous cell carcinoma, 1018, 1061-1062
clinical implications of, 1018
of laryngeal cancer, 1491
of oral cancer, 1315
Chemoradiation therapy (CRT), 1041-1043, 1052-1058
for cervical lymph node metastasis
postoperative, 1693-1694, 1694t
primary, 1693, 1693t
concomitant, 1052-1056, 1053t-1054t
as adjuvant therapy, 1056
induction chemotherapy with, 1041-1042, 1052-1053
with adjuvant therapy, 1056
for esophageal carcinoma
definitive, 1445-1447, 1446t-1447t
preoperative, 1444-1445, 1445t
for hypopharyngeal cancer, 1434, 1439, 1442-1444
RADPLAT technique for, 1592
for laryngeal carcinoma, 1501-1503, 1502f
glottic
in advanced stage, 1584-1585, 1584t
with nodal metastases, 1498
optimal dose-fractionation scheme for, 1585-1586
outcomes and prognostic factors with, 1586-1587, 1587t
RADPLAT technique for, 1592
supraglottic, in advanced stage, 1500, 1589
for maxillary sinus tumor, 1130
for nasopharyngeal carcinoma, 1355, 1699f
neck dissection after, 1724
for oral cancer, 1314-1315
RADPLAT technique for, 1054
for laryngeal and hypopharyngeal cancer, 1592
swallowing disorders due to, 1219
for thyroid cancer, 1772
Chemosomatosensory-evoked potentials, 632
Chemotherapy, 1015
adjuvant, for oral cancer, 1314-1315
combination, 1059-1060
for esophageal carcinoma
localized, 1444
metastatic, 1447
historical background of, 1051-1052
for hypopharyngeal cancer, 1433-1434, 1442
advanced, 1439
induction, 1443
for larynx preservation, 1443-1444
induction, 1056-1058, 1058f, 1058t-1059t
clinical trials of, 1056-1058
in concomitant chemoradiation, 1041-1042, 1052-1053
with adjuvant therapy, 1056
defined, 1056
for hypopharyngeal cancer, 1443
for laryngeal carcinoma, 1501-1503, 1502f
for oral cancer, 1314-1315
intra-arterial, 1939
for laryngeal carcinoma
early glottic, 1520
neoadjuvant, 1501-1503, 1502f
for melanoma, 1118
neoadjuvant, for laryngeal carcinoma, 1501-1503, 1502f
for oral cancer, 1314-1315
with radiation therapy (*See* Chemoradiation therapy (CRT))
Chemotherapy *(Continued)*
radiosensitizing, 1040-1043
for recurrent or metastatic disease, 1058-1061
combination, 1059-1060
prognostic factors with, 1058-1059
single agent, 1059
for rhabdomyosarcoma, 2841
for salivary gland neoplasms, 1199
single agent, 1059
for thyroid cancer, 1772
Chemotherapy resistance, gene therapy for, 24
CHEP. *See* Cricohyoidoepiglottopexy (CHEP).

early studies of speech reception in, 2246
for educational placement and support, 2251-2253, 2251f, 2255-2256
for language acquisition, 2249-2251, 2250f
more recent studies of speech reception in, 2246-2247, 2247f
quality-of-life studies for, 2252-2253, 2253f
selection criteria for, 2225-2226, 2235b
surgical techniques for, 2240
with cochlear ossification, 2235f, 2240
with combined electrical and acoustic stimulation, 2224, 2224f
complications of, 2241
with compromised healing, 2241
for congenital inner ear anomalies, 2739
cost effectiveness of, 2251
defined, 2219-2220
device(s) for, 2227-2233
external speech processors for, 2229
size, weight, and aesthetics of, 2232, 2232f
factors that affect choice of, 2231-2233
batteries as, 2233
external speech processor size, weight, and aesthetics as, 2232, 2232f
MRI compatibility as, 2231-2232
need for special electrode arrays as, 2231
technology differences in speech coding strategy and electrode configuration as, 2231
Cochlear implant(s) (CIs) *(Continued)*
internal receiver stimulators and electrode designs in, 2227-2229
HiRes 90K receiver/stimulator as, 2227-2228, 2228f
Med-El PulsarCI100 and SonataTI100 as, 2228-2229, 2228f-2230f
Nucleus Freedom device with Contour Advance electrode as, 2227, 2227f-2228f
maintenance of, 2255
programming of, 2255
signal processing strategies in, 2229-2231
Advanced Combination Encoder for, 2230, 2231f
analog stimulation as, 2230, 2230f
continuous interleaved sampling as, 2229-2230
fine structure, 2230-2231, 2231f-2232f
spectral emphasis, 2230
spectral peak extraction as, 2230, 2230f
temporal, 2229-2230, 2230f
ear selection for, 2235-2236
algorithm for, 2236f
physical characteristics in, 2235-2236
residual hearing level in, 2236
and speech recognition, 2245, 2245f
general background of, 2219-2220
in infants, 2247, 2724
infectious complications of, 2161
for labyrinthine dysplasia, 2240-2241
and language development, 2239-2240, 2249-2251, 2250f
map for, 2255
meningitis vaccination with, 2236-2237, 2237b
for meningitis-induced deafness, 2240
for neural hearing loss, 1899-1901
and neural plasticity
in animal models of deafness, 1881
in infants with hearing loss, 1885, 1885f
in older adults, 233, 2234-2235
and quality of life, 2251-2252, 2252f, 2252t
with otitis media, 2240
patient evaluation for, 2220-2222, 2234-2235
with acquired deafness, 2220-2221
with auditory neuropathy/auditory dyssynchrony, 2220
with chronic suppurative otitis media, 2221
diagnostic therapy in, 2235
with genetic hearing loss, 2220
genetic testing in, 2235
hearing tests in, 2234-2235
imaging in, 2221-2222, 2222f, 2235, 2235f, 2236b
otologic/medical evaluation in, 2220-2222
physical examination in, 2221, 2234
and quality of life, 2251
in adults and elderly, 2251-2252, 2252f, 2252t
in children, 2252-2253, 2253f
with residual hearing
in adults, 2245-2246
in children, 2240
ear selection for, 2236
results of, 2244-2251
in adults, 2244-2245
with hearing preservation, 2245-2246
predictors of, 2245, 2245f
quality-of-life studies for, 2251-2252, 2252f, 2252t
bilateral, 2247-2251
in children, 2246
auditory performance assessments for, 2246
early studies of speech reception in, 2246
for educational placement and support, 2251-2253, 2251f, 2255-2256
for language acquisition, 2249-2251, 2250f

Cochlear implant(s) (CIs) *(Continued)*
more recent studies of speech reception in, 2246-2247, 2247f
quality-of-life studies for, 2252-2253, 2253f
factors related to measurement of, 2244-2247
in infants, 2247
tests for, 2244
revision, 2241
speech perception with, 2244-2245
predictors of, 2245, 2245f
surgical technique for, 2237-2241
bony seat in, 2238, 2239f
in children, 2240
cochleostomy in, 2239
electrode insertion in, 2239
incisions and flap design for, 2237-2238, 2237f-2238f
mastoidectomy in, 2238-2239
preparation and draping in, 2237
receiver stimulator in, 2239
skin flap in, 2238
for tinnitus, 2137
Cochlear lesions, reorganization of central tonotopic maps after, 1877-1878, 1878f-1879f
in adult subjects, 1878-1879, 1881f
in developmental model, 1878, 1880f
Cochlear malformations. *See* Cochlear anomaly(ies).
Cochlear mechanics
active, 2062-2069, 2064f-2065f
conversion of basilar membrane displacement to radial shearing forces in, 2065-2067, 2069f
outer hair cells in, 2063-2064, 2066f-2067f
prestin (SLC26A5) in, 2064-2065, 2068f
radial displacement patterns of basilar membrane in, 2067, 2069f
tectorial membrane pathophysiology and, 2067-2069
passive, 2050-2062, 2061f-2062f
physical dimensions in, 2060, 2063f
traveling wave in, 2060-2069, 2062f-2064f
Cochlear microphonics (CMs)
in electrocochleography, 1907-1908
with neural hearing loss, 1899-1901, 1900f
Cochlear modiolus, in surgical anatomy of lateral skull base, 2439
Cochlear nerve
anatomy of, 1832f, 1854f, 2278f
anomalies of, 2735
in central auditory pathway, 1834-1835
imaging of, 1928-1929, 1929f
intraoperative monitoring of, 2552
direct action potentials for, 2554, 2554f
and outcome, 2554-2555
in surgical anatomy of lateral skull base, 2437f, 2439
Cochlear nerve aplasia, auditory brainstem implants for, 2263-2264
Cochlear nucleus
in auditory physiology, 1845-1846, 1846f
in central auditory pathway, 1835, 1835f
Cochlear ossification, cochlear implant with, 2235f, 2240
Cochlear otosclerosis, imaging of, 1921-1922, 1925f
Cochlear partition
anatomy of, 1840, 2050, 2061f
in auditory physiology, 1840-1842, 1842f
Cochlear promontory, 1825-1826
Cochlear ramus, 1854, 1856f
Cochlear transduction, 2049-2085
active, 2062-2069, 2064f-2065f
conversion of basilar membrane displacement to radial shearing forces in, 2065-2067, 2069f
outer hair cells in, 2063-2064, 2066f-2067f
prestin (SLC26A5) in, 2064-2065, 2068f
Cochlear transduction *(Continued)*
radial displacement patterns of basilar membrane in, 2067, 2069f
tectorial membrane pathophysiology and, 2067-2069
traveling wave in, 2062-2069, 2064f
endolymph homeostasis in, 2081-2083, 2083f-2084f
genetic basis for, 2050, 2051t-2058t
in murine models, 2050, 2058t-2060t
hair cell transduction in, 2070-2081, 2070f
adaptation of mechanoelectrical transduction currents in, 2078-2079, 2079f
and auditory neuropathy, 2081
and defects in cytoskeletal proteins leading to deafness, 2074-2076, 2076f
defects in hair cell–afferent dendrite synapses and, 2080-2081, 2080f
defects of other hair cell channels and, 2079-2080
hair bundle deflections and receptor potentials in, 2069f, 2071, 2072f
myosin VI in, 2078
stereocilia in, 2070-2071
anatomy of, 2070-2071, 2070f, 2072f
composition of, 2074, 2075f-2076f
cross-linkages between, 2076f, 2077-2078
dynamic regulation of length of, 2076-2077
transduction channels in, 2071-2073
effects of deficiencies of, 2079-2080
gating of, 2073-2074
ion selectivity of, 2073, 2073f
structure of, 2076f
passive, 2050-2062, 2061f-2062f
physical dimensions in, 2060, 2063f
traveling wave in, 2060-2062, 2062f-2063f
perilymphatic-endolymphatic barrier in, 2081, 2082f
Cochleariform process, 1826f, 1827
Cochleosaccular dysplasia, 2727-2728
Cochleosacculotomy, for Meniere's disease, 2126, 2362-2363, 2363f
Cochleostomy, for cochlear implant, 2239
Cochleotopic map reorganization. *See* Tonotopic map reorganization.
Cochleovestibular nerve, 1834-1835
Cochleovestibular nerve injury, in lateral skull base surgery, 2512
Cochlin, in deafness, 2051t-2058t
Codeine, for postoperative pain, 241t
in children, 2594
Coding strand, 4
Codman, Ernest, 52
Codons, 4
Coefficient of determination, 64, 72
Cogan's syndrome, 2341
clinical manifestations of, 2341
etiology and pathogenesis of, 2341
historical background of, 2341
inner ear disease in, 2165
sensorineural hearing loss due to, 2123-2124, 2341
serologic tests for, 2327
treatment of, 2341
typical *vs.* atypical, 2341
Cognitive development, sleep-disordered breathing and, 2791-2792
Cognitive expertise, 79t
Cognitive impairment
obstructive sleep apnea and, 2603-2604
pain with, 240
Cognitive-behavioral therapy (CBT), for tinnitus, 2135
Coherent scattering, 1032
Cohort study, 54, 54t
Coiled terminations, 1201
Coiled-coil domain-containing protein 50/Ymer *(CCDC50)* gene, in deafness, 2051t-2058t
COL1A1
in deafness, 2051t-2058t
in osteogenesis imperfecta, 2109
COL1A2, in osteogenesis imperfecta, 2109
COL2A1, in deafness, 2051t-2058t, 2095
COL4A3, in deafness, 2051t-2058t
COL4A4, in deafness, 2051t-2058t
COL4A5, in deafness, 2051t-2058t, 2097
COL9A1, in deafness, 2051t-2058t, 2069
COL11A1, in deafness, 2051t-2058t, 2095
COL11A2, in deafness, 2051t-2058t, 2069, 2092, 2095
Cold
common, pharyngitis due to, 196
dry air provocation test, in nonallergic rhinitis, 696
Cold air–induced rhinitis, 619b
Cold receptors, in nasal obstruction, 641
Cold steel débridement, interventional bronchoscopy for, 1010t
Colectins, in middle ear protection, 1871
Colestipol, for hyperthyroidism, 1739t
Colitis, ulcerative, oral manifestations of, 1254
Collagen
in skin flaps, 1071
for vocal fold medialization, 905-906
Collagen vascular disease
oral manifestations of, 1251-1252
otologic manifestations of, 2114
vertigo due to, 2201
Collagenase, in bone resorption, 1972-1973
Collagenase-I, in wound healing, 1077
Collecting duct, of salivary gland, 1133-1134
Collision kerma, 1033
Colloid bodies, in lichen planus, 1228
Colloid thyroid nodules, ultrasound of, 1644, 1647f
Colonic transposition, for hypopharyngeal and esophageal reconstruction, 1453, 1454f
Colony-forming unit–basophil mast cell (CFU-BM), 605
Colony-forming unit–eosinophil (CFU-Eo), 604
Colony-forming unit–erythroid (CFU-E), 605
Colony-forming unit–granulocyte-macrophage (CFU-GM), 604
Colony-forming units–megakaryocytes (CFU-MEG), 605
Color Doppler sonography, 1644
of salivary glands, 1167-1168
Columella
anatomy of, 509f
surface defects of, 348
hinge flap for, 348, 350f
paramedian forehead flaps for, 348
Columella retraction, correction of, 547-548, 548f
Columellar lengthening, in cleft-lip nose repair, 559, 566f
Columellar strut
for noncaucasian nose, 560f
in revision rhinoplasty, 593, 593f
COM. *See* Chronic otitis media (COM).
Coma, myxedema, 1749
Combination chemotherapy, for recurrent or metastatic disease, 1059-1060
Combined-modality therapy, for head and neck squamous cell carcinoma, 1052-1058
with biologic agents plus radiotherapy, 1054, 1058f
concomitant chemoradiation as, 1052-1056, 1053t-1054t
as adjuvant therapy, 1056
induction chemotherapy in, 1041-1042, 1052-1053
induction chemotherapy in, 1056-1058, 1058f, 1058t-1059t
in concomitant chemoradiation, 1041-1042, 1052-1053
RADPLAT technique for, 1054

Combitube, 109-110, 110f, 114t
Comet-tail artifact, with colloid thyroid nodule, 1644, 1647f
Common canaliculus
  anatomy of, 798f
  in endoscopic dacryocystorhinostomy, 800-801, 801f
Common carotid artery
  anatomy of, 2579, 2579f-2580f
  in extended neck dissection, 1719-1720
Common carotid artery injury, due to penetrating neck trauma
  imaging of, 1632f
  management of, 1632
Common cavity, of inner ear, 2728f-2729f, 2729t, 2731-2732
Common chemical sense
  in olfactory stimulation, 628-629
  of oral cavity, 1202
Common cochlear artery, anatomy of, 1854, 1856f
Common cold, pharyngitis due to, 196
Comorbidity, 53
Comparative genomic hybridization (CGH), for head and neck squamous cell carcinoma, 1019
Complement system, in humoral immune response, 607-608, 608f
Complement system defects, 2114
  otologic manifestations of, 2114
Complementary DNA, 11-12, 12f
Complete strip technique, for nasal tip refinement, 522, 527f-530f
Complete transfixion incisions, for nasal tip projection, 535-536, 536f
Completely-in-the-canal (CIC) hearing aid, 2270, 2270f
  comparison of features of, 2206t
  evolution of, 2267
  in infants, 2723-2724
Complex calyx endings, of hair cells, 1857, 1859f
Complex traits, 8
Complex-motion tomography, of pharynx and esophagus, 1393
Composite grafts, for nasal reconstruction, 368-369, 369f
Composite turnout flap, for nasal defects, 348, 351f
Compound action potential (CAP)
  in Bell's palsy, 2394
  electrically evoked, 1912-1913
    with cochlear implants, 1913f, 1914
Compound melanocytoma, 287
Compound muscle action potential (CMAP)
  for facial nerve injury, 2041, 2386
  for facial nerve monitoring, 2387
    after tumor removal, 2545
Compound nevus, 286
Compound solution of iodine, for hyperthyroidism, 1739t
Compressed analog (CA), for cochlear implants, 2230
Compression, of dynamic range, with traditional hearing aid, 2205-2207
Compression circuitry, for hearing aids, 2268
Compton scattering, 1032f, 1033
Computational fluid dynamics (CFD), CT with, 643
Computed radiography, of pharynx and esophagus, 1393
Computed tomography (CT), 131
  of acoustic neuroma, 2517
  algorithms for, 131, 131f
  applications of, 139-142
  of cervical lymphadenopathy, 139
  combined with PET, 138
  with computational fluid dynamics, 643
Computed tomography (CT) *(Continued)*
  contrast-enhanced, 132, 132f-133f, 139
    of cervical lymphadenopathy, 164
      with extracapsular spread, 164-166, 167f
      inflammatory (reactive), 164
      with invasion of carotid artery, 166-167
      metastatic, 164-165, 167f
      with non-Hodgkin's lymphoma, 165-166, 167f
    of salivary glands
      with AIDS-related parotid cysts, 1146f
      with pleomorphic adenoma, 1144f
      with sialolithiasis, 1148f
  for CSF rhinorrhea, 791, 792f
  of deep neck space infections, 204, 204f-205f
  of facial trauma, 142
  of Graves' ophthalmopathy, 1809, 1811f
  helical
    of laryngeal carcinoma, 1470
    of pharynx and esophagus, 1396
  high-resolution
    for cochlear implant, 2222, 2222f
      with otosclerosis, 2222, 2222f
      in preoperative evaluation, 2235, 2235f, 2236b
    for CSF rhinorrhea, 791, 791f, 2044
    for dizziness, 2326-2327
    for malignant otitis externa, 1947
    of superior canal dehiscence syndrome, 2340-2341, 2340f
    for temporal bone fracture, 2039, 2040f
  for hyperparathyroidism, 1786-1787
  for hypopharyngeal and cervical esophageal cancer, 1424, 1424f
  image display for, 131-132
  with intensity-modulated radiotherapy, 1044
  of laryngeal carcinoma, 1468-1479, 1494
    early glottic, 1516-1517
  of laryngeal trauma, 935-936, 936f
  of larynx and infrahyoid neck, 132f, 140
  of lateral skull base lesions, 2489
  of maxillofacial trauma, 325-326
    of lower third, 325-326
    of middle third, 325, 326f
    of upper third, 325, 325f
  multidetector, 131, 139
  of nasopharyngeal carcinoma, 1354
  of neck masses, 1637, 1637t
  of neck neoplasms, 1656
  of obstructive sleep apnea, 255, 255f
  of oral cancer, 1300
  of oropharyngeal cancer, 1366
  of paranasal sinus tumors, 1124
  of paranasal sinuses, 140-142, 141f, 662-663
    radiation exposure with, 663
    with rhinosinusitis
      diagnostic, 140-142, 141f
      intraoperative, 744, 772
      preoperative, 743, 744t, 763-764, 764f-765f, 764t
      and surgical outcome, 729
    technique for, 662-663, 664f
  patient cooperation for, 132, 132f
  of petrous apicitis, 1986-1987, 1988f
  of pharynx and esophagus, 1396
  radiation exposure from, 132-133, 133t
  of salivary glands, 139, 1148, 1166, 1180
    with AIDS-related parotid cysts, 1146f
    with parotid lipoma, 1166, 1167f
    with pleomorphic adenoma, 1144f, 1148
    with sialadenitis, 1148
    for sialography, 139-140, 1145f
    with sialolithiasis, 1144f, 1148, 1148f
    with Sjögren's syndrome, 1148
    with Warthin's tumor, 1146f
  spiral (helical), of laryngeal carcinoma, 1470
  of suprahyoid neck, 139, 141f
Computed tomography (CT) *(Continued)*
  of temporal bone and skull base, 142
  3D, of laryngeal carcinoma, 1470
  three-dimensional reconstruction from, 138, 140f
  of thyroid and parathyroid glands, 140
  windows for, 131-132, 131f
  xenon blood flow mapping with, 2491
Computed tomography angiography (CTA)
  of anterior skull base, 2475, 2475f
  of neck masses, 1637, 1637t
Computed tomography (CT) cisternography, for CSF rhinorrhea, 790, 790f
Computed tomography–sestamibi (CT-MIBI) fusion, for hyperparathyroidism, 1785-1786, 1786f
  to localize ectopic glands, 1785-1786, 1787f-1788f
  in re-exploration, 1785-1786, 1788f
  to refine minimally invasive approach, 1785-1786, 1786f
Computer imaging
  in facial analysis, 277-280, 279f-280f
  for revision rhinoplasty, 581-582
  prior to rhinoplasty, 514
Computer-aided modeling, in mandibular reconstruction, 1326-1327, 1327f
Computer-assisted navigation, in endoscopic sinus surgery, 772
Computer-assisted voice analysis, for children, 2878, 2878f
Computerized dynamic posturography (CDP), 2324, 2325f
  motor control test in, 2324-2325
  sensory organization test in, 2325-2326, 2325f-2326f
  use of, 2326-2327
Concha, 477
  bullosa, 741
    endoscopic sinus surgery with, 751, 752f
    imaging of, 668, 669f
  cavum, 2742f
  cymba, 2742f
Conchal cartilage grafts, in noncaucasian rhinoplasty, 569
Conchal hypertrophy, 478-479
Conchal-mastoid sutures, 476f, 477-478
Concomitant chemoradiation, 1052-1056, 1053t-1054t
  as adjuvant therapy, 1056
  induction chemotherapy with, 1041-1042, 1052-1053
    with adjuvant therapy, 1056
Condensation and rarefaction clicks, in auditory brainstem response testing, 1899-1901, 1900f
Conditioning activities, in vestibular rehabilitation, 2372-2373, 2379
Conductive hearing loss, 2017-2027
  audiogram of, 1888, 1888f

in arytenoid adduction, 913, 914f
surgical anatomy of, 1543f
Cricoarytenoid unit, in organ-preservation surgery, 1544
Cricohyoidoepiglottopexy (CHEP)
for glottic cancer, 1517t
supracricoid partial laryngectomy with, 1549-1550
complications of, 1551
extended procedures for, 1551
functional outcome of, 1551, 1551t-1552t
key surgical points for, 1550-1551
oncologic results of, 1549-1550
surgical technique for, 1550, 1550f-1551f
vs. total laryngectomy, 1564
Cricohyoidopexy (CHP)
for advanced supraglottic cancer, 1500
supracricoid laryngectomy with, 1555-1557
complications of, 1557
functional outcome of, 1556-1557, 1557t
key surgical points for, 1556
oncologic results of, 1555
partial, 1564
surgical technique for, 1555-1556, 1556f
Cricoid arch
repair of, 939f
surgical anatomy of, 1543f
Cricoid cartilage
anatomy of, 805-806, 1359f, 1422f
radiographic, 1471, 1473f
surgical, 1541, 1542f-1544f
laryngeal carcinoma of, 1541
physical examination of, 95, 96f
Cricoid lamina, surgical anatomy of, 1543f
Cricoid resection with thyrotracheal anastomosis, for laryngeal stenosis, 2921, 2922f
Cricoid ring, radiographic anatomy of, 1473, 1473f
Cricoid split operation, 2908f, 2910f, 2918-2919, 2918f-2919f
Cricoidectomy, for chronic aspiration
partial, 928
subperichondrial, 927-928, 929f
Cricopharyngeal achalasia, 1398-1399, 1400f
Cricopharyngeal chalasia, 1399
Cricopharyngeal dysfunction, 1398-1399, 1400f
Cricopharyngeal muscle
anatomy of, 1422
in arytenoid adduction, 915
delayed opening of, 1399
during swallow, 833
pharyngeal, 1216-1217, 1216f
in Zenker's diverticulum, 987
Cricothyroid (CT) joint
in arytenoid adduction, 915
surgical anatomy of, 1542f
Cricothyroid (CT) ligament, surgical anatomy of, 1541-1542, 1542f-1543f
Cricothyroid membrane (CTM)
anatomy of, 126
dilation of, 127, 128f
palpation and location of, 127, 127f
relocation of, 127, 127f
transverse incision in, 127, 127f
Cricothyroid (CT) muscle
anatomy of
applied, 807, 807f
surgical, 1543f
characteristics of, 918
in professional voice production, 846-847
Cricothyrotomy, 114t, 126-128
anatomic considerations for, 126
complications after, 128, 128f
contraindications for, 126-127
defined, 126
equipment for, 126b
historical perspectives on, 126
indications for, 126-127
percutaneous, 114t, 128
procedure for, 127
cricoid hook in, 127, 128f
dilation of cricothyroid membrane in, 127, 128f
palpation and location of cricothyroid membrane in, 127, 127f
relocation of cricothyroid membrane in, 127, 127f
tracheostomy tube insertion in, 127, 128f
transverse incision in cricothyroid membrane in, 127, 127f
vertical incision over cricoid cartilage in, 127, 127f
rapid five-step technique for, 128
Cricotracheal resection (CTR), for laryngeal stenosis, 2921, 2922f
Cricotracheal separation, management of, 937
Crile clamp, in repair of medial canthal ligaments, 337f
Crile, George, 1702-1703, 1726
Crista ampullaris
anatomy of, 1854, 1856f-1857f
embryogenesis of, 1852
Crista galli, 1124f
aerated, 670
bifid, with nasal dermoid, 2689, 2689f
in surgical anatomy of anterior cranial base, 2442-2443, 2443f, 2471, 2472f
Critical closing pressure, in skin flaps, 1068
Crohn's disease
esophagitis due to, 1405
oral manifestations of, 1254

Cromolyn sodium, for allergic rhinitis, 620
Cronin technique, in cleft-lip nose repair, 559, 566f
Crookes, William, 1031
Cross-face nerve grafting, 2419, 2424-2425
Crossing over, 3
Crossover, in audiologic testing, 1889
Cross-priming, 1024
Croton oil, for deep chemical peel, 394
Croup, 1465, 1465f, 2803-2806
  clinical features of, 2803-2804
  defined, 2803
  diagnosis of, 2804
  differential diagnosis of, 2804-2805, 2806t
  epidemiology of, 2803
  etiology of, 2803
  imaging of, 2804, 2804f-2805f
  laryngoscopy of, 2804, 2805f
  management of, 2805-2806, 2904
  membranous (bacterial), 1465, 1465f
  pathogenesis of, 2803-2804
  postintubation, 2593
  pseudo-membranous (*See* Bacterial tracheitis)
  spasmodic, 2805

  viral, 2803
Crouzonodermoskeletal syndrome, craniofacial anomalies in, 2641t
Crouzon's syndrome, craniofacial anomalies in, 2641t, 2645
Crow's feet, 428
CRS. *See* Chronic rhinosinusitis (CRS).
CRT. *See* Chemoradiation therapy (CRT).
"Crumple zones," of face, 322, 322t
Crus commune, 1851f, 1853f
Crus helicis, 1824f
CRYM, in deafness, 2051t-2058t
Cryoglobulinemia, sensorineural hearing loss due to, 2120
Cryotherapy
  interventional bronchoscopy with, 1010t
  for skin lesions, 294
  for unresectable tracheal tumor, 1621
Cryptococcal meningitis, in HIV, 223-224
Cryptococcosis, laryngeal and tracheal manifestations of, 892-893
μ-Crystallin, in deafness, 2051t-2058t
CS (carotid space)
  anatomy of, 203
  imaging of, 150-151, 151f-152f
  schwannoma of, 1663f
CSD (cat scratch disease)
  in children, 2818
  deep neck space infections due to, 201
  salivary gland involvement in, 1159
CSF. *See* Cerebrospinal fluid (CSF).
CSOM (chronic suppurative otitis media), cochlear implant for, 2221
CSP (cysteine-string protein), 2081
CSS (Chronic Sinusitis Survey), 57
CSS (Churg-Strauss syndrome)
  nasal manifestations of, 659
  otorrhea due to, 2196
CT. *See* Computed tomography (CT); Cricothyroid (CT).
CTA (computed tomography angiography)
  of anterior skull base, 2475, 2475f
  of neck masses, 1637, 1637t
CTAP-III (chemokine connective tissue–activating peptide-III), in wound healing, 1076
CTGF (connective tissue growth factor), in formation of granulation tissue, 1077
CTL(s) (cytotoxic T lymphocytes), 601, 602f
CTL2, in autoimmune inner ear disease, 2165
CTM. *See* Cricothyroid membrane (CTM).
CTR (cricotracheal resection), for laryngeal stenosis, 2921, 2922f
CTSIB (Clinical Test of Sensory Integration and Balance), 2317
CTV (clinical target volume), for radiotherapy, 1044
CTV (clinical tumor volume), for radiotherapy, 1036
Cuneiform cartilage, 1542f
Cuneiform tubercle, 1422f, 1543f
Cupula
  anatomy of, 1855, 1857f
  in vestibular system, 2278f, 2279-2283
    torsional pendulum model of, 2279-2283, 2282f
Cupulolithiasis, 2329-2330
  of lateral semicircular canal, 2331
Curets, for treatment and biopsy of skin lesions, 293
Curie (Ci), 1031-1032
Curie, Marie, 1031-1032
Curie, Pierre, 1031
Current steering, for cochlear implants, 2231, 2231f
Cushing's disease, oral manifestations of, 1251
Cutaneous branches, of cervical plexus, 2578, 2580f
Cutaneous diseases
  esophageal manifestations of, 979-980
  nasal manifestations of, 660-661
    in Behçet's disease, 660-661
    in pemphigoid, 660
    in pemphigus vulgaris, 660
    in scleroderma, 660
  oral manifestations of, 1253-1254
Cutaneous flaps. *See* Skin flap(s).
Cutaneous hemangiomas, and airway involvement, 2899, 2900f
Cutaneous neoplasms
  immunosuppression and, 213t, 215
  neck dissection for, 1718-1719
    definition and rationale for, 1718, 1718f
    technique for, 1718-1719
Cuticular plate, 1832-1833, 1833f, 1841f, 1857
CVA (cerebrovascular accident)
  chronic aspiration due to, 926b
  due to lateral skull base surgery, 2512
  oral manifestations of, 1250
Cx. *See* Connexin(s) (Cx).
CXC chemokines, 609t-612t
CXC3C chemokine, 611t-612t
CXCL-14, for head and neck squamous cell carcinoma, 1024
CXCR2 (chemokine receptor 2), in wound healing, 1076
CXCR4 (chemokine receptor 4), in head and neck squamous cell carcinoma, 1060
CXR (chest x-ray)
  of early glottic carcinoma, 1516
  for imaging of pharynx and esophagus, 1393
  for neck masses, 1637
Cyanoacrylates, for embolization, 1933
Cyanotic heart disease, anesthesia with, 2597
CyberKnife (CK) stereotactic radiotherapy
  for laryngeal and hypopharyngeal cancer, 1592
  for malignant skull base tumors, 1696
Cyclic adenosine monophosphate (cAMP)
  in olfactory transduction, 629
  in salivary gland secretion, 1137
Cyclin D1, in laryngeal carcinoma, 1505
Cyclin D3, in laryngeal carcinoma, 1505
Cyclin-dependent kinase inhibitor 2D *(Cdkn2d)* gene, in murine deafness, 2058t-2060t
Cyclooxygenase (COX) inhibitors, and skin flap viability, 1074
Cyclooxygenase-1 (COX-1) inhibitors, for head and neck squamous cell carcinoma, 1018
Cyclooxygenase-2 (COX-2), in laryngeal carcinoma, 1505
Cyclooxygenase-2 (COX-2) inhibitors
  for chemoprevention of oral cancer, 1315
  for head and neck squamous cell carcinoma, 1018
Cyclophosphamide
  for autoimmune inner ear disease, 2167
  for Wegener's granulomatosis, 658
Cyclosporine, for Graves' ophthalmopathy, 1811
Cylindroma, 288f, 292
Cymba conchae, 476-477, 476f, 1824f
Cymetra. *See* AlloDerm Regenerative Tissue Matrix (Cymetra).

rhinologic, 56t, 57
sleep, 56t, 57
symptom, 56t, 57-58
voice, 56t, 57
Disequilibrium, of aging, 233-234
defined, 233
diagnostic methods for, 233
treatment of, 234
vestibular pathology of, 233
Disk battery, ingestion of, 2941, 2958, 2958f
Dislocation, of temporomandibular joint, 1280
Dispersion, descriptive statistics for, 64t
Distal esophageal pressure, 958f
Distal sensory polyneuropathy (DSP), HIV-associated, 223
Distortion product otoacoustic emissions (DPOAEs), 1891, 1905
and audiometric tests, 1905, 1907f
clinical applications of, 1905-1907
defined, 1891, 1905
distortion product in, 1905
frequencies used in, 1905
with high-frequency hearing loss, 1905, 1907f
in infants, 2720-2721
in noise-induced hearing loss, 2146-2147, 2147f-2150f
with normal hearing, 1892f, 1905, 1907f
procedure for, 1891
Distraction osteogenesis
for craniofacial anomalies, 2654-2657, 2656f
for obstructive sleep apnea, 2610
for Robin sequence, 2673
Distress, palliative care for, 1103-1104
DIT (di-iodotyrosine)
in thyroid hormone release, 1738
in thyroid hormone synthesis, 1738
Diuretics
dizziness due to, 2310t
loop
in noise-induced hearing loss, 2147
ototoxicity of, 2174-2175
sensorineural hearing loss due to, 2120
for Meniere's disease, 2126, 2337
Divalproex (Depakote), for migraine, 2350
Divergence paralysis, 2314
Diverticulectomy, transcervical, 991f
Diverticulopexy technique, 992f
Diverticulostomy
endoscopic diathermic, 993f
endoscopic staple, 992-995
complications of, 995
electrocautery technique for, 993f
instruments for, 994f
laser technique for, 993f
limitations of, 994
positioning for, 993f
recurrence after, 995-997
results of, 994-995
technique of, 995f-996f
Diverticulum(a)
esophageal, 974-975, 974f-975f
classification of, 986
double, 986, 989f
mid-, 1402, 1403f
pseudo-, 975, 975f
imaging of, 1406, 1407f
pulsion, 986
traction, 986
types and sites of, 986, 987f-989f
pharyngeal, 1401-1402, 1402f
dysphagia due to, 2951
Zenker's. *See* Zenker's diverticulum (a).

with cochlear implants, 1913f, 1914
Electrically evoked long latency responses (ELLRs), 1913-1914
Electrically evoked middle latency responses (EMLRs), 1912-1914
Electroacoustic characteristics, of hearing aid, 2267-2268, 2268f
Electroacoustic stimulation, cochlear implants with, 2224, 2224f
hearing preservation and, 2245-2246

Electrocautery
  interventional bronchoscopy with, 1010t
  in otoplasty, 478
Electrocautery tonsillectomy, 2797-2799
Electrocochleography (ECoG), 1892-1896, 1907-1908
  and auditory brainstem responses, 1908
  clinical applications of, 1908
  with cochlear implant, 1913f
  cochlear microphonic in, 1907-1908
  defined, 1892-1894, 1907
  for dizziness, 2323, 2323f
  for Meniere's disease, 1892-1896, 1895f, 1908, 2337
  with normal hearing, 1894f, 1913f
  procedure for, 1894, 1908
  for sensorineural hearing loss, in adults, 2117
  SP/AP ratio in, 1892-1894
  summating potential in, 1892-1894, 1907
  whole-nerve action potential in, 1892-1894, 1907
Electrodes, for intraoperative cranial nerve monitoring
  recording, 2543-2544, 2543f
  stimulating, 2544, 2544f
Electrodiagnostic testing, of facial nerve function, 2385-2387
  electromyography in, 2386-2387
  electroneuronography in, 2041, 2386, 2387t
  maximal stimulation test in, 2040-2041, 2385-2386, 2387t
  nerve excitability test in, 2040-2041, 2385, 2387t
Electrodogram, 2230, 2230f
Electroglottography (EGG)
  for measurement of vocal fold vibration, 830, 835
  for professional voice, 849
Electrogustometry (EGM), 2383-2384
Electrolarynx voice and speech, physiology of, 1596, 1596f
Electrolyte composition, ideal, for infants, 2572t
Electromagnetic (EM) middle ear implantable hearing aids, 2208-2211
  Carina as, 2210-2211
    clinical results with, 2210-2211
    components of, 2210, 2210f
    history of, 2210
    placement of, 2210, 2211f
  Middle Ear Transducer (MET) as, 2027, 2210-2211
    clinical results with, 2210-2211
    comparison of features of, 2206t
    components of, 2210
    history of, 2210
    indications for, 2210, 2211f
    placement of, 2210, 2211f
  ossicular coupling in, 2207-2208
  sound transduction and coupling to auditory system with, 2205f
  transducer design for, 2207
  Vibrant Soundbridge as, 2208-2210
    clinical data on, 2209
    comparison of features of, 2206t
    components of, 2208-2209, 2208f
    for conductive and mixed hearing loss, 2210
    history of, 2208, 2210
    implantation of, 2209
    indications for, 2209, 2209f
Electromagnetic (EM) radiation, 1031, 1031f
Electromagnetic (EM) stimulation, to assess facial nerve function, 2388-2389
  in Bell's palsy, 2394-2395
Electro-mechanical voice devices, after total laryngectomy, 1572
Electromyography (EMG)
  artifacts in, 2547-2548, 2548f
  for Bell's palsy, 2394
Electromyography (EMG) *(Continued)*
  for cranial nerve monitoring
    anesthesia and, 2544
    of cochlear nerve, 2552
      and outcome, 2554-2555
    electrodes for
      recording, 2543-2544, 2543f
      stimulating, 2544, 2544f
    of facial nerve, 2387-2388, 2545-2548
      for acoustic neuroma and other cerebellopontine angle tumors, 2545
      activity evoked by electrical stimulation in, 2545-2546
      to assess functional status of nerves after tumor removal, 2545-2546
      to identify and map nerves in relation to tumor, 2545
      for intraoperative identification of nervus intermedius, 2546, 2546f
      limitations of, 2547-2548, 2548f
      during microvascular decompression, 2548-2549, 2549f
      during other otologic surgery, 2549
      and outcome, 2554
      during parotid surgery, 2549
      spontaneous and mechanically evoked activity in, 2546-2548, 2547f
    instrumentation for, 2543
    of ninth, tenth, eleventh, and twelfth cranial nerves, 2550-2552, 2551f-2552f
    stimulation criteria for, 2544
    of third, fourth, and sixth cranial nerves, 2549-2552, 2550f
    of trigeminal motor branch, 2550
  for facial nerve injury, 2041, 2386-2387
    evoked, 2386
  laryngeal, 835, 905
    for stridor, 2901
Electron beams, in radiotherapy, 1034, 1035f
Electroneuronography/electroneurography (ENoG)
  for Bell's palsy, 2394

Esophageal pH monitoring
ambulatory 24-hour, 958-960, 959f-960f
Bravo wireless pH capsule for, 961, 961f
for GERD-related laryngeal disease in children, 2945
multichannel intraluminal impedance for, 962
Restech Dx-pH Measurement System for, 962, 962f
Esophageal pseudodiverticula, 975, 975f
Esophageal reconstruction, 1448-1461
with circumferential defects, 1431-1432
classification of defects for, 1450
decision making on, 1450, 1451f
free tissue transfer for, 1454, 1454f
enteric, 1455-1457
gastro-omental donor site for, 1457-1458, 1457f
jejunal donor site for, 1455-1457, 1456f
jejunal free flap for, 1432-1433, 1433f
fasciocutaneous, 1433, 1455
antero-lateral thigh donor site for, 1455
other donor sites for, 1455
radial forearm donor site for, 1455
goals and principles of, 1450
local and regional flaps for, 1450-1452, 1452f
myocutaneous flaps for, 1452-1453
patient population for, 1448
perioperative counseling for, 1448-1449
postsurgical complications of, 1458, 1459f
posttreatment speech and swallowing outcomes of, 1459-1460
preoperative evaluation for, 1449-1450
visceral transposition for, 1453
colonic, 1453, 1454f
gastric, 1432, 1432f, 1453
voice rehabilitation after, 1458-1459
Esophageal retention cysts, 1416, 1416f
Esophageal rings, 966-967, 966f, 968f
transnasal esophagoscopy of, 983-984, 984f
Esophageal spasm, diffuse, 965
esophagogram of, 965, 966f
imaging of, 1400-1401, 1401f
manometric findings with, 959t, 965, 965f
Esophageal speech, 1459
physiology of, 1596, 1596f
after total laryngectomy, 1572
Esophageal squamous cell carcinoma, 973
due to caustic injury, 978
Esophageal stage, of deglutition, 1217, 2948
Esophageal stenosis, after hypopharyngeal reconstruction, 1458
Esophageal strictures, 965-966
due to caustic injury, 977-978, 978f-979f
in children, 2960-2962, 2960f-2961f
imaging of, 1405, 1405f
defined, 965-966
dilation of, 966
transnasal esophagoscopy in, 984, 984f
endoscopy of, 965-966, 967f
due to esophageal carcinoma, 1408, 1408f
etiology of, 965-966, 966b
extrinsic, 965-966, 966b
imaging of, 1407-1408
due to caustic injury, 1405, 1405f
due to esophageal carcinoma, 1408, 1408f
esophagram for, 965-966, 966f
inflammatory, 1403, 1404f
inflammatory, 1403, 1404f
intrinsic, 965-966, 966b
postlaryngectomy, 1416
refractory, 966
after total laryngopharyngectomy, 1575
treatment of, 966
mechanical therapy for, 2960-2962, 2960f-2961f
transnasal esophagoscopy in, 984, 984f
Esophageal symptoms, assessment of, 954-956

Esophageal tears, due to penetrating neck trauma, 1633-1634, 1634f
Esophageal testing, 956-963
  ambulatory 24-hour bile monitoring for, 960-961, 961f
  endoscopy for, 956-957
    equipment for, 956
    of esophageal varices, 958f
    for extraesophageal reflux, 899
    of gastroesophageal junction
      with Mallory-Weiss tear, 957f
      normal, 956-957, 957f
      with severe esophagitis, 957f
    of squamocolumnar junction, 956-957, 956f-957f
    technique of, 956-957
  esophageal manometry for, 957-958, 958f-959f, 959t
  esophageal pH monitoring for
    ambulatory 24-hour, 958-960, 959f-960f
    Bravo wireless pH capsule for, 961, 961f
    multichannel intraluminal impedance for, 962
    Restech Dx-pH Measurement System for, 962, 962f
  provocative, 962-963
Esophageal trauma, 941-942
  caustic, 942, 977-978
    clinical features of, 977
    etiology of, 977
    grading of, 977, 978t
    prognosis for, 977-978
    squamous cell carcinoma due to, 978
    strictures due to, 977-978, 978f-979f
  external, 941-942
  mechanisms of injury in, 933, 934f
  pill-induced, 976, 976b
Esophageal varices, 958f
  imaging of, 1411, 1411f
Esophageal webs, 966-967, 967f
  imaging of, 1407, 1408f
Esophageal-bronchial fistulas, 1009
Esophageal-tracheal fistulas, 1009
Esophagectomy, for caustic ingestion, 2961-2962, 2962f
Esophagitis
  caustic, 942, 977-978
    clinical features of, 977
    etiology of, 977
    grading of, 977, 978t
    imaging of, 1404-1405, 1405f
    prognosis for, 977-978
    squamous cell carcinoma due to, 978
    strictures due to, 977-978, 978f-979f
      imaging of, 1405, 1405f
  drug-induced, 1406, 1406f
  eosinophilic ("ringed," "feline," corrugated), 967-968, 969f
    dysphagia due to, 2954
  erosive, Los Angeles classification of, 969, 969f
  gastroesophageal junction in, 957f
  granulomatous, 1405
  infectious, 976-977
    due to *Candida albicans*, 976, 976f
      imaging of, 1404, 1405f
    due to cytomegalovirus, 976, 977f
    due to herpes simplex virus, 976-977, 977f-978f
      imaging of, 1404, 1405f
    imaging of, 1404, 1405f
  peptic, 1406
  radiation, 1406
  reflux, 968-969, 969f
    imaging of, 1403-1404, 1403f-1404f
  tuberculous, 1405
Esophagodiverticulostomy, endoscopic, 992
Esophagogastroduodenoscopy (EGD)
  for extraesophageal reflux, 899
  for laryngeal stenosis, 2917
Esophagogram, 1394, 1395f
  for extraesophageal reflux, 898
  mucosal-relief, 1394, 1395f
Esophagoscopy
  for foreign body removal, 2939t, 2940
  for penetrating neck trauma, 1631t, 1633-1634, 1634f
  transnasal (*See* Transnasal esophagoscopy (TNE))
Esophagus
  abdominal, 954f
  Barrett's
    endoscopic appearance of, 967f, 972, 972f
    gastroesophageal junction in, 957f
    GERD and, 972-973
    grading of dysplasia in, 973, 973t
    histologic appearance of, 972, 972f-973f
    imaging of, 1403-1404, 1404f
    long-segment, 972f
    short-segment, 972f
    surveillance for, 972-973, 973t
    transnasal esophagoscopy in, 983, 983f
  cancer of (*See* Esophageal cancer)
  cervical, 954f
    anatomy of, 1421-1422
    cancer of (*See* Esophageal cancer, cervical)
  congenital anomalies of, dysphagia due to, 2950t, 2953-2954, 2954f
  "corkscrew," 965, 966f
  defined, 953
  food impactions in, 975
  foreign bodies in, 975-976, 2935-2943
    airway obstruction due to, 1481, 1481f
    classification of, 975
    complications of, 2942, 2942f
    epidemiology of, 2936
    due to food impaction, 975
    imaging of, 1411, 1412f, 2939
    location of, 2936, 2937f
    management of, 2939-2941
      anesthesia for, 2940
      controversies in, 2942
      for disk batteries, 2941
      equipment for, 2939-2940, 2939t
      history of, 2935-2936
      for pills, 2941
      postoperative, 2941-2942
      for sharp objects, 2940-2941
      technique for, 2940
    perforation due to, 2941
    symptoms of, 2938
  normal anatomy and physiology of, 953-954, 954f-955f
  nutcracker, 959t, 965
    imaging of, 1401
  presby-, 1400
  radiographic anatomy of, 1397-1398, 1398f, 1400f
  thoracic, 954f
ESP (Early Speech Perception), for cochlear implant, 2225-2226
ESPAL (endoscopic sphenopalatine artery ligation), for epistaxis, 689-690, 689f-690f
Espin, in stereocilia, 2075, 2076f
Espin *(ESPN)* gene, in deafness, 2051t-2058t
ESRRB (estrogen-related receptor β) gene, in deafness, 2051t-2058t
ESS (Epworth Sleepiness Scale), 57, 253, 253f
ESS (empty sella syndrome), CSF rhinorrhea due to, 787
ESS (endoscopic sinus surgery). *See* Endoscopic sinus surgery (ESS).
Essential tremor, laryngeal hyperfunction due to, 840-841
Esteem-Hearing Implant, 2211-2212, 2212f
Esthesioneuroblastoma (ENB), 1697-1698
  epidemiology of, 1697
  pathogenesis of, 1697
  prognostic factors for, 1697
  treatment for
    approaches to, 1697-1698
    radiation therapy for, 1698, 1698f
    results of, 1697, 1698t
Esthetician, for aging skin, 402
Estlander flap, 352, 356f
Estrogen(s), for hyperparathyroidism, 1804
Estrogen-related receptor β *(ESRRB)* gene, in deafness, 2051t-2058t
Etanercept, for autoimmune inner ear disease, 2167
Ethacrynic acid, sensorineural hearing loss due to, 2120, 2175
Ethanol
  absolute, for embolization, 1933
  percutaneous administration of, for toxic thyroid adenoma, 1744
Ethical issues, with genetics, 9-10
Ethmoid bone, in surgical anatomy of anterior cranial base, 2442-2443, 2443f
Ethmoid bulla
  in endoscopic sinus surgery, 747, 748f
  normal anatomy of, 666-667, 667f
  surgical anatomy of, 740
Ethmoid complex, 740
Ethmoid foramina, in surgical anatomy of anterior cranial base, 2443-2444, 2444f
Ethmoid fractures, naso-orbital, 322
  classification of, 326-327, 327f
  physical examination of, 324, 324f
  repair of, 336-337, 337f
Ethmoid region, in surgical anatomy of anterior cranial base, 2444f
Ethmoid roof
  after functional endoscopic sinus surgery, 672f, 679
  in surgical anatomy of anterior cranial base, 2443
Ethmoid roof height, asymmetry in, 670-671
Ethmoid sinus(es)
  anatomy and physiology of, 320f, 664, 667
  growth and development of, 2619-2620
  roof of, 1124f
  in surgical anatomy of anterior cranial base, 2443, 2472f-2473f, 2473
Ethmoid sinus tumors, 1123, 1130
  external ethmoidectomy for, 1124-1125, 1125f
  staging of, 1129b
Ethmoid vessels, prior to endoscopic sinus surgery, 764, 764t, 765f
Ethmoidal labyrinth, 1124f
Ethmoidectomy
  endoscopic
    anterior, 747-748, 748f
    complete, 748-749, 749f-750f
    failure of, 766-767, 767f
    posterior, 747-748, 749f
  external, 757, 757f, 1124-1125, 1125f
    Lynch-Howarth, 778-779, 779f
  intranasal, 756-757
Ethnic differences, in otitis media, 2766
Ethnic noses, rhinoplasty for. *See* Noncaucasian rhinoplasty.
Ethylene oxide polyoxypropylene glycol (Addax), for cerumen removal, 1958t
Etomidate, for induction of anesthesia, 111
ETS (environmental tobacco smoke), and chronic rhinosinusitis, 707
ETT. *See* Endotracheal intubation (ETT).
European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC-HN35), 56

Eustachian tube, 1866-1875
  anatomy of, 1825, 1867-1870, 1867f
    anterior pad in, 1869, 1869f
    anterior view of, 1868f
    arterial supply in, 1870
    cartilaginous portion in, 1868-1869, 1869f
    dilatory muscles in, 1869-1870, 1869f
    histology of lumen of, 1870
    junctional portion of, 1868, 1868f
    lateral view of, 1868f
    in middle cranial base, 1699
    mucosa-associated lymphoid tissue in, 1870
    in oropharynx, 1360f
    osseous portion in, 1867, 1867f
    superior view of, 1867f
    tubal lumen in, 1867f, 1870
  embryology and postnatal development of, 1866-1867
  length of, 1866
  location of, 1867
  in otitis media, 2762-2763, 2763f
  patulous, 1872
  pharyngeal opening of, in surgical anatomy of anterior cranial base, 2472f, 2474
  physiology of, 1870-1872
    middle ear protection in, 1871-1872
    mucociliary clearance and drainage in, 1871
    pressure equalization in, 1870-1871
  shape of, 1867
  in surgical anatomy of lateral skull base, 2436f-2437f, 2438
Eustachian tube dysfunction, 1872-1874
  with abnormalities in lateral wall movement, 1872
  aging and, 1872
  classic theory of, 1870-1871
  with cleft palate, 1872-1873, 1873f
  ear pressure and, 1872
  with extraesophageal reflux, 1873
  hereditary component to, 1873-1874
  hypertrophic adenoids and, 1872, 1873f
  mucociliary clearance and, 1871
  nasal allergy and, 1872
  with nasopharyngeal neoplasms, 1873, 1873f
  pathophysiology of, 1872
  with pressure changes, 1872
  respiratory viruses and, 1871
  treatment of, 1874
Eustachian tube function, 1867
Eustachian tube function tests, 1874
Eustachian tube opening, in surgical anatomy of lateral skull base, 2436f
Eutectic mixture of local anesthetics (EMLA), for premedication of children, 2589
Euthyrox (levothyroxine, oral synthetic), for hypothyroidism, 1748-1749
Eversion, in wound repair, 306, 306f
Evidence, levels of, 69, 70t
  and grade of recommendation, 55, 55t, 69-70, 70t
Evidence-based medicine (EBM) recommendations, grading of, 55, 55t, 69-70, 70t
Evidence-based performance measurement, 76-90
  aggregate demand for, 77
  anatomy of performance measures in, 82, 83f
  definition of quality for, 76-77
  engaging in development of, 77-78
  implementation of
    barriers to, 89
    pathway for, 88f
    standardization and, 87-89
  medical professionalism and, 78-82
    board certification and maintenance of certification in, 79-80, 80b-81b
    Institute of Medicine in, 81-82
    physician education in, 79, 79t
Evidence-based performance measurement *(Continued)*
    state medical boards and maintenance of licensure in, 80-81
  motivation for, 76
  process of building a coherent system of, 77-78
  quality-based or value-based purchasing in, 78
  stakeholder groups in, 79-89, 84t-87t
  surgeon's role in, 89
  unifying response to demand for, 77-78
Evoked auditory brainstem response (EABR). *See* Auditory brainstem response (ABR).
Evoked electromyography, 2386
Evoked encephalomyography (EEMG), for facial nerve injury, 2041
Evoked long latency responses (ELLRs)
  auditory, 1912, 1913f
  electrically, 1913-1914
Evoked middle latency responses (EMLRs)
  auditory, 1912, 1913f
  electrically, 1912-1914
Evoked otoacoustic emissions (EOAEs), in infants, 2720-2721
Ewald's First Law, 2288
Ewald's Second Law, 2290-2291
Ewing's sarcoma (ES)
  in children, 2845
  malignant, 1671
  oral manifestations of, 1253
Ewing's sarcoma family of tumors (ESFTs), in children, 2845
Ex utero intrapartum treatment (EXIT procedure)
  for congenital high airway obstruction syndrome, 2869, 2870f, 2904-2905
  for laryngeal atresia, 2869
Ex vivo gene therapy, 18, 19f
Excisional surgery
  for scar revision, 295, 297f
    expansion with, 296-298
      serial, 296
      tissue, 296-298, 297f
  for skin lesions, 293
Excitation-inhibition asymmetry, of semicircular canals, 2290-2291, 2291f
Excitatory amino acid transporter 1 (EATT1), 2081
Excitatory postsynaptic potentials (EPSPs), in vestibular afferent nerve fibers, 2284-2285, 2284f
Excited state, of atom, 1032
Exclusion criteria, 68
Excretory duct, of salivary gland, 1162, 1163f
Exercise, nasal airflow during, 641
Exercise-induced asthma, in professional singers, 853
EXIT procedure (ex utero intrapartum treatment)
  for congenital high airway obstruction syndrome, 2869, 2870f, 2904-2905
  for laryngeal atresia, 2869
Exocrine disorders, oral manifestations of, 1251
Exogen phase, 374
Exons, 4, 5f
Exostoses, of external auditory canal
  imaging of, 1918, 1918f
  management of, 2022, 2024f
Expanded polytetrafluoroethylene (ePTFE)
  for craniofacial defect repair, 2657
  for nasal reconstruction, 368
  in noncaucasian rhinoplasty, 569, 570f
Expansion with excision, for scar revision, 296-298
  serial, 296
  tissue, 296-298, 297f
Experimental studies, data quality of, 59, 60t-62t
Expert opinion, 52, 54-55, 54t
Expiratory force, in phonation, 811-812
Expiratory resistance, in rhinomanometry, 650-651
Exposure keratitis, after facial nerve injury, 2420, 2420f
Exposure time, of surgical laser, 28
Expression microarrays, in head and neck squamous cell carcinoma, 1025
Expressivity, 7, 7f
Extended craniofacial resection, 1126-1127, 1127f
  supplemental management in, 1126-1127
Extended head posture, 2629
Extended maxillotomy, for middle cranial base surgery, 2455t, 2458, 2462f
Extended middle fossa approach, for posterior fossa neoplasms, 2532t, 2538
  advantages and disadvantages of, 2532t, 2538
  basic features of, 2538
  indications for, 2532t, 2538
  surgical exposure in, 2538f
  technique of, 2538
Extended neck dissection, 1703t, 1719-1721, 1720f
Extended vertical hemilaryngectomy, 1548
External acoustic meatus, 320f, 2010f
External auditory canal (EAC)
  anatomy of, 1822f, 1823, 1824f-1825f, 1829
  atresia of, 1917, 1917f
  benign neoplasms of, 1918, 1918f-1919f

indications for, 391, 392t
medium-depth, 393-394, 393f-394f
patient selection and education for, 391-392
and phenol toxicity, 395
postoperative care after, 396, 396f
prepeel preparations for, 392
superficial, 392-393, 403
contraindications to, 391, 392t
dermabrasion for, 397-399
complications of, 399
equipment for, 398, 398f
micro-, 402-403
patient selection and consultation for, 397-398
postoperative care after, 399, 399f
technique of, 398-399, 398f-399f
indications for, 391, 392t
laser, 399-402
CO_2, 400, 400f
Er:YAG, 400
nonablative, 402, 403t
postoperative care after, 401-402, 401f
nonablative, 402, 403t
laser, 402, 403t
microdermabrasion for, 402-403
superficial chemical peels for, 403
Facial schwannomas. *See* Facial nerve neuroma.
Facial skeletal growth, 2615f, 2617t
Facial skeleton
anatomy, physiology, and pathophysiology of, 319-323, 320f
general, 319
of lower third, 322-323, 323f
of middle third, 319-322
areas of protection in, 322, 322t
infraorbital nerve in, 320, 321f
maxillae in, 320, 321f
nasal bones in, 320
orbits in, 320-321, 322f
zygoma in, 319, 320f-321f
of upper third, 319, 319f
biomechanics of, 331-333, 331f
in lower third, 332-333, 332f
in middle third, 331-332, 331f
in upper third, 331
physical examination of, 95
Facial swelling, due to paranasal sinus tumor, 1123
Facial symmetry, through midsagittal plane, 269, 272f
Facial translocation approach, for middle cranial base surgery, 2455t, 2464-2466, 2467f
Facial trauma
due to burns, 314-316
assessment and treatment of, 315-316
classification of, 314-315, 315f
of eyelids, 316
of lips and oral commissure, 316
of nasal and a utricular cartilage, 316
fracture as (*See* Facial fracture(s))
due to frostbite, 316
in geriatric patients, 237
imaging of, 170-171, 170f-171f
CT for, 142
soft tissue, 302-317
approach to, 302-306
anesthesia in, 304
cleaning in, 304-305, 305f
history taking in, 302-303
infection control in, 305
physical examination in, 303-304, 303f
repair in, 305-306, 306f
tetanus prophylaxis for, 303
Facial trauma *(Continued)*

Fast neutron, 1034
Fast spin-echo (FSE) imaging, 134
Fasting, prior to anesthesia, 112
in children, 2589, 2590t
Fat(s), dietary, taste of, 1213
Fat saturation, for MRI, 135-136, 136f
Fat suppression methods, for MRI, 135-136, 136f
of laryngeal carcinoma, 1470
FBA. *See* Foreign body aspiration (FBA).
FDG-PET. *See* Fluorodeoxyglucose–positron emission tomography (FDG-PET).
Federation of State Medical Boards (FSMB), 80-81, 84t-87t
Feedback, with traditional hearing aid, 2204
Feedback suppression circuitry, for hearing aids, 2269
FEES (flexible endoscopic evaluation of swallowing), for dysphagia in children, 2949, 2950t
FEES (functional endoscopic evaluation of swallowing)
for chronic aspiration, 926
for laryngeal stenosis, 2917
"Feline" esophagitis, 967-968, 969f
Fenestra, creation of, in small fenestra stapedotomy, 2031-2032, 2032f
Fenestral otosclerosis, 1921-1922, 1925f
Fenretinide, for cancer chemoprevention, 1018, 1061-1062
Fentanyl
as adjunct to induction of anesthesia, 111
for anesthesia maintenance in children, 2591
for postoperative pain, 241t
Fentanyl sublingual spray, for mucositis, 1102
FESS. *See* Functional endoscopic sinus surgery (FESS).
Fever, pharyngoconjunctival, 198
"Fever blisters," in HIV, 226
Fexofenadine (Allegra), for nonallergic rhinitis, 701t
FFB. *See* Flexible fiberoptic bronchoscopy (FFB).
FFL (flexible fiberoptic laryngoscopy), for laryngomalacia, 2867
FFT (Fast Fourier Transform), in acoustic analysis, for voice evaluation, 829t, 830, 830f
FGF(s) (fibroblast growth factors), in wound healing, 1077-1078
FGFR(s) (fibroblast growth factor receptors), in craniofacial anomalies, 2640, 2642f
FGFR3 (fibroblast growth factor receptor 3) gene
in achondroplasia, 2633
in deafness, 2051t-2058t
FHM (familial hemiplegic migraine), 2349
Fiberoptic bronchoscope (FOB)
for awake fiberoptic nasotracheal intubation, 123-125, 125f
for difficult airway, 114t
Fiberoptic intubation (FOI), awake nasotracheal, 122-123
advantages of, 123
avoiding failure in, 125, 126b
bronchoscopy cart for, 123, 123f
conscious sedation for, 124
fiberoptic bronchoscope in, 123-125, 125f
historical perspective on, 122-123
indications for, 123, 123b
keys to successful, 124b
monitoring during, 124
nasal trumpet placement for, 124, 125f
optimal setup for, 125f
patient preparation for, 123-124
technique of, 124-125
topical anesthesia for, 124
Fiberoptic laryngoscope, rigid, for difficult airway, 114t
Fiberoptic nasopharyngoscopy, 101
of obstructive sleep apnea, 253, 254f
Fibrillated ePTFE (Gore-Tex), for chin implants, 465t
Fibrin glue, in intratympanic delivery, 2182
Fibrin sealants, for rhytidectomy, 416-420
Fibroadnexal tumor(s), 291-293
acrochordon as, 291
angiofibroma as, 292
atypical fibroxanthoma as, 292
cylindroma as, 288f, 292
dermatofibroma as, 288f
dermatofibrosarcoma protuberans as, 291-292
fibrous papule as, 288f, 292
hidrocystoma as, 292
keloids and hypertrophic scars as, 291
lipoma as, 293
neurofibromas as, 292
sebaceous hyperplasia as, 288f, 293
syringoma as, 292-293
trichoepithelioma as, 292
xanthelasma as, 293
Fibroblast(s), in formation of granulation tissue, 1077
Fibroblast growth factor(s) (FGFs), in wound healing, 1077-1078
Fibroblast growth factor receptor(s) (FGFRs), in craniofacial anomalies, 2640, 2642f
Fibroblast growth factor receptor 3 *(FGFR3)* gene
in achondroplasia, 2633
in deafness, 2051t-2058t
Fibroepithelial papilloma, 291
Fibroma
ameloblastic, 1274-1275
microscopic findings in, 1274-1275, 1275f
radiographic features of, 1274
treatment of, 1275
irritation, of oral cavity, 1288-1289, 1289f
ossifying, sinonasal, 725-726
subcutaneous, due to neck irradiation, 1695
Fibronectin, in wound contraction, 1078
Fibro-odontoma, ameloblastic, 1275
microscopic findings in, 1275, 1275f
radiographic findings in, 1275
treatment of, 1275
Fibrosarcoma
in children, 2842-2843, 2843f
of larynx, 1508
of neck, 1668
of paranasal sinuses, 1131
Fibrosis, due to radiotherapy, 1048
Fibrous dysplasia, 2110-2111
of anterior skull base, 2647f
cellular and molecular basis of, 2111
clinical manifestations of, 2111
histopathology of, 2111, 2111f
laboratory findings in, 2111
management of, 2111
otologic manifestations of, 2111
radiographic findings in, 2111, 2111f
of sinonasal tract, 718t, 725-726, 726f
Fibrous nonunion, 331, 339-340
Fibrous papule, 288f, 292
Fibrous tumor, solitary, of neck, 1671
Fibrous union, 331, 339-340
Fibroxanthoma, atypical, 292
Fibula flap, for free tissue transfer, 1082t, 1084-1085, 1085f
Fibula osteocutaneous free flap reconstruction
for mandibular defects, 1324-1325, 1325t
for oral cancer, 1316, 1316f
Field cancerization, in head and neck squamous cell carcinoma, 1016, 1061
Filter, in acoustic analysis, for voice evaluation, 830
Finasteride (Propecia), for hair loss, 377-378
Fine structure signal processing, for cochlear implants, 2230-2231, 2231f-2232f
Fine-needle aspiration biopsy (FNAB)
in children, 2574
of salivary glands, 2854
of lymphoma, 1675-1676
of neck masses, 1638
of oropharyngeal cancer, 1366
of salivary glands, 1149, 1149f, 1165-1166, 1180-1181
in children, 2854
of thyroid nodule, 1756-1758
repeat, 1759
ultrasound-guided, 1655f
ultrasound-guided, 1653-1654, 1655f
of parathyroid tumor, 1789
Fine-needle aspiration cytology (FNAC). *See* Fine-needle aspiration biopsy (FNAB).
Fire, in airway, 119
First aid measures, for epistaxis, 684
First bite syndrome
due to carotid paraganglioma surgery, 1660-1661
due to neck surgery, 1732
First branchial cleft cyst, otorrhea due to infection of, 2195
First genu, of facial nerve, 1826f, 1827-1828
FISH (fluorescence in situ hybridization), for head and neck squamous cell carcinoma, 1018-1019

Fissures of Santorini, 1823, 1944
Fistula(s)
  arteriovenous, embolization of
    dural, 1940-1942, 1940f
    facial, 1940, 1940f
  branchial cleft, 2585

    ultrathin, 1001, 1003f
  diagnostic, 999b, 1003-1007
    for bronchial wash, 1003
    for bronchoalveolar lavage, 1003-1004
    for bronchoscopic brush sampling, 1007
    for endobronchial and transbronchial biopsy, 1004-1005, 1004f-1005f
    general approaches to, 1003
    for transbronchial needle aspiration, 1005-1007, 1005f-1006f
    for visual examination, 1003
  imaging prior to, 999-1000
  indications for, 999, 999b
  patient discussion and informed consent for, 1000
  patient positioning and route of entry for, 1000
  sedation and airway management for, 1000
Flexible fiberoptic laryngoscopy (FFL), for laryngomalacia, 2867
Flexible fiberoptic nasopharyngoscopy, for recurrent respiratory papillomatosis, 2888
Flexible laryngeal mask airway, for children, 2599
Flexible laryngoscopy, 100, 814
  advantages of, 814
  disadvantages of, 814
  in neurologic evaluation, 834
  for professional voice disorders, 851-852, 852t
  protocols for, 816b, 818b
  technique of, 814
  troubleshooting for, 814
Floccular lesions, and vestibular function, 2308
Floccular peduncle, 1861
Flocculus, 2404f
Flonase (fluticasone propionate), for nonallergic rhinitis, 700t
Floor of mouth
  anatomy of, 1297-1298
  carcinoma of, 1307-1308
    cervical metastases of, 1308
    clinical presentation of, 1294f, 1307
    composite resection for, 1307-1308, 1308f, 1315f
    coronal partial mandibulectomy for, 1307-1308, 1308f
    imaging of, 1307
    invasive, 1307
    reconstruction for, 1307, 1315f
    segmental mandibulectomy for, 1307-1308, 1308f
    survival with, 1308
    transoral resection for, 1307
  vasculature of, 1296
Flow-volume loop, for airway stenosis, 945f
Floxin (ofloxacin) otic solution, for otitis externa, 1946, 1952, 1959t-1960t
Fluence, of surgical laser, 28
Fluid losses, expected, in children, 2572t
Fluid resuscitation
  for burns, 315
  for deep neck space infections, 205
Fluid secretion, by salivary glands, 1135, 1135f
Fluid utilization, during bed rest, for children, 2572t
Fluid-attenuated inversion recovery (FLAIR) imaging, of middle ear cholesteatoma, 1919, 1921f
Fluids and fluid management, in children, 2572
  and expected fluid losses, 2572t
  and fluid utilization during bed rest, 2572t
  and ideal electrolyte composition for infants, 2572t
Flumazenil, for premedication in children, 2589
Flunisolide (Nasalide, Nasarel)
  for nonallergic rhinitis, 700t
  for rhinosinusitis, 734t, 736
Fluorescein, intrathecal, for CSF rhinorrhea, 790, 2044
Fluorescence in situ hybridization (FISH), for head and neck squamous cell carcinoma, 1018-1019
Fluorescent tumor markers, for early glottic carcinoma, 1516
Fluoride, in saliva, 1139
Fluoride gel, for dental care during radiation therapy, 1331, 1331f
Fluoride therapy, for otosclerosis, 2034-2035
Fluorodeoxyglucose–positron emission tomography (FDG-PET), 137-138
  applications of, 144, 145f
  with intensity-modulated radiotherapy, 1044
  of laryngeal carcinoma, 1494-1495
    early glottic, 1517
  of oral cancer, 1300
  of salivary glands, 1150, 1168
Fluoroquinolones, for pediatric chronic sinusitis, 2779
Fluoroscopy
  of obstructive sleep apnea, 255
  of pharynx and esophagus, 1393-1394
5-Fluorouracil (5-FU)
  for chemical peels, 392-393
  in combination chemotherapy, 1059-1060
  for induction chemotherapy, 1056-1058, 1058f
  with radiotherapy, 1041-1042, 1052-1054
Fluosol-DA, and skin flap viability, 1073-1074
Fluticasone
  for obstructive sleep apnea, 257
  for rhinosinusitis, 734t
Fluticasone acetonide oil (DermOtic Oil), for eczematoid otitis externa, 1956
Fluticasone furoate (Veramyst), for nonallergic rhinitis, 700t
Fluticasone propionate (Flonase), for nonallergic rhinitis, 700t
Fluticasone propionate cream, for eczematoid otitis externa, 1955-1956
FM (frequency-modulated) receiver, for hearing aid, 2267
FM (frequency-modulated) system, personal, 2271
fMRI (functional magnetic resonance imaging)
  for cerebral blood flow evaluation, 2491
  of olfaction, 632
FNAB. *See* Fine-needle aspiration biopsy (FNAB).
FNAC (fine-needle aspiration cytology). *See* Fine-needle aspiration biopsy (FNAB).
F_0. *See* Frequency (F_0).
FOAVS (facio-oculo-auriculo-vertebral spectrum), craniofacial anomalies in, 2646-2647
FOB (fiberoptic bronchoscope)
  for awake fiberoptic nasotracheal intubation, 123-125, 125f
  for difficult airway, 114t
Focal length, of lens of laser, 28
Focal plane, of surgical laser, 28, 28f
FOI. *See* Fiberoptic intubation (FOI).

Folate deficiency, oral manifestations of, 1254
Foliate papillae, taste buds in, 1208
Follicular cyst, 1263-1264
  microscopic features of, 1264
  neoplastic potential of, 1264
  radiographic features of, 1264, 1264f
  treatment of, 1264, 1264f
Follicular lymphoma (FL), 1678
  clinical presentation of, 1674
  treatment and prognosis for, 1678
Follicular thyroid carcinoma, 1761-1762
  clinical presentation of, 1761-1762
  management and prognosis for, 1762
  pathology of, 1762
Follicular unit extraction (FUE), 384
Follicular-unit hair transplantation, 378, 378f-381f
  completion of procedure for, 383-384
  complications of, 384
  dissection of donor strip in, 382, 382f
  doll's hair appearance with, 378, 378f
  follicular unit extraction for, 384
  graft placement in, 383, 383f
  location of hairline in, 378-379, 381f, 383, 383f
  marking off donor strip of scalp for, 381-382, 382f
  marking out recipient regions for, 379-381, 382f
  micrografts in, 378, 379f-381f
  operative procedure for, 382-384
  postoperative care after, 384
  preoperative evaluation for, 378-382, 381f
  slivers of follicular units in, 382, 383f
  surrounding natural hair growth in, 382-383
Fontaine sign, positive, with carotid paragangliomas, 1659
Fontanelle(s)
  closure of, 2617t
  in newborn, 2615, 2618f
Food impactions, in esophagus, 975
Food sensitivity, and migraines, 2349
Foramen cecum, in surgical anatomy of anterior cranial base, 2442-2443, 2443f, 2471, 2472f
Foramen jugulare, in surgical anatomy of middle cranial base, 2445f
Foramen lacerum
  in surgical anatomy of anterior cranial base, 2472f
  in surgical anatomy of lateral skull base, 2435f, 2436-2437
  in surgical anatomy of middle cranial base, 2444, 2445f
Foramen magnum
  growth and development of, 2617t
  in surgical anatomy of lateral skull base, 2435f
Foramen of Huschke, 1823
Foramen ovale
  anatomy of, 1699
  in surgical anatomy of lateral skull base, 2435f, 2436-2438, 2437f, 2472f
  in surgical anatomy of middle cranial base, 2444, 2445f
Foramen rotundum
  in surgical anatomy of lateral skull base, 2435f, 2438
  in surgical anatomy of middle cranial base, 2444, 2445f
Foramen spinosum
  in surgical anatomy of lateral skull base, 2434, 2435f, 2437-2438, 2441
  in surgical anatomy of middle cranial base, 2444, 2445f
Forced opening test, of eustachian tube function, 1874
Forced oscillation rhinomanometry, 643-644
Fordyce spots, 99
Foregut duplication cysts, compression of pharynx and esophagus due to, 1408-1409, 1409f
Forehead
  aesthetic analysis of, 270-271
    for defect repair, 359
    eyebrow position in, 271, 275f
    eyebrow shape in, 271
    nasofrontal angle in, 270, 274f
  aesthetic proportions of, 428, 429f
  aging, 428-432, 429f
  fascial layers of, 440-441, 441f
Forehead defects, 359-363

postoperative management of, 1096-1098
complications and salvage in, 1097-1098
free flap monitoring in, 1097
pharmacologic, 1096-1097
aspirin in, 1096
dextran in, 1096-1097
heparin in, 1096
surgical techniques for, 1093-1096
drain placement and wound closure in, 1096
free flap harvest in, 1094
free flap inset and microvascular anastomosis in, 1094-1096, 1095f
neck recipient site surgery in, 1094
primary recipient site surgery in, 1093-1094
surgical incisions in, 1093
visceral, for oropharyngeal reconstruction, 1380, 1380f
Freer elevator, for septoplasty, 488, 489f
Frequency (F_0)
in acoustic analysis for voice evaluation, 829, 829t
characteristic, 1844-1845, 1845f
of sound waves, 1838-1839, 1839f
of ultrasound waves, 1643
Frequency distribution, 63, 66
Frequency gain response, for hearing aids, 2267-2268
Frequency response, in vestibular tests, 2302, 2303f
Frequency selective presaturation, for MRI, 135-136, 136f
Frequency-modulated (FM) receiver, for hearing aid, 2267
Frequency-modulated (FM) system, personal, 2271
Frey's syndrome, 2197
after parotidectomy, 1177
Friedreich's ataxia, 2357
Frontal bone
anatomy and physiology of, 319, 319f-320f
fracture of, 319, 319f
imaging of, 325, 325f
repair of, 333-334
surgical access to, 328, 328f-329f
osteomyelitis of, 777f
Paget's disease of, 779-780, 780f
in surgical anatomy of anterior cranial base, 2442-2443
Frontal branch, of facial nerve, 440, 441f
in anterior cranial base surgery, 2451, 2451f
Frontal mucocele, 783
Frontal nerve, 440
Frontal process, in endoscopic dacryocystorhinostomy, 799-800, 800f
Frontal recess
in endoscopic sinus surgery, 750
prior to endoscopic sinus surgery, 764, 764t
after functional endoscopic sinus surgery, 677
normal anatomy of, 665, 665f-667f
reconstruction of lateral wall of, 778-779, 779f
surgical anatomy of, 740-741
Frontal sinus(es)
anatomy of, 319, 319f, 665, 665f
surgical, 740-741
in anterior cranial base, 2442, 2443f, 2473, 2474f
biomechanics of, 331
cranialization of, 782, 783f
prior to endoscopic sinus surgery, 764t
external approaches to, 757
growth and development of, 2619-2620
obliteration of, 779-781
closure in, 780
complications after, 780-781
estimating limit of frontal sinus in, 780, 781f
incision for, 779-780, 780f
materials used for, 780
with Paget's disease, 779-780, 780f
postoperative monitoring after, 780-781
Frontal sinus(es) *(Continued)*
removal of all mucosa in, 780
template for, 779-780
osteoma of, 783-784, 784f
physiology of, 664
pneumosinus dilatans of, 783, 784f
Frontal sinus drainage procedure, median, 779, 779f
Frontal sinus fractures
classification of, 326
imaging of, 325, 325f
management of, 784
pediatric, 2711, 2712f
repair of, 333-334
Frontal sinus surgery
balloon catheter sinusotomy as, 782-783
cranialization of frontal sinus as, 782, 783f
endoscopic frontal sinusotomy as, 776-778
accessing frontal recess in, 777, 777f-778f
confirming location of instrument in, 777-778, 778f
contrainidications to, 781, 781f
history of, 775-776
indications for, 776-783
Lynch-Howarth external ethmoidectomy as, 778-779, 779f
median frontal sinus drainage procedure as, 779, 779f
obliteration of frontal sinuses as, 779-781
closure in, 780
complications after, 780-781
estimating limit of frontal sinus in, 780, 781f
incision for, 779-780, 780f
materials used for, 780
with Paget's disease, 779-780, 780f
postoperative monitoring after, 780-781
removal of all mucosa in, 780
template for, 779-780
Riedel's procedure as, 781-782
indications for, 781-782
postoperative appearance after, 781, 782f
for recurrent infection, 781
Frontal sinus tumors, 1123, 1130
Frontal sinusitis
acute, 775
anatomic variations and, 776
chronic, 775-783
Frontal sinusotomy
balloon catheter, 782-783
in endoscopic sinus surgery, 750-751, 768-771, 776-778
accessing frontal recess in, 777, 777f-778f
agger nasi cell in, 769, 771f-772f
and causes of frontal sinus disease, 769
challenges of, 768
confirming location of instrument in, 777-778, 778f
contrainidications to, 781, 781f
external approaches as adjunct to, 771, 773f
frontal bullar cell in, 772f
frontal recess dissection in, 769, 770b, 770t, 771f
frontal sinus cells in, 769-770, 772f
image-guided navigation system in, 771f
interfrontal sinus septal cell in, 771, 772f
preoperative evaluation for, 768-769
recessus terminalis in, 771
suprabullar cell in, 772f
supraorbital ethmoid cell in, 770-771, 772f
Frontalis muscle, 321f, 433f, 441-442, 444f
Frontobasal meningiomas, embolization of, 1938
Frontoethmoid mucocele, 776f-777f, 783
Frontoethmoid osteoma, 783-784, 784f
Frontoethmoid suture line, in surgical anatomy of anterior cranial base, 2443-2444
Frontoethmoidectomy, craniofacial, 1126, 1126f
Frontofacial monobloc advancement, for craniofacial anomalies, 2653-2654, 2655f-2656f
Frontolateral partial laryngectomy, for glottic cancer, 1517t
Frontolateral vertical hemilaryngectomy, 1548
Frontonasal prominences, in embryology
of lip, 2659-2660, 2661f, 2661t
of nose, 2691f
Fronto-orbital advancement, 2650-2653
bifrontal craniotomy in, 2651-2652, 2651f
for brachycephaly, 2652-2653
closure in, 2653
extent of, 2652-2653, 2653f-2654f
for lambdoid synostosis, 2653
for plagiocephaly, 2652-2653, 2653f
removal of bandeau in, 2651-2652, 2652f
repair of bony defects in, 2653, 2654f
reshaping of bandeau in, 2652, 2652f-2653f
resorbable plates in, 2653
splitting of bandeau in, 2652, 2653f
for trigonocephaly, 2652-2653, 2654f
Frost stitch, 328-329, 329f
Frostbite, 316
Frozen sections, of oropharyngeal cancer, 1366
FSE (fast spin-echo) imaging, 134
FSMB (Federation of State Medical Boards), 80-81, 84t-87t
5-FU. *See* 5-Fluorouracil (5-FU).
FUE (follicular unit extraction), 384
Fugimycin (tacrolimus), for eczematoid otitis externa, 1956
Full denture smile, 2417-2418
Full-thickness skin grafts (FTSGs), for nasal reconstruction, 365
Fully implantable middle ear system, 2027
Function, as outcome measure, 55
Functional Assessment of Cancer Therapy Head and Neck module (FACT-HN), 56
Functional dysphonia, 851
in children, 2879
Functional endoscopic evaluation of swallowing (FEES)
for chronic aspiration, 926
for laryngeal stenosis, 2917
Functional endoscopic sinus surgery (FESS)
abnormal facial growth and development due to, 2623-2625
extent of, 759-760
ostiomeatal complex in, 760, 760f
for pediatric chronic sinusitis, 2779-2781, 2780f-2781f
principles of, 743, 759
radiologic evaluation after, 677-680
expected findings in, 677-679, 679f
operative complications in, 679-680, 680f
Functional hearing loss, evaluation of, 1901
Functional magnetic resonance imaging (fMRI)
for cerebral blood flow evaluation, 2491
of olfaction, 632
Functional matrix hypothesis, of craniofacial growth and development, 2614
Functional Outcomes of Sleep Questionnaire (FOSQ), 57
Functional redundancy, in salivary proteins, 1139
Functional residual capacity, in infants, 2570
Fundamental frequency, 847, 2876
Fundoplication, for extraesophageal reflux, 901
Fungal diseases, 2106
oral manifestations of, 1252
otologic manifestations of, 2106, 2106f
Fungal labyrinthitis, 2160
Fungal laryngitis
acute, 884-885, 884f
chronic, 885
due to blastomycosis, 885
due to coccidioidomycosis, 885

Fungal laryngitis *(Continued)*
due to histoplasmosis, 885
due to paracoccidioidomycosis, 885
Fungal lymphadenopathy, in children, 2818-2819
Fungal otitis externa, 1944-1946, 1945f
otorrhea due to, 2195
topical therapies for, 1954-1955
acidifying agents in, 1954
antifungals in, 1954-1955
ototoxicity of, 1955
antiseptics in, 1955
options for, 1954
Fungal overgrowth, in chronic suppurative otitis media, 2221
Fungal pharyngitis, 199-200
Fungal rhinosinusitis, 709-2
allergic, 707, 712-715
in children, 2778, 2780, 2781f
chronic, 707, 733
classification of, 709
diagnosis of, 707, 712-713
endoscopic sinus surgery for, 761, 762f
epidemiology of, 713-714
imaging of, 706f, 713, 714f
immunochemical staining for, 731, 731f
pathogenesis of, 712-714, 714b
prognosis for, 713
therapy for, 713-715, 715b
chronic, 732-733
allergic, 707
invasive, 711
nonallergic, 715-716, 716t
classification of, 709
fungus balls in, 712, 712f, 714t
in immunocompromised host, 660, 710t
diagnosis of, 220-221, 220f
presentation and pathogenesis of, 220
treatment of, 221
invasive, 705, 709-712
due to *Aspergillus*, 705, 710-711, 712f
in immunocompromised host, 220-221, 220f
due to *Candida*, 711
chronic or indolent, 711
diagnosis of, 711, 711f-712f
due to mucormycosis, 705, 710, 711f
rapidly (fulminant), 709-710, 710f
surgical management of, 742, 761
therapy for, 711-712, 713t
nonallergic eosinophilic, 709, 715-716, 716t
noninvasive, 709
surgical management of, 742, 761
radiologic appearance of, 674-675, 676f
saprophytic, 712
Fungiform papillae, in taste, 1208, 1210, 1212
Fungus balls, of paranasal sinuses, 712, 712f, 714t, 765t
sphenoid, 767, 770f
*N*6-Furfuryladenine (Kinerase), for aging skin, 404
Furlow palatoplasty, 2670
surgical technique for, 2671-2672, 2672f
for velopharyngeal dysfunction, 2682-2683
Furnas suture technique, for otoplasty, 476-477
Furosemide, sensorineural hearing loss due to, 2120, 2175
Furunculosis, of external ear, 1949, 1949f, 2021
Fusiform incisions, for scar revision, 295, 297f
Fusobacterium spp, acute exacerbation of chronic rhinosinusitis due to, 707
F-wave, 2388

G

G protein(s), in salivary gland secretion, 1137
G protein mutations, in thyroid carcinoma, 1752-1753
G protein–coupled receptors
in gustatory transduction, 1208-1209
in olfactory transduction, 629
G1 phase, of cell cycle, 12, 13f
G2 phase, of cell cycle, 12, 13f
GA (genioglossal advancement), for obstructive sleep apnea, 259, 260f
Gabapentin (Neurontin)
for migraine, 2350
for neuropathic pain, 243, 244t
for tinnitus, 2137
GABHS (group A beta hemolytic *Streptococcus pyogenes*), pharyngitis due to, 191-193
in children, 2787
complications of, 2788
Gadolinium enhancement, for MRI, 134-135, 135f-136f
of laryngeal carcinoma, 1470
Gagner, Michel, 39
Gahne, Albert, 1774
Gain
with hearing aids, 2203-2204, 2267-2268
with linear amplification, 2268, 2268f
with nonlinear amplification, 2268, 2268f
target, 2271
vestibuloocular reflex, 2301-2304, 2301f, 2303f
Gait exercises, in vestibular rehabilitation, 2372-2373, 2378-2379
Galanin (GAL), in salivary gland secretion, 1137
Galea aponeurosis, 440
Galectin, in thyroid carcinoma, 1753
Galectin-3, in laryngeal carcinoma, 1505
Gallium-67 citrate scan, for malignant otitis externa, 1947
Gamma Knife radiotherapy, for skull base tumors
benign, 2557, 2558f, 2559t
malignant, 1696
Gamma radiation detection device, for hyperparathyroidism, 1802, 1803f
Gamma rays, 1031-1032
GAN. *See* Greater auricular nerve (GAN).
Ganglioneuroma, 151f
Gap junction(s), 2090f
in endolymph homeostasis, 2081-2083, 2083f-2084f
Gap junction membrane channel protein β1 *(GJB1)* gene, in deafness, 2051t-2058t
Gap junction membrane channel protein β2 *(GJB2)* gene
in deafness, 2051t-2058t, 2083, 2089-2090, 2097
genetic testing for, 2097-2098, 2235
of infants, 2723
Gap junction membrane channel protein β3 *(GJB3)* gene, in deafness, 2051t-2058t, 2083
Gap junction membrane channel protein β6 *(GJB6)* gene
in deafness, 2051t-2058t, 2083
genetic testing for, 2235
Garamycin Ophthalmic (gentamicin), for otitis externa, 1952, 1959t-1960t
Gardasil (human papillomavirus vaccine), 2886-2887, 2890t
Gardner-Robertson scale, for hearing outcomes, after stereotactic irradiation of vestibular schwannoma, 2562, 2562t
Gasserian ganglion, in surgical anatomy of lateral skull base, 2437f, 2438, 2440f
Gastric outlet obstruction, due to caustic ingestion, 2961
Gastric pull-up, for hypopharyngeal and esophageal reconstruction, 1432, 1432f, 1453
Gastric transposition, for hypopharyngeal and esophageal reconstruction, 1432, 1432f, 1453
Gastroesophageal endoscopy, 956-957
equipment for, 956
of esophageal varices, 958f
for extraesophageal reflux, 899
of gastroesophageal junction
Gastroesophageal endoscopy *(Continued)*
with Mallory-Weiss tear, 957f
normal, 956-957, 957f
with severe esophagitis, 957f
of squamocolumnar junction, 956-957, 956f-957f
technique of, 956-957
Gastroesophageal junction (GEJ)
with Barrett's esophagus, 957f
with hiatal hernia, 957f
with Mallory-Weiss tear, 957f
normal anatomy of, 956-957, 957f

Gastroesophageal reflux (GER)
defined, 2944-2945
physiologic or "functional," 2944
Gastroesophageal reflux disease (GERD), 894-903, 968-973
and airway obstruction, 2905-2906
classification of erosive esophagitis in, 969, 969f
defined, 894, 968, 2944-2945
diagnostic evaluation of, 896-900, 968-969
esophageal endoscopy in, 899, 969, 969f
esophagogram in, 898
history in, 896, 896b-897b
impedance testing in, 900
laryngeal sensory testing in, 898-899
manometry in, 899-900
pH probe monitoring in, 900
physical examination and laryngeal endoscopy in, 896-897, 897t, 898b
voice analysis in, 898
dysphagia due to, 2953
epidemiology of, 894
and esophageal adenocarcinoma, 899
esophageal pH monitoring for
ambulatory 24-hour, 958-960, 959f-960f
Bravo wireless pH capsule for, 961, 961f
multichannel intraluminal impedance for, 962
Restech Dx-pH Measurement System for, 962, 962f
extraesophageal (*See* Extraesophageal reflux (EER))
and head and neck cancer, 902-903
laryngeal stenosis due to, 2915, 2917
and laryngomalacia, 2867
nonerosive, 968
and obstructive sleep apnea, 253
oral manifestations of, 1254
otitis media in, 2765
otolaryngologic disorders associated with, 901-903
chronic laryngitis as, 901-902
contact ulcer and laryngeal granuloma as, 902, 902f-903f
pathophysiology of, 894-896, 968
epithelial resistance factors in, 895-896
esophageal acid clearance in, 895
lower esophageal sphincter in, 895, 895b
mechanisms of symptoms in, 896
upper esophageal sphincter in, 894-895
and pediatric chronic sinusitis, 2778-2779
professional voice disorders due to, 852
reflux esophagitis in, 968
and squamous cell carcinoma of larynx, 1491-1492, 1513
symptoms of, 968
treatment of, 900-901, 969-970
behavioral modification for, 900-901
bethanechol for, 901
H_2 blockers for, 901
over-the-counter antacids for, 901
promotility agents for, 901
proton pump inhibitors for, 901
sucralfate for, 901
surgical, 901
and vocal fold granuloma, 2881

Gastroesophageal reflux disease (GERD)-related laryngeal disease, in children, 2944-2947
diagnosis of, 2945
disorders due to, 2945-2946, 2945b
evidence of, 2946
history of, 2944
management of, 2946
physiopathology of, 2945
Gastrografin swallow, for penetrating neck trauma, 1633
Gastrointestinal disorders
in hyperparathyroidism, 1781
oral manifestations of, 1254
Gastrolaryngopharyngeal reflux (GLPR), and laryngeal stenosis, 2917
Gastro-omental flap, for hypopharyngeal and esophageal reconstruction, 1457-1458, 1457f
GATA3, in deafness, 2051t-2058t
Gaucher's disease, oral manifestations of, 1257
Gaze shift, cancellation of vestibulo-ocular reflex in, 2300-2301
Gaze stabilization
medial vestibulospinal tract in, 1865
vestibular system in maintaining, 2276-2277
anatomic and physiologic basis for, 2276-2277
clinical importance of, 2277
GBI (Glasgow Benefit Inventory), after stereotactic irradiation of vestibular schwannoma, 2564
GBLC (geometric broken line closure), for scar revision, 298, 299f-300f
G-CSF (granulocyte colony-stimulating factor), 604, 609t-610t
GCT (giant cell tumor)

of cerebellopontine angle, 2524, 2525f
sinonasal, 718t, 725, 725f
cavernous, 290
of cerebellopontine angle, 2524
epistaxis due to, 684f
of cerebellopontine angle, 2524, 2525f
cavernous, 2524
congenital, 2824, 2825f
cutaneous, and airway involvement, 2899, 2900f
Hemangioma(s) *(Continued)*
facial
embolization of, 1942
laser therapy for, 2827f-2828f, 2828
medical therapy for, 2826-2828
principles for management of, 2826-2828
surgical therapy for, 2827f-2828f, 2828
facial nerve
vs. facial nerve schwannomas, 2507
imaging of, 1924-1926, 1927f
intranasal, 2695
laryngeal, 874, 2871, 2871f
of masticator space, 152
neck masses due to, 1640, 2816, 2816f
of oral cavity, 1291
of salivary glands, 1172, 2859-2860, 2860f
spindle cell, 1668-1669
subglottic, 1468, 1468f, 2871, 2871f
dysphagia due to, 2953
stridor due to, 2899, 2900f
of trachea, 1613
Hemangioma of infancy (HOI), 290, 2823-2824
of airway
assessment and treatment of, 2828-2829, 2829f
complications of, 2825, 2826f
clinical presentation of, 2823, 2825f
complications of, 2825, 2826f-2827f
diagnosis of, 2823
focal, 2823, 2825f
imaging of, 2823, 2824f
laser therapy for, 2827f-2828f, 2828
medical therapy for, 2826-2828
natural history of, 2823, 2824f
obstruction of visual axis by, 2825, 2826f
persistent tissue changes due to, 2826, 2827f
in PHACES syndrome, 2824, 2825f
principles for management of, 2826-2828
segmental, 2823, 2824f-2825f
surgical therapy for, 2827f-2828f, 2828
ulceration of, 2825, 2827f
Hemangiopericytoma (HPC), of neck, 1670
Hematocrit, in children, 2571-2572
Hematogenous total joint infection, patients at potential increased risk of, 1253, 1253t
Hematologic disorders
oral manifestations of, 1256
preoperative evaluation of, 105-106
due to anticoagulants, 105
congenital, 105
hemoglobinopathies as, 106
due to liver failure, 105-106
thrombocytopenia as, 106
Hematolymphoid neoplasms
of larynx, 1509
extramedullary plasmacytoma as, 1509
lymphoma as, 1509
mucosal malignant melanoma as, 1509
of oropharynx, 1364, 1364f
Hematoma(s)
auricular, 97, 310, 2038
esophageal, 1416
fracture, 330
after liposuction, 459
due to neck surgery, 1729
after otoplasty, 478-479
due to rhytidectomy, 420-421, 425f
septal, 494
due to nasal fracture, 507
pediatric, 2708-2709, 2712f
due to sphenoidotomy, 768t
after total laryngectomy, 1571
Hematopoietic growth factors, 609t-610t
Hematopoietic tumors, of paranasal sinuses, 1131
Hemicrania continua, 248
Hemidystonia, 838
Hemifacial microsomia, 2585
Hemifacial spasm, 2401
facial nerve monitoring with microvascular decompression for, 2548-2549, 2549f
Hemiglossectomy, for tongue carcinoma, 1305-1306, 1305f
Hemilaryngectomy
for glottic cancer, 1517t, 1519t
extended, 1517t
vertical, 1496, 1518f, 1519t, 1547-1549
with anterior commissure involvement, 1497
swallowing disorders due to, 1220
vertical, 1547-1549
complications of, 1549
extended, 1548
frontolateral, 1548
functional outcome of, 1548
for glottic cancer, 1496, 1518f, 1519t, 1547-1549
with anterior commissure involvement, 1497
historical background of, 1540
with imbrication laryngoplasty, 1548, 1548f
key surgical points for, 1549
oncologic results of, 1547-1548, 1547t-1548t
posterolateral, 1548
radiographic appearance after, 1476, 1479f
surgical technique for, 1548
Hemilaryngopharyngectomy, supracricoid, for hypopharyngeal cancer, 1429, 1436
Hemimandibulectomy
for buccal carcinoma, 1309f
for tongue carcinoma, 1306f
Hemitransfixion incision, for septoplasty, 488, 489f
Hemochromatosis, oral manifestations of, 1257
Hemodialysis, oral sequelae of, 1255
Hemodilution, and skin flap viability, 1073
Hemoglobin level, in children, 2571-2572
Hemoglobinopathies
oral manifestations of, 1256
preoperative evaluation of, 106
Hemophilia, preoperative evaluation of, 105
Hemophilia A, oral manifestations of, 1256
Hemorrhage
after adenotonsillectomy, 2783f-2784f, 2794, 2799-2800, 2800f
cerebellar, 2354f
due to endoscopic sinus surgery, 754
functional, 679
due to neck surgery, 1723
of carotid artery, 1728
of internal jugular vein, 1729, 1729f
due to sphenoidotomy, 768t
due to thyroid surgery, 1770
vocal fold, 867-869
with capillary ectasia, 868f
diagnosis of, 868
history in, 868
laryngeal examination in, 868
vocal capability battery in, 868
epidemiology of, 867
pathophysiology and pathology of, 867-868
treatment of, 868-869
behavioral, 868
medical, 868
surgical, 868-869
Hemotympanum, due to temporal bone fracture, 2038, 2039f, 2046
Hennebert's sign, 2105, 2316, 2329-2330
in otosyphilis, 2341
with perilymph fistula, 2342
Hensen's cells, anatomy of, 1832, 1832f-1833f
Heparin
after free tissue transfer, 1096
preoperative use of, 105
Hepatic disease
oral manifestations of, 1255
preoperative evaluation of, 103-104
Hepatitis, oral manifestations of, 1252

HER1, in head and neck squamous cell carcinoma, 1060
HER2, in head and neck squamous cell carcinoma, 1060
Her2/neu
  in oral cancer, 1295
  in salivary gland neoplasms, 1199
Hereditary disorders, sensorineural hearing loss due to, in adults, 2117-2118
Hereditary hemorrhagic telangiectasia (HHT), 291
  epistaxis in, 691-692, 692f
  oral manifestations of, 1257
Hernia, hiatal, gastroesophageal junction in, 957f
Herpangina, 2785, 2786f
Herpes labialis, 1236, 1236f
Herpes simplex virus (HSV)
  and Bell's palsy, 2391-2393
  and chemical peels, 391-392, 397
  deafness due to, 2159-2160
    in infants, 2723
  esophagitis due to, 976-977, 977f-978f
    imaging of, 1404, 1405f
  Meniere's disease due to, 2163
  oral
    in HIV, 226
    primary infection with, 1235, 1252
      clinical features of, 1235, 1235f, 1252
      defined, 1235
      diagnosis of, 1235
      differential diagnosis of, 1235
      etiology and pathogenesis of, 1235
      treatment of, 1235, 1252
    recurrent infection with, 1235-1236, 1252
      clinical features of, 1236, 1236f
      defined, 1235
      differential diagnosis of, 1236
      etiology and pathogenesis of, 1235-1236
      histopathology of, 1236, 1237f
      vs. recurrent aphthous stomatitis, 1238, 1238t
      treatment of, 1236
  pharyngitis due to, 199, 199f
  vestibular neuritis due to, 2162-2163
Herpes simplex virus-1 (HSV-1) vector, for gene therapy of inner ear, 2191t, 2192
Herpes zoster facial paralysis, 2393, 2396
Herpes zoster ophthalmicus, 2396
Herpes zoster oticus, 1948, 1948f
  clinical features of, 2159, 2159f
  diagnosis of, 2159
  management of, 2159
  otorrhea due to, 2195
  sensorineural hearing loss due to, 2119, 2159
    sudden, 2127
  temporal bone pathology in, 2159
Herpesvirus vectors, for gene therapy, 18t
  of inner ear, 2191t, 2192
Herpetic gingivostomatitis, 1235, 1235f
Herpetic palsy, imaging of facial nerve in, 1924, 1927f
Herpetiform-type aphthous ulcerations, 1238, 1238f
Hertwig's epithelial root sheath, 1259
Hertz (Hz), 1838-1839, 1839f
Heschl's gyrus, 1847
Heteroduplex testing, 9
Heterogeneity, genetic, 8
Heteroplasmy, 8, 2089
Heterozygosity, 6, 2088
Hexachlorophene and alcohol (Septisol), for deep chemical peel, 394-395
HHIE (Hearing Handicap Inventory in the Elderly), 57
HHT (hereditary hemorrhagic telangiectasia), 291
  epistaxis in, 691-692, 692f
  oral manifestations of, 1257
HHV. *See* Human herpesvirus (HHV).
Hiatal hernia, gastroesophageal junction in, 957f
Hiatus secondarius, 740
Hiatus semilunaris
  normal anatomy of, 667, 667f
  surgical anatomy of, 740
HIB (*Haemophilus influenzae* type B), supraglottitis due to, 2807
HIB (*Haemophilus influenzae* type B) vaccine
  to prevent hearing loss, 2161
  to prevent otitis media, 2769
Hidrocystoma, 292
HIF (hypoxia inducible factor), in Warburg effect, 1028f
HiFocus 1j electrode system, 2227-2228, 2228f
High-density polyethylene (MEDPOR)
  for auricular reconstruction, 2744t
  for chin implants, 465t
High-dose-rate (HDR) radiotherapy, 1047
Highly active antiretroviral therapy (HAART), 211
High-resolution computed tomography (HRCT)
  for cochlear implant, 2222, 2222f
    with otosclerosis, 2222, 2222f
    in preoperative evaluation, 2235, 2235f, 2236b
  for CSF rhinorrhea, 791, 791f, 2044
  for dizziness, 2326-2327
  for malignant otitis externa, 1947
  of superior canal dehiscence syndrome, 2340-2341, 2340f
  for temporal bone fracture, 2039, 2040f
High-Risk Registry (HRR), for infant hearing loss, 2718-2719
High-speed digital imaging (HSDI), of larynx, 821-823
  applications of, 823
  assessment using, 822-823
  defined, 813
  equipment for, 821
  kymography in, 134f, 154, 822f
  limitations of, 823
Hilger facial nerve stimulator, for facial nerve injury, 2040-2041
Hillocks of His, embryogenesis of, 1824, 2741, 2742f
Hinge flaps, 346
  for nasal defects, 348, 350f, 371-372, 372f
HINT (Hearing in Noise Test), for cochlear implants, 2223, 2244
Hip strategy, 2308
HiRes 90K Bionic Ear device, 2227-2228, 2228f
Histamine provocation test, in nonallergic rhinitis, 695-696
Histamine$_1$ receptor antagonists (H_1 blockers), for allergic rhinitis, 620
Histamine$_2$ receptor antagonists (H_2 blockers)
  for extraesophageal reflux, 901
  for GERD, 970
Histiocytoma, malignant fibrous
  of larynx, 1508
  of neck, 1667
Histiocytosis(es)
  in children, 2847-2848
    classification of, 2847, 2847t
    clinical presentation and evaluation of, 2847-2848
    neck masses due to, 2819
    pathology of, 2847
    treatment of, 2848
  Langerhans' cell (*See* Langerhans' cell histiocytosis (LCH))

Hydrocortisone cream (Hytone cream)
after chemical peel, 396
for eczematoid otitis externa, 1955-1956
Hydrocortisone/propylene glycol/acetic acid otic solution (VoSol HC), for otitis externa
bacterial, 1953, 1959t-1960t
fungal, 1954, 1959t-1960t
Hydrodynamic delivery, of siRNA, 16
"Hydrodynamic" theory, of dental pain, 1202-1203
Hydrogen cyanide, in noise-induced hearing loss, 2147-2148
Hydrogen peroxide, for cerumen removal, 1958t
Hydromorphone
as adjunct to induction of anesthesia, 111
for anesthesia maintenance in children, 2592
Hydrops, endolymphatic
audiogram in, 1895f
electrocochleography in, 1892-1896, 1895f, 1908
idiopathic (*See* Meniere's disease)
otosclerosis with, 2035
sensorineural hearing loss due to, 2126-2127, 2199
stacked auditory brainstem response in, 1911
vertigo due to, 2202
Hydrops ex-vacuo model, of eustachian tube dysfunction, 1870
Hydroxyapatite (Bone Source), for chin implants, 465t
Hydroxyapatite cap, for ossiculoplasty, 2026t
Hydroxyapatite (VoCoM) implants, for medialization thyroplasty, 908-910, 908f, 910f
Hydroxychloroquine (Plaquenil)
ototoxicity of, 2176
sensorineural hearing loss due to, 2120
5-Hydroxytryptamine$_3$-receptor antagonists, for postoperative nausea and vomiting in children, 2593
Hydroxyurea, with radiotherapy, 1041
Hygiene hypothesis, of allergic rhinitis, 613-614
Hygroma, cystic, 156-157, 2815, 2901f
Hylan B gel (Hylaform), for vocal fold medialization, 905-906
Hyoepiglottic ligament, 1541-1542, 1542f-1543f
Hyoglossus muscle, 1296f, 1297-1298, 1298f
Hyoid bone
anatomy of, 805-806, 1296f, 1359f
radiographic, 1463f, 1471, 1471f, 1473f
surgical, 1541, 1542f-1543f
in breathing, 810
embryology of, 2583-2584
laryngeal carcinoma of, 1541
palpation of, in voice evaluation, 827, 828f
physical examination of, 95, 96f
Hyoid myotomy (HM), for obstructive sleep apnea, 259, 261f

Hyperacusis, 2138-2139
in Bell's palsy, 2393
defined, 2138
epidemiology of, 2138
evaluation of, 2138-2139
impact of, 2139
vs. recruitment, 2138
treatment of, 2139
Hyperacusis Questionnaire, 2138-2139
Hyperadrenalism, oral manifestations of, 1251
Hyperbaric oxygen (HBO) therapy
for osteoradionecrosis, 1048
with radiotherapy, 1041
for skin flap salvage, 1075
and skin flap viability, 1074
for soft tissue avulsions, 307
Hypercalcemia
due to benign tumors, 1783-1784, 1783t
definition of, 1782
differential diagnosis of, 1782, 1782t-1783t
drug-induced, 1783-1784, 1783t
due to endocrine disease, 1783-1784, 1783t
epidemiology of, 1782
familial hypocalciuric, 1783
due to granulomatous disorders, 1783-1784, 1783t
in hyperparathyroidism
differential diagnosis of, 1782, 1782t
evaluation of, 1782-1784
historical background of, 1774
pathogenesis of, 1781
of malignancy, 1783, 1783t
medical management of, 1804
non–PTH-mediated, nonmalignant, 1783-1784, 1783t
preoperative evaluation of, 104
Hypercalcemic crisis, 1781
Hypercalcemic syndrome, 1781
Hyperdynamic facial lines, 275, 279f
Hyperechoic tissue, 1643
Hyperfractionation, 1040
Hyperfunctional disorders, of larynx, 838-842
botulinum toxin therapy for, 839, 840f-841f
due to dystonia, 838-839, 838b
essential tremor as, 840-841
due to myoclonus, 840
due to pseudobulbar palsy, 839-840
stuttering as, 841-842
Hyperfunctional dysphonia, 834
Hyperkeratosis
of larynx, 1486
leukoplakic-type, 1231, 1231f
Hyperkinetic disorders, of facial nerve, 2401
management of, 2432
Hypermethylation, in head and neck squamous cell carcinoma, 1020-1022, 1021f
Hypernasality
after adenotonsillectomy, 2800
assessment of, 2678-2679, 2679t
in children, 2879
Hyperparathyroidism
asymptomatic, 1781
clinical course of untreated, 1782
clinical manifestations of, 1780-1781
cardiovascular, 1781
gastrointestinal, 1781
hypercalcemic abnormalities as, 1781
neurologic, 1781
neuromuscular, 1781
renal and urinary tract, 1781
skeletal, 1781
diagnosis of, 1784
etiology and pathogenesis of, 1774-1775, 1775f-1776f
familial, 1795-1797
in MEN-I, 1775, 1776f, 1795-1796
in MEN-IIA, 1796
Hyperparathyroidism *(Continued)*
neonatal, 1797
non-MEN (isolated), 1796-1797
historical background of, 1774
hypercalcemia in
evaluation of, 1782-1784, 1782t-1783t
historical background of, 1774
pathogenesis of, 1781
incidence of, 1780
localization study(ies) in, 1784-1789, 1784t
gamma radiation detection device for, 1802, 1803f
intraoperative, 1784t, 1789
invasive preoperative, 1784t, 1788-1789
parathyroid arteriography as, 1788
selective venous sampling for PTH as, 1788-1789
ultrasound-guided fine-needle aspiration as, 1789
mediastinal exploration as, 1801-1802, 1802f
noninvasive preoperative, 1784-1788, 1784t
computed tomography as, 1786-1787
computed tomography–sestamibi fusion as, 1785-1786, 1786f-1788f
magnetic resonance imaging as, 1787-1788, 1789f
pertechnetate (technetium 99m) thallous chloride (thallium 201) imaging as, 1784-1785
sestamibi–technetium 99m scintigraphy as, 1785, 1785f, 1788f, 1794f
technetium 99m sestamibi with single photon emission computed tomography as, 1785
ultrasonography as, 1786, 1788f-1789f
unsuccessful, 1801, 1801f-1802f
medical management of, 1804
oral manifestations of, 1251
due to parathyroid adenoma, 1774-1775, 1778-1779
due to parathyroid carcinoma, 1802-1804, 1803f
during pregnancy, 1804
preoperative evaluation of, 104
re-exploration for recalcitrant, 1798-1800
causes of failed exploration with, 1798
operative risk in, 1798-1799
operative strategy for, 1799-1800, 1799f-1800f
preoperative assessment for, 1798
renal failure–induced, 1797-1798
secondary, 1782-1783
recurrent, 1798
surgical management of, 1789-1804
gamma radiation detection device in, 1802, 1803f
indications for, 1789-1790
intraoperative PTH levels with, 1800-1801
for multiple-gland disease, 1794-1795
due to sporadic hyperplasia, 1794-1795, 1794f
due to true double adenoma, 1794, 1794f
parathyroidectomy as, 1790-1792
anesthesia and preparation for, 1790
closure of incision in, 1792
exploration of neck in, 1790-1792, 1791f
postoperative care after, 1792
for single-gland disease, 1792-1794
directed unilateral cervical exploration as, 1792-1793
endoscopic parathyroid exploration in, 1793-1794
minimally invasive techniques for, 1793
strategy and approach to, 1792
tertiary, 1783
and thyroid disease, 1801, 1801f-1802f
Hyperpigmentation
after chemical peel, 396-397
after rhytidectomy, 427
Hyperplasia
of larynx, 1486-1491
oropharyngeal, 1360
Hyperplastic candidiasis, 1231, 1231f
in HIV, 225
Hyperresponsiveness, in allergic rhinitis, 616-617
nonspecific, 617
specific, 616-617
Hypersensitivity, delayed-type, 601
Hypersensitivity reaction(s), 608-612
to ototopical antibiotics, 1954
Hypersomnia(s)
of central origin, 263-264, 264b
idiopathic, 262t, 264
Hypertension
benign (idiopathic) intracranial
CSF rhinorrhea due to, 787
facial paralysis due to, 2400-2401
sensorineural hearing loss due to, 2123
and epistaxis, 686-687
due to hyperparathyroidism, 1781
malignant, 119
pulmonary, due to obstructive sleep apnea, 2604
Hyperthyroidism. *See also* Graves' disease; Thyrotoxicosis.
antithyroid agents for, 1739t
oral manifestations of, 1251
preoperative evaluation of, 104
with thyroid nodule, 1756
Hypertrophic adenoids, and otitis media, 1872, 1873f
Hypertrophic scars, 291
after otoplasty, 479
due to rhytidectomy, 425-426
Hyperventilation, dizziness due to, 2316
Hypervitaminosis D, hypercalcemia due to, 1784
Hypnotic dependent sleep disorder, 262t
Hypoadrenalism, oral manifestations of, 1251
Hypocalcemia
after hypopharyngeal reconstruction, 1458
after thyroid surgery, 1771
Hypoechoic tissue, 1643
Hypoepiglottic ligament, in laryngeal cancer, 1484, 1484f
Hypofunctional disorders, of larynx, 842-843
due to central causes of vocal fold paresis, 842
due to medullary disorders, 842
due to multiple sclerosis, 843
due to myopathies, 842
due to neuromuscular junction disorders, 842
due to Parkinson's disease, 842-843
due to poliomyelitis, 842
psychogenic, malingering, and mixed causes of, 843
vocal fold paresis as, 843
Hypoglossal canal
anatomy of, 1823f
in surgical anatomy of lateral skull base, 2435f
in surgical anatomy of middle cranial base, 2445f
Hypoglossal nerve
anatomy of, 1295, 1296f, 1297-1298
distribution of, 2580f, 2581
intraoperative monitoring of, 2550-2552, 2552f
in surgical anatomy of lateral skull base, 2439f-2440f
Hypoglossal nerve injury
in lateral skull base surgery, 2512
due to neck surgery, 1730-1731
Hypoglossal nerve transposition, for facial nerve paralysis, 2419, 2424f-2426f, 2425-2426
Hypoglycemic agents, oral sequelae of, 1247t-1248t
Hypomethylation, in head and neck squamous cell carcinoma, 1021-1022
Hyponasality
assessment of, 2678, 2678f, 2678t
in children, 2879

Hypoparathyroidism
oral manifestations of, 1251
preoperative evaluation of, 104
sensorineural deafness, and renal dysplasia (HDR) syndrome, 2051t-2058t
Hypopharnygeal stenosis, 947-948
Hypopharyngeal cancer, 1421-1440
advanced-stage, 1438-1439
chemotherapy for, 1439
conventional treatment modalities for, 1442
quality of life with, 1439
radiation therapy for, 1591-1592
complications of, 1591
CyberKnife stereotactic approach for, 1592
future strategies and directions for, 1592
outcome and prognostic factors for, 1591
RADPLAT approach for, 1592
techniques and dose-fractionation schemes for, 1591
anatomy and, 1421-1422, 1422f
approach to management of, 1426
cervical lymph node metastasis of, 1422, 1422f, 1434-1439
incidence and distribution of, 1686f, 1688t
management of, 1434-1439
radiation therapy for, 1689t
chemoradiotherapy for, 1434, 1442
for advanced disease, 1439
after total laryngectomy, 1442-1443
chemotherapy for, 1433-1434, 1442
for advanced disease, 1439
induction, 1443
for larynx preservation, 1443-1444
clinical evaluation of, 1423
physical findings in, 1423
presenting symptoms in, 1423, 1423t
clinical presentation of, 1579
conventional treatment modalities for, 1441-1442
for advanced disease, 1442
for early disease, 1442
diagnostic evaluation/workup for, 1579
early-stage, radiation therapy for, 1590-1591
complications of, 1591
outcome and prognostic factors for, 1591, 1591t
techniques and dose-fractionation schemes for, 1590-1591
epidemiology of, 1441
etiology and biology of, 1425-1426
imaging of, 1413, 1413f-1414f, 1423-1424, 1579
barium swallow for, 1423-1424
CT for, 1424, 1424f
MRI for, 1424
PET/CT for, 1424, 1424f
incidence of, 1422-1423
location and patterns of spread of, 1425
neck dissection for, 1434-1439, 1716-1718
definition and rationale for, 1716-1717, 1717f
technique for, 1717-1718, 1717f
neck management for, 1580
new treatment modalities for, 1442, 1448, 1449f
overall management of, 1580, 1590
pathology of, 1424-1425
radiation therapy for, 1433, 1443, 1589-1592
with advanced-stage disease, 1591-1592
complications of, 1591
CyberKnife stereotactic approach for, 1592
future strategies and directions for, 1592
outcome and prognostic factors for, 1591
RADPLAT approach for, 1592
techniques and dose-fractionation schemes for, 1591
anatomic considerations in, 1578-1579, 1579f
with early-stage disease, 1590-1591
complications of, 1591
outcome and prognostic factors for, 1591, 1591t
Hypopharyngeal cancer *(Continued)*
techniques and dose-fractionation schemes for, 1590-1591
lymphatic drainage and, 1578-1579, 1579f
overview of, 1578
with recurrent disease, 1591-1592
therapeutic outcomes with, 1436
reconstruction for (*See* Hypopharyngeal reconstruction)
recurrent, radiation therapy for, 1591-1592
squamous cell carcinoma as, intensity-modulated radiotherapy of, 1046
staging of, 1367t, 1426-1434, 1426t-1427t, 1579-1580, 1580f
surgical management of, 1426-1431
endoscopic CO_2 laser resection for, 1429-1430, 1442
outcomes of, 1436-1438
history of, 1426
options for, 1426, 1427t
partial laryngopharyngectomy for, 1429, 1430f
partial pharyngectomy for, 1426-1429
via anterior transhyoid pharyngotomy, 1427-1429, 1428f
via lateral pharyngotomy, 1426-1427
via lateral transthyroid pharyngotomy, 1427, 1428f
via median labiomandibular glossotomy, 1429
supracricoid hemilaryngopharyngectomy for, 1429, 1436
therapeutic outcomes with, 1436-1439, 1437t
total laryngectomy with partial/total pharyngectomy for, 1430, 1431f
total pharyngo-laryngo-esophagectomy for, 1430-1431
therapeutic outcomes of, 1435-1436
with primary radiation therapy, 1436
with primary surgical therapy, 1436-1439, 1437t
Hypopharyngeal lipoma, 1425f
Hypopharyngeal mucosal space, imaging of, 158-159
with lesions, 159, 162f
normal anatomy in, 158-159, 159f-160f
Hypopharyngeal procedures, for obstructive sleep apnea, 258b, 259-260, 260f-261f
Hypopharyngeal reconstruction, 1431-1433, 1448-1461
with circumferential defects, 1431-1432
classification of defects for, 1450
decision making on, 1450, 1451f
free tissue transfer for, 1454, 1454f
enteric, 1455-1457
gastro-omental donor site for, 1457-1458, 1457f
jejunal donor site for, 1455-1457, 1456f
fasciocutaneous, 1433, 1455
antero-lateral thigh donor site for, 1455
other donor sites for, 1455
radial forearm donor site for, 1455
goals and principles of, 1450
jejunal free flap in, 1432-1433, 1433f
local and regional flaps for, 1450-1452, 1452f
myocutaneous flap(s) in, 1452-1453
pectoralis, 1431, 1431f
patient population for, 1448
perioperative counseling for, 1448-1449
postsurgical complications of, 1458, 1459f
posttreatment speech and swallowing outcomes of, 1459-1460
preoperative evaluation for, 1449-1450
visceral transposition for, 1453
colonic, 1453, 1454f
gastric, 1432, 1432f, 1453
voice rehabilitation after, 1458-1459
Hypopharynx
anatomy of, 1359f, 1421-1422, 1422f, 1578
radiographic, 1398f-1399f
dysphagia due to congenital conditions of, 2950t, 2951-2953, 2953f
lymphatic drainage of, 1422, 1422f, 2582
physical examination of, 99-100
Hypopigmentation
after chemical peel, 397
after rhytidectomy, 427
Hypopnea, 251b, 256f
obstructive, in children, 2607
Hypopnea index, 251b
Hypothalamic hypothyroidism, 1747
Hypothesis testing, 65, 66t
examples for, 65-66
null hypothesis in, 65, 66t
P value in, 65, 66t
type I and type II errors in, 65, 66t
Hypothyroidism, 1745-1749
clinical features of, 1745-1746, 1746b
due to endemic goiter, 1747
esophageal manifestations of, 979
etiology of, 1745, 1746b
due to excessive iodine intake, 1747
familial, 1747
goitrous, 1747
hearing loss due to, 1746
hoarseness due to, 1747
hypothalamic, 1747
laboratory diagnosis of, 1748, 1748t
after laryngectomy, 1747
due to lingual thyroid, 1287
management of, 1748-1749
myxedema coma due to, 1749
due to neck irradiation, 1695
nongoitrous, 1747
oral manifestations of, 1251
pituitary, 1747
during pregnancy, 1749
preoperative evaluation of, 104
prevalence of, 1745
after radiation therapy, 1747
due to radiation therapy, 1048
risk factors for, 1745-1746, 1746b
subclinical, 1747-1748
diagnosis of, 1747
effects on lipid, hypothyroid symptoms, and mood of, 1747-1748
natural history of, 1747
prevalence of, 1747
treatment of, 1748
surgery with, 1749
with thyroid nodule, 1756
after total laryngectomy, 1571
transient, 1747
vertigo due to, 1747
Hypotympanum, 1825-1826
Hypoventilation
central alveolar, 262t
obstructive, in children, 2607, 2607f
Hypoventilation syndromes, sleep-related, 263, 263b
Hypovolemic shock, due to pediatric facial fracture, 2699
Hypoxemia
newborn response to, 2571
during sleep in children, 2607
Hypoxemic syndromes, sleep-related, 263, 263b
Hypoxia
newborn response to, 2571
in noise-induced hearing loss, 2144-2145
and radiotherapy, 1041
Hypoxia inducible factor (HIF), in Warburg effect, 1028f
Hypoxic sensitizers, with radiotherapy, 1041
Hyrtl's fissure, 2736

Hysteria, *vs.* myofascial pain dysfunction syndrome, 1285t
Hytone cream (hydrocortisone cream)
after chemical peel, 396
for eczematoid otitis externa, 1955-1956
Hz (hertz), 1838-1839, 1839f

fat suppression methods for, 135-136, 136f
with frequency (chemical shift) selective presaturation (fat saturation), 135-136, 136f
gadolinium enhancement for, 134-135, 135f-136f
with gradient echo techniques, 136-137, 137f
pulse sequences for, 134-137, 135f-136f
with short T1 inversion recovery (STIR), 135-136, 136f
Imaging *(Continued)*
with spectral presaturation inversion recovery (SPIR), 135-136
T1-weighted, 134, 135f-136f
T2-weighted, 134, 135f-136f
three-dimensional reconstruction techniques in, 138, 139f
in nuclear medicine, 137-138
positron emission tomography as, 137-138
radionuclide imaging as, 138, 139f
ultrasound as, 137
of cochlear implants, 2221-2222, 2222f
of deep neck space infections, 204-205
CT for, 204, 204f-205f
MRI for, 204
plain film radiography for, 204-205
ultrasonography for, 204-205
in differential diagnosis, 144
of Graves' ophthalmopathy, 1809-1810, 1811f
of head and neck, 138-144
computed tomography for, 139-142
with cervical lymphadenopathy, 139
with facial trauma, 142
of larynx and infrahyoid neck, 132f, 140
of paranasal sinuses, 140-142, 141f
of salivary glands, 139
in sialography, 139-140, 1145f, 1150, 1150f
of suprahyoid neck, 139, 141f
of temporal bone and skull base, 142
of thyroid and parathyroid glands, 140
conventional radiography for, in sialography, 139-140, 1149-1150, 1149f
FDG-PET for, 144, 145f
magnetic resonance imaging for, 142-143
of larynx and infrahyoid neck, 142-143
of lymphadenopathy, 142
of paranasal sinuses, 143
of salivary glands, 142
of skull base, 143
of suprahyoid neck, 142
of temporal bone, 143
of thyroid and parathyroid glands, 143
ultrasound for, 143-144
of infrahyoid neck, 143-144
with metastatic lymphadenopathy, 143
of salivary glands, 143
of hypopharyngeal and cervical esophageal cancer, 1413, 1413f-1414f, 1423-1424
barium swallow for, 1423-1424
CT for, 1424, 1424f
MRI for, 1424
PET/CT for, 1424, 1424f
of infrahyoid neck, 157-159
anterior and posterior cervical (lateral cervical) spaces in, 158, 159f-160f, 162f
CT for, 140
hypopharyngeal mucosal space in, 158-159
with lesions, 159, 162f
normal anatomy in, 158-159, 159f-160f
normal anatomy in, 157-159, 159f-160f
prevertebral space in, 158, 159f-160f, 162f
retropharyngeal space in, 158
with lesions, 158, 161f
normal anatomy in, 158, 159f-160f
of larynx, 159-161, 813-824, 1462-1481
with benign mass(es), 1468
congenital cysts as, 1468
laryngocele as, 159-161, 163f, 1468, 1469f
squamous papillomas as, 1468, 1468f
subglottic hemangioma as, 1468, 1468f
with carcinoma, 1494-1495
of anterior commissure, 1474, 1474f
of aryepiglottic fold, 1475, 1478f
with cartilaginous invasion, 1474-1475, 1476f
for conservation laryngeal surgery, 1545-1546
of epiglottis, 1475, 1477f
glottic, 1474-1475, 1474f
Imaging *(Continued)*
with lymph node metastases, 1476, 1479f
normal anatomy and, 1470-1474
paraglottic, 1474
post-therapy, 1476-1479, 1479f
of pyriform sinus, 1475-1476, 1478f
subglottic, 1474, 1475f
supraglottic, 1475-1476
technique for, 1470, 1470f
transglottic, 161, 164f, 1475f, 1476, 1478f
CT for, 132f, 140
flexible endoscopy for, 814
advantages of, 814
disadvantages of, 814
for professional voice disorders, 851-852, 852t
protocols for, 816b, 818b
technique of, 814
troubleshooting for, 814
with foreign bodies, 1480-1481, 1480f-1481f
high-speed digital, 821-823
applications of, 823
assessment using, 822-823
defined, 813
equipment for, 821
kymography in, 134f, 154, 822f
limitations of, 823
with inflammatory disease, 1464-1466
croup as, 1465, 1465f
epiglottitis as, 159-161, 163f, 1406-1407, 1407f, 1464, 1464f-1465f
retropharyngeal abscess as, 1465-1466, 1466f
with laryngomalacia, 1466
MRI for, 142-143
with normal airway, 1462-1464
anatomy of, 1462-1464, 1463f-1464f
technique for, 1462
rigid endoscopy for, 813-814
advantages of, 813
disadvantages of, 813-814
for professional voice disorders, 851, 852t
protocols for, 816b, 818b
technique of, 814
troubleshooting for, 814
stroboscopy for, 818-821
of adynamic segments, 820
of amplitude of vibration, 820, 821f, 848, 848t
of closure pattern, 819, 820f, 848t, 849
common problems and solutions for, 815t-816t
defined, 813
flexible endoscopes in, 814
interpretation of, 848t
interval examination in, 847
of mucosal wave, 820, 848-849, 848t
in neurologic examination, 834
of periodicity, 821, 848, 848t
of phase closure, 819-820
for professional voice, 847-849, 848f, 848t
protocol for, 818-819, 818b
of regularity, 821
rigid endoscopes in, 813-814
of symmetry, 820, 847-848, 848t
of vertical closure level, 821
for vocal fold impairment, 905
with trauma, 159, 162f, 1479-1480, 1480f
videoendoscopy for, 814-818
of arytenoid and vocal fold motion, 816
common problems and solutions for, 815t-816t
defined, 813
flexible endoscopes for, 814
of laryngeal structure, 816
of mucous, 816-817
in neurologic examination, 834
protocol for, 814, 816b

Imaging *(Continued)*
rigid endoscopes for, 813-814
of supraglottic activity, 817, 817f
of vascularity, 817
of vocal fold edges, 818
with vocal cord paralysis, 1466-1467, 1467f
of lymph nodes, 164-167
anatomy and classification of, 163-164
with extracapsular spread, 164-166, 167f
inflammatory (reactive), 164
with invasion of carotid artery, 166-167
metastatic
contrast-enhanced CT of, 164-165, 167f
MRI of, 165-166, 168f
with non-Hodgkin's lymphoma, 165-166, 167f
normal anatomy in, 166f
of maxillofacial trauma, 325-326
of lower third, 325-326

Inferior cervical sympathetic ganglion, in root of neck, 2582
Inferior colliculus
in central auditory pathway, 1835f, 1836, 1846
tonotopic map reorganization in, 1878, 1879f, 1880
Inferior concha, 1359f
Inferior crus, of ear, 476f, 2742f
Inferior deep jugular lymph nodes, 1360f
Inferior hypophyseal arteries, in surgical anatomy of anterior cranial base, 2473f
Inferior incisive muscle, 321f
Inferior medial maxillectomy, 1125, 1125f
Inferior nasal meatus
normal anatomy of, 664
in surgical anatomy of anterior cranial base, 2472, 2472f
Inferior oblique muscles, 443f
in lower eyelid blepharoplasty, 448-449, 450f
semicircular canal planes and, 2287, 2288f
in surgical anatomy of lateral skull base, 2439f
Inferior orbital fissure, 322f
in surgical anatomy of anterior cranial base, 2443-2444, 2444f
in surgical anatomy of lateral skull base, 2441
in surgical anatomy of middle cranial base, 2445f

Inferior orbital rims, 319
Inferior petrosal sinus, in surgical anatomy of lateral skull base, 2489
Inferior punctum, of lacrimal apparatus, 798f
Inferior rectus muscles, 443f
  semicircular canal planes and, 2287, 2288f
Inferior tarsal muscle, 444
Inferior thyroid artery
  anatomy of, 1751, 1752f
  and parathyroid glands, 1778
  in root of neck, 2581-2582, 2581f
Inferior turbinate
  normal anatomy of, 665f, 1124f
  in surgical anatomy of anterior cranial base, 2472, 2472f-2473f
Inferior tympanic artery, 1828f
Inferior vestibular ganglion, 1854f, 2278f
Inferior vestibular nerve, in surgical anatomy of lateral skull base, 2437f, 2439
Inferior vestibular nucleus, 1861, 1862f
Inflammation
  in acutely raised skin flaps, 1070
  and rhinosinusitis, 731, 731f
  and skin flap viability, 1074
Inflammatory bowel disease, oral manifestations of, 1254
Inflammatory collateral cyst, 1263, 1263f
Inflammatory condition(s)
  of esophagus (*See* Esophagitis)
  of larynx, 1464-1466
    croup as, 1465, 1465f
    epiglottitis as, 159-161, 163f, 1464, 1464f-1465f
    laryngeal stenosis due to, 2915
    retropharyngeal abscess as, 1465-1466, 1466f
  of oral cavity, 1288-1290
    amyloidosis as, 1289-1290, 1290f
    fibroma as, 1288-1289, 1289f
    mucosal ulcerations as, 1289, 1289f
    necrotizing sialometaplasia as, 1289, 1299
    pyogenic granuloma as, 1289, 1289f
  of salivary glands, 1151-1161
    acute suppurative sialadenitis as, 1151-1153
      in children, 2856, 2856t
      clinical manifestations of, 1152, 1152f
      complications of, 1153, 1154f
      differential diagnosis of, 1152
      epidemiology of, 1151
      laboratory evaluation of, 1152
      pathogenesis of, 1151-1152, 1152f
      treatment of, 1152-1153, 1153f
    bacterial infections as, 1151-1153
      in children, 2856-2857, 2856t
    in children, 2855-2858
      abscess as, 2856
      due to actinomycosis, 2858
      acute suppurative sialadenitis as, 2856, 2856t
      bacterial, 2856-2857, 2856t
      chronic sialadenitis as, 2858
      diagnostic algorithm for, 2853, 2854f
      differential diagnosis of, 2851t
      due to Epstein-Barr virus, 2855
      granulomatous, 2857-2858, 2857f
      due to HIV, 2856
      due to mumps, 2855
      mycobacterial, 2857-2858, 2857f
      neonatal, 2857
      recurrent, 2856-2857
      sarcoidosis as, 2858
      viral, 2855
    chronic sialadenitis as, 1154, 1155f
      in children, 2858
    granulomatous infections as, 1158-1159
      due to actinomycosis, 1159
      due to cat scratch disease, 1159
      in children, 2857-2858, 2857f
Inflammatory condition(s) *(Continued)*
      due to nontuberculous mycobacterial disease, 1158-1159, 1158f
      due to toxoplasmosis, 1159-1160
      due to tuberculous mycobacterial disease, 1158
    neonatal suppurative parotitis as, 1153
    noninfectious, 1160-1161
    recurrent parotitis of childhood as, 1153-1154
    sialolithiasis as, 1155-1156, 1155f-1156f
    viral infections as, 1156-1158
      in children, 2855
      due to Epstein-Barr virus, 2855
      due to HIV, 1157-1158, 1157f, 2856
      due to mumps, 1156-1157, 2855
Inflammatory lymph nodes, 164
Inflammatory myofibroblastic tumor (IMT), of larynx, 1509-1510
Inflammatory neck masses, 1638
  due to granulomatous diseases, 1638
  due to lymphadenopathy/lymphadenitis, 1638
  due to sialadenitis/sialolithiasis, 1638
Inflammatory phase, of wound healing, 1076
Influenza vaccine, 197
  to prevent otitis media, 2769
Influenzavirus, pharyngitis due to, 196-197
Informed consent, 102
Infracochlear approach, for skull base lesions requiring drainage, 2539, 2540f
Infra-frequency sounds, adverse effects of, 2149
Infrahyoid muscles, characteristics of, 918-919
Infrahyoid neck, imaging of, 157-159
  anterior and posterior cervical (lateral cervical) spaces in, 158, 159f-160f, 162f
  CT for, 140
  hypopharyngeal mucosal space in, 158-159
    with lesions, 159, 162f
    normal anatomy in, 158-159, 159f-160f
  MRI for, 142-143
  normal anatomy in, 157-159, 159f-160f
  prevertebral space in, 158, 159f-160f, 162f
  retropharyngeal space in, 158
    with lesions, 158, 161f
    normal anatomy in, 158, 159f-160f
  ultrasound for, 143-144
Infrahyoid prevertebral space, imaging of, 158, 159f-160f, 162f
Infrahyoid retropharyngeal space, imaging of, 158, 159f-161f
Infralabyrinthine approach, for skull base lesions requiring drainage, 2539, 2540f
Infraorbital cells, 668-669, 670f
Infraorbital fissure, 1124f
Infraorbital foramen, 439-440, 1124f
Infraorbital groove, 322f
Infraorbital lymph node, 1360f
Infraorbital nerve, 320, 321f, 497, 497f
Infraorbital nerve block, 242
Infraorbital neurovascular bundle, 439-440
Infraorbital rims, surgical access to, 329
Infraparotid node, 1297f
Infrared video, for recording eye movements, 2317
Infratemporal access, for transnasal endoscopic-assisted anterior skull base surgery, 2483
Infratemporal fossa
  in surgical anatomy of lateral skull base, 2440-2441, 2440f
  in surgical anatomy of middle cranial base, 2444
Infratemporal fossa approaches, 2495-2501
  for middle skull base surgery, 2461-2464, 2464f
  postauricular, 2495-2500
    cervical dissection in, 2495, 2498f
    closure of external auditory canal in, 2495, 2497f
    extratemporal facial nerve dissection in, 2495-2496
    incisions and skins flaps in, 2495, 2497f
Infratemporal fossa approaches *(Continued)*
    radical mastoidectomy in, 2496, 2498f
    removal of external auditory canal wall skin and tympanic membrane in, 2495, 2497f
    type A, 2497-2499
      closure of wound in, 2499, 2499f
      exposure of jugular bulb and internal carotid artery in, 2498, 2498f-2499f
      facial nerve transposition in, 2497-2498, 2498f
      occlusion of sigmoid sinus in, 2498, 2498f
      tumor removal in, 2498-2499, 2499f
    type B, 2499-2500, 2500f
    type C, 2500, 2501f
  preauricular, 2500-2501, 2501f
Infratemporal fossa dissection, in subtotal or total temporal bone resection, 2494
Infratip lobule, 509f
Infratrochlear nerve, 321f, 497, 497f
Infundibular cells, 740
Infundibulum, 665f, 666-667

Interleukin-24 (IL-24), 609t-610t
Interleukin-25 (IL-25), 609t-610t
Interleukin-26 (IL-26), 609t-610t
Interleukin-27 (IL-27), 609t-610t
Interleukin-28 (IL-28), 609t-610t
Interleukin-29 (IL-29), 609t-610t
Intermaxillary fixation (IMF) screws, 330-331, 333f
Intermaxillary segment, in embryology of palate, 2660-2661, 2662f
Intermaxillary suture, 320f
Intermediate acoustic stria
anatomy of, 1835, 1835f
in auditory pathway, 1846
Intermediate crus, of nose, 496-497, 497f
Intermittent allergic rhinitis (IAR), 618
Intermittent apnea-reintubation anesthesia, with recurrent respiratory papillomatosis, 2891
Internal acoustic meatus, 2010f
Internal acoustic pore, in surgical anatomy of lateral skull base, 2437-2438
Internal auditory artery
anatomy of, 1826f, 1854, 2351f
in surgical anatomy of lateral skull base, 2437f, 2439f
Internal auditory canal (IAC)
anatomy of, 1823f
developmental anomalies of, 2735
and CSF leakage, 2735-2736, 2736f
narrow, 2735, 2735f
wide, 2735, 2735f
imaging of, 173, 1926-1928
with meningioma, 175f
with vestibular schwannoma, 173, 1928, 1928f
lipoma of, 2527, 2529f
narrow, 2735, 2735f
in surgical anatomy of lateral skull base, 2435f-2437f, 2438-2439
wide, 2735, 2735f
Internal auditory meatus, in surgical anatomy of middle cranial base, 2445f
Internal carotid artery (ICA)
aberrant, 1919-1920, 1921f-1922f
anatomy of, 1359f, 2579, 2580f
radiographic, 1471f, 1473-1474
aneurysms of upper cervical and petrous, 2504, 2504f-2505f
in extended neck dissection, 1719-1721, 1720f
injury to, 1632, 1633f
due to carotid paraganglioma surgery, 1661
paranasal sinuses and, 671-672
in postauricular approach to infratemporal fossa, 2498, 2498f-2499f
preoperative embolization of, 2446
preoperative management of, 2445-2446, 2446f, 2489
Internal carotid artery (ICA) *(Continued)*
algorithm for, 2490f, 2491-2492
cerebral blood flow assessment in, 2490-2491, 2490f
four-vessel arteriography in, 2489-2490, 2491f
in surgical anatomy of anterior cranial base, 2442-2443, 2472f-2473f, 2474, 2475f
in surgical anatomy of lateral skull base, 2436f-2437f, 2439f-2440f, 2489
in surgical anatomy of middle cranial base, 2444
tortuous, 1416, 1416f
Internal consistency, 55
Internal fixation, and facial growth, 2625-2626
Internal jugular vein (IJV)
anatomy of, 1359f, 2579f
radiographic, 1471f
in modified radical neck dissection, 1713f-1714f
in neck surgery, 1728-1729, 1729f
Internal jugular vein (IJV) hemorrhage, due to neck surgery, 1729, 1729f
Internal jugular vein (IJV) thrombosis, due to neck surgery, 1728-1729
Internal maxillary artery
anatomy of, 682
in surgical anatomy of lateral skull base, 2440f
Internal plexiform layer, of olfactory bulb, 628f
Internal pterygoid muscle, 1359f
Internal receiver stimulators and electrode designs, for cochlear implants, 2227-2229
HiRes 90K receiver/stimulator as, 2227-2228, 2228f
Med-El PulsarCI100 and SonataTI100 as, 2228-2229, 2228f-2230f
ear-level speech processors for, 2232f
Nucleus Freedom device with Contour Advance electrode as, 2227, 2227f-2228f
external speech processors for, 2232f
Internal thoracic artery, in root of neck, 2581-2582
Internal validity, 68-69, 68t, 69f
Internal valve compromise, nasal obstruction due to, 492, 493f
Internasal suture, 320f
International Classification of Functioning (ICF), 56
International Prognostic Index (IPI), for non-Hodgkin's lymphoma, 216
Interneurons, in neural plasticity, 1884
Interobserver reliability, 55
Interosseous fold, 1827f
Interpeak latencies, in auditory brainstem response, 1897
Interpolated flaps, 344-345, 344f
for nasal defects, 347-348
Interpupillary distances, in evaluation of maxillofacial trauma, 324, 324f
Interquartile range, 64t
Interrupted strip technique, for nasal tip refinement, 522, 532f-533f
Intersphenoid synchondrosis, 2619f
Interstereociliary linkages, 2076f, 2077-2078
Interstitial pressure, of skin flaps, 1068, 1069f
Interstitial system, and skin flaps, 1065-1066, 1065f
Intertragal incisure, 477
Intertragal notch, 2742f
Interval examination, in laryngeal stroboscopy, 847
Interventional neuroradiology, 1932-1943
for lesions of vascular etiology, 1939-1943
dural arteriovenous fistulas as, 1940-1942, 1941f
epistaxis as, 1939-1940, 1940f
facial arteriovenous fistulas as, 1940, 1940f
facial vascular malformations as, 1942, 1942f
hemangiomas of face and neck as, 1942
pseudoaneurysms as, 1942, 1943f
tinnitus-producing fibromuscular dysplasia of carotid artery as, 1943
Interventional neuroradiology *(Continued)*
materials and techniques for, 1932-1934
angiographic catheters as, 1932-1933
angiographic equipment as, 1932
embolic agents as, 1933-1934
provocative testing to ensure safety of embolization as, 1934, 1934f
for neoplasms, 1934-1939
inter-arterial chemotherapy as, 1939
juvenile angiofibroma as, 1937-1938, 1938f
meningiomas as, 1938, 1939f
paragangliomas as, 1934-1937, 1935f
carotid body tumor as, 1937, 1937f
glomus jugulare tumor as, 1935-1936, 1935f-1936f
glomus tympanicum tumor as, 1935
glomus vagale tumor as, 1936-1937, 1936f
thyroid, 1938-1939
Interventional techniques, for chronic pain, 245-246, 246t
In-the-canal (ITC) hearing aid, 2270, 2270f
In-the-ear (ITE) hearing aids, 2270, 2270f
in infants, 2723-2724
selection of, 2266-2267, 2270
Intra-arterial chemotherapy, 1939
Intra-articular disk, anterior displacement of
with reduction, 1280, 1282f
without reduction, 1279-1280, 1282f
Intra-axial tumor(s), 2528-2529
brainstem gliomas as, 2528
hemangioblastomas as, 2528
malignant choroid plexus papillomas and ependymomas of fourth ventricle as, 2528-2529, 2530f-2531f
medulloblastomas as, 2528
Intracapsular disorders, of temporomandibular joint, 1280-1282, 1281t
ankylosis as, 1281t, 1282
anterior disk displacement as
with reduction, 1280, 1282f
without reduction, 1279-1280, 1282f
degenerative joint disease as, 1281-1282, 1281t
Intracapsular subtotal tonsillectomy, for obstructive sleep apnea, 2609
Intracellular pH, in sour taste, 1209
Intracellular space, 1066-1067
Intracerebral injury, due to sphenoidotomy, 768t
Intracochlear membrane rupture, sudden sensorineural hearing loss due to, 2128
Intracordal cysts, 869-870
diagnosis of, 869
history in, 869
laryngeal examination in, 869
vocal capability battery in, 869
epidemiology of, 869
epidermoid inclusion, 868f-869f, 869
mucus retention (ductal), 869, 869f-870f
open, 869, 870f
pathophysiology and pathology of, 869
treatment of, 869-870
behavioral, 869-870
medical, 869
surgical, 870, 870f
Intracordal injection, for vocal fold paralysis, 907, 907f
Intracranial approach, for middle cranial base surgery, 2467
Intracranial complications
of endoscopic sinus surgery, 755, 755f
of otitic infections, 2347
Intracranial hypertension, benign (idiopathic)
CSF rhinorrhea due to, 787
facial paralysis due to, 2400-2401
sensorineural hearing loss due to, 2123
Intracranial paraganglioma, 2499f
Intracranial pressure (ICP), and CSF rhinorrhea, 786-787, 786b

Intracranial sources, of otorrhea, 2195b, 2197
Intradermal nevus, 286, 287f
IntraEar Microcatheter, 2182-2183, 2183f
Intraepithelial lymphocytes, in immune system, 605
Intraglandular parotid lymph node, 1360f
Intralabyrinthine shunt, for Meniere's disease, 2126
Intralesional corticosteroids, for scar revision, 299-300, 301f
Intralymphatic metastasis, of melanoma, 1112
Intramembranous bone formation, 2614
Intramuscular induction, of pediatric anesthesia, 2591
Intranasal dimensions, tests that assess, 643, 643f
Intranasal ethmoidectomy, 756-757
Intranasal hemangiomas, 2695
Intranasal steroids (INSs), for allergic rhinitis, 621
In-transit metastasis (ITM), of melanoma, 1110, 1117
Intraocular pressure, increased, in Graves' ophthalmopathy, 1808
Intraoperative cranial nerve monitoring, 2542-2556
  anesthesia and, 2544
  auditory brainstem response recording for, 2552-2554
    interpretation of, 2553-2554, 2553f
    and postoperative auditory function, 2553-2554
    reducing electrical and acoustic interference in, 2552-2553
    stimulus and recording parameters, electrodes, and placement in, 2552
  of cochlear nerve, 2552
    direct eighth nerve action potentials for, 2554
      detection and interpretation of changes in, 2554
      placement of electrodes in, 2554
      stimulus and recording parameters in, 2554
  electrodes for
    recording, 2543-2544, 2543f
    stimulating, 2544, 2544f
  of facial nerve, 2545-2549
    with acoustic neuroma and other cerebellopontine angle tumors, 2545
    activity evoked by electrical stimulation in, 2545-2546
    for assessment of functional status after tumor removal, 2545-2546
    electromyography for, 2545-2548
    for intraoperative identification of nervus intermedius, 2546, 2546f
    limitations of, 2547-2548, 2548f
    during microvascular decompression, 2548-2549, 2549f
    during other otologic surgery, 2549
    during parotid surgery, 2549
    spontaneous and mechanically evoked activity in, 2546-2548, 2547f
  future directions in, 2555-2556, 2555f
  instrumentation for, 2543
  ninth, tenth, eleventh, and twelfth, 2550-2552, 2551f-2552f
  and outcome, 2554-2555
    for cochlear nerve preservation, 2554-2555
    for facial and other motor cranial nerve preservation, 2554
  personnel for, 2542-2543
  stimulation criteria for, 2544
  third, fourth, and sixth, 2549-2550, 2550f
  of trigeminal motor branch, 2550
Intraoral positioning devices, for radiation therapy, 1331, 1333f
Intratemporal facial nerve surgery, 2403-2415
  combination approaches for, 2411-2412
  draping for, 2404-2405, 2405f
  for facial nerve tumors, 2413-2414, 2414t
  general surgical techniques for, 2404-2405
  instrumentation for, 2405
  intraoperative monitoring for, 2405, 2405f
Intratemporal facial nerve surgery *(Continued)*
  middle cranial fossa (transtemporal) approach for, 2407-2409
    advantages and uses of, 2408-2409
    for Bell's palsy, 2409-2410, 2409t-2410t
    limitations and potential complications of, 2409
    technique of, 2407-2408, 2408f-2409f
  nerve repair in, 2413-2414
  rerouting in, 2412, 2412f-2413f
    partial, 2412-2413
  retrolabyrinthine approach for, 2405-2406, 2405f-2406f
  retrosigmoid approach for, 2406-2407
    advantages and uses of, 2406-2407
    limitations and potential complications of, 2407
    technique of, 2406, 2407f
  surgical anatomy for, 2403-2404, 2404f
  translabyrinthine approach for, 2411
    advantages and uses of, 2411
    limitations and complications of, 2411
    technique of, 2411, 2411f-2412f
  transmastoid approach for, 2410-2411
    advantages and uses of, 2411
    limitations and complications of, 2411
    technique of, 2410, 2410f
Intratemporal fossa approaches, for middle cranial base surgery, 2455t
Intrathecal fluorescein, for CSF rhinorrhea, 790, 2044
Intratympanic delivery
  of gentamicin, 2185-2189
    clinical protocols for, 2187-2188
    complications of, 2188-2189
    concentration of, 2188
    dose of, 2188
    indications and contraindications for, 2189
    injection interval for, 2188
    mechanism of action of, 2185-2186
    for Meniere's disease, 2185-2189, 2338-2339, 2338f

quantitative, 2491
CT and MRI for, 2489

Lateral cranial base neoplasm(s) *(Continued)*
four-vessel arteriography in, 2489-2490, 2491f
preoperative carotid artery assessment in, 2489, 2490f
facial nerve schwannomas as, 2506-2508
diagnostic evaluation of, 2507
management and surgical approach to, 2507-2508
of jugular foramen, 2504
schwannomas as, 2504-2505, 2505f
paragangliomas as, 2505-2506
diagnostic evaluation of, 2505, 2506f-2507f
preoperative evaluation of, 2491f
radiotherapy for, 2506
surgical approach to, 2505-2506, 2507f
symptoms of, 2505
of parapharyngeal space, 2510, 2512f
of petrous apex, 2508, 2508f
sleeve resection of external auditory canal for, 2492
Lateral cranial base surgery, 2487-2513
choice of approach for, 2492-2501
complications of, 2511-2513
intraoperative, 2511
postoperative, 2512-2513
cerebrovascular, 2512-2513
cranial nerve deficits as, 2512
encephalocele and CSF leaks as, 2509
infratemporal fossa approaches for, 2495-2501
postauricular, 2495-2500
cervical dissection in, 2495, 2498f
closure of external auditory canal in, 2495, 2497f
closure of wound in, 2499, 2499f
exposure of jugular bulb and internal carotid artery in, 2498, 2498f-2499f
extratemporal facial nerve dissection in, 2495-2496
facial nerve transposition in, 2497-2498, 2498f
incisions and skins flaps in, 2495, 2497f
occlusion of sigmoid sinus in, 2498, 2498f
radical mastoidectomy in, 2496, 2498f
removal of external auditory canal wall skin and tympanic membrane in, 2495, 2497f
tumor removal in, 2498-2499, 2499f
type A, 2497-2499, 2498f-2499f
type B, 2499-2500, 2500f
type C, 2500, 2501f
preauricular, 2500-2501, 2501f
for nasopharyngeal tumors, 2510-2511
postsurgical encephalocele and CSF leaks with
diagnostic evaluation of, 2509
surgical approach to, 2509
Lateral cricoarytenoid (LCA) muscle
applied anatomy of, 806
characteristics of, 918
in professional voice production, 846-847
Lateral cricothyroid muscle, applied anatomy of, 806
Lateral crural grafts, in revision rhinoplasty, 589-590, 590f
Lateral crus(crura), of alar cartilage, 496-497, 497f, 509f
in cleft-lip nose repair, 562f
transposition of, 551
Lateral facial approach, for middle cranial base surgery, 2462, 2465f
Lateral lamella of cribriform plate (LLCP), and CSF rhinorrhea, 787, 787f
Lateral lemniscal nuclei, in central auditory pathway, 1835-1836, 1835f
Lateral lemniscus, in central auditory pathway, 1835-1836, 1835f, 1846
Lateral medullary syndrome, 2313, 2352f, 2354f

Lateral nasal prominences, in embryology
of lip, 2660, 2661f-2662f, 2661t
of nose, 2691f
Lateral nasal wall, in surgical anatomy of anterior cranial base, 2472, 2472f-2473f
Lateral nasal wall deformities, revision rhinoplasty for, 586
Lateral neck dissection, 1716-1718
definition and rationale for, 1716-1717, 1717f
technique for, 1717-1718, 1717f
Lateral olfactory tract, 628f
Lateral olivocochlear (LOC) reflex pathways, in efferent auditory system, 1848-1849
Lateral orbital rim, surgical access to, 328-329, 329f
Lateral orbital tubercle, 439
Lateral orbital wall, 439
Lateral orbital wall fractures, pediatric, 2712, 2714
Lateral periapical cyst, 1263
Lateral periodontal cyst, 1265-1266
microscopic features of, 1265-1266, 1265f
radiographic features of, 1265
treatment of, 1266
Lateral pharyngeal node, 1298f
Lateral pharyngeal space
anatomy of, 202
odontogenic infections of, 184-185, 186f
Lateral pharyngotomy approach
for hypopharyngeal cancer, 1426-1427
for oropharyngeal cancer, 1371, 1371f
Lateral pontomedullary syndrome, 2353f
Lateral process, 1824, 1825f, 1826-1827
Lateral pterygoid muscle
anatomy of, 1320
in surgical anatomy of lateral skull base, 2441
Lateral pterygoid plate, in surgical anatomy of middle cranial base, 2444, 2445f
Lateral pterygoid process, in surgical anatomy of lateral skull base, 2435f
Lateral radicular cyst, 1263
Lateral rectus muscle(s)
semicircular canal planes and, 2285-2287, 2286f-2287f
in surgical anatomy of anterior cranial base, 2472f
Lateral retropharyngeal nodes, 1422
Lateral rhinotomy
for middle cranial base surgery, 2455t, 2458, 2458f
for nasopharyngeal carcinoma, 1355-1356, 1355f
Lateral semicircular canal (LSSC)
anatomy of, 1826f, 1827, 1851f, 1854f, 2278f
dysplasia of, 2732, 2732f-2733f
imaging of, 1922f
in surgical anatomy of lateral skull base, 2436f, 2439f
Lateral sinus thrombosis
epidemiology of, 1980t-1981t
imaging of, 1996f-1997f, 1997
otitis media and, 2777
pathogenesis of, 1996
signs and symptoms of, 1996-1997
treatment of, 1997
Lateral skull base. *See* Lateral cranial base.
Lateral superior olive (LSO), in auditory pathway, 1834-1835, 1834f, 1846
Lateral thigh flap(s), 1082t
for hypopharyngeal and esophageal reconstruction, 1455
for oropharyngeal reconstruction, 1379
of tongue base, 1390-1391
of tonsils and pharyngeal wall, 1386-1387
Lateral transtemporal sphenoid approach, for middle cranial base surgery, 2462, 2465f
Lateral transthyroid pharyngotomy, for hypopharyngeal cancer, 1427, 1428f
Lateral vertical buttress, 319, 331, 331f
Lateral vestibular nucleus (of Dieters), 1860-1861, 1862f
Lateral vestibulospinal tract, in postural balance, 1865
Lateral view, of facial bones and sinuses, 130
Lateralized radicular cyst, 1263
Latex, adverse reactions to, 102
Lathyrogenic drugs, for caustic ingestion, 2959
Latissimus dorsi musculocutaneous flap, for oropharyngeal reconstruction, 1378, 1378f
of tongue base, 1389
Latissimus dorsi myocutaneous free flap, 1082t, 1083-1084, 1084f
for hypopharyngeal and esophageal reconstruction, 1452
for oropharyngeal reconstruction, 1380
of tongue base, 1389-1390, 1390f
LATS (long-acting thyroid stimulator), 1741
LC. *See* Laryngeal cleft (LC).
LCA (lateral cricoarytenoid) muscle
applied anatomy of, 806
characteristics of, 918
in professional voice production, 846-847
LCH. *See* Langerhans' cell histiocytosis (LCH).
LCR (laryngeal chemoreflex), 2570
LDH (lactate dehydrogenase), with melanoma, 1109-1110, 1113
LDL (low-density lipoprotein) cholesterol, subclinical hypothyroidism and, 1747
Leapfrog Group, 84t-87t, 87
Learning problems, obstructive sleep apnea and, 2603-2604
Leeches, medicinal, for flap salvage, 1075, 1098
LeFort I fractures, 326, 327f
pediatric, 2707
repair of, 334-335, 334f
LeFort I osteotomy(ies)
in cleft-lip nose repair, 559, 564f-565f
for juvenile nasopharyngeal angiofibroma, 1350-1351
for middle cranial base surgery, 2455t, 2458, 2460f
LeFort II fractures, 326, 327f
pediatric, 2707
repair of, 335-336, 335f-336f
LeFort III fractures, 326, 327f
pediatric, 2707
Left anterior–right posterior (LARP) semicircular canal plane, 2285, 2286f, 2287, 2288f
Legal issues
with difficult airway, 110
with noise-induced hearing loss, 2149-2151
Leiomyoma
esophageal, 1415-1416, 1415f
of trachea, 1613
Leiomyosarcoma, of neck, 1670
Leksell, Lars, 1696
Lemierre's syndrome, due to deep neck space infections, 207
Length-to-width ratio, of skin flaps, 1068, 1068f
Lentigo, solar (actinic, senilis), 288
Lentigo maligna (LM), 1108
surgical excision of, 1114
Lentigo maligna melanoma (LMM), 287f, 1108
surgical excision of, 1114
Lentiviral vectors, for gene transfer, 16, 18t
Leprosy, laryngitis due to, 885
Leptomeningeal nevus flammeus, 291
LES. *See* Lower esophageal sphincter (LES).
Leser-Trélat sign, 282
Lesser occipital nerve, 2578, 2580f
Lesser palatine nerve, 1297f
Lesser wing of sphenoid bone, in surgical anatomy of middle cranial base, 2444, 2445f
Lesser zygomatic muscle, reinnervation of, 2423f
Letterer-Siwe disease, 2100-2101
oral manifestations of, 1257
otologic manifestations of, 2102f
otorrhea as, 2196
Leucine-rich transmembrane *O*-methyltransferase *(LRTOMT)* gene, in deafness, 2051t-2058t
Leucovorin, for induction chemotherapy, 1056
Leukemia
oral manifestations of, 1256
otologic manifestations of, 2107, 2108f
otorrhea as, 2197
sensorineural hearing loss due to, 2123
Leukocytosis, in deep neck infections, 204
Leukoedema, oral, 1222-1223
clinical features of, 1222, 1223f
defined, 1222
etiology and pathogenesis of, 1222
histopathologic features of, 1222, 1223f
management of, 1223
Leukoencephalopathy, progressive multifocal, HIV-associated, 223
Leukoplakia
candidal, 1231, 1231f
oral, 1223-1225
chemoprevention of, 1225
clinical features of, 1224-1225, 1224f
defined, 1223
etiology of, 1223-1224, 1223f-1224f
hairy, 1226, 1226f
in HIV, 225-226, 226f
histopathologic features of, 1225, 1226f
malignant transformation of, 1223, 1298
proliferative verrucous, 1225, 1225f
thin, 1224f, 1225
of tongue, 1362f
treatment of, 1225
Leukoplakic-type hyperkeratosis, 1231, 1231f
Leukotriene modifiers
for allergic rhinitis, 620-621
for rhinosinusitis, 735t, 736
Levator anguli oris, 321f
Levator aponeurosis, 443f, 444
in upper eyelid blepharoplasty, 448
Levator labii, 442f
Levator labii superioris, reinnervation of, 2423f
Levator nasi, 442f
Levator palpebrae, 321f
Levator palpebrae superioris, 444
Levator repositioning, for velopharyngeal dysfunction, 2682
Levator scapulae muscle, 2579f
Levator veli palatini (LVP) muscle
anatomy of, 1360f, 1868f, 1870
in cleft palate, 2666-2667
development of, 1866
in pressure equalization, 1870
in velopharyngeal function, 2676, 2677t
Levels of evidence, 69-70, 70t
Lever ratio, in auditory physiology, 1840, 1840f
Levetiracetam, for neuropathic pain, 244t
Levocetirizine (Xyzal), for nonallergic rhinitis, 701t
Levothyroxine, oral synthetic (Euthyrox, Levothroid, Levoxyl, Synthroid, Unithroid), for hypothyroidism, 1748-1749
Lexical Neighborhood Test (LNT), for cochlear implant, 2225-2226
Lhermitte's sign, due to radiotherapy, 1049
LHFPL5 (lipoma HMGIC fusion partner-like 5) gene, in deafness, 2051t-2058t
Liability genes, 8
Licensure, maintenance of, 80-81
Lichen planus
esophageal manifestations of, 980
oral, 1226-1229, 1253-1254
atrophic or erythematous, 1227, 1227f
bullous variant of, 1227-1228
clinical differential diagnosis of, 1228
clinical features of, 1227-1228
erosive, 1227, 1228f
etiology and pathogenesis of, 1227
histopathologic features of, 1228, 1228f

Lichen planus *(Continued)*

parathyroid arteriography as, 1788
selective venous sampling for PTH as, 1788-1789
ultrasound-guided fine-needle aspiration as, 1789
mediastinal exploration as, 1801-1802, 1802f
noninvasive preoperative, 1784-1788, 1784t
computed tomography as, 1786-1787
computed tomography–sestamibi fusion as, 1785-1786, 1786f-1788f
magnetic resonance imaging as, 1787-1788, 1789f
pertechnetate (technetium 99m) thallous chloride (thallium 201) imaging as, 1784-1785
sestamibi–technetium 99m scintigraphy as, 1785, 1785f, 1788f, 1794f
technetium 99m sestamibi with single photon emission computed tomography as, 1785
ultrasonography as, 1786, 1789f
unsuccessful, 1801, 1801f-1802f
Lockwood's ligament, 439
LOH (loss of heterozygosity), in head and neck squamous cell carcinoma, 1019-1020, 1026
Long latency response (LLR)
auditory evoked, 1912, 1913f
electrically evoked, 1913-1914, 1913f
Long process incus, anatomy of, 1825f
Long-acting thyroid stimulator (LATS), 1741
Long-term average spectra (LTAS), in acoustic analysis for voice evaluation, 829t, 830
Long-term potentiation (LTP), in neural plasticity, 1882-1884
Longus capitis muscle, 2579f
Longus colli muscle, 2579f
Longus colli muscle flap, for lateral pharyngeal wall defects, 1384-1385
Loop diuretics
in noise-induced hearing loss, 2147
ototoxicity of, 2174-2175
sensorineural hearing loss due to, 2120
Loprox (ciclopirox olamine antifungal cream or solution), for fungal otitis externa, 1954-1955, 1959t-1960t
Loratadine (Claritin)
for allergic rhinitis, 620
for nonallergic rhinitis, 701t
for rhinosinusitis, 734t
Los Angeles classification, of erosive esophagitis, 969, 969f
Loss of heterozygosity (LOH), in head and neck squamous cell carcinoma, 1019-1020, 1026
Lotrimin (clotrimazole) cream, for fungal otitis externa, 1954-1955, 1959t-1960t
Lou Gehrig's disease, laryngeal hypofunction due to, 842
Low-density lipoprotein (LDL) cholesterol, subclinical hypothyroidism and, 1747
Lower esophageal sphincter (LES)
anatomy of, 953, 954f
in GERD, 895, 895b
impairment of, 1400
manometry of, 958, 958f
physiology of, 954, 955f
Lower esophageal sphincter (LES) pressure, 958f
Lower esophageal sphincter (LES) relaxation, transient, 954, 968
Lower eyelid
aesthetic analysis of, 445-446, 446f
paralysis of, 2420-2421, 2421f
Lower eyelid blepharoplasty, 448-449
subciliary approach to, 449, 450f-451f
transconjunctival approach to, 448-449, 450f
Lower eyelid retractors, 444
Lower jugular lymph nodes, in neck dissection, 1704, 1704f, 1706t
Lower lateral cartilage, of nose, 497f
in cleft-lip nose repair, 562f-564f
reshaping of, 577
Lower lip, of vocal folds, in mucosal wave propagation, 848-849
Lower lip defects
algorithm for, 351, 355f
midline, 352-353
LPC (linear predictive coding) spectrum, in acoustic analysis for voice evaluation, 829t, 830, 830f
LPR. *See* Laryngopharyngeal reflux (LPR).
LPSs (lipopolysaccharides), and toll-like receptors, 598
LRTOMT (leucine-rich transmembrane *O*-methyltransferase) gene, in deafness, 2051t-2058t
LSL (liposarcoma of the larynx), 1508
LSO (lateral superior olive), in auditory pathway, 1834-1835, 1834f, 1846
LSSC. *See* Lateral semicircular canal (LSSC).
L-strut, in septoplasty, 489-490, 490f
LTα (lymphotoxin α), 609t-610t
LTαβ (lymphotoxin αβ), 609t-610t
LTAS (long-term average spectra), in acoustic analysis for voice evaluation, 829t, 830
LTECs (laryngotracheoesophageal clefts), 2873-2874, 2873f
classification of, 2873, 2874f, 2874t
syndromes associated with, 2870t
LTP (long-term potentiation), in neural plasticity, 1882-1884
Lubrication, saliva in, 1140-1141
Ludwig classification, of hair loss, 376, 377f
Ludwig's angina
airway establishment for, 188
due to mandibular space infections, 184, 185f
Lugol's solution
for Graves' disease, 1742-1743
for hyperthyroidism, 1739t
Lumbar drains, for CSF rhinorrhea, 792
Lumbar puncture, for meningitis due to temporal bone infection, 1982
Lund-MacKay scoring system, 53
for chronic sinusitis, 674
Lung, anatomy of, 998-999
Lung carcinoma, tracheal invasion by, 1615
Lung function tests, for stridor, 2901
Lung imaging fluorescence endoscope (LIFE) system, for early glottic carcinoma, 1516
Lung volume(s), in children, 2570
Lung volume reduction, endoscopic/bronchoscopic, 1011
LVES (laryngeal videoendoscopy and stroboscopy). *See* Laryngeal stroboscopy; Laryngeal videoendoscopy.
LVP muscle. *See* Levator veli palatini (LVP) muscle.
Lyme disease, 2105-2106, 2400
diagnosis of, 2400
facial paralysis in, 2106, 2400
head and neck symptoms of, 2400
otologic manifestations of, 2106
sensorineural hearing loss due to, 2119
sudden, 2128
stages of, 2400
treatment of, 2400
Lymph node(s)
anatomy and classification in, 163-164
imaging of, 164-167
with extracapsular spread, 164-166, 167f
inflammatory (reactive), 164
with invasion of carotid artery, 166-167
metastatic
contrast-enhanced CT of, 164-165, 167f
MRI of, 165-166, 168f
with non-Hodgkin's lymphoma, 165-166, 167f
normal anatomy in, 166f
in immune system, 605
number of positive, in melanoma, 1111
Lymph node biopsy, sentinel. *See* Sentinel lymph node biopsy (SLNB).
Lymph node dissection
for melanoma
elective, 1114-1115
therapeutic, 1114, 1116
for salivary gland tumors, 1196-1197
Lymph node metastasis(es). *See* Cervical lymph node metastasis(es).
Lymph node regions, physical examination of, 96-97, 96f
Lymphadenitis, neck masses due to, 1638
Lymphadenopathy
in children
bacterial, 2818, 2818f-2819f
drug-induced, 2819
fungal, 2818-2819
reactive, 2818
suppurative, 2818, 2818f
viral, 2817-2818
imaging of, 164-167
CT of, 139
with extracapsular spread, 164-166, 167f
inflammatory (reactive), 164
with invasion of carotid artery, 166-167
metastatic
contrast-enhanced CT of, 164-165, 167f
MRI of, 165-166, 168f
MRI of, 142
with non-Hodgkin's lymphoma, 165-166, 167f
ultrasound imaging of, 143
in immunosuppressed patients, 218-219, 219t
neck masses due to, 1638
in children
bacterial, 2818, 2818f-2819f
fungal, 2818-2819
viral, 2817-2818
Lymphangiomas
of masticator space, 152, 153f
neck masses due to, 1640, 2815, 2815f
of posterior cervical space, 158, 162f
with salivary gland involvement, 2861f
Lymphatic clinical target volumes, selection and delineation of, 1044

Lymphatic drainage
of larynx and hypopharynx, 1578-1579, 1579f, 2582
of skin flaps, 1068
Lymphatic malformations, 2829-2830
associated conditions with, 2829-2830, 2831f
clinical assessment and behavior of, 2829, 2830f
diagnostic evaluation of, 2829
imaging of, 2824f, 2829
macrocystic, 2860-2861
mandibular overgrowth with, 2823f
of neck, 1640, 2815, 2815f
of salivary glands, 1172, 2860-2861, 2861f
sclerotherapy for, 2830-2831
spontaneous resolution of, 2830, 2831f
surgery for, 2831, 2832f
Lymphatic system
of neck, 1683, 1683f, 2582-2583
classification of cervical lymphatics in, 2582-2583
deep cervical lymph nodes in, 2582
for pharynx and larynx, 2582
superficial lymph nodes in, 2582
of oropharynx, 1359-1360, 1360f-1361f, 1361t
Lymphoblastic lymphoma (LL), 1679
clinical presentation of, 1674
fine-needle aspiration of, 1675
treatment and prognosis for, 1679
Lymphocytes
in allergic rhinitis, 616
B, 602f, 603
development of, 603
responses by, 603
T cell–dependent and T cell–independent, 606
in Graves' ophthalmopathy, 1807
intraepithelial, 605
large granular, 603-604
T, 600-603
cytotoxic, 601, 602f
development of, 600-601
effector, 601-603
helper, 601-602, 602f
priming of, 601
regulatory, 602-603
in wound healing, 1076
Lymphocytoma, due to Lyme disease, 2106
Lymphoepithelial carcinoma, of oropharynx, 1362
Lymphoepithelial cyst, benign, in HIV, 217-218, 218f
Lymphoepitheliomas, of hypopharynx and cervical esophagus, 1425
Lymphoid follicles, in immune system, 605
Lymphoid organs, 605
lymph nodes as, 605
Lymphoid stem cells, 599-600, 600f
Lymphoid tumors, of paranasal sinuses, 1131
Lymphoma(s)
biopsy of
core-needle, 1676
corticosteroids prior to, 1676
fine-needle aspiration, 1675-1676
open, 1676
Burkitt's, 1679
in children, 2838, 2839f
clinical presentation of, 1674
treatment and prognosis for, 1679
in children, 2819-2820, 2837
Burkitt's, 2838, 2839f
Hodgkin's, 2819, 2838-2840
clinical presentation of, 2819, 2839-2840
histopathology and molecular biology of, 2819, 2840, 2840f
imaging of, 2820f
management of, 2840
staging of, 2839-2840
neck masses due to, 2819-2820, 2820f
Lymphoma(s) *(Continued)*
non-Hodgkin's, 2819-2820, 2837
epidemiology of, 2837
histopathology and molecular biology of, 2838, 2839f
management of, 2838
presentation and evaluation of, 2837-2838, 2838t
staging of, 2838, 2839t
diffuse large B-cell, 1677-1678
clinical presentation of, 1674
of paranasal sinus and nasal cavity, 1680
treatment and prognosis for, 1680
of salivary glands, 1191-1192, 1192f
treatment and prognosis for, 1680
of thyroid, 1679
staging of, 1679
treatment and prognosis for, 1679
treatment and prognosis for, 1677-1678
of Waldeyer's ring, 1680
treatment and prognosis for, 1680
follicular, 1678
clinical presentation of, 1674
treatment and prognosis for, 1678
of head and neck, 1673-1681
biopsy of, 1674-1676
core-needle, 1676
corticosteroids prior to, 1676
fine-needle aspiration, 1675-1676
open, 1676
classification of, 1675, 1675t
clinical presentation of, 1674, 1674f
epidemiology of, 1673-1674
Hodgkin's, 1676-1677
clinical presentation of, 1674, 1674f
complications of, 1677
epidemiology of, 1673-1674
treatment and prognosis for, 1676-1677
nodal, 1676-1679
non-Hodgkin's
Burkitt's, 1674
clinical presentation of, 1674, 1674f
diffuse large B-cell, 1677-1678

of malignant otitis externa, 1947
of nasopharyngeal carcinoma, 1354
of neck masses, 1637, 1637t
of neck neoplasms, 1656-1657
of obstructive sleep apnea, 255
of oral cancer, 1300
of oropharyngeal cancer, 1366
of paranasal sinus tumors, 1124
of paranasal sinuses, 143, 664, 664f
prior to endoscopic sinus surgery, 764, 765t
permanent *vs.* superconducting magnets in, 133
of petrous apicitis, 1986-1987, 1988f-1989f
of pharynx and esophagus, 1396
pulse sequences for, 133-137, 135f-136f
of salivary glands, 142, 1145-1147, 1166, 1180
with adenoid cystic carcinoma, 1146-1147, 1146f-1147f
with glomus tumor, 1169f
with mucoepidermoid carcinoma, 1146, 1147f, 1168f
with pleomorphic adenoma, 1148f, 1167f-1168f, 1180f
with ranula, 1146, 1147f
for sensorineural hearing loss in adults, 2117
with short T1 inversion recovery (STIR), 135-136, 136f
of skull base, 143
anterior, 2475
lateral, 2489
slice thickness in, 133
with spectral presaturation inversion recovery (SPIR), 135-136
spin density–weighted, 134, 136f
for stereotactic radiation therapy, 2558
of suprahyoid neck, 142
surface coils in, 133
T1-weighted, 134, 135f-136f
T2-weighted, 134, 135f-136f
of temporal bone, 143
three-dimensional reconstruction from, 138, 140f
of thyroid and parathyroid glands, 143
Magnetic resonance (MR) sialography, 1147
Magnetic resonance (MR) spectroscopy, of laryngeal carcinoma, 1470
Magnetic search coil technique, for recording eye movements, 2317
Magnetic stimulation, to assess facial nerve function, 2388-2389
in Bell's palsy, 2394-2395
Maintenance activities, in vestibular rehabilitation, 2372-2373, 2379
Maintenance of certification (MOC), 80, 81b
MAIS (Meaningful Auditory Integration Scale), for cochlear implant, 2225
Major basic protein (MBP), 604
in allergic rhinitis, 616
Major histocompatibility complex (MHC) molecules, 599
Major histocompatibility complex (MHC)-restricted cytotoxicity, 603-604
Major histocompatibility complex (MHC) restriction, 603-604
Mal de débarquement (MDD) syndrome, 2357
Malabsorption diseases, oral manifestations of, 1254
Malar eminence
anatomy and physiology of, 319
biomechanics of, 332
Malar prominences, with aging, 444
MALDI-TOF (matrix-assisted laser desorption-ionization–time-of-flight), in head and neck squamous cell carcinoma, 1029
Male-pattern baldness, 374-376, 375f
Malignancy(ies)
in geriatric patients, 237-238
etiology of, 237
treatment of, 237-238
hypercalcemia of, 1783, 1783t
immunosuppression and, 212-217, 213t
cutaneous neoplasms in, 213t, 215
Hodgkin's lymphoma in, 213t, 217
Kaposi's sarcoma in, 212-215, 213t
epidemiology and pathogenesis of, 212-213
presentation and diagnosis of, 213-214, 214f
treatment of, 214-215
non-Hodgkin's lymphoma in, 213t, 215-216
diagnosis of, 216
epidemiology and presentation of, 216
prognosis and treatment for, 216-217
in posttransplantation lymphoproliferative disorder, 213t, 215, 217
squamous cell carcinoma in, 213t, 215
Malignant fibrous histiocytoma (MFH)
of larynx, 1508
of neck, 1667
Malignant giant cell tumor (MGCT), 1671
Malignant hypertension (MH), 119
Malignant melanoma (MM). *See* Melanoma.
Malignant mixed tumors, of salivary glands, 1186-1189
carcinoma ex pleomorphic adenoma as, 1187-1189, 1188f
metastasizing, 1189
true (carcinosarcoma), 1187, 1188f
Malignant otitis externa (MOE), 1947-1948
clinical manifestations of, 1947, 1947f
conductive hearing loss due to, 2021, 2023f
defined, 1947
immunosuppression and, 221-222, 1947
incidence and epidemiology of, 1947
investigations of, 1947
microbiology of, 1947
otorrhea due to, 2195
treatment of, 1947-1948
Malignant peripheral nerve sheath tumor (MPNST), 1670-1671
Mallear stria, 1824, 1825f
Malleolar artery, 1828f
Malleus, 97, 98f
anatomy of, 1826
in auditory physiology, 1839-1840, 1840f, 2018
in cochlear transduction, 2062f

Malleus fixation, 2024-2025
  small fenestra stapedotomy with, 2033
Mallory-Weiss syndrome, 1410-1411
Mallory-Weiss tear, gastroesophageal junction in, 957f
Malnutrition, palliative care for, 1104
Malocclusion
  after maxillofacial trauma, 339
  due to paranasal sinus tumor, 1123
Maloney bougies, for esophageal strictures, 966
MALT. *See* Mucosa-associated lymphoid tissue (MALT).
Malunion, after maxillofacial trauma, 339
Mammillary bodies, in surgical anatomy of anterior cranial base, 2481f
Mandible
  anatomy of, 320f, 322-323, 1319, 1320f
    alveolar canal in, 1319-1320
    alveolar process in, 1319, 1320f
    body of mandible in, 1319, 1320f
    coronoid and condylar processes in, 1319, 1320f
    dentulous *vs.* edentulous, 1319, 1320f
    mandibular notch in, 1319, 1320f
    mental foramen in, 1319, 1320f
    rami in, 1319, 1320f
  biomechanics of, 332-333, 332f
  body of, 1319, 1320f
  dentulous, *vs.* edentulous, 1319, 1320f
  in Down syndrome, 2632
  edentulous
    vs. dentulous, 1319, 1320f
    repair of, 339
  growth and development of, 2620-2621
    downward translation in, 2621, 2624f
    mandibular arch in, 2621, 2624f
    Meckel's cartilage in, 2620-2621, 2623f
    rotational changes in, 2621, 2625f
    size in, 2621, 2624f
    surface remodeling in, 2621, 2623f
  odontogenic tumors of, 1270-1271, 1271f
  osteoradionecrosis of, 1048
  physiology of, 320f, 322-323
  reconstruction of (*See* Mandibular reconstruction)
  in surgical anatomy of lateral skull base, 2440f
  surgical treatment of, 1310-1312
    with oral cancer
      for access, 1311
      mandible-sparing procedures in, 1311
      marginal mandibulectomy for, 1311, 1312f
      paramedian mandibulotomy in, 1311
      pull-through technique for, 1311, 1312f-1313f
      segmental mandibulectomy for, 1311-1312, 1312t
  tension and compression areas in, 331-332, 331f-332f
  vasculature of, 1296
Mandible-sparing procedures, 1311
Mandibular advancement, for obstructive sleep apnea, 257f
  in children, 2610
Mandibular ameloblastomas, 1274
Mandibular arch, in embryology of nose, 2691f
Mandibular branch, of facial nerve, 1194f
Mandibular changes, in geriatric patients, 236
Mandibular condylar fossa, in surgical anatomy of middle cranial base, 2444, 2445f
Mandibular discontinuity defects, maxillofacial prosthodontics for, 1340-1342, 1342f-1343f
Mandibular distraction, 2656, 2656f
  for obstructive sleep apnea in children, 2610, 2610f
  for Robin sequence, 2673
Mandibular division, of trigeminal nerve, in surgical anatomy of lateral skull base, 2437f, 2438, 2440f, 2441
Mandibular fix-bridge system, with free tissue transfer, 1093-1094
Mandibular fossa, 2011f
Mandibular fractures, 323
  classification of, 327
  imaging of, 325-326
  pediatric, 2704-2706
    arch and body, 2706, 2709f
    complications of, 2704
    condylar and subcondylar, 2704, 2706f-2708f
    epidemiology of, 2698
    symphyseal and parasymphyseal, 2704-2706, 2708f-2709f
  physical examination of, 325
  repair of, 337-339, 338f
  surgical access to, 329-330, 330f
  teeth in line of, 339
Mandibular hypoplasia, obstructive sleep apnea due to, 2610, 2610f
Mandibular movement, nonarticular conditions producing limitation of, 1285t
Mandibular nerve block
  for neuropathic pain, 246t
  for postoperative pain, 242
Mandibular notch, 1319, 1320f
Mandibular overgrowth, with lymphatic malformation, 2823f
Mandibular prominences, in embryology
  of lip, 2661f-2662f, 2661t
  of nose, 2691f
Mandibular prosthesis, 1340, 1341f-1342f
  with discontinuity defects, 1340-1342, 1342f-1343f
Mandibular reconstruction, 1315-1316, 1319-1328
  anatomy of mandible and, 1319, 1320f
    alveolar canal in, 1319-1320
    alveolar process in, 1319, 1320f
    body of mandible in, 1319, 1320f
    coronoid and condylar processes in, 1319, 1320f
    dentulous *vs.* edentulous, 1319, 1320f
    mandibular notch in, 1319, 1320f
    mental foramen in, 1319, 1320f
    rami in, 1319, 1320f
  background and history of, 1319, 1320f, 1322-1324
  classification of defects for, 1321-1322, 1323f
  computer-assisted modeling for, 1326-1327, 1327f
  current method(s) of, 1324-1326
  fibular free flap, 1316, 1316f
  future approaches to, 1327-1328, 1328f
  goals of, 1320, 1322
  location of defect and, 1316
  after mandibulectomy
    with anterior defect, 1321, 1321f
    with lateral defect, 1321, 1322f
    marginal, 1320
    segmental, 1321
  movement of mandible and, 1320
  outcomes of, 1326
  reconstruction plate alone for, 1324
  reconstruction plate with osseous free tissue transfer for, 1324
    advantages and disadvantages of, 1324
    flap inset in, 1324f, 1325
    flap options for, 1324, 1325t
    planning and harvesting of flaps in, 1324-1325, 1324f
  reconstruction plate with soft tissue flap for, 1325
    advantages and disadvantages of, 1325
    plate extrusion with, 1325, 1326f
    plate fracture with, 1325-1326, 1326f
    volume-based, 1325, 1326f
Mandibular reconstruction plate (MRP), 337-338, 1324
  with osseous free tissue transfer, 1324
    advantages and disadvantages of, 1324
    flap inset in, 1324f, 1325
    flap options for, 1324, 1325t
    planning and harvesting of flaps in, 1324-1325, 1324f
  with soft tissue flap, 1325
    advantages and disadvantages of, 1325
    plate extrusion with, 1325, 1326f
    plate fracture with, 1325-1326, 1326f
    volume-based, 1325, 1326f
Mandibular resection prosthesis, 1340, 1341f-1342f
Mandibular space involvement, in odontogenic infections, 181-184
  Ludwig's angina due to, 184, 185f
  masseteric, 184, 185f
  masticator, 184, 186f
  pterygomandibular (medial pterygoid), 184, 185f
  secondary, 184
  sub-, 183-184, 183f-184f
  sublingual, 183, 183f
  submental, 181-183, 183f
  temporal, 184, 185f
Mandibular splint, acrylic, for pediatric facial fractures, 2701, 2701f
Mandibular swing approach, for oropharyngeal cancer, 1371-1372, 1372f
Mandibulectomy
  for alveolar ridge carcinoma, 1304, 1304f-1305f, 1307f
  for excision of tumors in parapharyngeal space, 1176, 1176f
  mandibular resection prosthesis with, 1340, 1341f-1342f
  marginal, 1311, 1312f
    defect from, 1320, 1321f
  for retromolar trigone carcinoma, 1307, 1307f
  segmental, 1311-1312, 1312t
    defect from, 1321, 1321f
    free tissue transfer after, 1093-1094
Mandibulofacial dysostosis (MFD), 2585
  craniofacial abnormalities in, 2633-2635, 2633b, 2635f, 2646
Mandibulotomy
  for middle cranial base surgery, 2455t, 2458, 2460f
  paramedian, 1311
Mannequins, for difficult airway management, 118
Manometric rhinometry, 643-644
Manometry, esophageal, 957-958, 958f-959f, 959t
  for extraesophageal reflux, 899-900
  for swallowing disorders, 1219
Mantle cell lymphoma (MCL), 1678-1679
  treatment and prognosis for, 1678-1679
MAPK (mitogen-activated protein kinase) pathway, in thyroid carcinoma, 1753
Marble bone disease, 2112
Marcel Proust syndrome, 636
Marescaux, Jacques, 39
Marfanoid syndrome, craniofacial anomalies in, 2641t
Marfan's syndrome, oral manifestations of, 1257
Margin analysis, for biomarkers, in head and neck squamous cell carcinoma, 1027
Marginal cells, of taste buds, 1208
Marginal mandibular branch, of facial nerve, 2418-2419
"Marginal mandibular lip," 2431
Marginal zone lymphoma, of thyroid, 1679
Margin-reflex-distance (MRD), 446
Market accountability, 82
Marshall syndrome, deafness in, 2051t-2058t
Martell, Charles, 1774
MARVELD2, in deafness, 2051t-2058t

Marx hyperbaric oxygen regimen, after radiation therapy, 1333
Maser, 25
MASH (Multiple-Activity Scale for Hyperacusis), 2138-2139
Mask ventilation, difficult, 121-122
Masking, in audiologic testing, 1889-1890
  effective, 1889
  errors in, 1901-1902
Masking dilemma, 1890
Masking therapy, for tinnitus, 2134
MASS1, in deafness, 2051t-2058t
Masseter muscle
  anatomy of, 321f, 1320, 1359f, 1821
  in surgical anatomy of lateral skull base, 2440f
Masseter transfer, for facial nerve paralysis, 2427, 2428f
Masseteric space involvement, in odontogenic infections, 184, 185f
Mast cell(s)
  in adaptive immune system, 605
  in allergic rhinitis, 616
  in wound healing, 1078
Mast cell–mediated hypersensitivity reactions, 608-612
Mastication, 1206-1207, 1206f
  muscles and reflex control of, 1204-1205, 1204f-1205f
Masticator space (MS)
  anatomy of, 203
  imaging of, 151-152
    with adenoid cystic carcinoma, 155f
    with angiofibroma, 152, 154f
    with hemangioma and lymphangioma, 152, 153f
    with infection, 151-152, 152f
    normal anatomy on, 146f, 151-152
    with pseudotumors, 152
    with squamous cell carcinoma, 152, 154f
  odontogenic infections of, 184, 186f
Masticatory rhythm, 1206-1207
Mastoid abscess, due to temporal bone infection, 1980t
Mastoid air cell system, in pressure equalization, 1870-1871
Mastoid antrum, in surgical anatomy of lateral skull base, 2438
Mastoid bone
  anatomy of, 1823f
  imaging of, 1918-1920
  in surgical anatomy of lateral skull base, 2435, 2435f
Mastoid emissary vein, foramen for, 1822f
Mastoid foramen, 2010f
Mastoid obliteration, 2011
Mastoid part, of temporal bone, 1821-1822, 1822f, 1829
  anatomy of, 2009-2010, 2010f
Mastoid pneumatization, otitis media with effusion and, 1963-1964
Mastoid powder, for ear hygiene or chronic ear drainage, 1958
Mastoid process
  anatomy of, 2010f
  in craniofacial skeleton, 320f
  in osteology of temporal bone, 1821-1822, 1822f, 1824f
  in surgical anatomy of lateral skull base, 2435
  in surgical anatomy of middle cranial base, 2445f
Mastoid segment
  anatomy of, 1826f
    surgical, 2404, 2404f
  vulnerability to injury of, 1826f
Mastoid sources, of otorrhea, 2195-2196, 2195b
Mastoid tegmen, in surgical anatomy of lateral skull base, 2435f
Mastoid tip
  anatomy of, 1821-1822, 1822f
    in infants, 2010
  in surgical anatomy of lateral skull base, 2435f
Mastoidectomy, 2009-2016
  anatomic basis for, 2009-2010, 2010f
  canal wall down, 2010-2011
    for chronic otitis media with cholesteatoma, 1969, 1970t
    intact canal wall *vs.,* 2014
      indications for, 2014-2015, 2015f
    operative procedure for, 2013-2014, 2014f
  canal wall up (intact canal wall), 2010
    vs. canal wall down procedure, 2014
    for chronic otitis media with cholesteatoma, 1969, 1970t
    indications for, 2014-2015
  for cholesteatoma, 1969, 1970t, 2014-2015
  for cochlear implant, 2238-2239
  complication(s) of, 2015-2016
    dural tear as, 2015
    facial nerve injury as, 2015-2016
    horizontal semicircular fistula as, 2015
    sigmoid sinus and jugular bulb injury as, 2016
  history of, 2009
  nomenclature for, 2010-2011, 2010b
  operative procedure for, 2011-2014
    bur selection for, 2011
    facial nerve in, 2012, 2012f
    incision in, 2011, 2011f
    initial bur cuts in, 2011, 2011f
    irrigation in, 2011
    Körner's septum in, 2012
    location of antrum in, 2011-2012
    opening of epitympanum in, 2012-2013, 2013f
    opening of facial recess in, 2012, 2012f-2013f
    saucerization in, 2011-2012
    surgical site preparation in, 2011
    tegmen plate in, 2011-2012
    thinning of posterior wall in, 2011-2012
  radical, 2011
    modified, 2011
    in postauricular approach to infratemporal fossa, 2496, 2498f
  simple, 2010
Mastoiditis
  acute, 1983, 1983f

  anatomy and physiology of, 320, 320f-321f
  biomechanics of, 332
  frontal process of, 509f
  growth and development of, 2619-2620, 2621f-2622f
  odontogenic tumors of, 1270-1271
Maxillary ameloblastomas, 1274
Maxillary antrostomy, in endoscopic sinus surgery, 747, 747f
  failure of, 764-766, 766f
Maxillary antrum
  height of, 2617t
  malignant neoplasms of, 1122-1123
Maxillary artery
  anatomy of, 2580f
  in surgical anatomy of lateral skull base, 2441
Maxillary artery ligation, for epistaxis, 688
Maxillary crest, in septoplasty, 490, 490f
Maxillary division, of trigeminal nerve, in surgical anatomy of lateral skull base, 2437f, 2438, 2440f
Maxillary fractures
  classification of, 326, 327f
  imaging of, 325
  physical examination of, 324-325
  repair of, 334-337, 334f-336f
Maxillary gingivolabial sulcus approach, for pediatric facial fracture, 2701-2702, 2703f
Maxillary implants, in cleft-lip nose repair, 562f
Maxillary incisors, in chin analysis, 464, 464f
Maxillary lymph node, 1360f
Maxillary mega-incisor, 2690, 2691f
Maxillary nerve block
  for neuropathic pain, 246t
  for postoperative pain, 242
Maxillary obturation, prosthetic, 1338
  definitive, 1339-1340
    for dentate patients, 1339-1340, 1340f
    for edentulous patients, 1340, 1340f-1341f
  interim, 1339, 1339f
  surgical, 1338-1339
    abutments in, 1338-1339
    impressions for diagnostic casts in, 1338-1339, 1338f
    postoperative radiograph of, 1338, 1338f
    preoperative assessment for, 1338, 1338f
    preservation of support structures in, 1338
    removal of packing material and prosthesis in, 1339, 1339f
    securing of prosthesis in, 1338-1339, 1339f
    skin graft in, 1338-1339
Maxillary osteotomies, in cleft-lip nose repair, 559, 564f-565f
Maxillary process, in embryology of palate, 2662f
Maxillary prominences, in embryology
  of lip, 2659-2660, 2661f-2662f, 2661t
  of nose, 2691f
  of palate, 2660-2661
Maxillary prosthesis, 1338
  definitive, 1339-1340
    for dentate patients, 1339-1340, 1340f
    for edentulous patients, 1340, 1340f-1341f
  interim, 1339, 1339f
  surgical, 1338-1339
    abutments in, 1338-1339
    impressions for diagnostic casts in, 1338-1339, 1338f
    postoperative radiograph of, 1338, 1338f
    preoperative assessment for, 1338, 1338f
    preservation of support structures in, 1338
    removal of packing material and prosthesis in, 1339, 1339f
    securing of prosthesis in, 1338-1339, 1339f
    skin graft in, 1338-1339

Maxillary sinus(es)
anatomy and physiology of, 319f, 320, 664, 665f
growth and development of, 2619-2620, 2623f
medial wall of, prior to endoscopic sinus surgery, 764t
pneumatization of, prior to endoscopic sinus surgery, 764
surgical anatomy of, 740
in anterior cranial base, 2474

Melolabial fold, in aging, 406, 406f
Melolabial interpolated flap, for nasal defects, 348
Membrane attack complex (MAC), 608
Membranous labyrinth
anatomy of, 1831-1832, 1832f, 1852, 1853f
embryogenesis of, 1852
malformations limited to, 2727-2728, 2727b
malformations of osseous and, 2727b, 2728-2735
ruptures in, in Meniere's disease, 2334
Membranous labyrinthine dysplasia
complete, 2727
limited, 2727-2728
Membranous laryngotracheobronchitis. *See* Bacterial tracheitis.
MEN. *See* Multiple endocrine neoplasia (MEN).
MEN-1 tumor suppressor gene, in parathyroid neoplasm(s), 1775, 1776f
Meniere, Prosper, 2329, 2333
Meniere's disease, 2333-2339
atypical, 2335
bilateral, 2333
clinical course of, 2335
clinical features of, 2333, 2335, 2335t
sensorineural hearing loss as, 2126-2127, 2335t
fluctuating, 2199
history of, 2337
sudden, 2129
severity of, 2335, 2336t
tinnitus as, 2335t, 2337
vertigo as, 2202, 2335t
cochlear, 2335
diagnosis of, 2335-2337
AAO-HNS criteria for, 2335, 2335t
audiogram in, 1895f
clinical presentation in, 2335, 2335t
defined, 2333
dehydrating agents in, 2337
Meniere's disease *(Continued)*
electrocochleography in, 1892-1896, 1895f, 1908, 2337
electronystagmography in, 2337
hearing loss and tinnitus in, 2337
heat thrust testing in, 2337
history in, 2335-2337
imaging studies in, 2333-2334, 2334f
stacked auditory brainstem response in, 1911
vestibular evoked myopotentials in, 2337
endolymphatic hydrops in, 2333-2334, 2334f
etiology of, 2334-2335
infectious, 2163, 2335
familial, 2333
historical background of, 2329, 2333
imaging studies in, 2333-2334, 2334f
incidence of, 2333
and migraine, 2350
otosclerosis with, 2035
pathogenesis of, 2333-2334, 2334f
ruptures in membranous labyrinth in, 2334
severity of, 2335, 2336t
treatment of, 2126, 2337-2339
dietary modification and diuretics in, 2337
historical background of, 2329
intratympanic gentamicin for, 2185-2189, 2338-2339, 2338f
clinical protocols for, 2187-2188
complications of, 2188-2189
concentration of, 2188
dose of, 2188
indications and contraindications for, 2189
injection interval for, 2188
mechanism of action of, 2185-2186
number of injections of, 2188
pharmacokinetics of, 2186-2187, 2186f-2187f
practical considerations with, 2188
intratympanic steroids for, 2184, 2339
local overpressure therapy for, 2338
surgical, 2362-2364
cochleosacculotomy for, 2126, 2362-2363, 2363f
endolymphatic sac surgery for, 2126, 2339, 2363-2364, 2364f
labyrinthectomy for, 2339, 2362
vestibular nerve section for, 2339, 2362
symptomatic, 2338
vasodilators in, 2337-2338
vestibular, 2335
Meniett device, 2338
Meningioma(s)
of cerebellopontine angle, 2517-2518
diagnostic studies of, 2518
imaging of, 1928, 1928f, 2518, 2519f
in differential diagnosis, 1929t, 2518t
with intracanalicular extension, 2520f
sensorineural hearing loss due to, 2125, 2125f
signs and symptoms of, 2518
endovascular treatment of, 1938, 1938f
of internal auditory canal, 175f
jugular foramen, 1929-1930, 1930f
of posterior fossa
embolization of, 1938
with petrous apex involvement, 2508f
Meningitis
bacterial, hearing loss due to, 2160-2161
due to cranial base surgery, 2468
cryptococcal, in HIV, 223-224
due to CSF fistulas, 794, 2044
delayed, due to temporal bone fracture, 2037-2038, 2038f
hearing loss due to
cochlear implants for, 2240
sudden, 2127
due to inner ear anomalies, 2736f, 2737, 2739
due to otitis media, 1993-1994, 2777

Meningitis *(Continued)*
diagnosis of, 1993
imaging in, 1993-1994, 1994f
lumbar puncture for, 1982
epidemiology of, 1980t-1981t, 1993
pathogenesis of, 1993
pathology of, 1993
symptoms of, 1993
treatment of, 1993-1994
due to posterior fossa surgery, 2541
Meningitis vaccination, with cochlear implants, 2236-2237, 2237b
Meningocele
with CSF rhinorrhea, 787
defined, 2645, 2687
imaging of, 765t
Meningoencephalocele
anterior, surgical management of, 742
with CSF rhinorrhea, 787, 791f-792f
defined, 2645, 2687
endoscopic view of, 2646f
due to otitis media, 1992-1993, 1993f
Meningoencephalocystocele, defined, 2645
Menopause, oral health during and after, 1256-1257
Menstrual cycle
oral changes during, 1256
and professional voice, 850
Menstrual cycle synchrony, olfaction in, 630
Mental foramen, of mandible, 1319, 1320f
Mental nerve, in osseous genioplasty, 467, 470
Mental protuberance, 320f
Mental tubercle, 320f
Mentalis muscle, 442f
Mentalis strain, 461, 462f
Menthol, for vocal professionals, 855
Menthol-sensitive receptors, in nasal mucosa, 641-642
Mentocervical angle, in aesthetic analysis, 275, 279f
Mentoplasty, 461-474
chin implants in, 465-467
anesthesia for, 465
clinical example of, 470, 471f
complications after, 470
dissection planes for, 465-467, 467f
incision and approach for, 465-467, 467f
intraoral approach for, 467
subperiosteal *vs.* supraperiosteal placement of, 465-467, 467f
surgical procedure for, 465-467
types of, 465, 465t, 467
clinical examples of, 470, 471f-473f
complications after, 470
correction of soft tissue ptosis in, 465
osseous genioplasty in, 465, 467-470
anesthesia for, 467
clinical examples of, 470, 473f
complications after, 470
fixation in, 468-470, 470f
gingivolabial incision for, 467, 468f
inscription of bony midline in, 467-468, 469f
lateral extent of, 468, 469f
measurement of osteotomy site in, 467-468, 469f
subperiosteal dissection in, 467, 468f
three-dimensional movement of chin in, 468
vertical lengthening in, 468-470, 469f
vertical shortening in, 468-470, 470f
wound closure in, 470
patient evaluation for, 461-465
Burstone analysis in, 463, 463f
Gonzalez-Ulloa and Stevens analysis in, 464f
history in, 461
Holdaway "H" angle in, 463, 464f
horizontal relationships in, 463, 464f
lateral cephalometric radiograph in, 463, 463f
Mentoplasty *(Continued)*
panoramic radiograph (Panorex) in, 462-463, 462f
photography in, 461-462, 462f
physical examination in, 461, 462f
Ricketts analysis in, 463, 463f
Steiner analysis in, 463, 463f
symmetry in sagittal plane in, 464-465
vertical relationships in, 463-464, 464f
procedure selection for, 461, 462t, 465
MEP(s) (motor evoked potentials), transcranial electrical stimulation–induced, to assess facial nerve function, 2389
Meperidine
for pediatric anesthesia, 2592
for postoperative pain, 241t
Merbromin (Mercurochrome), for fungal otitis externa, 1955
Merkel cells, 1201
Merocel wicks, in atresiaplasty, 2756-2757
MERRF (myoclonic epilepsy and red ragged fibers) syndrome, sensorineural hearing loss in, 2094t, 2097
Mesotympanum, 1825-1826, 1827f
Messenger RNA, 11-12, 12f
Messerklinger technique, for endoscopic sinus surgery, 746
MET (D-methionine), for noise-induced hearing loss, 2145
MET (Middle Ear Transducer). *See* Middle Ear Transducer (MET).
MET (mechanoelectrical transduction) channel, in hair cell transduction, 2072f
MET (mechanoelectrical transduction) currents, adaptation of, in hair cell transduction, 2078-2079, 2079f
Meta-analyses, 70, 71t
Metabolic disorders
craniofacial anomalies due to, 2640
facial paralysis due to, 2401
otologic manifestations of, 2112-2114
in gout, 2113-2114
in mucopolysaccharidoses, 2112-2113, 2113f
in ochronosis, 2114
presbycusis due to, 232
sensorineural hearing loss due to, 2125
vertigo due to, 2201
Metabolic manipulation, and skin flap viability, 1074-1075
Metabolic myopathies, laryngeal hypofunction due to, 842
Metabolic presbycusis, 232
Metachronous lesion, in oral cancer, 1301-1302
Metallic artifacts
on CT, 139, 141f
on MRI, 134, 134f
Metallic coils, for embolization, 1933
Metastasis(es)
cervical lymph node (*See* Cervical lymph node metastasis(es))
to larynx, 1510
rapidly progressive hearing loss due to, 2200
to salivary glands, 1191
to skull base, 171, 173f
to trachea, 1615-1616
Metastasizing mixed tumor, of salivary glands, 1189
Metastatic (M) classification, for melanoma, 1111t, 1113
Metastatic disease, systemic chemotherapy for, 1058-1061
combination, 1059-1060
prognostic factors with, 1058-1059
single agent, 1059
Metastatic lesions
of cerebellopontine angle, 2526
of ear, 2107-2108, 2108f
otorrhea due to, 2196-2197
Metastatic lesions *(Continued)*
of neck, 1664
from distant tumor, 1664-1666
from regional tumor, 1664
from unknown primary, 1664, 1665f
Metastatic lymphadenopathy
CT of, 139
MRI of, 142
ultrasound of, 143
Metastatic workup, for melanoma, 1109-1110, 1110b, 1110t
Methacholine challenge test, in nonallergic rhinitis, 695
Methacrylates, for craniofacial defect repair, 2657
Methadone, for postoperative pain, 241t
Methicillin-resistant *Streptococcus aureus* (MRSA), rhinosinusitis due to
acute, 704, 732
chronic, 732, 733f
Methimazole
adverse reactions to, 1742
for Graves' disease, 1742
for hyperthyroidism, 1739t
D-Methionine (MET), for noise-induced hearing loss, 2145
Methotrexate (Rheumatrex)
for autoimmune inner ear disease, 2167
in combination chemotherapy, 1059-1060
dizziness due to, 2310t
for induction chemotherapy, 1056-1057
for recurrent or metastatic disease, 1059
for recurrent respiratory papillomatosis, 879
for sarcoidosis, 659
for Wegener's granulomatosis, 658
Methoxyisobutyl isonitrile (MIBI). *See* Sestamibi.
Methylation, in head and neck squamous cell carcinoma, 1020-1022, 1021f
Methylprednisolone
with chemical peel, 396
intratympanic delivery of
dosing for, 2185
pharmacokinetics of, 2183-2184
for sudden sensorineural hearing loss, 2184-2185
for vestibular neuritis, 2162
Methylprednisone, for rhinosinusitis, 734t
Metoclopramide
for extraesophageal reflux, 901
for GERD, 970
Metopic suture, 320f
Metopic synostosis, 2642-2643, 2643f
Metoprolol, intraoperative, 112
Metrizamide powder (Nycomed), for embolization, 1933
MeV (megaelectron volts), 1033
MFD (mandibulofacial dysostosis), 2585
craniofacial abnormalities in, 2633-2635, 2633b, 2635f, 2646
MFH (malignant fibrous histiocytoma)
of larynx, 1508
of neck, 1667
MGCT (malignant giant cell tumor), 1671
MH (malignant hypertension), 119
MHC (myosin heavy chain) isoforms
in lingual muscles, 1205
in muscles of mastication, 1204
MHC (major histocompatibility complex) molecules, 599
MHC (major histocompatibility complex)-restricted cytotoxicity, 603-604
MHC (major histocompatibility complex) restriction, 603-604
MIBI (methoxyisobutyl isonitrile). *See* Sestamibi.
MIBI-SPECT (technetium-99m sestamibi scintigraphy with single photon emission computed tomography), for hyperparathyroidism, 1785

Michel's aplasia, 2200, 2729
  imaging of, 2729f-2730f
  inherited, 2735
  relative incidence of, 2729t
Miconazole cream (Micatin, Monistat), for fungal otitis externa, 1954-1955, 1959t-1960t
Micro Retin A (tretinoin)
  for aging skin, 403-404
  with chemical peels, 392-393
  for chemoprevention of oral cancer, 1315
Microcirculatory changes, in acutely raised skin flaps, 1068-1069
Microcirculatory impairment, of skin flaps, 1071f
Microdebrider
  for adenoidectomy, 2797-2798
  for recurrent respiratory papillomatosis, 2891
  for stridulous child, 2909
Microdeletion chromosome 22 syndrome, cleft lip and palate in, 2673-2674, 2674f
Microdermabrasion, 402-403
Microfibrillar collagen (Avitene), for embolization, 1933
Microgenia, 463
Microglial cells, 604
Micrognathia
  dysphagia due to, 2950-2951
  and obstructive sleep apnea, 2610
Microlaryngoscopy, 864, 864f
Microlaryngoscopy partial cordectomy, for glottic cancer, 1517t
Microneurovascular muscle transfer, for facial nerve paralysis, 2429-2430
Microphone, for hearing aid, 2267
  directional, 2269
Microphthalmia transcription factor *(MITF)* gene, in deafness, 2051t-2058t, 2095
MicroRNAs (miRNAs, miRs), in head and neck squamous cell carcinoma, 1021, 1022f, 1027-1028
Microsatellite repeats, in head and neck squamous cell carcinoma, 1019
Microscopic direct laryngoscopy, for glottic cancer, 1519t
Microscopic examination, of ear, in children, 2574
Microsurgical débridement, for airway stenosis, 946, 946b, 946f
Microtia, 2741-2751
  atypical, 2742, 2743f
    reconstruction for, 2747-2748, 2749f-2750f
  classic, 2742, 2743f
  classification of, 2742
  ear anatomy and, 2742, 2742f
  embryology of, 2741, 2742f
  epidemiology of, 2741
  evaluation of, 2742-2743
  reconstruction for
    advantages and disadvantages of, 2744t
    atypical, 2747-2748, 2749f-2750f
    autogenous costochondral, 2744, 2744t
    classic, 2744-2747
      cartilage implantation in, 2744-2746
      carving of framework and helix in, 2746, 2746f
      construction of implant in, 2746, 2746f
      creation of postauricular sulcus in, 2746, 2748f
      donor site in, 2745, 2745f
      incision in, 2745-2746
      lobule transfer in, 2746, 2747f
      placement of implant in, 2746, 2747f
      templates in, 2744-2745, 2745f
      tragus reconstruction in, 2747, 2748f
    complications of, 2748-2751
    planning for, 2743-2744, 2744t
  treatment options for, 2744t
  type I, 2742, 2742f
Microtia *(Continued)*
  type II, 2742, 2743f
  type III, 2742, 2743f
Microvarices, of larynx, 817
Microvascular decompression, facial nerve monitoring with, 2548-2549, 2549f
Microvascular reconstruction, total glossectomy with, 1390
Microvillar cells, of olfactory epithelium, 626, 627f
Microwaves, effect on hearing of, 2149
Midazolam
  for adenotonsillectomy, 2797
  as adjunct to induction of anesthesia, 111
  for premedication in children, 2589
    with congenital heart disease, 2596
Middle cerebral artery, 2351f
Middle cervical sympathetic ganglion, in root of neck, 2582
Middle constrictor muscle, 1296f
Middle cranial base
  anatomy of, 1699
  central and lateral compartments of, 2454-2455, 2455f
  surgical anatomy of, 2444

  mucociliary clearance and drainage of, 1871
  protection of, 1871-1872
  salivary gland choristoma of, 2200-2201
  sound transfer in, 2017-2019
Middle ear aeration, in sound transmission, 2000
Middle ear atelectasis, 1964, 1964f-1965f
  tympanoplasty with, 2003-2004
Middle ear cavity, 1825-1826
Middle ear effusion (MEE)
  collection vehicle for aspiration of, 2773-2774, 2774f
  and hearing loss in infants, 2722
  otitis media with (*See* Otitis media with effusion (OME))
Middle ear function, tests to evaluate, 1890-1891, 1890f
Middle ear implants, 2207-2212
  basic design features of, 2207-2208
    ossicular coupling as, 2207-2208
    transducer design as, 2207
  electromagnetic, 2208-2211
    Carina as, 2210-2211
      clinical results with, 2210-2211
      components of, 2210, 2210f
      history of, 2210
      placement of, 2210, 2211f
    Middle Ear Transducer (MET) as, 2027, 2210-2211
      clinical results with, 2210-2211
      comparison of features of, 2206t
      components of, 2210
      history of, 2210

Middle ear implants *(Continued)*
indications for, 2210, 2211f
placement of, 2210, 2211f
ossicular coupling in, 2207-2208
sound transduction and coupling to auditory system with, 2205f
transducer design for, 2207
Vibrant Soundbridge as, 2208-2210
clinical data on, 2209
comparison of features of, 2206t
components of, 2208-2209, 2208f
for conductive and mixed hearing loss, 2210
history of, 2208, 2210
implantation of, 2209
indications for, 2209, 2209f
location of, 2204f
piezoelectric, 2211-2212
Esteem-Hearing Implant as, 2211-2212, 2212f
ossicular coupling in, 2207-2208
sound transduction and coupling to auditory system with, 2205f
transducer design for, 2207
total *vs.* partial, 2208
Middle ear muscle reflex pathways, in efferent auditory system, 1847, 1848f
Middle ear pressure changes, eye movements evoked by, 2316, 2316f
Middle ear sources, of otorrhea, 2195-2196, 2195b
Middle Ear Transducer (MET), 2027, 2210-2211
clinical results with, 2210-2211
comparison of features of, 2206t
components of, 2210
history of, 2210
indications for, 2210, 2211f
placement of, 2210, 2211f
Middle Eastern patient, hump reduction in, 570-573
concept of, 570-571
results of, 574f-575f
technique for, 571-573, 575f
Middle fossa approach
for middle cranial base surgery, 2467
for posterior fossa neoplasms, 2532t, 2534-2536
advantages and disadvantages of, 2532t, 2536
basic features of, 2534
extended, 2532t, 2538
advantages and disadvantages of, 2532t, 2538
basic features of, 2538
indications for, 2532t, 2538
surgical exposure in, 2538f
technique of, 2538
indications for, 2532t, 2534-2535
surgical exposure in, 2535f
technique of, 2535-2536, 2535f
Middle fossa craniotomy, for facial nerve decompression, 2042-2043
Middle jugular lymph nodes, in neck dissection, 1704, 1704f, 1706t-1708t
Middle latency response (MLR)
auditory evoked, 1912, 1913f
electrically evoked, 1912-1914
Middle meningeal artery
groove for, 1822f
in surgical anatomy of lateral skull base, 2437f, 2438, 2440f
Middle meningeal artery sulcus, in surgical anatomy of lateral skull base, 2436f
Middle nasal meatus
normal anatomy of, 664-665, 665f-667f
in surgical anatomy of anterior cranial base, 2472, 2472f
Middle skull base. *See* Middle cranial base.
Middle temporal artery, sulcus for, 2010f
Middle turbinate
in endoscopic sinus surgery, 751, 751f, 771
normal anatomy of, 667
paradoxic, 668, 669f
surgical anatomy of, 739-740
in anterior cranial base, 2472, 2472f-2473f
Middle vault deformities, revision rhinoplasty for, 585-586, 586f
Midesophageal diverticula, 974, 974f
imaging of, 1402, 1403f
Midface
aesthetic ideals for, 447
aging of, 444, 444f
congenital malformations of nose due to developmental errors of, 2690-2693, 2691f
in Down syndrome, 2632
Midface fractures, pediatric, 2707, 2710f
Midface lift, 2431
Midface soft tissue laxity and sagging, after facial paralysis, 2431
Midfacial clefting, 2690, 2692
Midfacial degloving approach
for middle cranial base surgery, 2455t, 2458, 2459f
for pediatric facial fracture, 2701-2702
Midfacial split approach, for middle cranial base surgery, 2455t, 2458-2461, 2463f
Midforehead brow lift, 430, 431t
Midforehead flap, 344-345
Midforehead lift, 430, 431t
Midline cleft, 2586
Midline lesions, of neck, 2586
Midline malignant reticulosis, 659-660
Migraine, 246-247, 2347-2350
auditory symptoms of, 2348-2349
distortion as, 2349
hearing loss as, 2123, 2348-2349
phonophobia as, 2349
tinnitus as, 2349
without aura, 2347b
aura with, 2347, 2347b
basilar, 2349
diagnosis and classification of, 2347, 2347b
epidemiology of, 2347
etiology of, 2349
familial hemiplegic, 2349
familial vestibulopathy with, 2344
family history of, 2349
without headache, 2349
management of, 2349-2350, 2350f
with neurotologic symptoms, 2349
vestibular disorders associated with, 2350
benign paroxysmal positional vertigo as, 2350
Meniere's disease as, 2350
vestibular disorders related to, 2350-2351
benign paroxysmal vertigo of childhood as, 2350-2351
paroxysmal torticollis as, 2351
vestibular symptoms of, 2347-2348
motion sickness as, 2348
nonspecific dizziness as, 2347
vertigo as, 2202, 2347-2348, 2348f
Migraine accompaniments, 2349
Migraine equivalent, 2349
MII (multichannel intraluminal impedance), 962
Milia, 289
after skin resurfacing, 451
Millard forked-flap technique, in cleft-lip nose repair, 559, 566f
Millard rotation advancement closure, for cleft lip, 2667-2668, 2667f
advancement flap in, 2668, 2668f
closure in, 2668, 2668f
rotation flap in, 2667-2668, 2668f
Millicurie (mCi), 1031-1032
Mineral oil, for cerumen removal, 1958t
Mini Rhinoconjunctivitis QoL Questionnaire, 57
Minimal cross-sectional area (MCA), in rhinomanometry and acoustic rhinometry, 643f, 644
anatomic, 644
physiologic, 644
Minimally invasive sinus technique (MIST), 743, 752, 760
Minimally invasive techniques, for parathyroid surgery, 1793
Minimally invasive thyroidectomy, 1769, 1769f
Mini-mantle field technique, for glottic cancer, 1586
Minimum Speech Test Battery for Adult Cochlear Implant Users (MSTB), 2223, 2244
Miniplate, for mandibular fracture, 338
MinK, in deafness, 2051t-2058t
Minoxidil, for hair loss, 376-377
MIO (maximum interincisal opening), 1280
miR(s) (microRNAs), in head and neck squamous cell carcinoma, 1021, 1022f, 1027-1028
miRNAs (microRNAs), in head and neck squamous cell carcinoma, 1021, 1022f, 1027-1028
MirrorSuite, 279-280
MIST (minimally invasive sinus technique), 743, 752, 760
MIT (monoiodotyrosine)
in thyroid hormone release, 1738
in thyroid hormone synthesis, 1738
MITF (microphthalmia transcription factor) gene, in deafness, 2051t-2058t, 2095
Mitochondrial disorders, 8, 8f, 2088f, 2089
Mitochondrial DNA (mtDNA), 2089
Mitochondrial encephalopathy, lactic acidosis, and strokelike episodes (MELAS) syndrome, sensorineural hearing loss in, 2094t, 2097
Mitochondrial mutations, in head and neck squamous cell carcinoma, 1024-1025, 1028f
Mitochondrial sensorineural hearing loss
nonsyndromic, 2093, 2093t
screening for, 2090t
syndromic, 2094t, 2097
Mitogen-activated protein kinase (MAPK) pathway, in thyroid carcinoma, 1753
Mitomycin C
for airway stenosis, 946, 2918
for caustic ingestion, 2960
with radiotherapy, 1041
Mitotic death, due to radiation, 1037
Mitral cell, of olfactory bulb, 628f
Mivacurium, for pediatric anesthesia, 2593t
Mixed acinus, 1134, 1134t
Mixed apnea index, 251b
Mixed sleep apnea, 251b
MLC (multileaf collimator), in radiotherapy, 1035-1036
MLR (middle latency response)
auditory evoked, 1912, 1913f
electrically evoked, 1912-1914
MM (malignant melanoma). *See* Melanoma.
MMA (maxillomandibular advancement), for obstructive sleep apnea, 260, 261f
MMF. *See* Maxillomandibular fixation (MMF).
MMP. *See* Mucous membrane pemphigoid (MMP).
MMP(s) (matrix metalloproteinases)
in bone resorption, 1972
in head and neck squamous cell carcinoma, 1019-1020
MMP-1 (matrix metalloproteinase-1), in head and neck squamous cell carcinoma, 1077
MMR (mediastinal mass ratio), for lymphomas, 1676
MNTB (medial nucleus of trapezoid body), in auditory pathway, 1834f
Möbius syndrome, facial paralysis in, 2397
MOC (maintenance of certification), 80, 81b
MOC (medial olivocochlear) reflex pathways, in efferent auditory system, 1848-1849, 1848f

MOC (medial olivocochlear) "unmasking," 1849
Modafinil, for obstructive sleep apnea, 257
Modal register, of voice production, 850-851
Mode, 64t
Mode-locked lasers, 34
Modified barium swallow (MBS), 1394, 1396
  for swallowing disorders, 1217-1218, 1219f
    in children, 2949, 2950t
Modified radical neck dissection (MRND), 1711-1712
  definition of, 1703t, 1711, 1712f
  historical perspective on, 1703
  indications for, 1711
  for oral cancer, 1313
  results of, 1721
  technique for, 1711-1712, 1713f-1714f
Modified Schobinger incision, for radical neck dissection, 1709, 1710f
Modified voice use, for vocal abuse, 853
Modiolus, anatomy of, 1831, 1832f, 1834, 1840, 1841f, 2049-2050
MOE. *See* Malignant otitis externa (MOE).
Mohr-Tranebjaerg syndrome, deafness in, 2051t-2058t, 2094t, 2097
Mole(s), 286
  atypical, 1107
Molecular biology, 11-12
  cell division in, 12, 13f
  gene expression in, 11-12, 12f
  of laryngeal cancer, 1492
Molecular biomarkers
  for head and neck squamous cell carcinoma, 1026-1027
    epidermal growth factor receptor as, 1026
    human papillomavirus as, 1026
    loss of heterozygosity as, 1026
    margin analysis for, 1027
    in oral rinses and saliva, 1026
    other, 1026-1027
    polymorphisms in DNA repair enzymes as, 1027
    serum analysis for, 1026-1027
  for laryngeal squamous cell carcinoma, 1493, 1505
  for salivary gland neoplasms, 1194
Molecular genetics, of orofacial clefts, 2662-2664
Molecular staging, of melanoma, 1118
Molluscum contagiosum, 282-283, 283f
Mometasone, for otitis media with effusion, 2772
Mometasone furoate nasal spray (Nasonex)
  for nonallergic rhinitis, 700t
  for rhinosinusitis, 734t, 736
"Mona Lisa" smile, 2417-2418
Mondini, Carlo, 2728-2729
Mondini malformation, 172-173, 174f
  congenital hearing loss due to, 2200
  CSF otorrhea due to, 2197
Mondini's dysplasia, 2730-2731
  embryogenesis of, 2728f-2729f, 2729t, 2730-2731
  familial, 2735
  histology of, 2730-2731, 2731f
  historical background of, 2728-2729
  imaging of, 2730-2731, 2731f
  relative incidence of, 2729t
  subtypes of, 2730-2731, 2731f
Monistat (miconazole cream), for fungal otitis externa, 1954-1955, 1959t-1960t
Monobloc advancement, for craniofacial anomalies, 2653-2654, 2655f-2656f
Monocyte(s)
  in adaptive immune system, 604
  in allergic rhinitis, 616
  in wound healing, 1076
Monocyte chemoattractant protein-1 (MCP-1), in wound healing, 1076
Monoiodotyrosine (MIT)
  in thyroid hormone release, 1738
  in thyroid hormone synthesis, 1738
Mononucleosis, infectious
  adenotonsillar disease in, 2785-2786, 2786f
  pharyngitis due to, 198-199, 198f
  sudden sensorineural hearing loss due to, 2127
  vestibular neuritis due to, 2162
Monosodium glutamate (MSG), taste of, 1213
Monostotic fibrous dysplasia, of paranasal sinuses, 1132
Montelukast
  for allergic rhinitis, 620-621
  for rhinosinusitis, 735t, 736
Montgomery T-tube, 1009
Moraxella catarrhalis
  otitis media due to, 2763
  rhinosinusitis due to
    acute, 704, 704f, 732
    acute exacerbation of chronic, 707
Moraxella catarrhalis vaccine, to prevent otitis media, 2769
Morphine
  as adjunct to induction of anesthesia, 111
  for pediatric anesthesia maintenance, 2591-2592
  for postoperative pain, 241t
  topical, for mucositis, 1102
Morquio's syndrome, 2113
Morsicatio, 1223
Mosaicism, 5
Motion artifacts, on MRI, 133-134, 134f
Motion sickness, 2357
  and migraine, 2348
Motor control test, 2324-2325
Motor evoked potentials (MEPs), transcranial electrical stimulation–induced, to assess facial nerve function, 2389
Motor function, oral, 1203-1207
  autonomic reflexes in, 1205-1206
  jaw-tongue reflexes in, 1205
  lingual muscles and reflexes in, 1205
  mastication as, 1206-1207, 1206f
  muscles of mastication and reflex control in, 1204-1205, 1204f-1205f
  oral phase of deglutition as, 1206f, 1207
Motor nerve complications, of neck surgery, 1729-1731
  facial, 1729-1730
  hypoglossal, 1730-1731
  phrenic, 1731, 1731f
  spinal accessory, 1730, 1731f
  vagus, 1730
Motor vehicle collisions
  laryngeal trauma due to, 2914
  pediatric facial fractures due to, 2698
Mouth. *See* Oral cavity.
Mouth breathing, 809, 2628-2629
  and craniofacial growth, 2792-2793
Movement disorders, sleep-related, 265, 265b
MPD syndrome. *See* Myofascial pain dysfunction (MPD) syndrome.
MPFR (maximum phonational frequency range), 829
M-plasty, for forehead defects, 359-360, 362f
MPNST (malignant peripheral nerve sheath tumor), of neck, 1670-1671
MPS. *See* Mucopolysaccharidoses (MPS).
MPT (maximum phonation time)
  in tracheoesophageal speech, 1597
  in voice evaluation, 828, 849
MPZ (myelin protein zero) gene, in deafness, 2051t-2058t, 2081
MR (magnetic resonance) cisternography, for CSF rhinorrhea, 790-791, 790f
MR (magnetic resonance) sialography, 1147
MR (magnetic resonance) spectroscopy, of laryngeal carcinoma, 1470
MRA. *See* Magnetic resonance angiography (MRA).
MRD (margin-reflex-distance), 446
MRI. *See* Magnetic resonance imaging (MRI).
MRND. *See* Modified radical neck dissection (MRND).
MRP. *See* Mandibular reconstruction plate (MRP).
MRSA (methicillin-resistant *Streptococcus aureus*), rhinosinusitis due to
  acute, 704, 732
  chronic, 732, 733f
MS. *See* Masticator space (MS); Multiple sclerosis (MS).
MSG (monosodium glutamate), taste of, 1213
MSLT (multiple sleep latency test), 263-264
MSO (medial superior olive), in auditory pathway, 1834-1835, 1834f, 1846
MST (maximal stimulation test)
  for Bell's palsy, 2394
  for facial nerve injury, 2040-2041, 2382t, 2385-2386
MSTB (Minimum Speech Test Battery for Adult Cochlear Implant Users), 2223, 2244
M&T (myringotomy with tympanostomy tube insertion)
  for acute otitis media, 2771
  for otitis media with effusion, 2772
MTC. *See* Medullary thyroid carcinoma (MTC).
mtDNA (mitochondrial DNA), 2089
m-tetra(hydroxyphenyl)chlorin (Foscan), for recurrent respiratory papillomatosis, 2892
MTRNR1, 2093t
MTTS1, 2093t
MUC5AC gene, in otitis media, 1871
Mucins, in saliva, 1140-1141
Mucoceles, 289
  in children, 2859
  endoscopic sinus surgery for, 742, 760f, 761, 762f
  frontoethmoid, 776f-777f, 783
  imaging of, 169, 169f, 676, 678f, 765t
  of petrous apex, 2524t, 2525, 2527f
  surgical management of, 742
Mucociliary diseases, nasal manifestations of, 661
  in cystic fibrosis, 661
  in primary ciliary dyskinesia, 661
Mucocutaneous end organs, 1201
Mucocutaneous junction, in cleft lip, 2665
Mucocutaneous lymph node syndrome, in children, 2819
Mucoepidermoid carcinoma (MEC)
  of larynx, 1506-1507
  of salivary glands
    in children, 2820, 2846, 2846f, 2862-2863
    differential diagnosis of, 1183
    grading of, 1183, 1184t
    histopathology of, 1182-1183, 1183f
    imaging of, 1146, 1147f, 1168f
    minor, 1363
  of trachea, 1615
Mucoepithelial changes, with aging, 234
Mucolytic agents
  for rhinosinusitis, 735t, 736
  for vocal professionals, 855
Mucoperichondrium, in rhinoplasty, 539-540, 546
Mucopolysaccharidoses (MPS), 2112-2113
  craniofacial anomalies due to, 2640
  and obstructive sleep apnea, 2606
  otologic manifestations of, 2113, 2113f
Mucormycosis
  otologic manifestation of, 2106f
  rhinosinusitis due to, 705, 710, 711f
Mucosa, effects of radiotherapy on, 2626t
Mucosa-associated lymphoid tissue (MALT)
  in eustachian tube, 1870
  in middle ear protection, 1871

Mucosa-associated lymphoid tissue (MALT) lymphoma, 1679-1680
clinical presentation of, 1674
of salivary glands, 1191-1192, 1192f, 1679-1680
treatment and prognosis for, 1680
of thyroid, 1679
staging of, 1679
treatment and prognosis for, 1679
Mucosal changes, in geriatric patients, 236
Mucosal edema, olfactory dysfunction due to, 625, 635f
Mucosal grafts, for airway stenosis, 946-947
Mucosal immune system, 605
Peyer's patches and lymphoid follicles in, 605
tonsils in, 605
Mucosal lesions, oral. *See* Oral mucosal lesions.
Mucosal melanocytic nevi, of oral cavity
clinical features of, 1241
histopathologic features of, 1242
treatment of, 1243
Mucosal melanoma, 1108-1109
of larynx, 1509
of oropharynx, 1364-1365, 1364f-1365f
Mucosal ulcerations, of oral cavity, 1289, 1289f
Mucosal wave, laryngeal videostroboscopy of, 820, 848-849, 848t
Mucosal-relief esophagogram, 1394, 1395f
Mucositis
palliative care for, 1101-1102
due to radiotherapy, 1047, 1047f, 1102
Mucotrol, for mucositis, 1102
Mucous acinus, 1134, 1134f, 1134t
Mucous cysts, 289
Mucous membrane pemphigoid (MMP)
esophageal manifestations of, 980
nasal manifestations of, 660
ocular scarring (symblepharon) due to, 1233-1234, 1234f
oral, 1233-1235, 1254
clinical differential diagnosis of, 1234, 1234t
clinical features of, 1233-1234, 1233f-1234f
defined, 1233
etiology and pathogenesis of, 1233
histopathologic features of, 1234-1235, 1234f
treatment of, 1235
Mucous retention cysts, 289
in children, 2859
imaging of, 676, 677f
of larynx, 869, 869f-870f
of petrous apex, 2525, 2526f
Muenke syndrome, deafness in, 2051t-2058t
Muenke-type craniosynostosis, 2641t
Müller maneuver, in obstructive sleep apnea, 253, 254f
Müller's muscle
anatomy of, 443f, 444
in upper eyelid blepharoplasty, 448, 449f
Multicellular theory, of salivary gland tumorigenesis, 1163
Multichannel intraluminal impedance (MII), 962
Multifactorial traits, 8
MULTIFIRE ENDO GIA 30 stapler, 993-994
Multileaf collimator (MLC), in radiotherapy, 1035-1036
Multinodular thyroid gland, ultrasound imaging of, 1644
Multiple endocrine adenomatosis type 3, oral manifestations of, 1257
Multiple endocrine neoplasia type I (MEN-I)
defined, 1795
epidemiology of, 1795
familial hyperparathyroidism in, 1795-1796
genetic basis for, 1775, 1776f, 1795
Multiple endocrine neoplasia type IIA (MEN-IIA)
defined, 1773
familial hyperparathyroidism in, 1796
genetic basis for, 1796
and medullary thyroid carcinoma, 1763-1764
Multiple endocrine neoplasia type IIB (MEN-IIB), and medullary thyroid carcinoma, 1763-1764
Multiple myeloma, 2106-2107
otologic manifestations of, 2107, 2107f
Multiple sclerosis (MS)
laryngeal hypofunction due to, 843
oral manifestations of, 1255
preoperative evaluation of, 106
sensorineural hearing loss due to, 2122-2123
sudden, 2129
vertigo due to, 2202
vestibular symptoms of, 2356, 2356f
Multiple sleep latency test (MSLT), 263-264
Multiple system atrophy, laryngeal hypofunction due to, 843
Multiple-Activity Scale for Hyperacusis (MASH), 2138-2139
Multivariate analysis, 72
Mumps
salivary gland involvement in, 1156-1157
in children, 2855
sensorineural hearing loss due to, 2119, 2157-2158, 2158f
clinical features of, 2157
diagnosis of, 2157
experimental, 2158
sudden, 2127
temporal bone pathology in, 2158, 2158f
vestibular neuritis due to, 2162
Mumps vaccine, for recurrent respiratory papillomatosis, 2890t, 2892-2893
Mupirocin, for rhinosinusitis, 734, 735t
Murine removal kit (carbamide peroxide), for cerumen removal, 1958t
Muscarinic receptors, in salivary gland secretion, 1136-1137
Muscle fibers, characteristics of, 918
Muscle flaps, for free tissue transfer, 1082t, 1083-1084
latissimus, 1082t, 1083-1084, 1084f
rectus abdominis, 1082t, 1083
Muscle neoplasms, of larynx, 881
Muscle relaxants
oral sequelae of, 1247t-1248t
for pediatric anesthesia, 2592, 2593t
Muscle tension dysphonia, 842, 853
Muscle transfers, for facial nerve paralysis, 2427-2430
masseter, 2427, 2428f
microneurovascular, 2429-2430
temporalis, 2427-2429, 2429f
Muscle weakness, due to hyperparathyroidism, 1781
Muscular disorders, chronic aspiration due to, 926b
Muscular dystrophy(ies)
laryngeal hypofunction due to, 842
myotonic, oral manifestations of, 1255
Muscular tension dysphonia, 842, 853
Muscular triangle, of neck, 96, 96f, 2578f
Muscularis uvulae
in cleft palate, 2666-2667
in velopharyngeal function, 2676, 2677t
Musculocutaneous arteries, 1065, 1065f
Musculocutaneous flaps, 1067, 1067f
for free tissue transfer, 1082t, 1083-1084
latissimus, 1082t, 1083-1084, 1084f
for oropharyngeal reconstruction, 1380
for oropharyngeal reconstruction, 1380
rectus abdominis, 1082t, 1083
for oropharyngeal reconstruction, 1380
Musculoskeletal tension, in voice evaluation, 827-831, 828f
Mustache transplantation, 384
Mustarde suture technique, for otoplasty, 475-478, 476f-477f
Mutation testing, 9, 9f-10f
MV (megavoltage) electrons, 1033
MV (megavoltage) x-rays, 1033-1034
MVN (medial vestibular nucleus), 1861, 1862f
in velocity storage, 2296
M-wave, 2388
MX350-1, for head and neck squamous cell carcinoma, 1018
Myasthenia gravis
abnormal pharyngeal motility due to, 1398
edrophonium test for, 835
laryngeal hypofunction due to, 842
oral manifestations of, 1255
Mycelex (clotrimazole) cream, for fungal otitis externa, 1954-1955, 1959t-1960t
Mycobacterial infection
lymphadenopathy due to, 2818, 2819f
of salivary glands
in children, 2857-2858, 2857f
nontuberculous, 1158-1159, 1158f
tuberculous, 1158
Mycobacterial laryngitis, 885-886, 886f
Mycobacterial mastoiditis, 2196
Mycobacterium tuberculosis. *See* Tuberculosis (TB).
Mycophenolate mofetil, microtia due to, 2741
Mycoplasma pneumoniae, pharyngitis due to, 194-195
Mycoplasma spp, bullous myringitis due to, 1948
Mycostatin (nystatin cream), for fungal otitis externa, 1954-1955, 1959t-1960t
Mycotic diseases. *See* Fungal diseases.
Myectomy, selective, for synkinesis, 2432
Myelin protein zero *(MPZ)* gene, in deafness, 2051t-2058t, 2081
Myeloid stem cells, 600, 600f
Myeloma, multiple, 2106-2107
otologic manifestations of, 2107, 2107f
Myelopathy, due to radiotherapy, 1049
Myenteric plexus, 953, 954f
Myers-Cotton classification, of airway stenosis, 944, 944t
MYH9 (myosin heavy chain IX) gene, in deafness, 2051t-2058t
MYH14 (myosin heavy chain XIV) gene, in deafness, 2051t-2058t
Mylohyoid muscle, anatomy of, 1296f-1297f, 1297-1298, 1320, 2578f
MYO. *See* Myosin.
Myocardium, of newborn, 2571
Myoclonic epilepsy and red ragged fibers (MERRF) syndrome, sensorineural hearing loss in, 2094t, 2097
Myoclonus, oculopalatolaryngopharyngeal, 840
Myocutaneous flaps, 1067, 1067f
for free tissue transfer, 1082t, 1083-1084
latissimus, 1082t, 1083-1084, 1084f
for oropharyngeal reconstruction, 1380
for oropharyngeal reconstruction, 1380
rectus abdominis, 1082t, 1083
for oropharyngeal reconstruction, 1380
for hypopharyngeal and esophageal reconstruction, 1452-1453
Myoepithelial carcinoma, of salivary glands, 1191
Myoepithelial cells, of salivary glands, 1134, 1134f, 1163f
Myoepithelioma, of salivary glands, 1171
Myofascial pain dysfunction (MPD) syndrome, of temporomandibular joint, 1283-1285
clinical features of, 1283-1284
defined, 1283
differential diagnosis of, 1284t-1285t
epidemiology of, 1283
etiology of, 1283, 1283f
treatment of, 1284-1285, 1286f
Myopathies, laryngeal hypofunction due to, 842
Myosin(s), in stereocilia, 2076f
Myosin 1A *(MYO1A)* gene, in deafness, 2051t-2058t
Myosin 1c, in adaptation of mechanoelectrical transduction currents, 2079, 2079f

Myosin heavy chain (MHC) isoforms
in lingual muscles, 1205
in muscles of mastication, 1204
Myosin heavy chain IX *(MYH9)* gene, in deafness, 2051t-2058t
Myosin heavy chain XIV *(MYH14)* gene, in deafness, 2051t-2058t
Myosin IIIA, in stereocilia, 2077
Myosin IIIA *(MYO3A)* gene, in deafness, 2051t-2058t
Myosin VI, in stereocilia, 2078
Myosin VI *(MYO6)* gene, in deafness, 2051t-2058t, 2078
Myosin VIIA *(MYO7A)* gene, in deafness, 2051t-2058t, 2077-2078, 2096
Myosin XVA, in hair bundle development, 2077
Myosin XVA *(MYO15A)* gene, in deafness, 2051t-2058t, 2076
Myositis, *vs.* myofascial pain dysfunction syndrome, 1285t
Myositis ossificans, *vs.* myofascial pain dysfunction syndrome, 1285t
Myotomy, surgical, for achalasia, 964-965
Myotonic muscular dystrophy, oral manifestations of, 1255
Myringitis
bullous, 1948, 1948f
defined, 1955
granular, 1955
otorrhea due to, 2196
topical therapies for, 1955
Myringotomy
for acute otitis media, 2771
with tympanostomy tube insertion, 2771
for eustachian tube dysfunction, 1874
for otitis media with effusion, 2772
with tympanostomy tube insertion, 2772
Myringotomy with tympanostomy tube insertion (M&T)
for acute otitis media, 2771
for otitis media with effusion, 2772
Myxedema, pretibial, and Graves' ophthalmopathy, 1808
Myxedema coma, 1749
Myxoma, odontogenic, 1276-1277, 1276f
microscopic findings in, 1276
radiographic findings in, 1276
treatment and prognosis for, 1276-1277, 1277f

N

N (nodal) classification, for melanoma, 1111-1113, 1111t
*N*6-furfuryladenine (Kinerase), for aging skin, 404
Na^+. *See* Sodium (Na^+).
NaCl (sodium chloride), gustatory response to, 1208-1209
NADP-regulated thyroid hormone–binding protein, in deafness, 2051t-2058t
NA-EFRS (nonallergic eosinophilic fungal rhinosinusitis), 709, 715-716, 716t
Na^+,K^+ (sodium-potassium) pump, ATPase-driven, in salivary gland secretion, 1135
NAP-2 (neutrophil-activating peptide-2), in wound healing, 1076
Napoleon I, 251
NAR. *See* Nonallergic rhinitis (NAR).
Narcolepsy, 262t, 264
Narcotic analgesics. *See* Opioids.
NARES (nonallergic rhinitis with eosinophilia syndrome), 619b, 696
Narrow-band imaging (NBI), of larynx, 813, 823-824, 823f-824f
Nasacort (triamcinolone), for nonallergic rhinitis, 700t
Nasal airflow, 485-487
during exercise, 641
peak, 643
physical factors affecting, 643
in rhinomanometry
measurement of, 647
and transnasal pressure, 643
with rhinosinusitis, 730
and transnasal pressure, 643
Nasal allergy, and otitis media, 1872
Nasal base sculpting, for noncaucasian nose, 556-557, 559f-560f
Nasal block, 501-502
Nasal bones, anatomy and physiology of, 320
Nasal breathing function, 640-642
anatomy of, 641-642
septum and turbinates in, 641
nasal valve in, 641, 641f
site of sensation of obstruction in, 641-642
assessment of, 642-644
acoustic rhinometry for, 643-645
in allergic rhinitis, 651
to assess effect of treatment, 651-652
equipment for, 486-487, 486f, 644
interpretation of results of, 645
intranasal dimensions and cross-sectional area in, 643, 643f
intranasal sites assessed by, 644
reporting results of, 645
rhinogram generated by, 486-487, 487f, 645
vs. rhinomanometry, 644
for snoring and sleep apnea, 651
sources of variability in, 651
technical concerns and testing pitfalls with, 645
technique of, 644-645
nasal examination in, 642
objective testing of nasal airway in, 642-644
air stream through nose in, 643
to assess effects of treatment, 651-652
for challenge testing in allergic rhinitis, 651
in clinical evaluation of patient with nasal obstruction, 652-656
complementary information in, 656
correlation between results and symptoms with, 654
criteria for, 642
history of, 642
in identifying site of pathology affecting airflow, 655-656
intranasal dimensions and cross-sectional area in, 643, 643f
laser Doppler velocimetry for, 643-644
for normal nasal airway, 652t-653t, 654f
other methods of, 643-644
role of, 651-652
for snoring and sleep apnea, 651
sources of variability in, 651
and threshold level at which patient feels airway restriction, 655
when results do not match physical findings or symptoms, 653-654
when symptoms are not due to airway restriction, 653
patient history in, 642
rhinomanometry for, 643-651
vs. acoustic rhinometry, 644
active *vs.* passive, 647-648
in allergic rhinitis, 651
anterior *vs.* posterior, 645-647, 648f-649f
to assess effect of treatment, 651-652
for children, 645
defined, 642
equipment for, 645
examining pressure-flow curve in, 648-649, 649f-650f
inspiratory or expiratory values in, 650-651
Nasal breathing function *(Continued)*
intranasal sites assessed by, 644
maximum (vertex) resistance in, 650
measurement of nasal airflow in, 647
measurement of transnasal pressure in, 645-647, 648f
nasal airflow and transnasal pressure in, 643
nasal resistance in, 649-650, 650f
parameters in, 649-651, 650f
reporting results of, 648-651
sources of variability in, 651
technical concerns and testing pitfalls with, 645-648
technique of, 645, 645f-648f
unilateral *vs.* bilateral measurements in, 648, 649f
pathologic conditions affecting, 642
physiologic factors affecting, 640-641
Nasal bridge length, 2617t
Nasal cartilage, burns of, 316
Nasal cavity
bony outlines of, 672, 672f
imaging of, 169, 170f
lymphoma of, 1680
therapy and prognosis for, 1680
in surgical anatomy of anterior cranial base, 2443, 2471-2473, 2472f-2473f
Nasal challenge testing, objective measurement methods in, 651
Nasal clefts, 2690, 2692
Nasal cycle, 486, 641
MRI of, 664, 664f
Nasal defects, 346-350, 364-372
aesthetic units and, 346-347, 347f, 364
approach to, 346-347
extending into alar facial sulcus, 348
cheek advancement flap for, 348, 349f
cheek pedicle transposition flap for, 348, 349f
full-thickness alar, 347, 371-372
bipedicle mucosal advancement flap for, 347, 347f
free cartilage grafts for, 348
melolabial interpolated flap for, 348
full-thickness central defects of tip or dorsum as, 348
composite turnout flap for, 348, 351f
paramedian forehead flaps for, 348-350, 352f-354f
involving skeletal supporting structures, 367-371
grafting material for
alloplastic, 368
autogenous cartilage as, 368-369, 369f-370f
bone as, 369, 370f
homograft tissues as, 368
selection of, 367-368
prosthetic management of, 1345, 1345t, 1346f
reconstruction of, 364-372
external covering layer in, 364-367
framework in, 367-371
internal lining in, 371-372
surface defects of nasal tip, columella, sidewalls, and dorsum as, 348, 364-367
bilobed flaps for, 365-366, 365f
complications of local flaps for, 366
dorsonasal (Rieger) flap for, 365-366
forehead flap for, 366-367, 368f
full-thickness skin grafts for, 365
glabellar flaps for, 365-366
healing by second intention for, 365
hinge flap for, 348, 350f
melolabial flap for, 366, 367f
paramedian forehead flaps for, 348
primary closure for, 365, 365f
retroauricular flap for, 365-366
transposition flaps for, 365-366, 366f
vestibular lining reconstruction for, 371-372, 371f-372f
V-Y advancement flap for, 345-346, 346f

Nasal depth, anterior and posterior, 2617t
Nasal dilator strips, for obstructive sleep apnea, 257
Nasal dorsum
  cartilaginous, 509f
  full-thickness central defects of, 348
    composite turnout flap for, 348, 351f
    paramedian forehead flaps for, 348-350, 352f-354f
  growth and development of, 2617t
  reconstruction of, 371
  surface defects of, 348
    hinge flap for, 348, 350f
    paramedian forehead flaps for, 348
Nasal endoscopy, 100
  for CSF rhinorrhea, 791
  in endoscopic sinus surgery, 746, 763
Nasal Endoscopy Simulator, 49
Nasal examination
  in assessment of nasal breathing function, 642
  for professional voice disorders, 851
Nasal fracture(s), 496-507
  acute intervention for, 500
  algorithm for management of, 501, 502f
  cantilever bone graft for, 505, 505f
  classification of, 498-499, 498f-499f
  complications of, 507
  diagnostic assessment of, 499-500
    history in, 499
    physical examination in, 499-500
    radiography in, 325, 500
  external compression plating for, 506
  external nasal splinting for, 504
  injuries associated with, 498

for oral cavity cancer, 1312-1314, 1313f, 1713-1716
definition and rationale for, 1713, 1714f
technique for, 1713-1716, 1715f-1716f
for oropharyngeal cancer, 1716-1718
definition and rationale for, 1716-1717, 1717f
technique for, 1717-1718, 1717f
posterolateral, 1718-1719
after radiation therapy, 1694, 1721
radical, 1705-1709
anterior triangle dissection in, 1709-1710
defined, 1703t, 1705, 1709f
dissection of upper neck compartments in, 1710-1711
flap elevation in, 1709, 1711f
historical perspective on, 1702-1703
incision planning for, 1709, 1710f
indications for, 1705
modified, 1711-1712
definition of, 1703t, 1711, 1712f
historical perspective on, 1703
indications for, 1711
results of, 1721
technique for, 1711-1712, 1713f-1714f
nodular masses at site of, 1476
for oral cancer, 1313
positioning for, 1709
posterior triangle dissection in, 1709
results of, 1721
results of, 1721-1722
for salivary gland tumors, 1196-1197
selective, 1712-1713
for cancer of midline structures of anterior lower neck, 1719
definition and rationale for, 1719, 1719f
technique for, 1719, 1720f
for cutaneous malignancies, 1718-1719
definition and rationale for, 1718, 1718f
technique for, 1718-1719
definition of, 1703t, 1712
historical perspective on, 1703
for oral cavity cancer, 1313, 1713-1716
definition and rationale for, 1713, 1714f
technique for, 1713-1716, 1715f-1716f
for oropharyngeal, hypopharyngeal, and laryngeal cancer, 1716-1718
definition and rationale for, 1716-1717, 1717f
technique for, 1717-1718, 1717f
rationale for, 1712-1713
results of, 1721
for thyroid cancer, 1719, 1719f-1720f
sequelae of, 1722
supraomohyoid, 1313-1314, 1703
for oral cancer, 1313-1314, 1713
definition and rationale for, 1713, 1714f
technique for, 1713-1716, 1715f-1716f
Neck dissection *(Continued)*
terminology of, 1703, 1703t
therapeutic, 1702
Neck injury. *See* Neck trauma.
Neck irradiation
indications for neck node dissection after, 1694
late complications after, 1694-1695
with N0 status, 1688, 1690, 1692, 1692t

facial nerve (*See* Facial nerve neuroma)
neck masses due to, 1640
Neuromuscular blockers (NMBs), intraoperative, 111-112
Neuromuscular disorders
chronic aspiration due to, 926b
and obstructive sleep apnea in children, 2605-2606
Neuromuscular junction disorders, laryngeal hypofunction due to, 842
Neuromuscular pedicle (NMP)
for facial nerve paralysis, 2426-2427
for laryngeal reinnervation, 919-922
for bilateral paralysis, 920
complications of, 922
future of, 922
history of, 917
indications for, 920
laboratory investigations of, 919-920
rationale for, 919
reported results of, 920-921
technique for, 920, 921f
for unilateral paralysis, 920
Neuromuscular symptoms, of hyperparathyroidism, 1781
Neuronal control, of salivary gland secretion, 1136
neurotransmitters and receptors in, 1136-1137, 1136f, 1137t
signal transduction in, 1137-1138
adenylate cyclase system in, 1137
G proteins in, 1137
phospholipase C system in, 1137-1138
Neurontin (gabapentin)
for migraine, 2350
for neuropathic pain, 243, 244t
for tinnitus, 2137
Neuropathic pain
anticonvulsant agents for, 243-244, 244t
antidepressants for, 244-245, 245t
interventional techniques for, 245-246, 246t
palliative care for, 1103
Neuropathies, in HIV, 223-225
Neuropeptide(s), in allergic rhinitis, 615
Neuropeptide Y (NPY), in salivary gland secretion, 1137
Neuropraxia, of facial nerve, 2040
Neurotmesis, 2384-2385
of facial nerve, 2040
Neurotologic examination, for temporal bone fracture, 2038-2039
Neurotologic manifestations, of immunosuppression, 221-223
malignant otitis externa as, 221-222
in middle ear, 222-223
due to *P. jiroveci* and *A. fumigatus,* 222-223
Neurotologic surgery, cranial nerve monitoring in, 2542-2556
anesthesia and, 2544
auditory brainstem response recording for, 2552-2554
interpretation of, 2553-2554, 2553f
and postoperative auditory function, 2553-2554
reducing electrical and acoustic interference in, 2552-2553
stimulus and recording parameters, electrodes, and placement in, 2552
of cochlear nerve, 2552
direct eighth nerve action potentials for, 2554
detection and interpretation of changes in, 2554
placement of electrodes in, 2554
stimulus and recording parameters in, 2554
of facial nerve, 2545-2549
with acoustic neuroma and other cerebellopontine angle tumors, 2545
activity evoked by electrical stimulation in, 2545-2546
for assessment of functional status after tumor removal, 2545-2546
electromyography for, 2545-2548
for intraoperative identification of nervus intermedius, 2546, 2546f
limitations of, 2547-2548, 2548f
during microvascular decompression, 2548-2549, 2549f
during other otologic surgery, 2549
during parotid surgery, 2549
spontaneous and mechanically evoked activity in, 2546-2548, 2547f
future directions in, 2555-2556, 2555f
instrumentation for, 2543
ninth, tenth, eleventh, and twelfth, 2550-2552, 2551f-2552f
and outcome, 2554-2555
for cochlear nerve preservation, 2554-2555
for facial and other motor cranial nerve preservation, 2554
personnel for, 2542-2543
recording electrodes for, 2543-2544, 2543f
stimulating electrodes for, 2544, 2544f
stimulation criteria for, 2544
third, fourth, and sixth, 2549-2550, 2550f
of trigeminal motor branch, 2550

Neurotologic symptoms, migraine with, 2349
Neurotology, gene therapy in, 23
Neurotransmitters, in salivary gland secretion, 1136-1137, 1136f, 1137t
Neurotrophic factors, for facial nerve paralysis, 2427
Neurotrophic tyrosine receptor kinase type 1, in thyroid carcinoma, 1753
Neurotrophin(s) (NTs)
  in gene therapy of inner ear, 2192
  for prevention of ototoxicity, 2189-2191
Neurotrophin-3 (NT-3)
  in gene therapy of inner ear, 2192
  for prevention of ototoxicity, 2190
Neutron, fast, 1034
Neutron beam radiotherapy, for salivary gland neoplasms, 1198-1199
Neutron therapy, 1046
Neutrophil(s)

Olfactory ensheathing cells, 626
Olfactory epithelium
cell types in, 626, 626f
basal cells as, 626f, 627
microvillar cells as, 626, 627f
olfactory ensheathing cells as, 626
olfactory receptor neuron as, 626, 626f-627f
supporting or sustentacular cells as, 626-627, 626f
and lamina propria, 626, 626f
in olfactory stimulation, 625-627
and respiratory epithelium, 625, 625f
Olfactory glomeruli, 628, 628f
Olfactory hallucinations, 636
Olfactory knob, 626, 627f
Olfactory map, 628, 630
Olfactory mucus, in olfactory stimulation, 625
Olfactory receptor neuron, 626, 626f-627f
Olfactory reference syndrome, 636
Olfactory stimulation, 624-629
common chemical sense in, 628-629
nasal passageways in, 624-625, 625f
olfactory bulb in, 628, 628f
olfactory connection to brain in, 628
olfactory epithelium in, 625-627
cell types of, 626, 626f
basal cells as, 626f, 627
microvillar cells as, 626, 627f
olfactory ensheathing cells as, 626
olfactory receptor neuron as, 626, 626f-627f
Olfactory stimulation *(Continued)*
supporting or sustentacular cells as, 626-627, 626f
and lamina propria, 626, 626f
and respiratory epithelium, 625, 625f
olfactory mucus in, 625
orthonasal, 631
retronasal, 631
vomeronasal organ in, 627-628, 627f
Olfactory testing, 631-632
factors affecting, 632-633
adaptation and habituation as, 633
age as, 632-633
gender as, 633
Olfactory transduction, 629-630, 629f
Olfactory-evoked potentials, 632
Oligogenic disorders, 4, 8
with complex traits, 8
genetic heterogeneity and, 8
mitochondrial, 8, 9f
sporadic cases of, 8
with X-linkage, 8, 8f
Oligonucleotides, 9
Olive oil, for cerumen removal, 1958t
Olivocochlear bundle, in auditory pathway, 1834-1835, 1834f
Olivocochlear reflex pathways, in efferent auditory system, 1848-1849, 1848f
Olopatadine hydrochloride
for allergic rhinitis, 620
for rhinosinusitis, 734t, 737
OM. *See* Otitis media (OM).
OM-6 scale, 57
Omalizumab, for rhinosinusitis, 735t, 737
allergic fungal, 715
OMC (ostiomeatal complex)
in functional endoscopic sinus surgery, 760, 760f
imaging of, 168f-169f, 169
surgical anatomy of, 739, 740f
OME. *See* Otitis media with effusion (OME).
Omega epiglottis, 1464
Omentum flaps, for free tissue transfer, 1082t
Omeprazole, for extraesophageal reflux, 901
Omohyoid muscle
anatomy of, 2578f
in neuromuscular pedicle procedure, 920, 921f
OMU (ostiomeatal unit)
in chronic sinusitis, 674, 674f
after functional endoscopic sinus surgery, 677-679
and sinus physiology, 664-670
ONC-HIT (Office of the National Coordinator for Health Information Technology), 84t-87t, 89
Oncocytic adenoma, of parathyroid gland, 1778
Oncocytic neoplasms, of larynx, 881
Oncocytic papillary cystadenoma, of salivary glands, 1171
Oncocytoma, of salivary glands, 1171
Oncogenes, 12
in head and neck squamous cell carcinoma, 1016, 1019-1020
modification of, 21-22
in thyroid carcinoma, 1752-1753
Ondansetron, for postoperative nausea and vomiting in children, 2593
Onlay tip cartilage grafts, for nasal tip projection, 535-536, 537f, 549-550, 550f-551f
Onodi cells, 669, 740, 749f
in surgical anatomy of anterior cranial base, 2473
Onyx, for embolization, 1933
Onyx-015 vector, in gene therapy, 22
OOPS (operation on placental support), for congenital high airway obstruction syndrome, 2904-2905
OPC. *See* Oropharyngeal candidiasis (OPC).

Open approach, for nasal tip refinement, 522-535, 534f-535f
  indications for, 521b
Open bite deformities, 461, 462f
Open laryngeal surgery
  for laryngeal trauma, 936-937, 939f
  for stridulous child, 2909-2910, 2910f
Open mouth posture (OMP), 2628-2630, 2629f
Open quotient, in measurement of vocal fold vibration, 830-831
Open reduction, for subcondylar fractures, 338-339
Open reduction with internal fixation (ORIF), for pediatric facial fractures, 2701-2702
Open sky incision, for nasal fracture repair, 505, 505f
Open supraglottic laryngectomy (OSGL), for early supraglottic cancer, 1498-1500, 1498f
"Open-book" fracture, of nose, 2708, 2711f
Open-canal fittings, for hearing aids, 2270
Open-fit technology, for hearing aids, 2270
Operation on placental support (OOPS), for congenital high airway obstruction syndrome, 2904-2905
OPGL (osteoprotegerin ligand), 609t-610t
Ophthalmic artery(ies), in surgical anatomy of anterior cranial base, 2472f-2473f
Ophthalmic complications, of endoscopic sinus surgery, 754-755
Ophthalmic division, of trigeminal nerve, 440
  in surgical anatomy of lateral skull base, 2437f, 2438
Ophthalmic division block, 242
Ophthalmologic considerations, with posterior fossa surgery, 2541
Ophthalmopathy, Graves'. *See* Graves' ophthalmopathy.
Opioids
  addiction *vs.* tolerance to, 240, 242
  as adjuncts to induction of anesthesia, 111
  in children
    for anesthesia maintenance, 2591-2592
    for pain, 2572
      postoperative, 2594
  chronic use of, and postoperative pain control, 241
  for noncancer chronic pain, 243
  via patient-controlled analgesia, 240, 241t
Opsoclonus, 2313
Optic canal(s), 322f, 335f
  fracture of, 2479, 2479f
  in surgical anatomy of anterior cranial base, 2442-2444, 2443f, 2472f, 2473-2474
  in surgical anatomy of middle cranial base, 2444, 2445f
Optic chiasm, in surgical anatomy of anterior cranial base, 2475f
Optic foramen, 320-321, 440, 1124f
  in surgical anatomy of anterior cranial base, 2444f
Optic nerve(s)
  paranasal sinuses and, 672, 672f
  in surgical anatomy of anterior cranial base, 2473f-2475f
Optic nerve decompression, combined endoscopic orbital and, for Graves' ophthalmopathy, 1815
Optic nerve injury, in functional endoscopic sinus surgery, 679, 680f
Optic nerve involvement, in Graves' ophthalmopathy, 1808-1809, 1809t
Optical coherence tomography (OCT), for premalignant lesions of larynx, 1489, 1490f
Optical resonating chamber, of carbon dioxide laser, 26, 27f
Optical stimulation, to assess facial nerve function, 2389
Opticocarotid recess, in surgical anatomy of anterior cranial base, 2473-2474
Optokinetic afternystagmus (OKAN), 2319
Optokinetic nystagmus (OKN), 2277, 2314
Optokinetic testing, 2318-2319
Optokinetic tracking, 2306f, 2307t, 2318-2319
Oral appliances, for obstructive sleep apnea, 257, 257f
Oral breathing, 809
Oral cancer, 1249-1250, 1293-1318
  adenoid cystic carcinoma as, 1299
  adjunctive chemotherapy for, 1314-1315
  of alveolar ridge, 1304-1305
    clinical presentation of, 1304, 1304f
    epidemiology of, 1304
    mandibulectomy for, 1304, 1304f-1305f, 1307f
    maxillary, 1304
    neck dissection for, 1304
    survival with, 1304-1305
  anatomic basis for, 1295-1298, 1295f
    alveolar ridge in, 1297-1298
    arteriovenous, 1295-1296, 1296f-1297f
    buccal mucosa in, 1295f, 1298
    floor of mouth in, 1297-1298
    hard palate in, 1295f, 1298
    lips in, 1296-1297, 1297f
    retromolar trigone in, 1295f, 1297, 1298f
    tongue in, 1297, 1298f
  of buccal mucosa, 1308-1309
    clinical appearance of, 1308f
    epidemiology of, 1308
    radiation and chemoradiation for, 1309
    reconstruction for, 1308-1309, 1309f
    squamous cell, 1308, 1308f
    surgical treatment of, 1308-1309, 1309f
    survival with, 1309
    verrucous, 1308
  cervical lymph node metastasis of
    incidence and distribution of, 1685f, 1688t
    radiation therapy for, 1689t
  chemoprevention of, 1315
  desmoplastic-neurotropic melanoma as, 1299
  diagnostic evaluation of, 1299-1300
    endoscopy for, 1300
    history and physical examination in, 1299-1300, 1300f
  epidemiology of, 1295
  etiology of, 1293-1295, 1294f
  of floor of mouth, 1307-1308
    cervical metastases of, 1308
    clinical presentation of, 1294f, 1307
    composite resection for, 1307-1308, 1308f, 1315f
    coronal partial mandibulectomy for, 1307-1308, 1308f
    imaging of, 1307
    invasive, 1307
    reconstruction for, 1307, 1315f
    segmental mandibulectomy for, 1307-1308, 1308f
    survival with, 1308
    transoral resection for, 1307
  of hard palate, 1309-1310
    cervical metastases of, 1310
    clinical appearance of, 1310f
    epidemiology of, 1309-1310
    Kaposi's sarcoma of, 1309-1310
    melanoma of, 1242f, 1309-1310
    reconstruction for, 1310, 1311f
    resection of, 1310, 1310f-1311f
    squamous cell carcinoma as, 1310, 1310f
    survival with, 1310
  imaging of, 1300
  of lip, 1302-1304
    clinical findings in, 1294f, 1302, 1302f
    epidemiology of, 1302
    neck metastases of, 1303-1304
    prognostic features of, 1303
    resection and reconstruction of, 1303-1304, 1303f
Oral cancer *(Continued)*
      Abbe-Estlander flap in, 1303-1304, 1303f
      Karapandzic fan flap in, 1303-1304, 1303f
    survival with, 1304
  long-term management and rehabilitation for, 1316-1317
    follow-up in, 1317, 1317t
    pain management in, 1316
    palliative care in, 1316
    for speech and swallowing, 1316
  molecular biology of, 1294-1295
  neck dissection for, 1312-1314, 1313f, 1713-1716
    definition and rationale for, 1713, 1714f
    technique for, 1713-1716, 1715f-1716f
  organ preservation protocols for, 1315
  pathology of, 1298-1299
  photodynamic therapy for, 1315
  premalignant lesions and, 1298-1299
  preoperative assessment of, 1300
  preoperative interventions for, 1300
  prognosis for, 1300-1302, 1301t
  radiation therapy for, 1314
    brachytherapy as, 1314, 1314f
    external beam, 1314
    package time for, 1314
  of retromolar trigone, 1306-1307
    clinical presentation of, 1306
    resection for, 1307, 1307f
    survival with, 1307
  sarcomas as, 1299, 1299f
  second primary tumors with, 1301-1302
  squamous cell carcinoma as, 1299
    of alveolar ridge–retromolar trigone, 1307f
    basaloid, 1299
    of buccal mucosa, 1308f
    epidemiology of, 1295
    etiology of, 1293-1295, 1294f
    of floor of mouth, 1294f, 1315f
    of hard palate, 1310f

    malignant neoplasms as, 1249-1250
    neurologic, 1254-1255
      Bell's palsy as, 1255
      dementias (including Alzheimer's disease) as, 1254-1255
      multiple sclerosis as, 1255
      myasthenia gravis as, 1255
      myotonic muscular dystrophy as, 1255
      Parkinson's disease as, 1255
    pulmonary, 1250-1251
    renal, 1255
Oral motor function, 1203-1207
  autonomic reflexes in, 1205-1206
  jaw-tongue reflexes in, 1205
  lingual muscles and reflexes in, 1205
  mastication as, 1206-1207, 1206f
  muscles of mastication and reflex control in, 1204-1205, 1204f-1205f
  oral phase of deglutition as, 1206f, 1207
Oral mucosal lesions, 1222-1244
  pigmented, 1241-1243
    amalgam tattoo as, 1243
      clinical features of, 1243, 1243f
      defined, 1243
      differential diagnosis of, 1243
      etiology of, 1243
      histopathologic features of, 1243, 1243f
      treatment of, 1243
    melanoma as, 1242-1243
      clinical features of, 1242, 1242f
      differential diagnosis of, 1242
      etiology and pathogenesis of, 1241, 1241t
      histopathologic features of, 1242-1243, 1242f-1243f
      treatment of, 1243
    melanotic macules as, 1241
      clinical features of, 1241, 1241f
      defined, 1241

Oral mucosal lesions *(Continued)*
differential diagnosis of, 1242
etiology and pathogenesis of, 1241, 1241t
histopathologic features of, 1242, 1242f
treatment of, 1243
mucosal melanocytic nevi as
clinical features of, 1241
histopathologic features of, 1242
treatment of, 1243
red/white, 1222-1231
candidiasis as, 199-200, 1229-1231, 1252
acute, 1230, 1230f, 1230t
angular cheilitis due to, 1230, 1230f
chronic, 1230, 1230t
clinical features of, 1230-1231
defined, 1229
differential diagnosis of, 1231
erythematous, 1230, 1230f
etiology and pathogenesis of, 1229-1230
histopathologic/diagnostic features of, 1231, 1231f
hyperplastic, 1231, 1231f
pseudomembranous, 1230, 1230f
risk factors for, 1229, 1230t
treatment of, 1231
leukoedema as, 1222-1223
clinical features of, 1222, 1223f
defined, 1222
etiology and pathogenesis of, 1222
histopathologic features of, 1222, 1223f
management of, 1223
leukoplakia as, 1223-1225
chemoprevention of, 1225
clinical features of, 1224-1225, 1224f
defined, 1223
etiology of, 1223-1224, 1223f-1224f
hairy, 1226, 1226f
histopathologic features of, 1225, 1226f
malignant transformation of, 1223, 1298
proliferative verrucous, 1225, 1225f
thin, 1224f, 1225
treatment of, 1225
lichen planus as, 1226-1229, 1253-1254
atrophic or erythematous, 1227, 1227f
bullous variant of, 1227-1228
clinical differential diagnosis of, 1228
clinical features of, 1227-1228
erosive, 1227, 1228f
etiology and pathogenesis of, 1227
histopathologic features of, 1228, 1228f
and oral carcinoma, 1229, 1298-1299
plaque form of, 1227
reticular-type, 1227, 1227f
systemic diseases and, 1228
treatment of, 1228
submucous fibrosis as, 1229, 1295
clinical features of, 1229
defined, 1229
etiology and pathogenesis of, 1229
histologic/diagnostic features of, 1229
treatment of, 1229
verruciform xanthoma as, 1229
clinical features of, 1229
defined, 1229
etiology and pathogenesis of, 1229
histopathologic/diagnostic features of, 1229
treatment of, 1229
vesiculobullous/ulcerative, 1231-1240
erythema multiforme as, 1239-1240, 1254
clinical features of, 1239, 1239f-1240f
defined, 1239
differential diagnosis of, 1239
etiology and pathogenesis of, 1239
histopathologic features of, 1239-1240
treatment of, 1240

Oral mucosal lesions *(Continued)*
mucous membrane (cicatricial) pemphigoid as, 1233-1235, 1254
clinical differential diagnosis of, 1234, 1234t
clinical features of, 1233-1234, 1233f-1234f
defined, 1233
etiology and pathogenesis of, 1233
histopathologic features of, 1234-1235, 1234f
treatment of, 1235
pemphigus vulgaris as, 1231-1233, 1254
clinical differential diagnosis of, 1232
clinical presentation of, 1232, 1232f
defined, 1231-1232
etiology/pathogenesis of, 1232
histopathologic features of, 1232-1233, 1232f-1233f
treatment of, 1233
primary herpes simplex infection as, 1235, 1252
clinical features of, 1235, 1235f, 1252
defined, 1235
diagnosis of, 1235
differential diagnosis of, 1235
etiology and pathogenesis of, 1235
treatment of, 1235, 1252
recurrent aphthous stomatitis as, 1236-1239
clinical features of, 1237-1238
defined, 1236-1237
differential diagnosis of, 1238, 1238t
etiology and pathogenesis of, 1237, 1237t
herpetiform-type, 1238, 1238f
histopathologic features of, 1239
major, 1237-1238, 1238f
minor, 1237, 1238f
treatment of, 1239
recurrent herpes simplex infection as, 1235-1236, 1252
clinical features of, 1236, 1236f
defined, 1235
differential diagnosis of, 1236
etiology and pathogenesis of, 1235-1236
histopathology of, 1236, 1237f
vs. recurrent aphthous stomatitis, 1238, 1238t
treatment of, 1236
traumatic (eosinophilic) granuloma as, 1240
clinical features of, 1240, 1240f
defined, 1240
differential diagnosis of, 1240
etiology of, 1240
histopathologic features of, 1240, 1240f
treatment of, 1240
Oral mucosal pigmentation, inherited and congenital disorders affecting, 1257
Oral phosphate salts, for hyperparathyroidism, 1804
Oral preparatory stage, of deglutition, 1215, 1216f, 2948
Oral preservation treatment, *vs.* total laryngectomy, 1564
Oral rinses, biomarkers in, for head and neck squamous cell carcinoma, 1026
Oral sequelae, of medications for systemic diseases, 1246, 1247t-1248t
Oral somesthesia, 1201-1202, 1201f-1202f
Oral stage, of deglutition, 1206f, 1207, 1215, 1216f, 2948
Oral treatment considerations, due to systemic conditions, 1246, 1246t
Oral warts, in HIV, 227
Oral-facial-digital syndrome, 1257
Orbicularis muscle, in aging, 406, 406f
Orbicularis oculi muscle
with aging, 444
anatomy of, 433f, 441-443, 442f-443f
botulinum toxin for, 432, 433f
in lower eyelid blepharoplasty, 448-449, 450f
origin of, 443
paralysis of, 2420, 2420f, 2423f

Orbicularis oculi muscle *(Continued)*
sphincter mechanism of, 443, 443f
in upper eyelid blepharoplasty, 448
Orbicularis oris muscle, 442f
in cleft lip, 2665-2666, 2665f-2666f
Orbit(s)
anatomy and physiology of, 320-321, 322f, 439-444
biomechanics of, 332
effects of radiotherapy on, 2626t
endoscopic surgery of, 763
growth and development of, 2617t
invasive small cell carcinoma of, 170f
in surgical anatomy of anterior cranial base, 2443-2444, 2444f
Orbital apex, 320-321
Orbital apex fractures, pediatric, 2712, 2713f
Orbital blowout fractures, 170f, 321, 325, 326f
pediatric, 325, 326f
Orbital cellulitis, due to odontogenic infections, 181, 182f
Orbital complications
of functional endoscopic sinus surgery, 679, 680f
of rhinosinusitis, 676-677
Orbital decompression, for Graves' ophthalmopathy, 1811-1816
approaches to, 1811, 1812f
balanced, 1814
without bone removal, 1816
combined endoscopic and open approach to, 1814
combined endoscopic orbital and optic nerve, 1815
endoscopic, 1814, 1815f-1816f
goal of, 1811
indications for, 1811
results of, 1811-1812
three-wall, 1815-1816
transantral, 1812-1814
complications of, 1814
modifications of, 1814
outcome of, 1812-1814, 1813f-1814f
technique for, 1812, 1812f-1813f
two-wall, 1816
Orbital defects, prosthetic management of, 1345t, 1346-1347, 1347f
Orbital dystopia, surgical correction of, 2654
Orbital echography, of Graves' ophthalmopathy, 1810
Orbital edema, preseptal, due to rhinosinusitis, 676
Orbital enucleation, prosthesis for, 1346
Orbital evisceration, prosthesis for, 1346
Orbital exenteration
prosthesis for, 1346-1347
radial maxillectomy with, 1125-1126
Orbital fat pads, 443-444, 444f
Orbital floor, 439-440
surgical access to, 328-329
Orbital floor fractures, pediatric, 2712-2713, 2714f-2715f
Orbital fractures
blowout, 170f, 321, 325, 326f
pediatric, 325, 326f
imaging of, 325, 326f
pediatric, 2711-2714
evaluation of, 2712, 2713f
of lateral/medial orbital wall, 2712, 2714, 2716f
of orbital apex, 2712, 2713f
of orbital floor, 2712-2713, 2714f-2715f
of orbital roof, 2712-2713, 2716f
patterns of, 2711-2712
physical examination of, 324
repair of, 336
surgical access to, 328-329, 329f
Orbital hemorrhage, after blepharoplasty, 449
Orbital hypertelorism, surgical correction of, 2654

Orbital periosteum, 439
Orbital rim, lateral, surgical access to, 328-329, 329f
Orbital roof, in surgical anatomy of anterior cranial base, 2443
Orbital roof fractures, pediatric, 2712-2713, 2716f
Orbital septum
  anatomy of, 443, 443f
  in lower eyelid blepharoplasty
    with subciliary approach, 449, 450f
    transconjunctival, 448-449, 450f
  in upper eyelid blepharoplasty, 448, 449f
Orbital wall(s), 439
Orbital wall fractures, pediatric, 2712, 2714, 2716f
Ordinal scales, 63, 63t
ORFFF (osteocutaneous radial forearm free flap), 1082t, 1085-1086, 1086f-1087f
Organ of Corti
  anatomy of, 1832, 1832f, 1840, 1841f
  in auditory physiology, 1841f
  in cochlear transduction, 2061f, 2067f, 2069f
  embryogenesis of, 1852
  in noise-induced hearing loss, 2142-2143, 2142f
Organ preservation treatment
  for laryngeal carcinoma, 1501-1503, 1502f (*See also* Conservation laryngeal surgery)
    current paradigm for, 1558-1559
    glottic, 1497
      chemoradiation as, 1584-1585
      targeted biologic agents with radiation therapy as, 1585
    management of neck after, 1502-1503
    recurrence after, 1503-1504
    supraglottic, 1500
  for oral cancer, 1315
  principles of, 1544
Orientation, hearing aid, 2273-2274
ORIF (open reduction with internal fixation), for pediatric facial fractures, 2701-2702
ORN (osteoradionecrosis), 1048, 1314, 1317, 1478-1479
ORNC (overpressure radionuclide cisternography), for CSF rhinorrhea, 790
Orocutaneous fistula, 179, 180f
Orodigitofacial dysostosis, 1257
Orofacial clefts. *See also* Cleft lip; Cleft palate.

middle ear atelectasis due to, 1964, 1964f-1965f
sensorineural hearing loss due to, 1974
tympanosclerosis due to, 1974
OTOA (otoancorin) gene, in deafness, 2051t-2058t
Otoacoustic emissions (OAEs), 1891-1892, 1904-1907
with acoustic neuroma, 1891-1892, 1893f, 1897
advantages of, 1906
and audiograms, 1905, 1906f
and auditory neuropathy or dyssynchrony, 1907
clinical applications of, 1905-1907
cochlear echoes in, 1891
distortion product, 1891, 1905
and audiometric tests, 1905, 1907f
clinical applications of, 1905-1907
defined, 1891, 1905
distortion products in, 1905
frequencies used in, 1905
with high-frequency hearing loss, 1905, 1907f
in infants, 2720-2721
with normal hearing, 1892f, 1905, 1907f
procedure for, 1891
evoked
in infants, 2720-2721
types of, 1891, 1905
with neural hearing loss, 1899-1901
for noise-induced hearing loss
early detection of, 2146-2147, 2147f-2150f
susceptibility to, 2144
with normal hearing, 1905, 1906f
with otitis media, 2762
procedure for, 1891
with sensorineural hearing loss, 1905, 1906f, 2117
spontaneous, 1905
stimulus-frequency, 1891
transient evoked, 1891, 1905
with acoustic neuroma, 1891-1892, 1893f
advantages of, 1891
analysis of, 1905
clinical applications of, 1905-1907
defined, 1891, 1905
in infants, 2720-2721
with normal hearing, 1892f
Otoancorin *(OTOA)* gene, in deafness, 2051t-2058t
Otocadherin, in deafness, 2051t-2058t
Otocerol (arachis oil, almond oil, rectified camphor oil), for cerumen removal, 1958t
Otoconia. *See* Otolith(s).
Otoconial membrane
response to head acceleration by, 2283
in vestibular system, 1855, 1858f
Otocyst, 1851-1852, 1851f
Otoferlin *(OTOF)* gene, in deafness, 2051t-2058t, 2080-2081
Otogelin, 2067
Otogelin *(Otog)* gene, in murine deafness, 2058t-2060t, 2067-2069
Otolith(s), in vestibular system, 1855, 1858f
anatomy of, 2277, 2278f
arrangement of, 2278, 2280f
estimated patterns of excitation and inhibition for, 2278, 2281f
morphologic polarizations of stereociliary bundles in, 2278, 2280f
Otolith membrane
response to head acceleration by, 2283
in vestibular system, 1855, 1858f
Otolithic crisis of Tumarkin, 2300
Otologic disease, outcome scales for, 56t, 57
Otologic manifestations
of immunosuppression, 221-223
malignant otitis externa as, 221-222
in middle ear, 222-223
due to *P. jiroveci* and *A. fumigatus,* 222-223
of systemic diseases, 2100-2115, 2101t
of bone, 2108-2112

infectious, 2196
noninfectious, 2196
tympanic membrane, middle ear, and mastoid, 2195-2196, 2195b
topical therapies for, 1957-1958
with tympanostomy tubes, 1971, 2774-2775
Otos (otospiralin) gene, in murine deafness, 2058t-2060t
Otosclerosis, 2028-2035
alternative treatment of, 2034-2035
fluoride therapy as, 2034-2035
hearing aids as, 2034
clinical course of, 2028-2029
clinical presentation of, 2028
defined, 2028
evaluation of, 2029-2030
audiometry in, 2030, 2030f
history in, 2029-2030
physical examination in, 2030
far-advanced, 2035
fenestral and cochlear, imaging of, 1921-1922, 1925f
histopathology of, 2028-2029, 2029f-2030f
inheritance of, 2028-2030

Otosclerosis *(Continued)*
with Meniere's disease, 2035
prevalence of, 2028, 2029t
sensorineural hearing loss due to, 2124
small fenestra stapedotomy for, 2030-2032
with laser minus prosthesis, 2033
laser *vs.* microdrill in, 2033
postoperative care after, 2032-2033
postoperative complication(s) of, 2030, 2034
facial paralysis as, 2030, 2034
perilymph fistula as, 2034
reparative granuloma as, 2034
sensorineural hearing loss as, 2030, 2034
serous labyrinthitis as, 2034
taste disturbance as, 2034
tinnitus as, 2034
tympanic membrane perforation as, 2034
vertigo as, 2030, 2034
procedure for, 2030-2032
anesthesia for, 2030
creation of fenestra in, 2031-2032, 2032f
flap elevation in, 2031, 2031f
incisions for, 2031
measurement of distance from incus to footplate in, 2031, 2031f-2032f
placement of prosthesis in, 2031-2032, 2032f
positioning for, 2031, 2031f
removal of posterior superior bony wall in, 2031, 2031f
stapedectomy *vs.,* 2030
surgical problems in, 2033-2034
chorda tympani nerve damage as, 2034
exposed, overhanging facial nerve as, 2033
fixed malleus as, 2033
floating footplate as, 2033
intraoperative vertigo as, 2034
perilymph gusher as, 2034
solid or obliterated footplate as, 2033
tympanic membrane perforation as, 2034
stapedectomy for
in children, 2035
revision, 2035
vs. stapedotomy, 2030
Otoscopy
in children, 2574
pneumatic, for otitis media, 2761-2762
for temporal bone fractures, 2038f-2039f
Otospiralin *(Otos)* gene, in murine deafness, 2058t-2060t
Otospondylomegaepiphyseal dysplasia (OSMED) syndrome, deafness in, 2051t-2058t
Otospongiosis, 2028
imaging of, 1921-1922, 1925f
Otosyphilis, 2105, 2105f, 2341-2342

in HIV, 224
treatment for, 2341-2342
Ototopical agents
acidifying, 1959t-1960t
for acute bacterial otitis externa, 1953
for fungal otitis externa, 1954
for acute bacterial otitis externa, 1951-1953
acidifying agents as, 1953
antibiotics as, 1951-1953
failure to respond to, 1953, 1953t
options for, 1951-1953, 1951f
antibiotics as, 1959t-1960t
for acute bacterial otitis externa, 1951-1953
evidence-based data on, 1952
hypersensitivity reaction to, 1954
mechanism of action of, 1951
ototoxicity of, 1953-1954
resistance to, 1953
antifungals as, 1959t-1960t
for fungal otitis externa, 1954-1955
ototoxicity of, 1955
Ototopical agents *(Continued)*
anti-inflammatories as
for eczematoid otitis externa, 1956-1957
mechanism of action of, 1951
antiseptics as, 1955
for fungal otitis externa, 1955
for cerumen impaction, 1957
options for, 1957, 1958t
for ear hygiene and chronic draining ear, 1957-1958, 1961f
for eczematoid otitis externa, 1955-1957
anti-inflammatory and immunosuppressive agents as, 1956-1957
options for, 1955
steroids as, 1955-1956
for fungal otitis externa, 1954-1955
acidifying agents as, 1954
antifungals as, 1954-1955
antiseptics as, 1955
options for, 1954
history of, 1950
immunosuppressive, for eczematoid otitis externa, 1956-1957
mechanism of action of, 1950-1951
for antibiotics, 1951
for anti-inflammatories, 1951
for myringitis, 1955
defined, 1955
options for, 1955
sensorineural hearing loss due to, 2119-2120
steroids as
classes of, 1956, 1956t
for eczematoid otitis externa, 1955-1956
hypersensitivity reaction to, 1954
mechanism of action of, 1951
ototoxicity of, 1956
summary of available, 1959t-1960t
for viral infections, 1957, 1957f
options for, 1957
Ototoxicity, 2169-2178
of aminoglycoside antibiotics, 1953-1954, 2169
clinical manifestations of, 2170

  techniques of, 2669-2670
  timing of, 2668-2669
  two-flap, 2669-2670, 2670f
    surgical technique for, 2670-2671, 2670f-2671f
Palifermin, for mucositis, 1102
Palindromic sequence, 9
Palliative care, 1100-1105
  for dysphagia and speech dysfunction, 1104
  for end of life, 1104
  for mucositis, 1101-1102
  for nutrition, 1104
  for oral cancer, 1316
  oral hygiene in, 1101
  for pain, 1103
  pretreatment management in, 1101
  for psychological distress, 1103-1104
  for taste dysfunction, 1103
  for xerostomia, 1102-1103
Palliative treatment, for tracheal tumors, 1619-1624
Pallister-Hall syndrome (PHS), 2874
Palmaz stent, for tracheal stenosis, 2929-2930
Palmoplantar hyperkeratosis, deafness in, 2051t-2058t
Palmoplantar keratoderma, deafness in, 2051t-2058t
Palpebral conjunctiva, 444
Palpebral fissure, 442, 445
Palpebral opening, in aesthetic analysis, 271
Palpebral springs, for lagophthalmos, 2421
Pancuronium, for pediatric anesthesia, 2593t
Panfacial fractures, 339
Panje prosthesis, 1598f
Panoramic radiograph (Panorex), for mentoplasty, 462-463, 462f
Pansynostosis, 2641t
PaO_2 (arterial oxygen tension), in children, 2570, 2571t
Papillary cystadenoma, of salivary glands
  lymphomatosum, 1170-1171
    imaging of, 1146, 1146f
  oncocytic, 1171
Papillary dermis, 1065
Papillary squamous cell carcinoma (PSCC), of larynx, 1506
Papillary thyroid carcinoma, 1760-1761
  clinical presentation of, 1760
  management and prognosis for, 1760-1761
  pathology of, 1760
  ultrasound of, 1646f
    metastatic, 1648f-1649f

Papilloma(s)
choroid plexus, 2528-2529, 2530f
fibroepithelial, 291
inverted (Schneiderian, inverted type)
ductal, of salivary glands, 1171-1172
of nasopharynx, 1349
sinonasal, 718-720, 1127
endoscopic appearance of, 718-719, 719f
epidemiology of, 718
with frontal sinus involvement, 720, 720f
histologic appearance of, 718
human papillomavirus and, 718
imaging of, 719, 719f
postoperative surveillance for, 720
recurrence of, 720
sites for, 718
and squamous cell carcinoma, 718
surgical approach for, 718t, 719-720, 720f, 763, 1127
of oral cavity, 1290, 1290f
squamous
of larynx, 1468, 1468f
of nasopharynx, 1349
of oral cavity, 1290, 1290f
of trachea, 1612
Papillomatosis
aural, 1957, 1957f
management options for, 1957
laryngeal, stridor due to, 2898, 2899f
recurrent respiratory (*See* Recurrent respiratory papillomatosis (RRP))
PAR (perennial allergic rhinitis), 617-618
and pediatric chronic sinusitis, 2778
Parabrachial nucleus, in gustatory pathway, 1212-1213
Paracoccidioidomycosis, laryngitis due to, 885
Paradental cyst, 1264-1265
radiographic features of, 1265
Paradoxic nasal obstruction, 484, 486
Paragangliomas (PGLs), 1657
carotid, 1657-1658, 2506f
anatomy and physiology of, 1658-1659
classification of, 1660
clinical presentation and diagnosis of, 1659-1660
endovascular treatment of, 1937, 1937f
etiology of, 1659, 1659t
history of, 1657-1658
imaging of, 1658f, 1660-1661
malignancy of, 1660
multicentricity of, 1660-1661
observation for, 1661-1662
radiation therapy for, 1661
surgical management of, 1660-1661
of cerebellopontine angle, 2522-2523, 2523f-2524f
endovascular treatment of, 1934-1937, 1935f
for carotid body tumor, 1937, 1937f
for glomus jugulare tumor, 1935-1936, 1935f-1936f
for glomus tympanicum tumor, 1935
for glomus vagale tumor, 1936-1937, 1936f
epidemiology of, 1657-1659
familial syndromes of, 1659, 1659t, 2506f
glomus jugulare, 2505, 2506f
endovascular treatment of, 1935-1936, 1935f-1936f
surgical approach to, 2506, 2507f
glomus tympanicum, 2505-2506
endovascular treatment of, 1935
glomus vagale, 2506f
endovascular treatment of, 1936-1937, 1936f
imaging of, 151, 152f
intracranial, 2499f
jugular, 1662f, 2499f
of larynx, 1508
neck masses due to, 1641
Paragangliomas (PGLs) *(Continued)*
nomenclature for, 1657
pathology of, 1657, 1658f
of skull base, 171, 174f, 1929, 1930f

of temporal bone, 2505-2506
diagnostic evaluation of, 2505, 2506f-2507f
preoperative evaluation of, 2491f
radiotherapy for, 2506
surgical approach to, 2505-2506, 2507f
symptoms of, 2505
vagal, 1661-1662
clinical presentation and diagnosis of, 1662
management of, 1662-1663
Paraglottic space (PGS)
anatomy of, 1484-1485, 1484f-1485f
radiographic, 1471f, 1473
surgical, 1542, 1543f-1544f
laryngeal cancer of
anatomic basis for, 1484-1485, 1484f-1485f
imaging of, 1474
Parainfluenza virus, pharyngitis due to, 196
Parakeratinizing odontogenic keratocyst, 1262, 1267-1268
in basal cell nevus syndrome, 1268
microscopic features of, 1268
radiographic features of, 1267-1268, 1268f
treatment of, 1268
Parakeratosis, of larynx, 1486
Palaryngeal space, radiographic anatomy of, 1471f, 1473
Paralytic agents, intraoperative, 111-112
Paramedian forehead flaps, for nasal defects, 348, 352f-353f
Paramedian mandibulotomy, 1311
Paramedian pontine reticular formation (PPRF), in velocity-to-position integration, 2296, 2297f
Paranasal sinus(es)
anatomy of
normal, 167, 664-668, 665f
agger nasi cell in, 665-666, 665f-666f
anterior ostiomeatal channels in, 666f
anterior ostiomeatal unit in, 664, 665f
basal lamella and sinus lateralis in, 665f, 667f
ethmoid bulla in, 666-667, 667f
ethmoid sinuses in, 664, 667
frontal recess in, 665, 665f-667f
frontal sinuses in, 664-665, 665f
hiatus semilunaris in, 667, 667f
inferior meatus in, 664
inferior turbinate in, 665f
infundibulum in, 665f, 666-667
maxillary sinuses in, 664, 665f
middle meatus in, 664-665, 665f-667f
middle turbinate in, 667
ostiomeatal channels in, 664
ostiomeatal unit in, 664-670
posterior ostiomeatal unit in, 664
primary ostium in, 665, 665f
retrobullar (suprabullar) recess in, 667
sphenoethmoidal recess in, 667, 668f
sphenoid sinus in, 664, 665f, 667-668, 668f
superior meatus in, 664-665
uncinate process in, 666-667, 666f-667f
variations in, 741
surgical, 739-741, 1124f
anatomic variations in, 741
anterior skull base in, 741
ethmoid complex in, 740
frontal sinus in, 740-741
maxillary sinus in, 740
middle turbinate in, 739-740
ostiomeatal complex in, 739, 740f
sphenoid sinus in, 740, 740f
in transnasal endoscopic-assisted anterior skull base surgery, 2473-2474, 2473f
Paranasal sinus(es) *(Continued)*
bony outlines of, 672, 672f
effects of radiotherapy on, 2626t
growth and development of, 2619-2620, 2623f
imaging of, 167-169, 662-2
with anatomic variations and congenital abnormalities, 668-670
aerated crista galli as, 670
asymmetry in ethmoid roof height as, 670
cephalocele as, 670, 671f
of concha bullosa, 668, 669f
extensive pneumatization of sphenoid sinus as, 669, 671f
giant ethmoid bullosa as, 669
Haller or infraorbital cells as, 668-669, 670f
medial deviation or dehiscence of lamina papyracea as, 669
nasal septal deviation as, 668, 669f
Onodi or sphenoethmoidal cells as, 669
paradoxic middle turbinate as, 668, 669f
of uncinate process, 668, 670f
with complications of inflammatory disease, 676-677
inflammatory polyps as, 676, 678f
mucocele as, 676, 678f
mucous retention cyst as, 676, 677f
orbital, 676-677
with congenital and developmental anomalies, 167
conventional radiography for, 130, 662
Caldwell view in, 662, 663f
Waters view in, 662, 663f
CT for, 140-142, 141f, 662-663
radiation exposure with, 663
technique of, 662-663, 664f
after functional endoscopic sinus surgery, 677-680
expected findings in, 677-679, 679f
operative complications in, 679-680, 680f
for image-guided surgery, 680-681, 743-744, 745f
registration in, 680-681
tracking systems in, 681
with inflammatory disease, 167-168, 168f, 672-675
acute rhinosinusitis as, 672-673, 673f
allergic rhinosinusitis as, 675
chronic rhinosinusitis as, 673-674, 674f-675f
fungal rhinosinusitis as, 674-675, 676f
granulomatous rhinosinusitis as, 675
interpretation of, 670-672
evaluation of bony outlines in, 672, 672f
evaluation of critical relationships for surgical planning in, 671-672, 672f
identification and description of important structures in, 671
MRI for, 143, 664, 664f
nasal cycle in, 664, 664f
with normal anatomy, 664-668, 665f
agger nasi cell in, 665-666, 665f-666f
anterior ostiomeatal channels in, 666f
anterior ostiomeatal unit in, 664, 665f
basal lamella and sinus lateralis in, 665f, 667f
ethmoid bulla in, 666-667, 667f
ethmoid sinuses in, 664, 667
frontal recess in, 665, 665f-667f
frontal sinuses in, 664-665, 665f
hiatus semilunaris in, 667, 667f
inferior meatus in, 664
inferior turbinate in, 665f
infundibulum in, 665f, 666-667
maxillary sinuses in, 664, 665f
middle meatus in, 664-665, 665f-667f
middle turbinate in, 667
ostiomeatal channels in, 664
posterior ostiomeatal unit in, 664

Paranasal sinus(es) *(Continued)*

undescended, 1789f
water clear cell, 1778
Parathyroid adenomatosis 1 oncogene *(PRAD1),* in hyperparathyroidism, 1774-1775, 1775f
Parathyroid arteriography, 1788
Parathyroid carcinoma, 1779, 1802-1804, 1803f
Parathyroid disorder(s), 1773-1805
historical background of, 1774
hyperparathyroidism as (*See* Hyperparathyroidism)
oral manifestations of, 1251

Parathyroid exploration
causes of failed, 1798
endoscopic, 1793-1794
indications for, 1789-1790
minimally invasive techniques for, 1793
for multiple-gland disease, 1794-1795
repeat, 1798-1800
causes of failed exploration with, 1798
operative risk in, 1798-1799
operative strategy for, 1799-1800, 1799f-1800f
preoperative assessment for, 1798
for single-gland disease, 1792-1794
surgical strategy and approach to, 1792
technique for, 1790-1792, 1791f
Parathyroid gland(s)
anatomy of, normal, 1777
vascular, 1778
ectopic
CT-MIBI fusion imaging of, 1786f-1787f
intraoperative photograph of, 1788f
intrathyroidal, 1777, 1788f
mediastinal, 1802, 1803f
technetium-99 sestamibi imaging of, 1774
ultrasound of, 1645
embryology of, 1780, 1780f, 2585f
enlargement of
multiple glandular, 1779
single glandular, 1778-1779
histopathology of, 1778
imaging of, 162-163, 165f
CT for, 140
MRI for, 143
ultrasound imaging for, 1644-1645, 1650f-1652f
inferior, 1777
location of, 1777
morphologic characteristics of, 1777-1778
preoperative evaluation of, 104
superior, 1777
supernumerary, 1777
CT-MIBI fusion imaging of, 1787f
mediastinal, 1802, 1803f
in MEN-I, 1795-1796
during thyroid surgery, 1752, 1765f, 1766
Parathyroid gland hyperplasia, 1779
chief cell, 1779
sporadic, 1794-1795, 1794f
ultrasound of, 1645
water clear cell, 1779
Parathyroid hormone (PTH)
in calcium homeostasis, 1775-1777
functions of, 1775
historical background of, 1774
immunometric "sandwich" assays of, 1776-1777
intraoperative levels of, 1792-1793, 1800-1801
metabolism of, 1776
secretion and regulation of, 1775-1777
selective venous sampling for, 1788-1789
Parathyroid hormone (*PTH*) gene, in hyperparathyroidism, 1774-1775, 1775f
Parathyroid hyperplasia, 1779
chief cell, 1779
sporadic, 1794-1795, 1794f
ultrasound of, 1645
water clear cell, 1779
Parathyroid neoplasm(s), etiology and pathogenesis of, 1775, 1776f
Parathyroid surgery, 1789-1804
gamma radiation detection device in, 1802, 1803f
indications for, 1789-1790
intraoperative PTH levels with, 1792-1793, 1800-1801
for multiple-gland disease, 1794-1795
due to sporadic hyperplasia, 1794-1795, 1794f
due to true double adenoma, 1794, 1794f
parathyroidectomy as, 1790-1792
anesthesia and preparation for, 1790
closure of incision in, 1792
Parathyroid surgery *(Continued)*
exploration of neck in, 1790-1792, 1791f
postoperative care after, 1792
for single-gland disease, 1792-1794
directed unilateral cervical exploration as, 1792-1793
endoscopic parathyroid exploration in, 1793-1794
minimally invasive techniques for, 1793
strategy and approach to, 1792
Parathyroidectomy, 1790-1792
anesthesia and preparation for, 1790
with autotransplantation
for MEN-I, 1795
for renal failure–induced hyperparathyroidism, 1797-1798
closure of incision in, 1792
exploration of neck in, 1790-1792, 1791f
postoperative care after, 1792
radiation-guided, 1793
subtotal, for renal failure–induced hyperparathyroidism, 1797-1798
Parent(s), of child as patient, 2573

  postoperative care after, 396
  results of, 396f
  technique of, 395
  toxicity of, 395
Phenotype, 2088
Phenoxybenzamine, and skin flap viability, 1073
Phentolamine, and skin flap viability, 1073
Phenylephrine
  for allergic rhinitis, 620
  for rhinosinusitis, 736
Phenylpropanolamine, for rhinosinusitis, 735t, 736
Phenylthiocarbamide (PTC), taste sensitivity to, 1211-1212
Phenytoin, for neuropathic pain, 243
Pheochromocytoma, 120, 1657
  preoperative evaluation of, 105
Pheromones, 624, 627-628, 630, 631b
Philtrum, embryology of, 2660, 2662f
Phonation
  defined, 833
  in geriatric patients, 234-237
    acoustic changes in, 236
    dental/mandibular changes in, 236
    factors affecting vocal quality in, 234, 235t
    glandular changes in, 236
    histologic changes in, 234-235, 235f
    laryngoscopic appearance in, 235-236
    mucosal changes in, 236
    respiratory changes in, 236
    and sense of taste, 236
    treatment of, 236-237
  process of, 833
  in speech, 810-811, 811b, 811f
Phonation threshold pressure, in voice evaluation, 828, 828t
Phoneme-specific velopharyngeal dysfunction, 2679
Phonetically Balanced Kindergarten (PBK) Test, for cochlear implant, 2225
Phonetogram, in acoustic analysis for voice evaluation, 829, 829f, 829t
Phonophobia, with migraine, 2349
Phonotrauma, laryngitis due to, 883-884, 884f
Phosphatase and tensin homolog (PTEN) gene, in thyroid carcinoma, 1753
Phosphate, in saliva, 1139
Phosphate salts, oral, for hyperparathyroidism, 1804
Phospholipase C system, in salivary gland secretion, 1137-1138
Photoaging skin types, 275, 276b, 391, 391t
Photodisintegration, 1033
Photodynamic therapy (PDT)
  interventional bronchoscopy with, 1010t
  for oral cancer, 1315
  for premalignant lesions of larynx, 1491
  for recurrent respiratory papillomatosis, 2890t, 2892
  for unresectable tracheal tumor, 1621

Photoelectric effect, 1032-1033, 1032f
Photoglottography, for voice evaluation, 835
Photography, prior to rhinoplasty, 514, 515f
Photolysis, fractional, for facial resurfacing, 403t
Photon, 1031
  absorption of, 26, 26f
  spontaneous emission of, 26, 26f
  stimulated emission of, 26, 26f
Photon beams, in radiotherapy, 1033-1034, 1035f
Phrenic ampulla, 1397-1398, 1400f
Phrenic nerve, 2579f
Phrenic nerve injury, 1731, 1731f
Phrenic nerve paralysis, due to neck surgery, 1731
Phrenic nerve paresis, due to neck surgery, 1731, 1731f
Phrenic nerve reinnervation, 917
PHS (Pallister-Hall syndrome), 2874
PHYH gene, in Refsum disease, 2096
Physical examination, 94-101
  of children, 2574
  for chronic rhinosinusitis, 743
  for disorders of professional voice, 851-852, 852t
  of ears, 97-98
    auricles in, 97
    external auditory canal in, 97
    hearing assessment in, 97-98, 98t
    tympanic membrane in, 97, 98f
  of facial skeleton, 95
  of facial trauma, 303-304, 303f
  of facies, 95, 95t
  of general appearance, 95
  of larynx and hypopharynx, 99-100, 99f-100f
    flexible endoscopy in, 100
  of maxillofacial trauma, 323-325
    of lower third, 325
    of middle third, 324-325, 324f
    of upper third, 324
  of nasopharynx, 100-101
  of neck, 95, 96f
    adenopathy in, 95-96
    lymph node regions in, 96-97, 96f
    thyroid gland in, 95
    triangles of, 96-97, 96f
  for nonallergic rhinitis, 699
  of nose, 100
  of oral cavity, 98-99
  of oropharynx, 99, 99f
  of parotid gland, 95
  of skin, 95
Physician Consortium for Performance Improvement (PCPI), 82-87, 84t-87t
Physician education, and performance measurement, 79, 79t
Physician-patient relationship, 78-82
PI(s) (protease inhibitors), 211
Pickwickian syndrome, 251
Picture archival and communication systems (PACS), 138
Piebald syndrome, deafness in, 2051t-2058t
Pierre Robin syndrome, craniofacial abnormalities in, 2630-2631, 2630f
Piezoelectric middle ear implantable hearing aids, 2211-2212
  Esteem-Hearing Implant as, 2211-2212, 2212f
  ossicular coupling in, 2207-2208
  sound transduction and coupling to auditory system with, 2205f
  transducer design for, 2207
Pigeon feeder, 2665, 2665f
Pigmentation changes
  after blepharoplasty, 451
  after chemical peel, 396-397
  after liposuction, 459
  after rhytidectomy, 427
  after skin resurfacing, 451
Pigmented oral mucosal lesions, 1241-1243
  amalgam tattoo as, 1243
    clinical features of, 1243, 1243f
    defined, 1243
    differential diagnosis of, 1243
    etiology of, 1243
    histopathologic features of, 1243, 1243f
    treatment of, 1243
  melanoma as, 1242-1243
    clinical features of, 1242, 1242f
    differential diagnosis of, 1242
    etiology and pathogenesis of, 1241, 1241t
    histopathologic features of, 1242-1243, 1242f-1243f
    treatment of, 1243
  melanotic macules as, 1241
    clinical features of, 1241, 1241f
    defined, 1241
    differential diagnosis of, 1242
    etiology and pathogenesis of, 1241, 1241t
    histopathologic features of, 1242, 1242f
    treatment of, 1243
  mucosal melanocytic nevi as
    clinical features of, 1241
    histopathologic features of, 1242
    treatment of, 1243
Pilar cysts, 289
Pillars
  of Corti, 1832, 1832f
  of facial skeleton, 331, 331f
Pill-induced esophageal injury, 976, 976b, 2941
Pilocarpine, for xerostomia due to radiotherapy, 1048
Pimecrolimus cream, for eczematoid otitis externa, 1956
Pinch test, 445, 446f, 447-448, 448f
Pinched nasal tip, revision rhinoplasty for, 590, 591f-592f
Pincushioning, with local flaps, 366
Pindborg tumor, 1276
  microscopic findings in, 1276
  radiographic findings in, 1276, 1276f
Pinna(e)
  anatomy of, 476-477, 476f
  in sound transmission, 2019
Piriform sinus. *See* Pyriform sinus(es).
Pistol, neck trauma due to, 1625
Piston prosthesis, for otosclerosis
  measurement of, 2031, 2031f-2032f
  placement of, 2031-2032, 2032f
Pitch
  in computed tomography, 131
  disordered perception of, with traditional hearing aid, 2207
Pitch control, 812
Pituitary diseases, oral manifestations of, 1251
Pituitary fossa
  in surgical anatomy of anterior cranial base, 2443f
  in surgical anatomy of middle cranial base, 2445f
Pituitary gland, in surgical anatomy of anterior cranial base, 2473f-2475f
Pituitary hypothyroidism, 1747
Pituitary stalk, in surgical anatomy of anterior cranial base, 2474-2475, 2475f
Pivotal flaps, 343-345
  effective length of, 343, 343f
  interpolated, 344-345, 344f
  rotation, 343-344, 343f
  transposition, 344, 344f
PJVK (pejvakin) gene, in deafness, 2051t-2058t
PLA (polylactic acid), in resorbable plating system, for pediatric facial fractures, 2700, 2700t-2701t
Placebo effect, 61, 62t
Plagiocephaly, synostotic, 2643-2644, 2643f-2644f
  anterior, 2643f
  deformational, 2643f-2644f, 2644
  front-orbital advancement for, 2652-2653, 2653f
  posterior, 2643f
Plain film radiography. *See* Conventional radiography (CR).
Planning tumor volume (PTV), for radiotherapy, 1036, 1044-1045, 1045f
Planum sphenoidale, in surgical anatomy of anterior cranial base, 2442-2443, 2443f, 2471, 2472f
Plaquenil (hydroxychloroquine)
  ototoxicity of, 2176
  sensorineural hearing loss due to, 2120
Plasmablastic lymphoma (PBL), 216
Plasmacytoma
  extramedullary, 2107
    of larynx, 1509
  solitary bone, 2107
Plasmid(s), 15-16, 15f
Plasmid vector, for gene therapy of inner ear, 2191t
Plasmin, in wound healing, 1077
Plasminogen activator, in bone resorption, 1972-1973
Plastic surgery, gene therapy for, 22-23
  with reconstructive tissue flaps and wound healing, 22-23
  with skin grafting, 23
Plasticity, neural. *See* Neural plasticity.
Plastipore, for ossiculoplasty, 2026t
Platelet(s), in adaptive immune system, 605
Platelet count, preoperative evaluation of, 106
Platelet disorders, oral manifestations of, 1256
Platelet glycoprotein IIb/IIIa inhibitor, and skin flap viability, 1074
Platelet-derived growth factor (PDGF), in wound healing, 1076
Plating systems, permanent *vs.* resorbable, for pediatric facial fractures, 2700-2701, 2700t-2701t
Platinum derivatives, in noise-induced hearing loss, 2147
Platybasia, 2355
Platysma, 321f, 442f
Platysmal myocutaneous flap, for oropharyngeal reconstruction, 1377, 1378f
  of tongue base, 1389
  of tonsils and pharyngeal wall, 1385
Play audiometry, for otitis media, 2762
Pleconaril, for rhinosinusitis, 734t
Pleiotropism, 7
Pleomorphic adenoma(s)
  in children, 2819
  of larynx, 881
  of oral cavity, 1291-1292, 1292f
  of parapharyngeal space, 1663-1664, 1665f
  of salivary gland, 1168-1169
    carcinoma ex, 1187-1189, 1188f
    in children, 2861-2862
    clinical features of, 1166f, 1169
    histopathology of, 1169
    imaging of, 1143
      CT for, 1144f, 1148
      MRI for, 1148f, 1167f-1168f, 1180f
      parotid, 150, 150f
      ultrasound imaging, 1149, 1149f
    of lacrimal gland, 1169, 1170f
    malignant transformation of, 1169
    metastasizing, 1189
    of palate, 1169, 1169f
    pathogenesis of, 1168-1169
    recurrent, 1169, 1170f
    sites of, 1169, 1169f-1170f
    submandibular, 1653f
  sinonasal, 718t
PLGA (polymorphous low-grade adenocarcinoma), of salivary glands, 1184-1185, 1186f

Plica aryepiglottica, 1543f
Plica interarytaenoidea, 1543f
Plica stapedis, 1827f
Plica ventricularis, 815t-816t, 853
  surgical anatomy of, 1543f
Plica vocalis, 1543f
PLLA (poly L-lactic acid), in resorbable plating system, for pediatric facial fractures, 2700, 2700t-2701t
PLMD (periodic limb movement disorder), 262t, 265
Plummer-Vinson syndrome, 967
  and postcricoid carcinoma, 1425-1426
Plumping grafts, for nasal tip projection, 535-536, 536f
Pluripotent stem cells, in adaptive immune system, 599-600, 600f
PMCA2, in deafness, 2051t-2058t, 2080
PML (progressive multifocal leukoencephalopathy), HIV-associated, 223
PMMML (primary mucosal malignant melanoma of the larynx), 1509
PMP22 (peripheral myelin protein 22) gene, in deafness, 2051t-2058t, 2081
PMS. *See* Pharyngeal mucosal space (PMS).
Pneumatic dilation
  for achalasia, 964-965
  for tracheal stenosis, 2928, 2928f
Pneumatic otoscopy, for acute otitis media, 2761-2762
Pneumatization
  of petrous apex, 1867, 1986
    asymmetric, 1922-1923, 1924t, 1925f
      vs. neoplasms, 2525, 2526f
    via infralabyrinthine cell tract, 1988f
    via retrolabyrinthine cell tract, 1988f
    via supralabyrinthine cell tract, 1987f
  of sphenoid sinus, 669, 670f
Pneumocephalus, due to cranial base surgery, 2468
Pneumococcal capsular polysaccharide vaccine (PPV23, Pneumovax), with cochlear implants, 2236-2237, 2237b
Pneumococcal conjugate vaccine (PCV7, Prevnar)
  with cochlear implants, 2237, 2237b
  to prevent otitis media, 2763, 2768
    maternal immunization with, 2768-2769
Pneumococcal polysaccharide–meningococcal outer membrane protein complex conjugate (PncOMPC) vaccine, to prevent otitis media, 2768
Pneumococcal vaccine
  to prevent hearing loss, 2161
  to prevent otitis media, 2768
    maternal immunization with, 2768-2769
Pneumocystis jiroveci
  otologic manifestations of, 2114-2115
  otomastoiditis due to, immunosuppression and, 222
Pneumolabyrinth, 2737, 2737f
Pneumomediastinum, 1410, 1410f
Pneumonia, aspiration, 1250
Pneumosinus dilatans, 783, 784f
Pneumothorax
  due to neck surgery, 1733
  tension, *vs.* anaphylactic reaction, 119
Pneumovax (pneumococcal capsular polysaccharide vaccine), with cochlear implants, 2236-2237, 2237b
PNH (polymyxin, neomycin, and hydrocortisone), for otitis externa, 1946, 1952, 1959t-1960t
PnoOMPC (pneumococcal polysaccharide–meningococcal outer membrane protein complex conjugate) vaccine, to prevent otitis media, 2768
Pogonion, in chin analysis, 463, 463f-464f
Point estimate, 65
Point of equilibrium, in radiation, 1033
Poiseuille's equation, 1073, 2897
Poliomyelitis, laryngeal hypofunction due to, 842
Politzer test, of eustachian tube function, 1874
Politzerization, 1870
Pollybeak deformity, 512, 512f, 539, 539f
  revision rhinoplasty for, 584-585, 586f
Poly D-lactic acid (PDLA), in resorbable plating system, for pediatric facial fractures, 2700, 2700t
Poly L-lactic acid (PLLA), in resorbable plating system, for pediatric facial fractures, 2700, 2700t-2701t
Polyamide mesh, for nasal reconstruction, 368
Polyarteritis nodosa, sensorineural hearing loss due to, 2124, 2166
Polychondritis, relapsing
  laryngeal and tracheal manifestations of, 890
  sensorineural hearing loss due to, 2124
Polyclitus, 269
Polydimethylsiloxane. *See* Silicone (polydimethylsiloxane, Silastic).
Polydioxanone (PDS), in resorbable plating system, for pediatric facial fractures, 2700, 2700t
Polyethylene, high-density
  for auricular reconstruction, 2744t
  for chin implants, 465t
Polyethylene implant, for nasal reconstruction, 368
Polygenic traits, 8
Polyglycolic acid (PGA), in resorbable plating system, for pediatric facial fractures, 2700, 2700t-2701t
Polylactic acid (PLA), in resorbable plating system, for pediatric facial fractures, 2700, 2700t-2701t
Polymer(s), for craniofacial defect repair, 2657
Polymer allografts, for ossiculoplasty, 2006
Polymerase chain reaction (PCR), 8-9
Polymorphic reticulosis, 659-660
Polymorphisms, in DNA repair enzymes, in head and neck squamous cell carcinoma, 1027
Polymorphous low-grade adenocarcinoma (PLGA), of salivary glands, 1184-1185, 1186f
Polymyositis, oral manifestations of, 1252
Polymyxin, neomycin, and hydrocortisone (PNH, Cortisporin Otic Solution), for otitis externa, 1946, 1952, 1959t-1960t
Polyneuropathy, in Bell's palsy, 2391, 2392t
Polyostotic fibrous dysplasia, oral manifestations of, 1257
Polyp(s)
  aural, 1965
  nasal
    endoscopic sinus surgery for, 751-752
    olfactory dysfunction due to, 625, 634f
    surgical management of, 741
  in paranasal sinuses, 676, 678f
  vocal fold, 867-869
    with capillary ectasia, 868f
    in children, 2882
    diagnosis of, 868
      history in, 868
      laryngeal examination in, 868
      vocal capability battery in, 868
    epidemiology of, 867
    pathophysiology and pathology of, 867-868
    treatment of, 868-869
      behavioral, 868
      medical, 868
      surgical, 868-869
    in vocal professional, 846
Polypeptides, in saliva, 1140
Polypoid granulation tissue, of larynx, 880
Polyposis
  sinonasal
    in aspirin-exacerbated respiratory disease, 732f
    endoscopic sinus surgery for, 751-752
Polyposis *(Continued)*
    with methicillin-resistant *Staphylococcus aureus* infection, 733f
    surgical management of, 741
  vocal fold, 872-873, 872f
    diagnosis of, 872
      history in, 872
      laryngeal examination in, 872
      vocal capability battery in, 872
    epidemiology of, 872
    management of, 872-873
      behavioral, 872
      medical, 872
      surgical, 872-873, 873f
    pathophysiology and pathology of, 872
Polyrhinia, 2690-2692
Polysomnography (PSG), for obstructive sleep apnea, 255, 255b, 256f
  in children, 2606-2607, 2607f, 2607t, 2794
    indications for, 2608
Polytef injection, for vocal fold paralysis in children, 2879
Polytetrafluoroethylene (Teflon), for vocal fold medialization
  history of, 905
  by injection, 905-906
    complications of, 907, 908f
Polytetrafluoroethylene carbon, for nasal reconstruction, 368
Polytetrafluoroethylene (Gore-Tex) implant, for saddle nose deformity, 555, 558f
Polytetrafluoroethylene (Gore-Tex) strip, for medialization thyroplasty, 908, 910, 911f
Polyvinyl alcohol (PVA, PVA Foam, Trufill, Contour Emboli), for embolization, 1933
Pons
  in surgical anatomy of anterior cranial base, 2474f
  in surgical anatomy of lateral skull base, 2439f
Pontine arteries, 2351f
Pontine-mesencephalic sulcus, in surgical anatomy of lateral skull base, 2439f
PONV (postoperative nausea and vomiting), in children, 2593
Popcorn activity, in facial nerve monitoring, 2547f
Population
  accessible, 68, 68t
  target, 68, 68t
Porous high-density polyethylene implant, for nasal reconstruction, 368
PORP. *See* Partial ossicular replacement prosthesis (PORP).
Porphyromonas gingivalis, 1252
PORT (postoperative radiation therapy), 1042-1043
Port wine stain, 291, 2832-2833
Porus acusticus
  anatomy of, 1822
  in surgical anatomy of lateral skull base, 2437-2438
Posaconazole, for fungal rhinosinusitis, 712, 713t
POS-Head/Neck (Patient Outcomes of Surgery–Head/Neck), 57
Positional testing, 2315-2316, 2315f
  after vestibular rehabilitation, 2373f-2374f
Positioning template, in microtia reconstruction, 2744-2745, 2745f
Positron, 1031-1032
Positron emission tomography (PET), 137-138
  applications of, 144, 145f
  for cerebral blood flow evaluation, 2491
  with intensity-modulated radiotherapy, 1044
  of laryngeal carcinoma, 1494-1495
    early glottic, 1517
  of nasopharyngeal carcinoma, 1354
  of neck masses, 1637, 1637t
  of neck neoplasms, 1656-1657
  of olfaction, 632

Positron emission tomography (PET) *(Continued)*
of oral cancer, 1300
of oropharyngeal cancer, 1366
of paranasal sinus tumors, 1124
of salivary glands, 1150, 1168
Positron emission tomography/computed tomography (PET/CT), 138
for hypopharyngeal and cervical esophageal cancer, 1424, 1424f
of laryngeal carcinoma, 1470, 1470f, 1494-1495
of neck neoplasms, 1656-1657
of pharynx and esophagus, 1396-1397, 1397f
for tumor recurrence, 1418, 1419f-1420f
Postauricular abscess, 1985, 1985f-1986f
Postauricular approach(es)
to infratemporal fossa, 2495-2500
cervical dissection in, 2495, 2498f
closure of external auditory canal in, 2495, 2497f
extratemporal facial nerve dissection in, 2495-2496
incisions and skin flaps in, 2495, 2497f
radical mastoidectomy in, 2496, 2498f
removal of external auditory canal wall skin and tympanic membrane in, 2495, 2497f
type A, 2497-2499
closure of wound in, 2499, 2499f
exposure of jugular bulb and internal carotid artery in, 2498, 2498f-2499f
facial nerve transposition in, 2497-2498, 2498f
occlusion of sigmoid sinus in, 2498, 2498f
tumor removal in, 2498-2499, 2499f
type B, 2499-2500, 2500f
type C, 2500, 2501f
for mastoidectomy, 2011, 2011f
for tympanoplasty, 2001-2002
Postauricular ecchymosis, 97
Postauricular lymph node, 1360f
Postauricular sulcus, in microtia reconstruction, 2746, 2748f
Postcricoid carcinoma
Plummer-Vinson syndrome and, 1425-1426
total laryngopharyngectomy for, 1573
Postcricoid region, 1421
Posterior ampullary nerve, 1854f, 2278f
Posterior auricular artery, 2580, 2580f
Posterior canal benign paroxysmal positional vertigo (PC-BPPV)
anatomic and physiologic basis for, 2288-2289, 2288f
conversion of, 2332
positional testing for, 2315, 2315f, 2331, 2331f
repositioning maneuver for, 2331-2332, 2332f
surgical treatment of, 2332
Posterior cerebral artery(ies), 2351f
in surgical anatomy of anterior skull base, 2481f
Posterior cervical (PC) space, 158, 159f-160f, 162f
Posterior clinoid process, in surgical anatomy of lateral skull base, 2435f
Posterior commissure scar, 2915, 2916f
Posterior commissure stenosis, 948
Posterior communicating artery, 2351f
Posterior cranial fossa. *See* Posterior fossa.
Posterior cricoarytenoid (PCA) ligament, 1542f
Posterior cricoarytenoid (PCA) muscle
anatomy of
applied, 806, 806f
surgical, 1542f
botulinum toxic injection of, for spasmodic dysphonia, 841f
in breathing, 808-809, 808f
characteristics of, 918
compartmentalization of, 806-807, 807f
reinnervation of, 917-918
Posterior cricoid division, laryngofissure with, for laryngeal stenosis, 2919, 2919f
Posterior ethmoid, prior to endoscopic sinus surgery, 764t
Posterior ethmoid air cells, and internal carotid artery, 671-672
Posterior ethmoid branch, 483f
Posterior ethmoidal artery
anatomy of, 682-683, 1124f
in surgical anatomy of anterior cranial base, 2471-2473, 2472f
Posterior ethmoidal foramen, 322f, 439
Posterior ethmoidectomy, in endoscopic sinus surgery, 747-748, 749f
Posterior facial vein
anatomy of, 1359f
in parotidectomy, 1195-1196, 1195f
Posterior fontanelle, 2618f
Posterior fossa
in surgical anatomy of anterior cranial base, 2475f
in surgical anatomy of lateral skull base, 2435f, 2438-2440, 2439f
Posterior fossa neoplasm(s), 2514-2541
of cerebellopontine angle
acoustic neuroma as, 2514-2517
diagnostic studies of, 2516-2517
imaging of, 2517, 2517t-2518t
natural history of, 2515, 2515f-2516f
signs and symptoms of, 2515-2516
arachnoid cysts as, 2523-2524
chondrosarcomas as, 2527, 2528f-2529f
chordomas as, 2526-2527, 2527f-2528f
common, 2514-2524, 2515b
dermoid tumors as, 2527
differential diagnosis of, 2517t-2518t
facial nerve neuroma as, 2519-2522
diagnostic studies of, 2519-2522
imaging of, 2519-2522, 2521f
signs and symptoms of, 2519
glomus tumors as, 2522-2523, 2523f-2524f
hemangiomas as, 2524, 2525f
lipomas as, 2527, 2529f-2530f
meningiomas as, 2517-2518
diagnostic studies of, 2518
imaging of, 1928, 1928f, 1929t, 2518, 2518t, 2519f-2520f
signs and symptoms of, 2518
metastatic, 2526
other cranial nerve neuromas as, 2522, 2522f
primary cholesteatomas as, 2518-2519
diagnostic studies of, 2519
imaging of, 2519, 2520f-2521f
signs and symptoms of, 2518-2519
teratomas as, 2527
uncommon, 2515b, 2526-2527
differential diagnosis of, 2514, 2515b
intra-axial, 2528-2529
brainstem gliomas as, 2528
hemangioblastomas as, 2528
malignant choroid plexus papillomas and ependymomas of fourth ventricle as, 2528-2529, 2530f-2531f
medulloblastomas as, 2528
meningiomas as
embolization of, 1938
with petrous apex involvement, 2508f
of petrous apex, 2524-2526
vs. asymmetrical pneumatization, 2525, 2526f
vs. carotid artery aneurysms, 2525, 2527f
cholesterol granulomas as, 2524-2525, 2524t, 2526f
giant cell tumors as, 2526
mucocele, mucus retention cysts, and petrous apex effusion as, 2524t, 2525, 2526f-2527f
requiring drainage, surgical approaches for, 2539
infralabyrinthine, 2539, 2540f
middle cranial fossa, 2539
Posterior fossa neoplasm(s) *(Continued)*
transcanal intracochlear, 2539, 2540f
translabyrinthine, 2539
surgical approaches for, 2529-2539, 2532t
combined (petrosal), 2532t, 2539
advantages and disadvantages of, 2532t, 2539
basic features of, 2539
indications for, 2532t, 2539
technique of, 2539, 2539f
complications of, 2540-2541
CSF leaks as, 2540
facial nerve injury as, 2541
involving anteroinferior cerebellar artery, 2540
meningitis as, 2541
ophthalmologic, 2541
with drainage, 2539
infralabyrinthine, 2539, 2540f
middle cranial fossa, 2539
transcanal intracochlear, 2539, 2540f
translabyrinthine, 2539
experimental, 2539
extended middle fossa, 2532t, 2538
advantages and disadvantages of, 2532t, 2538
basic features of, 2538
indications for, 2532t, 2538
surgical exposure in, 2538f
technique of, 2538
middle fossa, 2532t, 2534-2536
advantages and disadvantages of, 2532t, 2536
basic features of, 2534
indications for, 2532t, 2534-2535
surgical exposure in, 2535f
technique of, 2535-2536, 2535f
patient management with, 2540-2541
intraoperative, 2540
postoperative, 2540
preoperative, 2540
retrolabyrinthine, 2532t, 2536
advantages and disadvantages of, 2532t, 2536
basic features of, 2536
indications for, 2532t, 2536
surgical exposure in, 2536f
technique of, 2536, 2536f
retrosigmoid (suboccipital), 2532t, 2533-2534
advantages and disadvantages of, 2532t, 2534
basic features of, 2533
indications for, 2532t, 2533
surgical exposure in, 2533f
technique of, 2534, 2534f
selection of, 2539-2540
transcochlear, 2532t, 2537
advantages and disadvantages of, 2532t, 2537
basic features of, 2537
indications for, 2532t, 2537
surgical exposure in, 2537f
technique of, 2537, 2537f
translabyrinthine, 2530-2533, 2532t
advantages and disadvantages of, 2532t, 2533
basic features of, 2530
indications for, 2530, 2532t
requiring drainage, 2539
surgical exposure in, 2531f
technique of, 2530-2532, 2533f
tumor removal in, 2532-2533
transotic, 2532t, 2537-2538
advantages and disadvantages of, 2532t, 2538
basic features of, 2537
indications for, 2532t, 2537-2538
technique for, 2538, 2538f
vestibular symptoms of, 2354
Posterior glottic gap, laryngeal videostroboscopy of, 819, 820f
Posterior hypopharyngeal wall, 1421
Posterior hypopharyngeal wall carcinoma, total laryngopharyngectomy for, 1573

Posterior incudal ligament, anatomy of, 1827f
Posterior inferior cerebellar artery, 2351f
Posterior lamella, of eyelid, 442
Posterior laryngeal clefts, dysphagia due to, 2952-2953
Posterior lateral nasal artery, in surgical anatomy of anterior cranial base, 2473f
Posterior mallear fold, 1825f
Posterior medial scalene muscle, 2579f
Posterior nasal depth, 2617t
Posterior ostiomeatal unit, 664
Posterior petrous apex (PPA), 1975-1976, 1976f
  pneumatic, 1976, 1977f
Posterior pole, 320f
Posterior semicircular canal
  anatomy of, 2278f
  in surgical anatomy of lateral skull base, 2436f, 2439f
Posterior semicircular canal occlusion, 2360-2361, 2361f
Posterior semicircular duct, 1851f, 1854f
Posterior spiral vein, 1856f
Posterior suspensory ligament, 1751
Posterior triangle, of neck, 2577-2579, 2578f-2579f
  accessory nerve in, 2578-2579, 2580f
  arterial branches in, 2579
  cutaneous branches of cervical plexus in, 2578, 2580f
  fascia in, 2577
    deep, 2577-2578, 2578f-2579f
    superficial, 2577
Posterior triangle dissection, 96, 96f, 1709
Posterior triangle lymph nodes, 1704, 1704f, 1706t-1708t
Posterior vestibular artery, 1854, 1856f
Posterior vestibular vein, 1856f
Posterior wall augmentation, for velopharyngeal dysfunction, 2683-2684
Posterolateral fontanelle, 2618f
Posterolateral neck dissection, 1718-1719
Posterolateral vertical hemilaryngectomy, 1548
Postexposure prophylaxis (PEP), for HIV infection, 212, 212t
Postintubation croup, in children, 2593
Postintubation granuloma(s), 939, 941f
  of vocal folds, 875-876, 875f
    diagnosis of, 875-876
      history in, 875
      vocal capability battery in, 875-876
    epidemiology of, 875
    management of, 876
    pathophysiology and pathology of, 875
Postobstructive pulmonary edema, 119
Postoperative dysphonia, 873-874, 873f
  diagnosis of, 873-874
    history in, 873
    laryngeal examination in, 874
    vocal capability battery in, 873-874
  epidemiology of, 873
  management of, 874
    behavioral, 874
    medical, 874
  pathophysiology and pathology of, 873, 874f
Postoperative epistaxis, 685f
Postoperative management, for children, 2575
Postoperative nausea and vomiting (PONV), in children, 2593
Postoperative neck and face, imaging of, 173-174, 175f-176f
Postoperative radiation therapy (PORT), 1042-1043
Postparotidectomy fistula, 1728
Postpolio syndrome, laryngeal hypofunction due to, 842
Postsaccadic drift, 2308, 2313
Poststreptococcal glomerulonephritis, 2788
Post-styloid compartment, 202
Poststyloid space, 1699
Post-tetanic potentiation, 1884
Posttransplantation lymphoproliferative disorder (PTLD), 213t, 215, 217
  in children, 2818, 2840
Postural balance, lateral vestibulospinal tract in, 1865
Postural control exercises, in vestibular rehabilitation, 2372-2373, 2378-2379
Postural rehabilitation, posturography in, 2326
Postural tone, sudden changes in saccular activity and changes in, 2300
  anatomic and physiologic basis for, 2300
  clinical importance of, 2300
Posture
  in vestibular function, 2308
  vestibular system in maintaining stability of, 2276-2277
    anatomic and physiologic basis for, 2276-2277
    clinical importance of, 2277
  in voice evaluation, 827
Posturography, 2324, 2325f
  dynamic
    for ablative vestibular surgery, 2365
    for vestibular rehabilitation, 2376-2377
  motor control test in, 2324-2325
  sensory organization test in, 2325-2326, 2325f-2326f
  use of, 2326-2327
Potassium (K^+)
  in endolymph homeostasis, 2081-2082, 2084f
  in saliva, 1139
Potassium (K^+) channels, in hair cell transduction, 2073, 2073f
  effects of deficiencies of, 2079-2080
Potassium iodide, saturated solution of
  for Graves' disease, 1742-1743
  for hyperthyroidism, 1739t
Potassium-titanyl-phosphate (KTP) laser, 31t, 33
  for facial resurfacing, 403t
  for recurrent respiratory papillomatosis, 880, 880f, 2891
  for stridulous child, 2908
POU3F4, in deafness, 2051t-2058t, 2083
POU4F3, in deafness, 2051t-2058t
Povidone-iodine (Betadine), for embolization, 1933
Powder insufflator, for ear hygiene or chronic ear drainage, 1958, 1961f
Power
  of statistical test, 65, 66t
  of surgical laser, 27, 29f
Powered microsurgical debrider, interventional bronchoscopy with, 1010t
PPA (posterior petrous apex), 1975-1976, 1976f
  pneumatic, 1976, 1977f
PPAR (peroxisome proliferator-activated receptor), for chemoprevention of oral cancer, 1315
PPIs. *See* Proton pump inhibitors (PPIs).
PPNET (peripheral primitive neuroectodermal tumor), 2845
PPRF (paramedian pontine reticular formation), in velocity-to-position integration, 2296, 2297f
PPS. *See* Parapharyngeal space (PPS).
PPV23 (pneumococcal capsular polysaccharide vaccine), with cochlear implants, 2236-2237, 2237b
Practice performance assessment, 79t
PRAD1 (parathyroid adenomatosis 1 oncogene), in hyperparathyroidism, 1774-1775, 1775f
Pramoxine hydrochloride and hydrocortisone (Pramosone steroid cream), after chemical peel, 396
Preauricular infratemporal approach, 2500-2501, 2501f
Preauricular node, 1297f
Precapillary sphincter, 1066
Precision, 65
Prednisolone, for hemangioma of infancy, 2826-2828
Prednisone
  for autoimmune inner ear disease, 2166
  for Graves' ophthalmopathy, 1811
  for herpes zoster oticus, 1948
  for hyperthyroidism, 1739t
  for otosyphilis, 2341-2342
  for rhinosinusitis, 734t
  for sarcoidosis, 659
  for Wegener's granulomatosis, 658
Preeclampsia, and facial palsy, 2399
Preemptive analgesia, 241
Preepiglottic space (PES)
  anatomy of, 1484, 1484f
    radiographic, 1471f, 1473, 1473f
    surgical, 1542, 1543f
  laryngeal cancer of
    anatomic basis for, 1484, 1484f
    imaging of, 1495
Pregabalin (isobutyl-GABA), for neuropathic pain, 243, 244t
Preglandular node, 1298f
Pregnancy
  facial paralysis in, 2399
  hyperparathyroidism during, 1804
  hypothyroidism during, 1749
  oral health during, 1256
  rhinitis during, 696, 702
  rhinosinusitis during, 737
  thyroid neoplasms during, 1770
Pregnancy gingivitis, 1256
Pregnancy granuloma, 1256
Pregnancy tumor, 1256
Premalignant lesions
  for head and neck cancer, 1061
  of larynx, 1486-1491, 1489f-1490f
    treatment of, 1489-1490, 1490t
      in-office, 1490-1491
  of oral cavity, 1298-1299
Premature infants, anesthesia for, 2595
Prematurity, and otitis media, 2766
Premaxillary bone deformity, in cleft lip, 2666, 2666f
Premedication, for anesthesia in children, 2589
  with congenital heart disease, 2596
Prenatal diagnosis, of cleft lip and palate, 2661-2662, 2663f
Prenatal testing, for sensorineural hearing loss, 2098
Preoperative embolization, for juvenile nasopharyngeal angiofibroma, 1351
Preoperative evaluation, 101-107
  of allergy, 102
  of cardiovascular system, 102
  consent in, 102
  of endocrine disorders, 104-105
    of adrenal gland, 104-105
    diabetes mellitus as, 105
    of parathyroid, 104
    of thyroid, 104
  of hematologic disorders, 105-106
    due to anticoagulants, 105
    congenital, 105
    hemoglobinopathies as, 106
    due to liver failure, 105-106
    thrombocytopenia as, 106
  of hepatic disorders, 103-104
  of neurologic disorders, 106
  of older patients, 106-107
  of renal system, 103
  of respiratory system, 102-103
  routine screening tests in, 101
PRES, in deafness, 2051t-2058t

Presbycusis, 232
defined, 232
etiologies of, 232
inner ear conductive (mechanical), 232, 2126
neural, 232, 2126
sensorineural hearing loss due to, 2125-2126, 2126f
sensory, 232, 2126
strial (metabolic), 232, 2126
with tinnitus, 2132
treatment of, 233
types of, 232
Presbyesophagus, 1400
Presbyphagia, 237
diagnostic testing for, 237
treatment of, 237
Presbyphonia, 234-237
acoustic changes in, 236
dental/mandibular changes in, 236
factors affecting vocal quality in, 234, 235t
glandular changes in, 236
histologic changes in, 234-235, 235f
laryngoscopic appearance in, 235-236
mucosal changes in, 236
respiratory changes in, 236
and sense of taste, 236
treatment of, 236-237
Presbystasis, 233-234
defined, 233
diagnostic methods for, 233
treatment of, 234
vestibular pathology of, 233
Preseptal orbital edema, due to rhinosinusitis, 676
Preshunt sphincters, 1066
Pressure changes, and eustachian tube dysfunction, 1872
Pressure flow measurement, for velopharyngeal dysfunction, 2679
Prestin
in hair cells, 1844
and outer hair cell motility, 2064-2065, 2068f
Prestyloid compartment, 202
Presyncope, 2346
Pretibial myxedema, and Graves' ophthalmopathy, 1808
Pretrichial forehead lift, 430, 431t
Prevalence, 61
Prevascular node, 1298f
Prevertebral fascia, 202, 2577-2578, 2578f, 2580f
Prevertebral layer, 202
Prevertebral space (PVS)
anatomy of, 203
infrahyoid, 158, 159f-160f, 162f
odontogenic infections of, 186, 186f
suprahyoid, 146f, 153
Prevnar (pneumococcal conjugate vaccine)
with cochlear implants, 2237, 2237b
to prevent otitis media, 2763, 2768
maternal immunization with, 2768-2769
Primary auditory cortex, 1847
Primary autoimmune inner ear disease, sensorineural hearing loss due to, 2124
Primary ciliary dyskinesia, nasal manifestations of, 661
Primary closure
of forehead defects, 359-362
of lip defects, 351
of nasal defects, 365, 365f
for oropharyngeal reconstruction, 1376
of tongue base, 1387-1388
of tonsil and pharyngeal wall, 1383-1384
Primary mucosal malignant melanoma of the larynx (PMMML), 1509
Primary ostium, of maxilla, 665, 665f
Primo passagio, 851
Primordial cyst, 1265
Probe therapy, in voice evaluation, 831
Proboscis lateralis, 2690, 2692, 2692f
Procerus muscle, 321f, 433f, 441-442, 442f
Processus vocalis, 1543f
Professional accountability, 82
Professional standing, 79t
Professional voice disorders, 844-858
anatomic considerations with, 845-846
basement membrane and lamina propria in, 846, 846f
blood vessels in, 845-846
cover-body theory of vocal fold vibration in, 845, 845f
causes of, 852-854
anxiety as, 853
extraesosphageal reflux as, 852
laryngeal hygiene as, 852-853
laryngitis as, 853
pulmonary disease as, 853
vocal abuse and misuse as, 853
vocal fold varices as, 853-854
evaluation of, 850-852
history of present illness in, 850-851
medical history in, 850
physical examination in, 851-852, 852t
laryngeal stroboscopy for, 847-849, 848f, 848t
management of, 854-857
medical therapy for, 854-855, 854b
speech language pathologist and vocal pedagogue in, 852, 855
surgical therapy for, 855-857, 856f-857f
postoperative care after, 856-857, 858t
performance cancellation due to, 854, 854b
types of
cysts as, 856, 857f
superficial vocal cord lesions as, 855-856, 856f
vocal fold varices as, 846-847, 856, 857f
voice analysis for, 849-850
acoustic measures in, 849
aerodynamic measures in, 849
electroglottography in, 849
perceptual analysis in, 850
spectrometry in, 849
voice outcomes in, 850
voice production and, 846-847
Professional voice patients, related surgical procedures in, 857-858
Professional voice production, 846-847
Programmable hearing aids, 2267, 2269
programming of, 2273
Progressive bulbar palsy (PBP), laryngeal disorders due to, 839-840, 842
Progressive multifocal leukoencephalopathy (PML), HIV-associated, 223
Progressive spinal muscular atrophy (PSMA), laryngeal hypofunction due to, 842
Progressive supranuclear palsy (PSP), laryngeal hypofunction due to, 843
Progressive systemic sclerosis (PSS), esophageal manifestations of, 979, 979f
Prokinetic agents
for extraesophageal reflux in children, 2946
for GERD, 970
Proliferating cell nuclear antigen (PCNA), in salivary gland neoplasms, 1194
Proliferation phase, of wound healing, 1076-1078
formation of granulation tissue in, 1077-1078
angiogenesis in, 1077-1078
dermal matrix in, 1077
reepithelialization in, 1076-1077
keratinocyte migration in, 1076-1077
keratinocyte proliferation in, 1077
wound contraction in, 1078
Proliferative verrucous leukoplakia, 1225, 1225f
Promoter(s), of gene expression, 19
Promoter hypermethylation, in head and neck squamous cell carcinoma, 1021
Promotility agents, for extraesophageal reflux, 901
PROP (propylthiouracil), taste sensitivity to, 1211-1212
Propecia (finasteride), for hair loss, 377-378
Proper cochlear artery, 1854, 1856f
Prophylaxis
antibiotic
for acute otitis media, 2771
for burns, 315
for orthopedic joint patients, 1253, 1253t
for sinus surgery, 743, 773
for temporal bone fractures, 2044-2045
for cluster headaches, 248
for CSF fistulas, 794
for migraines, 247
postexposure, for HIV infection, 212, 212t
subacute bacterial endocarditis, for pediatric surgery, 2596, 2596t-2597t
for trigeminal neuralgia, 248
Propofol, for anesthesia induction, 111
in children, 2590
Propoxyphene, for postoperative pain, 241t
Propranolol (Inderal)
for hyperthyroidism, 1739t
for migraine, 2349
for thyroid storm, 1745
Proptosis
in Graves' ophthalmopathy, 1808, 1809t
due to paranasal sinus tumor, 1123-1124
Propylene glycol, for cerumen removal, 1958t
Propylene glycol and acetic acid otic solution (VoSol), for otitis externa, 1946, 1953, 1959t-1960t
Propylthiouracil (PROP), taste sensitivity to, 1211-1212
Propylthiouracil (PTU)
adverse reactions to, 1742
for Graves' disease, 1742
for hyperthyroidism, 1739t
Prosody, in voice evaluation, 826-827
Prospective studies, 61
Prostaglandins (PGs)
in acutely raised skin flaps, 1070, 1070f
in bone remodeling, 1973
and skin flap viability, 1073
Prostate carcinoma, skull base metastases of, 173f
Prosthesis(es)
ossicular (*See* Ossicular prosthesis(es))
for velopharyngeal dysfunction, 2681-2682, 2681f-2682f
voice (*See* Voice prosthesis(es))
Prosthetic ear, 1345-1346, 1345t, 1346f
Prosthetic eye, 1345t, 1346-1347, 1347f
Prosthetic management
of acquired facial defects, 1344-1345, 1345t
auricular, 1345-1346, 1345t, 1346f
nasal, 1345, 1345t, 1346f
orbital/ocular, 1345t, 1346-1347, 1347f
of head and neck defects (*See* Maxillofacial prosthodontics)
of tumor-ablative surgical defects, 1337-1338
of mandible, 1340, 1341f-1342f
discontinuity, 1340-1342, 1342f-1343f
of maxilla, 1338
of soft palate, 1343-1344, 1344f
of tongue, 1342-1343, 1344f
Prosthetic maxillary obturation, 1338
definitive, 1339-1340
for dentate patients, 1339-1340, 1340f
for edentulous patients, 1340, 1340f-1341f
interim, 1339, 1339f
surgical, 1338-1339
abutments in, 1338-1339
impressions for diagnostic casts in, 1338-1339, 1338f
postoperative radiograph of, 1338, 1338f
preoperative assessment for, 1338, 1338f
preservation of support structures in, 1338

Prosthetic maxillary obturation *(Continued)*
removal of packing material and prosthesis in, 1339, 1339f
securing of prosthesis in, 1338-1339, 1339f
skin graft in, 1338-1339
Prosthetic nose, 1345, 1345t, 1346f
Prosthetic obturation
maxillary (*See* Prosthetic maxillary obturation)
for soft palate reconstruction, 1381
Protease inhibitors (PIs), 211
Protection, saliva in, 1140-1141
Protein(s)
formation of, 4, 5f, 11-12, 12f
salivary, 1139-1140, 1139t-1140t
Protein tyrosine phosphatase receptor Q (Ptprq)
and interstereociliary linkages, 2077
in stereocilia, 2076f
Protein tyrosine phosphatase receptor Q *(Ptprq)* gene, in murine deafness, 2058t-2060t
Proteomics, in head and neck squamous cell carcinoma, 1029
Protocadherin-15 (PCDH15), in tip links, 2074
Protocadherin-15 *(PCDH15)* gene, in deafness, 2051t-2058t, 2074
Proton beam radiotherapy, for malignant skull base tumors, 1696
Proton pump inhibitors (PPIs)
for extraesophageal reflux, 901
in children, 2946
for GERD, 970
for laryngoesophageal reflux, 901, 971
for rhinosinusitis, 735t
Proton therapy, 1046
Proto-oncogenes, in head and neck squamous cell carcinoma, 1016, 1019-1020
Protopic (tacrolimus), for eczematoid otitis externa, 1956
Provocation testing
in nonallergic rhinitis, 695-696
objective measurement methods in, 651
Provocative testing, of esophagus, 962-963
Provox 2 anterograde replacement system, 1598f
Provox voice rehabilitation system, 1598f
Proximal esophageal pressure, 958f
Prussak's space, anatomy of, 1826-1827
PS (Pendred syndrome). *See* Pendred syndrome (PS).
PS (parotid space)
anatomy of, 203
imaging of, 149-150, 150f-151f
P_s (subglottic air pressure)
in professional voice production, 846
in voice evaluation, 828, 828t, 849
PSCC (papillary squamous cell carcinoma), of larynx, 1506
Pseudallescheria boydii, invasive fungal rhinosinusitis due to, 705
Pseudoaneurysms
embolization of, 1942, 1943f
due to radiotherapy, 1049
Pseudoarthrosis, 331, 339-340
Pseudobulbar palsy (PBP), laryngeal disorders due to, 839-840, 842
Pseudodiverticula, esophageal, 975, 975f
imaging of, 1406, 1407f
Pseudoephedrine, for rhinosinusitis, 736
Pseudoepiglottitis, postlaryngectomy, 1416, 1417f
Pseudoepitheliomatous hyperplasia (PEH), of larynx, 1493
Pseudohypoacusis
evaluation of, 1901
sensorineural hearing loss due to, 2125
Pseudohypoparathyroidism, oral manifestations of, 1251
Pseudomembranous candidiasis, 1230, 1230f
in HIV, 225, 226f
Pseudo-membranous croup. *See* Bacterial tracheitis.
Pseudomonas aeruginosa, otitis externa due to, 1945, 2194-2195
malignant, 1947
Pseudoretropharyngeal mass, 1462, 1463f
Pseudosarcoma, of larynx, 1506
Pseudosulcus, due to extraesophageal reflux, 897
Pseudotumor(s)
cerebri, CSF rhinorrhea due to, 787
of masticator space, 152
Pseudovallecula, prevention of formation of, 1599-1600, 1601f
PSG (polysomnography), for obstructive sleep apnea, 255, 255b, 256f
in children, 2606-2607, 2607f, 2607t, 2794
indications for, 2608
PSMA (progressive spinal muscular atrophy), laryngeal hypofunction due to, 842
PSP (progressive supranuclear palsy), laryngeal hypofunction due to, 843
PSS (progressive systemic sclerosis), esophageal manifestations of, 979, 979f
Psychiatric disorders, olfactory dysfunctions in, 636
Psychogenic disorders, sensorineural hearing loss due to, 2129
Psychological distress, palliative care for, 1103-1104
Psychological effects, of radiotherapy, 2626t
Psychometric validation, 55
Psychotherapeutic agents, oral sequelae of, 1247t-1248t
Psychotropic medications, in palliative care, 1104
PTA (pure-tone average), 1888-1889
PTC (phenylthiocarbamide), taste sensitivity to, 1211-1212
PTEN (phosphatase and tensin homolog) gene, in thyroid carcinoma, 1753
Pterygoid hamulus, 1297f, 1360f
Pterygoid muscle, 1320
Pterygoid plate, 1124f
Pterygoid plate fractures, 171f
Pterygoid process, 2445f
Pterygoid venous plexus, 2441
Pterygomandibular involvement, in odontogenic infections, 184, 185f
Pterygomaxillary fissure, 2441
Pterygomaxillary fossa, 2435f
Pterygopalatine fossa
anatomy of, 1699
in surgical anatomy of anterior cranial base, 2473
Pterygopalatine ganglion
anatomy of, 1297f
in surgical anatomy of anterior cranial base, 2473
PTH. *See* Parathyroid hormone (PTH).
PTLD (posttransplantation lymphoproliferative disorder), 213t, 215, 217
in children, 2818, 2840
Ptosis
brow, 445, 445f
of chin, 465, 466f
of nasal tip, 484, 485f
caudal extension graft for, 576, 576f
due to overaggressive resection of caudal septum, 492, 492f
revision rhinoplasty for, 590-593, 593f
after rhinoplasty, 519, 520f
of upper eyelid
evaluation of, 446-447, 447f
repair of, 447-448, 447f-449f
Ptprq (protein tyrosine phosphatase receptor Q)
and interstereociliary linkages, 2077
in stereocilia, 2076f
Ptprq (protein tyrosine phosphatase receptor Q) gene, in murine deafness, 2058t-2060t
PTS (permanent threshold shift), 2121, 2141
PTU (propylthiouracil)
adverse reactions to, 1742
for Graves' disease, 1742
for hyperthyroidism, 1739t
PTV (planning tumor volume), for radiotherapy, 1036, 1044-1045, 1045f
Puberty, oral health during, 1256
Pull-through technique, as mandible-sparing procedure, 1311, 1312f-1313f
Pulmonary artery anomalies, tracheal compression due to, 2926
Pulmonary diseases
oral manifestations of, 1250-1251
professional voice disorders due to, 853
Pulmonary edema
after adenotonsillectomy, 2800
postobstructive, 119
Pulmonary function, in geriatric patients, 236
Pulmonary function testing
for airway stenosis, 944, 945f
in children, 2917
preoperative, 103
for tracheal neoplasms, 1616
Pulmonary hypertension, due to obstructive sleep apnea, in children, 2604
Pulmonary vascular resistance, factors influencing, 2597, 2597t
Pulpitis, *vs.* myofascial pain dysfunction syndrome, 1284t
Pulse sequences, for MRI, 133-137, 135f-136f
Pulsed dye laser (PDL), 30
585-nm, 31t, 33
for facial resurfacing, 403t
for premalignant lesions of larynx, 1490-1491
for recurrent respiratory papillomatosis, 880, 880f, 2891
for stridulous child, 2908
Pulsion diverticula, 986
Punch biopsy, for skin lesions, 293
Punnett squares, 2088, 2089f
Pure tone, 1838-1839
Pure-tone audiometry, 1888, 1888f
air-conduction testing in, 1888
masking for, 1889-1890
errors in, 1901-1902
bone-conduction testing in, 1888, 1888f-1889f
for conductive hearing loss, 2020, 2020f
for sensorineural hearing loss, in adults, 2117
Pure-tone average (PTA), 1888-1889
Pure-tone Stenger test, 1901
Purkinje cells, in modification of vestibuloocular reflex, 2301, 2301f
Purkinje, Jan E., 2329
PVA (polyvinyl alcohol), for embolization, 1933
PVA Foam (polyvinyl alcohol), for embolization, 1933
pVHI (Pediatric Voice Handicap Index), 2876
PVOS (Pediatric Voice Outcomes Survey), 57, 2876
PVQOL (Pediatric Voice-Related Quality-of-Life survey), 57, 2876
PVS. *See* Prevertebral space (PVS).
Pyogenic granuloma, 290
of oral cavity, 1256, 1289, 1289f
on septum, 685f
Pyramidal eminence
anatomy of, 1825-1829, 1827f
in surgical anatomy of lateral skull base, 2436f
Pyramidal lobe, of thyroid gland, 1751, 1751f
Pyriform aperture, 641f
edge of, 509f
Pyriform aperture stenosis, congenital nasal, 2692-2693
clinical presentation of, 2692-2693
diagnosis of, 2693, 2693f
operative management of, 2693, 2693f
pathogenesis of, 2690, 2692
Pyriform sinus(es)
anatomy of, 1421, 1422f
radiographic, 1397, 1463f, 1471f, 1472
lymphatic drainage from, 1422, 1422f

Pyriform sinus carcinoma, 162f
advanced, 1438-1439
chemotherapy for, 1439
quality of life with, 1439
imaging of, 1413f, 1423-1424, 1424f, 1475-1476, 1478f
surgical management of
endoscopic CO_2 laser resection for, 1429-1430, 1442
outcomes of, 1436-1438
partial laryngopharyngectomy for, 1429, 1430f
partial pharyngectomy for, 1426-1429
via anterior transhyoid pharyngotomy, 1427-1429, 1428f
via lateral pharyngotomy, 1426-1427
via lateral transthyroid pharyngotomy, 1427, 1428f
via median labiomandibular glossotomy, 1429
supracricoid hemilaryngopharyngectomy for, 1429, 1436
total laryngectomy with partial/total pharyngectomy for, 1430, 1431f
total laryngopharyngectomy for, 1573-1574
Pyriform sinus mucosa, in arytenoid adduction, 915
Pyrosis, 954

Q

Q (quality factor), of radiation, 133
QALY (quality-adjusted life-year), costs per, for cochlear implants
in adults, 2251, 2252t
in children, 2252-2253, 2253f
QASC (Quality Alliance Steering Committee), 84t-87t
QIOs (quality improvement organizations), 84t-87t
QOL. *See* Quality of life (QOL).

laboratory evaluation in, 514-515
photography and imaging in, 514, 515f
revision, 580-594
for alar pinching and retraction, 587, 587f-589f
for caudal septal deviation, 593
for caudal septal excision (short nose), 593
computer imaging for, 581-582
for dorsal irregularity, 584
due to errors of omission, 582, 582t
due to excessive excision, 582, 582t, 583f
due to failure to restabilize, 582, 582t
general considerations with, 582-583, 582t, 583f
grafting material for, 583, 584f
due to gross errors of judgment, 582-583, 582t, 583f
for improperly placed radix graft, 584
for lateral nasal wall deformities, 586
for low dorsum/saddle deformity, 584, 585f
for middle vault deformities, 585-586, 586f
due to minor errors of technique, 582, 582t
for nasal tip deformities, 588
irregularities and bossae as, 588-589, 590f
overrotation (short nose) as, 590, 590f-591f
persistently wide or bulbous tip as, 589-590, 590f
pinched tip as, 590, 591f-592f
ptotic tip as, 590-593, 593f
for overly narrowed alar base, 593-594, 594f
patient interview for, 580-581
photography for, 581
physical examination for, 581
for pollybeak deformity, 584-585, 586f
of skin–soft tissue envelope, 581, 594
for supra-alar and external valve collapse, 586-587, 587f
for saddle nose deformity, 554-555
dynamic adjustable rotational tip graft in, 555, 559f
implant material in, 555, 556f-557f
indications for, 555, 558f

Rhinoplasty *(Continued)*
for septal and columella modifications, 546-548, 546f-547f
caudal repositioning in, 547, 547f
dorsal draw suture in, 548, 549f
making final septal assessment in, 548, 549f
septocolumellar complex in, 548, 549f-550f
shortening of caudal septum in, 547-548, 547f-548f
with septal deviation, 513-514, 514f, 546, 546f-547f
special techniques in, 545-567
for cleft-lip nose, 557-559, 561f
Abbé flap in, 563f-564f
with bilateral deformity, 559, 561f, 563f-564f, 566
columellar lengthening in, 559, 566f
external approach to, 559, 561f
lateral ala thinning and placement of maxillary implants in, 562f
Le Fort I maxillary osteotomies in, 559, 564f-565f
with nasal stenosis, 559, 566f
open approach to, 559, 562f
repositioning and suturing lower lateral cartilage in, 562f
with severe deformity, 559, 564f-565f
suturing together medial crura in, 561f-562f
with unilateral deformity, 557, 559, 561f-562f
external approach for, 545-546, 546f
incisions and soft tissue elevation for, 545-546, 546f
for nasofrontal angle modifications, 548-549, 550f
for noncaucasian nose (*See* Rhinoplasty, noncaucasian)
open approach for, 545-546
preoperative analysis for, 545-546
for saddle nose deformity, 554-555
dynamic adjustable rotational tip graft in, 555, 559f
implant material in, 555, 556f-557f
indications for, 555, 558f
for septal and columella modifications, 546-548, 546f-547f
caudal repositioning in, 547, 547f
dorsal draw suture in, 548, 549f
making final septal assessment in, 548, 549f
septocolumellar complex in, 548, 549f-550f
shortening of caudal septum in, 547-548, 547f-548f
for tip and alar asymmetries, 549-551
alar batten grafts in, 550, 551f
suture techniques in, 550-551
tip grafts in, 549-550, 550f-551f
transposition techniques in, 551

radiographic, 1398f-1399f
Rosenthal's canal, 1832f, 1834
Rose's position, for adenotonsillectomy, 2798, 2798f
Rotation advancement closure, for cleft lip, 2667-2668, 2667f
advancement flap in, 2668, 2668f
closure in, 2668, 2668f
rotation flap in, 2667-2668, 2668f
Rotation flaps, 343-344, 343f
for cheek defects, 357-358, 359f
in cleft lip repair, 2667-2668, 2668f
for forehead repair, 362
advancement, 360-362, 362f
Rotatory chair testing, 2320-2323
bias velocity in, 2322
with cerebellar abnormalities, 2322
directionally dependent asymmetries in, 2322
interpretation of, 2297-2299
protocol for, 2320-2322
step changes in head velocity in, 2322-2323, 2323f
with unilateral vestibular loss, 2322, 2322f
for vestibular rehabilitation, 2377
Roughness, in voice evaluation, 827t
Round window
anatomy of, 1826f, 1831, 1840
in cochlear transduction, 2062f
Round window membrane (RWM), 2179-2183
with aging, 2180
anatomy of, 2179-2180, 2180f
delivery of therapeutic agents across
kinetics of, 2181, 2181f
method of, 2182-2183, 2182f-2183f
"false," 2180
obstructive adhesions of, 2181-2182
permeability of, 2180-2181
physiology of, 2180, 2181f
Round window niche, in surgical anatomy of lateral skull base, 2436f
Rowe midfacial disimpacters, 335-336
Roxithromycin, for rhinosinusitis, 733, 734t
RPC (recurrent parotitis of childhood), 1153-1154
RPS. *See* Retropharyngeal space (RPS).
RQLQ (Rhinitis Quality of Life Questionnaire), 642
RRP. *See* Recurrent respiratory papillomatosis (RRP).
RSDI (Rhinosinusitis Disability Index), 642
RSI (Reflux Symptom Index), 826, 826t, 896, 897b
RSI (rapid-sequence induction), 112-113
in children, 2590
RSTLs (relaxed skin tension lines), 269-270, 274f
and scars, 295, 296f
RSV (respiratory syncytial virus) vaccine, to prevent otitis media, 2769
RT. *See* Radiation therapy (RT).
Rubella, congenital deafness due to, 2154, 2156-2157, 2157f, 2723
Rubeola. *See* Measles.
Rubin osteotome, for rhinoplasty, 540, 540f
with hump reduction, 573
Ruffini's endings, 1202
RWM. *See* Round window membrane (RWM).

treatment and prognosis for, 1680
metastatic, 1191
minor salivary gland excision for, 1196
mixed, 1186-1189
carcinoma ex pleomorphic adenoma as, 1187-1189, 1188f
metastasizing, 1189
true (carcinosarcoma), 1187, 1188f
molecular markers for, 1194
mucoepidermoid carcinoma as
in children, 2820, 2846, 2846f, 2862-2863
differential diagnosis of, 1183
grading of, 1183, 1184t
histopathology of, 1182-1183, 1183f
imaging of, 1146, 1147f, 1168f
with N+ neck, 1197
with N0 neck, 1196-1197
of oropharynx, 1362-1363
other, 1191
parotidectomy for, 1194-1196
branches of facial nerve in, 1194, 1194f
elevation of skin flap in, 1195
external carotid artery in, 1195-1196
with facial nerve involvement, 1196
greater auricular nerve in, 1195
main trunk of facial nerve in, 1195, 1195f
marginal mandibular branch of facial nerve in, 1195, 1195f
modified Blair incision for, 1195, 1195f
partial deep, 1194-1196, 1196f

Salivary gland neoplasm(s) *(Continued)*
retromandibular (posterior facial) vein in, 1195-1196, 1195f
superficial, 1194-1195
total, 1194-1196
patient evaluation for, 1178-1181
biopsy in, 1180-1181
physical examination in, 1178-1179
radiologic studies in, 1180, 1180f
staging in, 1181, 1181t
prognostic variables for, 1192-1194, 1193t
clinical, 1192-1193
histologic, 1193-1194
molecular markers as, 1194
radiation therapy for, 1197-1199
adjuvant, 1197-1198, 1198t
in children, 2863
of neck, 1198
neutron beam, 1198-1199
salivary duct carcinoma as, 1189-1190, 1189f
small cell carcinoma as, 1190-1191, 1190f
squamous cell carcinoma as, 1190
sublingual gland excision for, 1196
submandibular gland excision for, 1196
surgical treatment of, 1194-1197
neck masses due to, 1640
radiation and, 1163
ultrasonography of, 1645-1647, 1653f-1654f
Salivary gland secretion, 1133-1136
anatomy of secretory unit in, 1133-1134, 1134f
neuronal control of, 1136
neurotransmitters and receptors in, 1136-1137, 1136f, 1137t
signal transduction in, 1137-1138
adenylate cyclase system in, 1137
G proteins in, 1137
phospholipase C system in, 1137-1138
process of, 1134-1136
ductal, 1136
fluid, 1135, 1135f
macromolecule, 1135-1136
Salivary gland unit, 1162, 1163f
Salivary pH, 2384
Salivation, reflex, 1205-1206
Sal-like 1 *(SALL1)* gene, in deafness, 2051t-2058t
Salmon patch, 290-291
Salpingopharyngeal fold, 1359f
Salpingopharyngeus muscle
anatomy of, 1870
development of, 1866
Salt restriction, for Meniere's disease, 2337
Salty taste
individual differences in, 1211-1212
peripheral sensitivity to, 1211
transduction of, 1208-1209
Sample size
calculation of, 74
determination of, 68t
small, 73, 73t
Sampling methods, 68-69, 68t-69t
SAN. *See* Spinal accessory nerve (SAN).
Sanguinaria, oral leukoplakia due to, 1223-1224, 1224f
SANS, in deafness, 2051t-2058t, 2077-2078
Saphenous vein repair, for aneurysms of upper cervical and petrous internal carotid artery, 2504, 2505f
Saprophytic fungal rhinosinusitis, 712
SAQLI (Sleep Apnea Quality of Life Index), 57
SAR (seasonal allergic rhinitis), 617-618
and pediatric chronic sinusitis, 2778
Sarcoidosis, 2104-2105
in children, 2819
salivary gland involvement in, 2858
clinical course of, 659
clinical presentation of, 2104
diagnosis of, 659
Sarcoidosis *(Continued)*
epidemiology of, 658-659, 2104
of epiglottis, 1465f
etiology of, 658
facial paralysis in, 2400

and skin flap survival, 1075
and squamous cell carcinoma
of head and neck, 1016
of larynx, 1491, 1512-1513
of oral cavity, 1293-1294, 1365
Smooth pursuit, 2277, 2306f, 2307t
evaluation of
in bedside exam, 2313-2314
testing for, 2318, 2319f
Smooth pursuit tracking system, in vestibular compensation, 2375
SMS (submandibular space)
anatomy of, 202
imaging of, 146f, 156-157, 158f
odontogenic infections of, 183-184, 183f-184f
SMV (submentovertex) view, of facial bones and sinuses, 130
SNAI2, in deafness, 2051t-2058t, 2095
Snap test, 445, 446f
SND. *See* Selective neck dissection (SND).
Snell's waltzer mice, 2078
SNHL. *See* Sensorineural hearing loss (SNHL).
Sniffer, chronic, 483-484
Sniffin' Sticks, 631
Sniffing, in olfaction, 625
SNORE-25 (Symptoms of Nocturnal Obstruction and Respiratory Events), 57
Snoring, 251, 266
acoustic rhinometry for, 651
in children
due to obstructive sleep apnea. *See* Obstructive sleep apnea (OSA).
primary, 2602-2603
due to upper airway resistance syndrome, 2602-2603
SNOT-20 (Sinonasal Outcome Test), 57, 642, 730
SNPs (single nucleotide polymorphisms), 9
in head and neck squamous cell carcinoma, 1019
SNUC (sinonasal undifferentiated carcinoma), 1698-1699
SOC (superior olivary complex), in central auditory pathway, 1835, 1835f, 1846
Social history, 94
Socioeconomic status, and otitis media, 2767
SOD (superoxide dismutase), and skin flap viability, 1074
Sodium (Na^+)
in saliva, 1139
in taste, 1208
Sodium bicarbonate, for cerumen removal, 1958t
Sodium channels, in taste, 1208
Sodium chloride (NaCl), gustatory response to, 1208-1209
Sodium restriction, for Meniere's disease, 2126
Sodium salts, gustatory response to, 1208-1209
Sodium tetradecyl sulfate (Sotradecol), for embolization, 1933
Sodium/hydrogen (Na^+,H^+) exchanger, in salivary gland secretion, 1135
Sodium/iodide symporter (NIS), in thyroid hormone synthesis, 1737
Sodium-potassium (Na^+,K^+) pump, ATPase-driven, in salivary gland secretion, 1135
Sodium-potassium-chloride (Na^+,K^+-$2Cl^-$) cotransporter, in salivary gland secretion, 1135
Soft palate
anatomy of, 1295f, 1359f, 1366
cancers of
cervical lymph node metastasis of, 1361t
clinical presentation of, 1365
management of, 1368-1369, 1368f
neurologic evaluation of, 834
during pharyngeal swallow, 1216, 1216f
taste buds on, 1208, 1211
Soft palate reconstruction, 1381-1383
algorithm for, 1384f
free flaps for, 1382
Gehanno method for, 1382
Lacombe and Blackwell's method for, 1382-1383
other groups' experience with, 1383
radial forearm, 1382, 1383f
local flaps for, 1381
buccinator musculomucosal, 1381-1382, 1381f
palatal island mucosal, 1382
Superior Constrictor Rotation-Advancement Flap (SCARF) as, 1382, 1382f
uvulopalatal, 1377f, 1381
prosthetic obturation for, 1381
speech function after, 1383
Soft palate resection, prostheses for, 1343-1344, 1344f
Soft tissue(s), effects of radiotherapy on, 2626t
Soft tissue avulsions, 307, 308f
Soft tissue flap(s)
for free tissue transfer, 1082t, 1083
anterolateral thigh, 1082t, 1083
lateral arm, 1082t, 1083
lateral thigh, 1082t
radial forearm, 1082t, 1083, 1083f
tubed, 1087, 1091f
scapular-parascapular, 1082t
ulnar forearm, 1082t
Soft tissue flap(s) *(Continued)*
mandibular reconstruction plate with, 1325
advantages and disadvantages of, 1325
plate extrusion with, 1325, 1326f
plate fracture with, 1325-1326, 1326f
volume-based, 1325, 1326f
Soft tissue landmarks and reference points, in facial analysis, 270b, 271f
Soft tissue sarcomas, 1666, 1666t
Soft tissue stenosis, of external auditory canal, 2021-2022, 2023f
Soft tissue trauma, 302-317
approach to, 302-306
anesthesia in, 304
cleaning in, 304-305, 305f
history taking in, 302-303
infection control in, 305
physical examination in, 303-304, 303f
repair in, 305-306, 306f
tetanus prophylaxis for, 303
to ears, 308f, 310, 310f
etiology of, 302
to eye, 303
to eyelids, 303, 303f, 307-309, 308f
to facial nerve, 309
to lacrimal apparatus, 307-309, 308f
with large-segment, composite avulsions or amputations, 312, 312f
to lips, 309-310, 309f
to nose, 310-312, 311f
to parotid duct, 312-313, 314f
to salivary glands, 312, 313f
sialocele and salivary fistula due to, 313-314
types of injuries in, 306-307
abrasion as, 306
avulsions as, 307, 308f
laceration as, 307
Soft tissue tumors, of oropharynx, 1363-1364, 1364f
SOHND. *See* Supraomohyoid neck dissection (SOHND).
Solar cheilitis, 283
Solar keratoses, 283, 284f
Solar (actinic) lentigo, 288
Solitary fibrous tumor, 1671
Solute carrier family 4 member 7 *(Slc4a7)* gene, in murine deafness, 2058t-2060t
Solute carrier family 12 member 2 *(Slc12a2)* gene, in murine deafness, 2058t-2060t
Solute carrier family 12 member 6 *(Slc12a6)* gene, in murine deafness, 2058t-2060t
Solute carrier family 12 member 7 *(Slc12a7)* gene, in murine deafness, 2058t-2060t
Solute carrier family 17 member 8 *(SLC17A8)* gene, in deafness, 2051t-2058t, 2081
Solute carrier family 19 member 2 *(SLC19A2)* gene, in deafness, 2051t-2058t
Solute carrier family 26 member 4 *(SLC26A4)* gene, in deafness, 2051t-2058t, 2096, 2098
Solute carrier family 26 member 5 (SLC26A5), and outer hair cell motility, 2064-2065, 2068f
Solute carrier family 26 member 5 *(SLC26A5)* gene, in deafness, 2051t-2058t
SOM (serous otitis media), immunosuppression and, 222-223
Somatic gene therapy, 14, 15f
Somatic tinnitus, 2132-2133, 2132t
Somesthesia, oral, 1201-1202, 1201f-1202f
Somnolence, daytime, 263-264
obesity and, 251
Sonotubometry, for eustachian tube assessment, 1874
SOOF (suborbicularis oculi fat), 444, 447
after facial paralysis, 2431
Sore throat. *See* Pharyngitis.
SOREMPs (sleep onset REM periods), 263-264

SOT (sensory organization test), 2325-2326, 2325f-2326f
Sotradecol (sodium tetradecyl sulfate), for embolization, 1933
Sound, 1838-1839, 1839f
  defined, 2017
  eye movements evoked by, 2316, 2339-2340, 2340f
Sound enrichment, for tinnitus, 2133-2134
Sound localization
  in binaural processing, 2248
  external ear in, 1839
  with traditional hearing aid, 2207
Sound pressure, 1839
Sound pressure level (SPL), 1839, 2140
  in acoustic analysis for voice evaluation, 829, 829t
Sound protection, eustachian tube in, 1871-1872
Sound stimulation, for tinnitus, 2133-2134
Sound transduction, with hearing aids, 2205f
Sound transfer, in middle ear, 2017-2019
Sound transmission, 2000, 2017-2019, 2050-2060, 2062f
Sour taste
  peripheral sensitivity to, 1211
  transduction of, 1209
Source-filter hypothesis, of speech, 812
Southern blotting, 9
SOX2, in deafness, 2051t-2058t
SOX10, in Waardenburg syndrome, 2095
SP (substance P), in salivary gland secretion, 1137
SP (summating potential), in electrocochleography, 1892-1894, 1907
  in Meniere's disease, 2337
Space-frequency map, 2060-2061, 2063f
SP/AP (summating potential/action potential) ratio, 1892-1894
  in Meniere's disease, 2337
Spasmodic dysphonia, 839
  botulinum toxin therapy for, 839, 840f-841f
  voice breaks in, 834-835
Spatial coherence, 26, 27f
SPCC (spindle cell carcinoma), of larynx, 1506
SPEAK (spectral peak extraction), for cochlear implants, 2230, 2230f
Speaking tasks, in pediatric voice evaluation, 2877-2878
SPECT. *See* Single photon emission computed tomography (SPECT).
Spectral displays, in acoustic analysis for voice evaluation, 829t, 830, 830f
  of professional voice, 849
Spectral emphasis strategies, for cochlear implants, 2230
  Advanced Combination Encoder as, 2230, 2231f
  spectral peak extraction as, 2230, 2230f
Spectral karyotyping (SKY), for head and neck squamous cell carcinoma, 1019
Spectral peak extraction (SPEAK), for cochlear implants, 2230, 2230f
Spectral presaturation inversion recovery (SPIR), MRI with, 135-136
Spectral shape, distortion of, with traditional hearing aid, 2204
Spectral tilt, in acoustic analysis for voice evaluation, 830
β-Spectrin 4 *(Spnb4)* gene, in murine deafness, 2058t-2060t, 2081
Spectrogram, in acoustic analysis for voice evaluation, 830, 830f
Spectrometry, for voice analysis of professional voice, 849
Speech
  alaryngeal (*See* Alaryngeal voice and speech)
  defined, 833
  effects of radiotherapy on, 2626t
Speech *(Continued)*
  esophageal, 1459
    physiology of, 1596, 1596f
    after total laryngectomy, 1572
  after hypopharyngeal and esophageal reconstruction, 1459-1460
  laryngeal function in, 810-812, 811b, 811f, 833
  scanning, 837-838
  after surgical resection of oral cancer, 1316
  tracheoesophageal
    physiology of, 1597, 1597f
    after total laryngectomy, 1572
Speech aid, for soft palate resection, 1343, 1344f
Speech analysis, for velopharyngeal dysfunction, 2678-2679, 2678f, 2678t-2679t
Speech bulb prosthesis, for velopharyngeal dysfunction, 2681, 2682f
Speech control, sensory input to, 812
Speech detection threshold (SDT), 1888-1889
Speech discrimination testing, 1889
  for sensorineural hearing loss in adults, 2117
Speech dysfunction, palliative care for, 1104
Speech endoscopy, for velopharyngeal dysfunction, 2680, 2680f
Speech language pathologist, for professional voice disorders, 855
Speech mapping, with hearing aid, 2273
Speech pathologist, for benign vocal fold mucosal disorders, 863, 864f
Speech perception, with cochlear implants
  in adults, 2244-2245
    predictors of, 2245, 2245f
  in children
    early studies of, 2246
    more recent studies of, 2246-2247, 2247f
    tests for, 2246
Speech reception, with cochlear implants
  in adults, 2244-2245
    predictors of, 2245, 2245f
  in children
    early studies of, 2246
    more recent studies of, 2246-2247, 2247f
    tests for, 2246
Speech reception threshold (SRT), 1888-1889
  masking for, 1889
Speech recognition, with cochlear implants
  in adults, 2244-2245
    predictors of, 2245, 2245f
  in children
    early studies of, 2246
    more recent studies of, 2246-2247, 2247f
    tests for, 2246
Speech recognition tests, for cochlear implants, 2223
Speech rehabilitation, after laryngectomy. *See* Voice rehabilitation.
Speech testing, in audiologic test battery, 1888-1889
Speech therapy, for velopharyngeal dysfunction, 2680-2681
  articulation in, 2681
  compensatory strategies in, 2681
  resonance in, 2681
Speech videofluoroscopy, for velopharyngeal dysfunction, 2679-2680
Speech-language development, otitis media and, 2776
Sphenoethmoid synchondrosis, 2619f
Sphenoethmoidal cells, 669, 740, 749f
  in surgical anatomy of anterior cranial base, 2473
Sphenoethmoidal encephalocele, 2687t
Sphenoethmoidal recess(es)
  normal anatomy of, 667, 668f
  in surgical anatomy of anterior cranial base, 2472
Sphenoid bone, 320f
  lesser and greater wings of, 322f, 335f
  in surgical anatomy of anterior cranial base, 2442-2443, 2443f
  in surgical anatomy of lateral skull base, 2435f
Sphenoid ostium(ia), 740, 741f, 2472, 2473f
Sphenoid sinus(es)
  anatomy of
    normal, 664, 665f, 667-668, 668f
    surgical, 740, 741f
      in anterior cranial base, 2443, 2472f-2474f, 2473
  prior to endoscopic sinus surgery, 764, 764t
  extensive pneumatization of, 669, 670f
  external approaches to, 757
  after functional endoscopic sinus surgery, 679
  growth and development of, 2619-2620
  and internal carotid artery, 671-672
  and optic nerve, 672, 672f
Sphenoid sinus tumors, 1123, 1130
Sphenoid spine, in surgical anatomy of middle cranial base, 2444, 2445f
Sphenoidotomy
  in endoscopic sinus surgery, 748, 749f
    complications of, 767, 768t
    for fungus ball, 768f-769f
    with image-guided navigation system, 770f
  in middle cranial base surgery
    transethmoidal, 2455-2457, 2455t, 2456f
    transseptal, 2455-2457, 2455t, 2456f
Spheno-occipital synchondrosis, 2617-2619, 2619f-2620f
Spheno-orbital encephalocele, 2687t
Sphenopalatine artery
  anatomy of, 682
  septal branch of, 483f
Sphenopalatine artery ligation, endoscopic, for epistaxis, 689-690, 689f-690f
Sphenopalatine foramen
  in surgical anatomy of anterior cranial base, 2473f
  in surgical anatomy of lateral skull base, 2435f
Sphenopalatine ganglion, 497
Sphincter pharyngoplasty, for velopharyngeal dysfunction, 2683
Spider angioma, 291
Spin density–weighted image, 134, 135f-136f
Spinal accessory lymph nodes
  anatomy of, 1360f
  in neck dissection, 1705f
Spinal accessory nerve (SAN)
  intraoperative monitoring of, 2550-2552, 2550f
  in modified radical neck dissection, 1712, 1713f-1714f, 1730
  in neck dissection, 1722
  in posterior triangle, 2578-2579, 2579f-2580f
  in surgical anatomy of lateral skull base, 2436f, 2438, 2439f-2440f, 2440
Spinal accessory nerve (SAN) injury
  in lateral skull base surgery, 2512
  due to neck surgery, 1730, 1731f
Spinal accessory nerve (SAN) transposition, for facial nerve paralysis, 2426
Spinal cord input, to vestibular nuclei, 1864
Spinal nerve, posterior ramus of, 2579f
Spindle cell carcinoma (SPCC), of larynx, 1506
Spindle cell hemangioendothelioma, 1668-1669
Spindle cell hemangioma, 1668-1669
Spindle-shaped gap, laryngeal videostroboscopy of, 819, 820f
Spine of Henle, anatomy of, 1822f, 2009-2010
Spinocerebellar atrophy, 2357
SPIR (spectral presaturation inversion recovery), MRI with, 135-136
Spiral CT, of laryngeal carcinoma, 1470
Spiral ganglion, anatomy of, 1832f, 1834, 1854f, 2278f

Spiral ganglion cells, in auditory physiology, 1844, 1845f
Spiral ganglion neurons (SGNs), salvage of, 2189-2191
Spiral lamina, 1831, 1832f, 1834
Spiral ligament
  anatomy of, 1832f
  in auditory physiology, 1841f
  in cochlear transduction, 2061f
Spiral limbus
  anatomy of, 1832
  in auditory physiology, 1841f
Spiral modiolar artery, 1854, 1856f
Spirochaeta denticulata, Vincent's angina due to, 2786
Spitz nevus, 287
SPL (sound pressure level), 1839, 2140
  in acoustic analysis for voice evaluation, 829, 829t
Spleen, in immune system, 605
Splenius muscle, 2579f
Splice sites, 4, 5f
Split bridge, for cochlear implant, 2238-2239, 2238f
Split-thickness skin graft (STSG), in atresiaplasty
  creation of, 2756, 2757f
  placement of, 2756, 2757f-2758f
  suturing of, 2756-2757, 2758f
Spnb4 (β-spectrin 4) gene, in murine deafness, 2058t-2060t, 2081
Spontaneous emission, of radiation, 26, 26f
Spontaneous ventilation anesthesia
  in children, 2599-2600
  with recurrent respiratory papillomatosis, 2891
Spot size, of surgical laser, 27-28, 28f-29f
Spreader grafts
  in revision rhinoplasty for middle vault deformities, 585-586
  for saddle nose deformity, 555, 559f
  for septal and alar asymmetries, 550, 551f
  in septoplasty, 490-491, 491f
  for twisted nose, 554, 555f
SPTs (second primary tumors)
  of larynx, 1492, 1510
  in oral cancer, 1301-1302
Spurring, nasal septal deviation with, 482, 482f, 489, 494, 669f
SQA (Surgical Quality Alliance), 84t-87t, 88
Squamocolumnar junction (SCJ), of esophagus
  with Barrett's esophagus, 957f, 972
  with hiatal hernia, 957f
  normal anatomy of, 956-957, 956f-957f
  in transnasal esophagoscopy, 982-983, 983f
Squamosa, in surgical anatomy of lateral skull base, 2434, 2435f-2436f
Squamous cell carcinoma (SCC), 285-286
  basaloid
    of hypopharynx and cervical esophagus, 1425
    of larynx, 1506
  cervical lymph node metastasis of (*See* Cervical lymph node metastasis(es))
  clinical presentation of, 285f, 286
  cutaneous, immunosuppression and, 213t, 215
  defined, 1361
  epidemiology of, 285
  epistaxis due to, 686f
  esophageal, 973
    due to caustic injury, 978
    cervical, 1425
      imaging of, 1414f, 1424f
    imaging of, 1412-1415
    localized, 1444-1447
      definitive chemoradiation for, 1445-1447, 1446t-1447t
      postoperative therapy for, 1444-1447
      preoperative therapy for, 1444-1445, 1445t
    metastatic, 1447
Squamous cell carcinoma (SCC) *(Continued)*
  of external auditory canal and temporal bone
    computed tomography of, 2502f
    imaging of, 1918, 1919f
    symptoms and signs of, 2502
  extraesophageal reflux and, 902-903
  head and neck (*See* Head and neck squamous cell carcinoma (HNSCC))
  of hypopharynx, 1425
    chemoradiation for, 1442-1444
    chemotherapy for, 1442
      induction, 1443
      after total laryngectomy, 1442-1443
    conventional treatment modalities for, 1441-1442
      for advanced disease, 1442
      for early disease, 1442
    epidemiology of, 1441
    imaging of, 1414f, 1424f
    new treatment modalities for, 1442
    radiation therapy for, 1443
      intensity-modulated, 1046
  laryngeal, 1491
    acantholytic, 1506

  suturing of, 2756-2757, 2758f
Student's *t*-test, 70-71
Study design, 54-55, 54t
  case series as, 54-55, 54t
  case-control, 54, 54t
  and data interpretation, 59-61, 60t-61t
  and data quality, 59, 60t
  expert opinion as, 52, 54-55, 54t
  grading of evidence-based medicine recommendations as, 55, 55t
  observational (cohort), 54, 54t
  other types of, 55
  randomized trial as, 52, 54, 54t
Study sample, 68t
Stunning, with radioactive iodine, 1771
Sturge-Weber syndrome, 291
  oral manifestations of, 1257
Stuttering, 841-842
Styloglossus muscle, 1296f, 1297, 1359f
Stylohyoid ligament
  embryology of, 2583-2584
  ossification of, 1480, 1481f
Stylohyoid muscle, 1296f, 1359f
Styloid foramen, 2404f
Styloid ligament, 2583f
Styloid process
  anatomy of, 320f, 1296f, 1822-1823, 1822f, 1824f, 1826f, 2010f
    radiographic, 1398f
  elongated, *vs.* myofascial pain dysfunction syndrome, 1284t
  embryology of, 2583-2584, 2583f
  in surgical anatomy of lateral skull base, 2435, 2435f
  in surgical anatomy of middle cranial base, 2445f
Stylomastoid artery, 1826f
Stylomastoid foramen
  anatomy of, 1822-1823, 1824f
  annular ligament of, 1826f
  in surgical anatomy of lateral skull base, 2435
  in surgical anatomy of middle cranial base, 2445f
Stylopharyngeus muscle, 1296f, 1359f

Subacute bacterial endocarditis (SBE) prophylaxis, for pediatric surgery, 2596, 2596t-2597t
Subarcuate artery, in surgical anatomy of lateral skull base, 2439f
Subarcuate fossa
  anatomy of, 1823f, 2010f
  in surgical anatomy of lateral skull base, 2435f, 2438
Subciliary approach
  for lower eyelid blepharoplasty, 449, 450f-451f
  for pediatric facial fracture, 2705f
Subclavian artery, root of neck and, 2581-2582, 2581f
Subclavian steal syndrome, 2351
Subclavian triangle, of neck, 2578f
Subcondylar fractures, 322-323, 1280, 1281t
  pediatric, 2704, 2706f-2708f
  physical examination of, 325
  repair of, 338-339
Subcranial approach, for anterior cranial base surgery, 2454, 2454f
Subcutaneous emphysema
  of infrahyoid retropharyngeal space, 161f
  of neck, 1410, 1410f
Subcutaneous fibroma, due to neck irradiation, 1695
Subcutaneous immunotherapy (SCIT), for allergic rhinitis, 621
Subcutaneous layer, 1065
Subcutaneous tissue, thinning of, in nasal tip refinement, 577, 577f
Subcutaneous tunnels, in liposuction, 456, 456f
Subdural abscess, otitis media and, 2777
Subdural empyema, 1994-1995
  epidemiology of, 1980t-1981t, 1994-1995
  imaging of, 1995
  in neonates, 1995
  otitis media and, 2777
  symptoms of, 1995
  treatment of, 1995
Subglottal resections, for tracheal tumors, 1619, 1620f
Subglottic air pressure (P_s)
  in professional voice production, 846
  in voice evaluation, 828, 828t, 849
Subglottic airway, radiographic anatomy of, 1463f
Subglottic cancer
  anatomic basis for, 1483-1484, 1483f, 1483t
  cervical metastases of, 1494
  clinical presentation of, 1493, 1579
  imaging of, 1474, 1475f
  staging of, 1488t, 1580f
  treatment of, 1501-1503, 1501f
    radiation therapy for, 1589-1590
Subglottic cyst, 2871, 2871f
Subglottic hemangioma, 1468, 1468f, 2871, 2871f
  dysphagia due to, 2953
  stridor due to, 2899, 2900f
Subglottic stenosis (SGS), 945f, 950-951. *See also* Laryngeal stenosis.
  anterior, in children, 2923
  balloon dilatation for, 2906, 2906f
  congenital, 2870-2871, 2913-2914
  dysphagia due to, 2953
  gastroesophageal reflux and, 2945
  due to internal laryngeal trauma, 2914-2915
  stridor due to, 2899, 2900f
Subglottis, 99, 99f
  anatomy of, 1483-1484, 1483f, 1483t, 1578
    surgical, 1544f
  embryology of, 1482
  physical examination of, 100
Subharmonic frequencies, 847
Subjective visual horizontal (SVH), perceptual test of, 2300
Subjective visual vertical (SVV), perceptual test of, 2300, 2323
Sublingual artery, 1296f
Sublingual gland(s)
  anatomy of, 1133-1134
    in children, 2850-2853
    radiographic, 1144-1145
  contributions to saliva of, 1134t
  malignant neoplasms of
    excision of, 1196
    physical examination of, 1179
Sublingual immunotherapy (SLIT), for allergic rhinitis, 621-622
Sublingual lymph nodes, 2582
Sublingual space (SLS)
  anatomy of, 202
  imaging of, 156
    with abscess and cellulitis, 156, 157f
    with congenital lesions, 156
    normal anatomy in, 146f, 154, 156
    with ranula, 156, 157f
    with squamous cell carcinoma, 156
  odontogenic infections of, 183, 183f
Submandibular fossa, 1296f
Submandibular gland(s)
  anatomy of, 1133-1134, 1296f
    in children, 2850-2853
    radiographic, 1144, 1399f
  contributions to saliva of, 1134t
  CT of, 139
  neuronal control of, 1136
  physical examination of, 96f
  pleomorphic adenoma of, 1653f
  salivary flow rate and composition of saliva in, 1138t
  sialolithiasis of, 1155
    imaging of, 1144f, 1154, 1157f
    surgical management of, 1156, 1156f
  sialolithiasis promoting factors in, 1140
  trauma to, 312
Submandibular gland neoplasm(s)
  benign
    clinical features of, 1165
    excision of, 1174, 1174f
  malignant
    excision of, 1196
    physical examination of, 1179
Submandibular gland resection, robotic surgery for, 40-41, 42f-43f
Submandibular lymph nodes
  anatomy of, 1297f-1298f, 1360f, 2582
  in neck dissection, 1704-1705, 1704f-1705f, 1706t-1708t
Submandibular region, musculature of, 1296f
Submandibular space (SMS)
  anatomy of, 202
  imaging of, 146f, 156-157, 158f
  odontogenic infections of, 183-184, 183f-184f
Submandibular triangle, of neck, 96, 96f, 2578f
Submental lipectomy, 456
Submental lymph nodes
  anatomy of, 1297f-1298f, 1360f
  in neck dissection, 1704, 1704f-1705f, 1706t-1708t
Submental space involvement, in odontogenic infections, 181-183, 183f
Submental triangle, 2578f
Submentoplasty, 411-413
  aesthetic considerations for, 411, 412f
  procedure for, 411-413, 413f
  results of, 414f-415f
Submentovertex (SMV) view, of facial bones and sinuses, 130
Submucous cleft palate (SMCP), 2659, 2661f, 2674
  bifid uvula with, 2793, 2793f
Submucous fibrosis, oral, 1229, 1298
  clinical features of, 1229
  defined, 1229
  etiology and pathogenesis of, 1229
Submucous fibrosis, oral *(Continued)*
  histologic/diagnostic features of, 1229
  treatment of, 1229
Submuscular recess lymph nodes, in neck dissection, 1707t-1708t
Suboccipital approach, for posterior fossa neoplasms, 2532t, 2533-2534
  advantages and disadvantages of, 2532t, 2534
  basic features of, 2533
  indications for, 2532t, 2533
  surgical exposure in, 2533f
  technique of, 2534, 2534f
Suboccipital lymph nodes
  anatomy of, 1718f
  dissection of, 1718-1719
Suborbicularis oculi fat (SOOF), 444, 447
  after facial paralysis, 2431
Subparotid node, 1298f
Subperichondrial cricoidectomy, for chronic aspiration, 927-928, 929f
Substance P (SP), in salivary gland secretion, 1137
Substitution, in vestibular compensation, 2375
Substitution exercises, in vestibular rehabilitation, 2372-2373, 2378
Sub-superficial musculoaponeurotic system dissection, for cheek defects, 357-358, 360f
Subtemporal craniectomy, for middle cranial base surgery, 2465f, 2467, 2467f
Subtemporal-preauricular infratemporal approach, for middle cranial base surgery, 2462, 2466f
Subtilisin, and interstereociliary linkages, 2077
Subtotal laryngectomy, for glottic cancer, 1517t
Subtotal thyroidectomy, for Graves' disease, 1743
Succinate-dehydrogenase (SDH), in familial paraganglioma syndromes, 1659, 1659t
Succinylcholine
  in children
    for anesthesia maintenance, 2592
    for rapid-sequence anesthesia induction, 2590
  intraoperative, 111-112
Sucralfate
  for caustic ingestion, 2959-2960
  for extraesophageal reflux, 901
  for GERD, 970
Suction lipectomy, 452, 456
Sudden infant death syndrome (SIDS), 2570
Sufentanil, as adjunct to induction of anesthesia, 111
Suicide genes, 16, 21
Sulcus vocalis, 2882
Sulindac, for head and neck squamous cell carcinoma, 1018
Sullivan, Colin, 251
Sumatriptan (Imitrex), for migraine, 2349
Summating potential (SP), in electrocochleography, 1892-1894, 1907
  in Meniere's disease, 2337
Summating potential/action potential (SP/AP) ratio, 1892-1894
  in Meniere's disease, 2337
Summation, in auditory processing, 1846, 2248
Sun-reactive skin types, 275, 276b, 391, 391t
Superantigens, in chronic rhinosinusitis, 706, 732
Superficial cervical fascia, 202, 2577
Superficial cervical lymph nodes, 2582
Superficial cervical plexus block, 242
Superficial musculoaponeurotic system (SMAS), 405, 406f
  in deep-plane rhytidectomy, 406, 407f
  and temporoparietal fascia, 440-441, 441f
Superficial musculoaponeurotic system (SMAS) flap, 405-406, 409
Superficial petrosal artery, 1826f, 1828f
Superficial petrosal nerve, 1826f
Superficial spreading carcinoma, 285f
Superficial spreading melanoma, 285f, 1108
Superficial temporal artery, 2580f

Superficial vocal fold lesions, in vocal professional, 855-856, 856f
Superficial x-rays, energy for, 1034
Superior alveolar arteries, 1295-1296
Superior ampullary nerve, 1854f, 2278f
Superior canal benign paroxysmal positional vertigo
  positional testing for, 2331
  repositioning maneuver for, 2332
Superior canal dehiscence syndrome (SCDS). *See* Superior semicircular canal dehiscence (SSCD) syndrome.
Superior canaliculus, of lacrimal apparatus, 798f
Superior cerebellar artery, 2351f
  in surgical anatomy of anterior skull base, 2481f
Superior cervical sympathetic ganglion, in root of neck, 2582
Superior constrictor muscle
  anatomy of, 1359f
  in velopharyngeal function, 2676, 2677t
Superior Constrictor Rotation-Advancement Flap (SCARF), for reconstruction of soft palate, 1382, 1382f
Superior crus, of ear, 476f, 2742f
Superior deep jugular lymph nodes, 1360f
Superior incudal fold, 1827f
Superior laryngeal nerve, in surgical anatomy of lateral skull base, 2440f
Superior laryngeal nerve (SLN)
  anatomy of, 807, 1422
  injury during thyroid surgery of, 1770
  in taste, 1211
  and thyroid gland, 1751-1752
Superior malleolar fold, 1827f
Superior malleolar ligament, 1827f
Superior medial pyriform involvement, supraglottic laryngectomy for laryngeal cancer with, 1554-1555
Superior mediastinal adenopathy, total laryngopharyngectomy with, 1574, 1574f
Superior mediastinal lymph nodes, in neck dissection, 1704, 1704f, 1706t-1708t
Superior nasal meatus
  normal anatomy of, 664-665
  in surgical anatomy of anterior cranial base, 2472, 2472f
Superior oblique muscles
  semicircular canal planes and, 2287, 2288f
  in surgical anatomy of lateral skull base, 2439f
Superior olivary complex (SOC), in central auditory pathway, 1835, 1835f, 1846
Superior ophthalmic vein thrombosis, due to rhinosinusitis, 676
Superior orbital fissure, anatomy of, 322f, 440, 1823f
  surgical
    in anterior cranial base, 2443-2444, 2444f
    in lateral skull base, 2435f, 2438
    in middle cranial base, 2444, 2445f
Superior orbital fissure syndrome, 320-321
Superior petrosal sinus, in surgical anatomy of lateral skull base, 2436f, 2438, 2489
Superior petrosal sinus impression
  anatomy of, 1823f
  in surgical anatomy of lateral skull base, 2435f
Superior petrosal sulcus, 1823f
Superior petrosal vein, in surgical anatomy of lateral skull base, 2439f
Superior pharyngeal constrictor muscle, 1360f
Superior punctum, of lacrimal apparatus, 798f
Superior rectus muscle(s), 443f
  semicircular canal planes and, 2287, 2288f
  in surgical anatomy of anterior cranial base, 2472f
Superior saccular nerve, 1854f, 2278f
Superior semicircular canal
  anatomy of, 1827, 1854f, 2278f
  in surgical anatomy of lateral skull base, 2436f-2437f, 2439f
Superior semicircular canal dehiscence (SSCD) syndrome, 1842, 1843f, 2339-2341
  anatomic and physiologic basis for, 2290, 2290f
  auditory manifestations of, 2341
  clinical features of, 2339
  eye movements evoked by pressure changes in, 2316f
  hearing loss due to, 2020-2021, 2021f
  imaging of, 1920-1921, 1922f
    high-resolution CT for, 2340-2341, 2340f, 2362f
  ocular responses to sound in, 2339-2340, 2340f
  pathophysiology of, 2339-2340, 2339f-2340f
  severity of, 2340
  treatment of, 2341
    surgical, 2361
  vestibular evoked myogenic potentials in, 2341
Superior semicircular duct, 1851f
Superior tarsal muscle, 443f, 444
Superior tarsal plate, 321f
Superior thyroid artery
  anatomy of, 1751-1752, 2579-2580, 2580f
  and parathyroid glands, 1778
Superior thyroid notch, radiographic anatomy of, 1472f
Superior turbinate, in surgical anatomy of anterior cranial base, 2472, 2472f
Superior tympanic artery, 1828f
Superior vestibular ganglion, 1854f, 2278f
Superior vestibular nerve, 2404f
  in surgical anatomy of lateral skull base, 2437f, 2438-2439
Superior vestibular nucleus (of Bechterew), 1860, 1862f
Supernumerary nostril, 2690-2692
Superoxide anion radical (O_2^-), in acutely raised skin flaps, 1070-1071, 1071f
Superoxide dismutase (SOD), and skin flap viability, 1074
Supervoltage x-rays, 1034
Supporting cells
  of olfactory epithelium, 626-627, 626f
  in vestibular system, 1854-1855, 1858f
Suppurative lymphadenopathy, in children, 2818, 2818f
Supra-alar collapse, revision rhinoplasty for, 586-587, 587f
Supra-alar pinching, revision rhinoplasty for, 585-586, 586f
Suprabullar cells, in endoscopic sinus surgery, 749, 750f
Suprabullar recess
  normal anatomy of, 667
  surgical anatomy of, 740
Supraclavicular lymph nodes, in neck dissection, 1705f
Supraclavicular nerve, 2578, 2580f
Supraclavicular triangle, of neck, 96, 96f
Supracricoid hemilaryngopharyngectomy (SCHLP), for hypopharyngeal cancer, 1429, 1436
Supracricoid laryngectomy
  with cricohyoidopexy, 1555-1557
    complications of, 1557
    functional outcome of, 1556-1557, 1557t
    key surgical points for, 1556
    oncologic results of, 1555
    surgical technique for, 1555-1556, 1556f
  historical background of, 1540
Supracricoid partial laryngectomy (SCPL)
  with anterior commissure involvement, 1497
  historical background of, 1540
  intermediate, 1531
  supraglottic, in advanced stage, 1500
Supracricoid partial laryngectomy with cricohyoidoepiglottopexy (SCPL-CHEP), 1549-1550
  complications of, 1551
  extended procedures for, 1551
  functional outcome of, 1551, 1551t-1552t
  key surgical points for, 1550-1551
  oncologic results of, 1549-1550
  surgical technique for, 1550, 1550f-1551f
  vs. total laryngectomy, 1564
Supracricoid partial laryngectomy with cricohyoidopexy (SCPL-CHP), 1564
Supraglottic activity, videoendoscopy of, 817, 817f
Supraglottic cancer
  advanced-stage
    chemoradiation for, 1500, 1589
    radiation therapy for, 1589
      outcomes and prognostic factors for, 1589, 1590t
      techniques and dose-fractionation schemes for, 1589
  anatomic basis for, 1483-1484, 1483f, 1483t, 1542-1543
  cervical metastases of, 1493-1494
  chemoradiation for, 1500, 1589
  clinical evaluation of, 1545
  clinical presentation of, 1493, 1579
  conservation laryngeal surgery for, 1551-1552, 1552t
    horizontal partial laryngectomies as, 1553-1554
    spectrum of, 1557-1560
    supracricoid laryngectomy with cricohyoidopexy as, 1555-1557
      complications of, 1557
      functional outcome of, 1556-1557, 1557t
      key surgical points for, 1556
      oncologic results of, 1555
      surgical technique for, 1555-1556, 1556f
    supraglottic laryngectomy as, 1553-1554
      with arytenoid, aryepiglottic fold, or superior medial pyriform involvement, 1554-1555
      with base of tongue extension, 1555
      complications of, 1555
      extended procedures for, 1554
      functional outcome of, 1555
      key surgical points for, 1554-1555, 1554f
      oncologic results of, 1553, 1553t
      surgical technique for, 1553-1554, 1554f
  early-stage, radiation therapy for, 1496, 1588-1589
    complications of, 1589
    outcomes and prognostic factors for, 1589, 1589t
    techniques and dose-fractionation schemes for, 1588-1589
  imaging of, 1475-1476
    of aryepiglottic folds, 1475, 1478f
    of epiglottis, 1475, 1477f
    of pyriform sinuses, 1475-1476, 1478f
  neck dissection for, 1500-1501
  radiation therapy for
    with advanced-stage disease, 1589
      outcomes and prognostic factors for, 1589, 1590t
      techniques and dose-fractionation schemes for, 1589
    with early-stage disease, 1496, 1588-1589
      complications of, 1589
      outcomes and prognostic factors for, 1589, 1589t
      techniques and dose-fractionation schemes for, 1588-1589
  staging of, 1488t, 1580f
  treatment of, 1498-1501
    in advanced stage, 1500
    in early stage, 1498-1500, 1498f

Supraglottic cancer *(Continued)*
with nodal metastases, 1500-1501
transoral laser microsurgery for, 1531
Supraglottic jet ventilation, for pediatric anesthesia, 2600
Supraglottic lacerations, 1634
Supraglottic laryngectomy, 1553-1554
with arytenoid, aryepiglottic fold, or superior medial pyriform involvement, 1554-1555
with base of tongue extension, 1555
complications of, 1555
extended procedures for, 1554
functional outcome of, 1555
historical background of, 1540
key surgical points for, 1554-1555, 1554f
oncologic results of, 1553, 1553t
surgical technique for, 1553-1554, 1554f
swallowing disorders due to, 1220
Supraglottic partial laryngectomy (SGL), for early-stage supraglottic cancer, 1498-1500, 1498f
Supraglottic stenosis, 947-948
Supraglottic subtotal laryngectomy, recurrence after, 1476
Supraglottis, 99, 99f
anatomy of, 1483-1484, 1483f, 1483t, 1578
surgical, 1542-1543, 1544f
embryology of, 1482
innervation of, 1544
Supraglottitis, 883, 1464
in children, 2806-2809
clinical features of, 2807
complications of, 2808-2809
diagnosis of, 2807-2808, 2807f-2808f
differential diagnosis of, 2806t
endoscopy of, 2808, 2808f
epidemiology of, 2806-2807
etiology of, 2807
histology of, 2807, 2807f
historical background of, 2806-2807
imaging of, 2807f, 2808
management of, 2808
clinical presentation of, 2807
defined, 1464
differential diagnosis of, 1464, 1465f, 2806t
imaging of, 159-161, 1406-1407, 1464
in children, 2807f, 2808
CT for, 1406
plain film, 163f, 1406, 1407f, 1464, 1464f
pseudo-, postlaryngectomy, 1416, 1417f
Supraglottoplasty, for laryngomalacia, 2867, 2868f
Suprahyoid musculature, palpation of, in voice evaluation, 827, 828f
Suprahyoid neck, imaging of, 146-157
carotid space in, 150-151, 151f-152f
CT for, 139, 141f
masticator space in, 151-152
with adenoid cystic carcinoma, 155f
with angiofibroma, 152, 154f
with hemangioma and lymphangioma, 152, 153f
with infection, 151-152, 152f
normal anatomy on, 146f, 151-152
with pseudotumors, 152
with squamous cell carcinoma, 152, 154f
MRI for, 142
normal anatomy in, 146-157, 146f-147f
oral cavity in, 153-156
with abscess, 156f
with congenital lesions, 154-156
with non-Hodgkin's lymphoma, 157f
normal anatomy on, 146f, 153-156
with squamous cell carcinoma, 154, 156f
parapharyngeal space in, 131, 146f
parotid space in, 149-150, 150f-151f
Suprahyoid neck, imaging of *(Continued)*
pharyngeal mucosal space in, 148-149
with inflammatory lesions, 148, 148f
with non-Hodgkin's lymphoma, 148-149, 149f
normal anatomy on, 146f, 148-149
with squamous cell carcinoma, 148, 149f
with Tornwaldt cyst, 148
prevertebral space in, 146f, 153
retropharyngeal space in, 146f, 152f, 153, 155f
sublingual space in, 156
with abscess and cellulitis, 156, 157f
with congenital lesions, 156
normal anatomy in, 146f, 154, 156
with ranula, 156, 157f
with squamous cell carcinoma, 156
submandibular space in, 146f, 156-157, 158f
Suprainfundibular cell, surgical anatomy of, 740
Supralabyrinthine approach, for facial nerve decompression, 2041-2042, 2043f
Supralaryngeal obstruction, in neonate, 2905, 2905f
Supramandibular lymph node, 1360f
Supramarginal gyrus, in central auditory pathway, 1837
Suprameatal spine, 2010f
in surgical anatomy of lateral skull base, 2435f
Supraomohyoid neck dissection (SOHND), 1703
for oral cancer, 1313-1314, 1713-1716
definition and rationale for, 1713, 1714f
technique for, 1713-1716, 1715f-1716f
Supraorbital artery, 439
Supraorbital bandeau, in fronto-orbital advancement
removal of, 2651-2652, 2652f
reshaping of, 2652, 2652f-2653f
splitting of, 2652, 2653f
Supraorbital cells, in frontal sinusitis, 776
Supraorbital ethmoid cells, surgical anatomy of, 741
Supraorbital foramina, in surgical anatomy of anterior cranial base, 2442, 2443f
Supraorbital nerve, 321f, 439-440, 441f
Supraorbital neurovascular pedicle, technique for preserving, 2451, 2451f
Supraorbital notch, 322f
in surgical anatomy of anterior cranial base, 2442, 2443f
Supraorbital rims, 319
Suprascapular artery
anatomy of, 2579
in root of neck, 2581-2582, 2581f
Suprascapular vein, 2579
Supratrochlear nerve, 321f, 440, 441f, 497, 497f
Supratubal recess
anatomy of, 1826f, 1827
in mastoidectomy, 2012-2013, 2013f
Sural nerve, for facial nerve grafting, 2422
Surface-enhanced laser desorption-ionization–time-of-flight (SELDI-TOF), in head and neck squamous cell carcinoma, 1029
Surfactant, in middle ear protection, 1871
Surfer's ear, imaging of, 1918, 1918f
Surgical decompression, for Bell's palsy, 2395
Surgical drainage and decompression, of odontogenic infections, 188-190
of deep neck space, 189-190
of jaw space, 189, 189f
vestibular, 188-189
Surgical history, 94
Surgical margins, with melanoma, 1113-1114, 1114t
Surgical myotomy, for achalasia, 964-965
Surgical Quality Alliance (SQA), 84t-87t, 88
Surrogate endpoints, biomarkers as, 1026
Surveillance, after surgical resection of oral cancer, 1317, 1317t
Survival analysis, 64, 72
Survival curve, 64
Survival rate, 64t
Susceptibility bias, *vs.* efficacy of treatment, 62t
Sushruta, 475
Sustained-release devices, for intratympanic delivery, 2182-2183, 2182f-2183f
Sustentacular cells, of olfactory epithelium, 626-627, 626f
Sutton's disease, in HIV, 227, 227f
Suturing
for facial trauma, 305-306, 306f
for nasal tip refinement, 522, 530f-531f, 550-551
for otoplasty, 477-478, 477f
complications of, 479
history of, 475-476, 476f
Mustarde technique for, 475-478, 476f-477f
for septoplasty, 491, 491f
Sv (sievert), 133
SVH (subjective visual horizontal), perceptual test of, 2300
SVV (subjective visual vertical), perceptual test of, 2300, 2323
Swallowing, 833, 1215-1221
functional endoscopic evaluation
for chronic aspiration, 926
for laryngeal stenosis, 2917
functions of, 2948
after hypopharyngeal and esophageal reconstruction, 1459-1460
inefficient, 1217
maturation of, 2948
physiology of, 954, 955f, 1207
stage(s) of, 1215, 1218f, 2948
esophageal, 1217, 2948
oral, 1206f, 1207, 1215, 1216f, 2948
oral preparatory, 1215, 1216f, 2948
pharyngeal, 1216, 2948
airway protection during, 1216-1217
cricopharyngeal (upper esophageal sphincter) opening during, 1217
delayed triggering of, 1215
neuromuscular activities in, 1216, 1216f
pharyngeal pressure generation during, 1217
programmed, 1216-1217
voluntary, 1215
after surgical resection of oral cancer, 1316
after total laryngectomy, 1572
Swallowing disorder(s). *See* Dysphagia.
Sweet taste
individual differences in, 1211-1212
peripheral sensitivity to, 1211
transduction of, 1209
Swimmer's ear, 97
Symblepharon, due to cicatricial pemphigoid, 1233-1234, 1234f
Symmetry, laryngeal videostroboscopy of, 820, 847-848, 848t
Sympathetic control, of salivary gland secretion, 1136
Sympathetic nerve injury, due to neck surgery, 1732, 1732f
Sympathetic trunk, in root of neck, 2582
Sympathomimetics, oral sequelae of, 1247t-1248t
Symphyseal region, anatomy and physiology of, 322-323
Symphysis
anatomy and physiology of, 322-323
menti, 320f
Symptoms, outcome scales for, 56t, 57-58
Symptoms of Nocturnal Obstruction and Respiratory Events (SNORE-25), 57
Synaptic bars, of hair cells, 1833-1834, 1833f, 1857, 1859f
Synaptic plasticity, 1884, 1884f
Synaptic ribbons, of hair cells, 1833-1834, 1833f, 1857, 1859f
Synaptic strengthening, Hebb's postulate for, 1884, 1884f
Synaptobrevin, 2080-2081

Synchondroses, in craniofacial growth and development, 2617-2619, 2619f-2620f
Synchronous lesion, in oral cancer, 1301-1302
Synergistic effect, of chemoradiation, 1041
Synkinesis, 904, 2384-2385
  with Bell's palsy, 2396
  management of, 2432
    botulinum A toxin for, 2432
    selective myectomy for, 2432
Synostosis
  coronal
    bilateral, 2644, 2645f
    fronto-orbital advancement for, 2652-2653, 2653f-2654f
    unilateral, 2643-2644, 2644f, 2648f
  craniofacial, 2639
  imaging of, 2648, 2648f
  lambdoid, 2643-2644
    fronto-orbital advancement for, 2653
  metopic, 2642-2643, 2643f
  pan-, 2641t
  sagittal, 2642, 2643f
    surgical management of, 2650, 2650f-2651f
Synovial sarcoma (SS), 1670
Synthetic biomimetic materials, for craniofacial defect repair, 2658
Synthroid (levothyroxine, oral synthetic), for hypothyroidism, 1748-1749
Syphilis
  diagnosis of, 2341
  HIV and, 224
  oral manifestations of, 1252, 1257
  otologic manifestations of, 2105, 2105f, 2341-2342
    early *vs.* late, 2341
    treatment for, 2341-2342
  pharyngitis due to, 194
    in children, 2786
  sensorineural hearing loss due to, 2119, 2161
    fluctuating, 2199
    in infants, 2723
    sudden, 2127-2128
Syringoma, 292-293
Systematic sample, 68, 69t
Systemic disease(s)
  laryngeal and tracheal manifestations of, 889-893
    in actinomycosis, 893
    in amyloidosis, 891, 891f
    in blastomycosis, 885, 892
    in candidiasis, 884-885, 884f, 893
    in coccidioidomycosis, 885, 893
    in cryptococcosis, 892-893
    in histoplasmosis, 885, 892
    in pemphigus, 887, 887f, 891-892, 892f
    in relapsing polychondritis, 890
    in rheumatoid arthritis, 891, 891f
    in sarcoidosis, 890-891, 890f
    in tuberculosis, 885-886, 886f, 892
    in Wegener's granulomatosis, 889-890, 890f
    in whooping cough, 892
  nasal manifestations of, 657-1
    cutaneous, 660-661
      in Behçet's disease, 660-661
      in pemphigoid, 660
      in pemphigus vulgaris, 660
      in scleroderma, 660
    granulomatous, 657-659
      in Churg-Strauss syndrome, 659
      in sarcoidosis, 658-659
      in Wegener's granulomatosis, 658
    immunodeficiency, 660
      in AIDS, 660
      sinusitis in immunocompromised patient as, 660
    mucociliary, 661
      in cystic fibrosis, 661
      in primary ciliary dyskinesia, 661
Systemic disease(s) *(Continued)*
    neoplastic, 659-660
      in T-cell lymphoma, 659-660
  oral manifestations of, 1245-1258
    arthritides and bone disorders as, 1253
      Ewing's sarcoma as, 1253
      osteoarthritis as, 1253
      Paget's disease as, 1253
      Reiter's syndrome as, 1253
      rheumatoid arthritis as, 1253, 1253t
    cerebrovascular, 1250
    collagen-vascular and granulomatous, 1251-1252
      dermatomyositis-polymyositis as, 1252
      sarcoidosis as, 1252
      scleroderma as, 1252
      Sjögren's syndrome as, 1251
      systemic lupus erythematosus as, 1251-1252
      Wegener's granulomatosis as, 1252
    dermatologic, 1253-1254
      erythema multiforme as, 1254
      lichen planus as, 1253-1254
      mucous membrane pemphigoid as, 1254
      pemphigus vulgaris as, 1254
    endocrine and exocrine, 1251
      adrenal, 1251
      diabetes mellitus as, 1251
      parathyroid, 1251
      pituitary, 1251
      thyroid, 1251
    gastrointestinal, 1254
      Behçet's syndrome as, 1254
      Crohn's disease and ulcerative colitis as, 1254
      gastroesophageal reflux disease as, 1254
      malabsorption diseases as, 1254
    of heart, 1246-1249, 1249t
    hematologic, 1256
      bleeding disorders as, 1256
      hemoglobin problems as, 1256
      white blood cell disorders as, 1256
    infectious, 1252
      bacterial, 1252
      fungal, 1252
      viral, 1252
    inherited and congenital, 1257
    of liver, 1255
    malignant neoplasms as, 1249-1250
    neurologic, 1254-1255
      Bell's palsy as, 1255
      dementias (including Alzheimer's disease) as, 1254-1255
      multiple sclerosis as, 1255
      myasthenia gravis as, 1255
      myotonic muscular dystrophy as, 1255
      Parkinson's disease as, 1255
    pulmonary, 1250-1251
    renal, 1255
  oral sequelae of medications for, 1246, 1247t-1248t
  oral treatment considerations due to, 1246, 1246t
  otologic manifestations of, 2100-2115, 2101t
    of bone, 2108-2112
      in fibrous dysplasia, 2110-2111, 2111f
      in osteitis fibrosa cystica, 2112
      in osteogenesis imperfecta, 2109-2110, 2110f
      in osteopetroses, 2111-2112, 2112f-2113f
      in Paget's disease, 2108-2109, 2109f
    collagen vascular and autoimmune, 2114
    genetically determined, 2115
    granulomatous and infectious, 2100-2106
      in Langerhans' cell histiocytosis, 2100-2101, 2101f-2102f
      in Lyme disease, 2105-2106
      in mycotic diseases, 2106, 2106f
      otorrhea as, 2196
      in sarcoidosis, 2104-2105, 2104f
      in syphilis, 2105, 2105f
Systemic disease(s) *(Continued)*
      in tuberculosis, 2101-2103, 2102f-2103f
      in Wegener's granulomatosis, 2103-2104, 2103f-2104f
    immunodeficiency, 2114-2115
      in AIDS, 2114-2115
      primary of congenital, 2114
    neoplastic, 2106-2108
      in leukemia, 2107, 2108f
      metastatic, 2107-2108, 2108f
      in multiple myeloma, 2106-2107, 2107f
    otorrhea as, 2196
    storage and metabolic, 2112-2114
      in gout, 2113-2114
      in mucopolysaccharidoses, 2112-2113, 2113f
      in ochronosis, 2114
  with rhinitis, 698-699, 698b
Systemic lupus erythematosus (SLE), oral manifestations of, 1251-1252
Systemic vascular resistance, factors influencing, 2597, 2597t

T

T & T olfactometer, 631
T cell(s), 600-603
  cytotoxic, 601, 602f
  development of, 600-601
  effector, 601-603

presentation and evaluation of, 2846, 2846t
nasopharyngeal, 2695, 2696f
neck masses due to, 1639-1640, 2816, 2816f
Terbinafine, for rhinosinusitis, 713t, 735t
Terminal cell, surgical anatomy of, 740
Tessier, Paul, 318
Test-retest reliability, 55
Tetanus prophylaxis, for facial trauma, 303
Tetracaine-adrenaline-cocaine (TAC) anesthesia, for facial trauma, 304
Tetracycline, for embolization, 1933
3,5,3′,5′-Tetraiodothyronine (T_4), 1737. *See also* Thyroid hormone(s).
oral synthetic, for hypothyroidism, 1748-1749
serum free, 1740
in thyrotoxicosis, 1742
Tetraspan membrane protein of hair cell stereocilia *(TMHS)* gene, in deafness, 2051t-2058t
TFCP2L3 (transcription factor cellular promotor 2-like 3) gene, in deafness, 2051t-2058t
TG. *See* Thyroglobulin (TG).
TGF (transforming growth factor), 609t-610t
TGF-α (transforming growth factor α), in wound healing, 1076
TGF-β (transforming growth factor β), 609t-610t
in wound healing, 1076
TH1 cells, 601
in otitis media, 2764
TH2 cells, 601
in otitis media, 2764
TH17 cells, 601-602
Thalamus, in auditory pathway, 1846-1847
Thalassemia
oral manifestations of, 1256
preoperative evaluation of, 106
Thalidomide, microtia due to, 2741
Thallium 201 (Tl 201) imaging, for hyperparathyroidism, 1784-1785
Thallous chloride imaging, for hyperparathyroidism, 1784-1785
Thanatophoric dysplasia, craniofacial anomalies in, 2641t
Therapeutic lymph node dissection (TLND), for melanoma, 1114, 1116
Thermal ablation, interventional bronchoscopy with, 1010t
Thermal laryngeal trauma, 939-941
etiology of, 940-941
incidence of, 939-940
management of, 941
Thermal sensitivity, of oral cavity, 1201
Thermoregulation, vascular supply of skin in, 1064
θ-defensins, 599
THI (Tinnitus Handicap Inventory), 2135, 2138
Thiamine-responsive megaloblastic anemia syndrome, deafness in, 2051t-2058t
Thiazide diuretics, hypercalcemia due to, 1784
Thiopental, for anesthesia induction, 111
in children, 2590
Third "mobile window," in superior canal dehiscence syndrome, 2339-2340
Third-gain rule, for hearing aids, 2271
Thoracic duct, anatomy of, 2582
Thornwaldt cyst. *See* Tornwaldt cyst.
THRB (thyroid hormone receptor β) gene, in deafness, 2051t-2058t

Three-dimensional conformal radiotherapy (3DCRT), 1043
  for cervical metastases, 1691-1692
  for glottic cancer
    advanced-stage, 1585-1586
    early-stage, 1581, 1581f-1582f
Three-dimensional (3D) CT, of laryngeal carcinoma, 1470
Three-dimensional reconstruction, from CT or MRI, 138, 140f
Three-field technique, for radiation therapy, for glottic cancer, 1586, 1587f
Three-wall orbital decompression, for Graves' ophthalmopathy, 1815-1816
Threshold, of auditory neurons, 1839-1840, 1844-1845, 1845f
Throat, sore. *See* Pharyngitis.
Throat cultures, 2787
Thrombocytopenia
  oral manifestations of, 1256
  preoperative evaluation of, 106
Thromboxane synthetase, in acutely raised skin flaps, 1070, 1070f
"Through-and-through" resection, for buccal carcinoma, 1308-1309, 1309f
Through-the-scope (TTS) balloons, for esophageal strictures, 966
Thrush, 1230, 1230f
  in HIV, 225, 226f
Thulium laser, for stridulous child, 2908
Thunderclap headache, 248
Thymic cysts, 2817
Thymopharyngeal cysts, 2585
Thyroarytenoid (TA) muscle
  anatomy of
    applied, 806-807, 807f
    surgical, 1543f
  botulinum toxin injection of, for spasmodic dysphonia, 840f
  in breathing, 810f
  characteristics of, 918
  in pitch control, 812
  in professional voice production, 846-847
Thyrocervical trunk, in root of neck, 2581-2582
Thyroepiglottic ligament, surgical anatomy of, 1542f-1543f
Thyroglobulin (TG)
  serum measurement of, 1740
    with thyroid nodule, 1756
  in thyroid hormone storage and release, 1737f, 1738
  in thyroid hormone synthesis
    iodination of, 1737f, 1738
    synthesis of, 1737-1738, 1737f
Thyroglossal duct carcinomas, 2847
Thyroglossal duct cyst(s), 2814-2815, 2871-2872
  clinical presentation of, 2814-2815, 2815f
  vs. ectopic thyroid, 2815
  embryology of, 2586, 2814
  imaging of, 161-162, 165f
  infected, needle aspiration of, 206, 206f
  neck masses due to, 1639
  Sistrunk operation for, 2815
  squamous cell carcinoma arising in, 1671
  vallecular, 2871-2872, 2872f
Thyrohyoid ligament, surgical anatomy of, 1542f
Thyrohyoid membrane, surgical anatomy of, 1541-1542, 1542f-1543f
Thyrohyoid muscle, characteristics of, 918-919
Thyrohyoid space, palpation of, in voice evaluation, 827, 828f
Thyroid adenoma, 1758-1759
  autonomously functioning, 1759
  in children, 2819
  clinical presentation of, 1758
Thyroid adenoma *(Continued)*
  management and prognosis for, 1759
  pathology of, 1758-1759
  sestamibi–technetium 99m scintigraphy of, 1785f
  toxic, 1744
Thyroid alar cartilage graft, for laryngeal stenosis, 2919, 2921f
Thyroid antibody status, 1740-1741
Thyroid binding inhibitory immunoglobulins (TBII), 1741
Thyroid cancer
  anaplastic, 1764
    clinical presentation of, 1764
    management and prognosis for, 1764
    pathology of, 1764
  in children, 1769-1770, 2820
  clinical presentation of, 1751
  epidemiology of, 1751
  etiology of, 1753
  follicular, 1761-1762
    clinical presentation of, 1761-1762
    imaging of, 161-162, 165f
    management and prognosis for, 1762
    pathology of, 1762
  follow-up for, 1772
  in geriatric patients, 238
  Graves' disease and, 1742
  Hürthle cell, 1762-1763
    clinical presentation of, 1762
    management and prognosis for, 1762-1763
    pathology of, 1762
  insular, 1764
  with laryngeal invasion, 1510
  lymphoma as, 1764
  medullary, 1763-1764
    clinical presentation of, 1763
    management and prognosis for, 1763-1764
    nodal metastasis of, 1766
    pathology of, 1763
  metastatic, 1764
    ultrasound imaging of, 1644, 1648f-1649f
  molecular basis for, 1752-1753
  papillary, 1760-1761
    clinical presentation of, 1760
    management and prognosis for, 1760-1761
    pathology of, 1760
  during pregnancy, 1770
  risk factors for, 1753
    with aggressive behavior, 1756, 1756t
  selective neck dissection for, 1719, 1719f-1720f
  squamous cell, 1764
  staging and classification of, 1753-1754
    AGES and MACIS, 1754
    AMES, 1754, 1756t
    TNM, 1754, 1755t
  surgical management of (*See* Thyroid surgery)
  tracheal invasion by, 1615
  ultrasound of, 1644, 1646b, 1646f
    metastatic, 1644, 1648f-1649f
Thyroid capsule, anatomy of, 1751
Thyroid cartilage
  anatomy of, 805-806, 1359f
    radiographic, 1471, 1473f
    surgical, 1541, 1542f-1544f
  laryngeal carcinoma of, 1541
    imaging of, 1474-1475, 1476f
  palpation of, in voice evaluation, 827, 828f
  physical examination of, 95, 96f
  repair of, 936-937
Thyroid cyst, 1759-1760
  clinical presentation of, 1759-1760
  management and prognosis for, 1760
  pathology of, 1760
Thyroid dermopathy, and Graves' ophthalmopathy, 1808
Thyroid disorder(s), 1735-1749
  history and review of symptoms for, 1736
  hyperparathyroidism and, 1801, 1801f-1802f
  hypothyroidism as, 1745-1749
    clinical features of, 1745-1746, 1746b
    due to endemic goiter, 1747
    etiology of, 1745, 1746b
    due to excessive iodine intake, 1747
    familial, 1747
    goitrous, 1747
    hearing loss due to, 1746
    hoarseness due to, 1747
    hypothalamic, 1747
    laboratory diagnosis of, 1748, 1748t
    after laryngectomy, 1747
    management of, 1748-1749
    myxedema coma due to, 1749
    nongoitrous, 1747
    pituitary, 1747
    prevalence of, 1745
    after radiation therapy, 1747
    risk factors for, 1745-1746, 1746b
    subclinical, 1747-1748
      diagnosis of, 1747
      effects on lipid, hypothyroid symptoms, and mood of, 1747-1748
      natural history of, 1747
      prevalence of, 1747

      acoustic desensitization protocol as, 2135
      ambient stimulation as, 2133-2134
      combined with education and counseling, 2134-2135
      personal listening devices as, 2134
      total masking therapy as, 2134
    cognitive-behavioral, 2135
    electric stimulation as, 2136-2137
      via cochlear implants, 2137
      transcutaneous, 2136-2137
    pharmacologic, 2137
    transcranial magnetic stimulation as, 2135-2136
Tinnitus Handicap Inventory (THI), 2135, 2138
Tinnitus retraining therapy (TRT), 2134-2135
  for hyperacusis, 2139
Tinnitus-producing fibromuscular dysplasia, of carotid artery, endovascular treatment for, 1943
Tip links
  in auditory physiology, 1841f, 1842, 1843f
  composition of, 2072f, 2074
  in hair cell transduction, 2072f, 2073-2074
  in vestibular physiology, 2277-2278, 2279f
Tip projection, 520, 535-536
  in aesthetic analysis, 273-274, 277f
  autogenous cartilage struts for, 535-536, 536f
  cephalic rotation for, 519, 536, 549-550, 551f
  onlay tip cartilage grafts for, 535-536, 537f, 549-550, 550f-551f
  partial-transfixion *vs.* complete-transfixion incisions for, 535-536, 536f
  plumping grafts for, 535-536, 536f
  transdomal sutures for, 536
Tip ptosis, 484, 485f
  caudal extension graft for, 576, 576f
  due to overaggressive resection of caudal septum, 492, 492f
  revision rhinoplasty for, 590-593, 593f
  after rhinoplasty, 519, 520f
Tip recoil, 513, 513f
Tip rotation, in aesthetic analysis, 273-274, 277f
Tip support mechanisms, 519, 520f
Tirapazamine, with radiotherapy, 1041
Tissue adhesives, for facial trauma, 306
Tissue débridement, interventional bronchoscopy for, 1008-1009, 1010t
Tissue effects, of surgical laser, 28-30, 30f
Tissue engineering, in mandibular reconstruction, 1327-1328, 1328f
Tissue expansion
  for forehead repair, 363
  for hair loss, 384, 385f
  for scar revision, 296-298, 297f
  and skin flap viability, 1074
Tissue flaps, gene therapy for, 22-23
Tissue-radiation characterizations, 1039-1040, 1039f
Titanium, for craniofacial defect repair, 2657
Titanium chain link implants, for lagophthalmos, 2421
Titanium prostheses, for ossiculoplasty, 2006, 2025-2026, 2026t
TIV (trivalent inactivated influenza vaccine), to prevent otitis media, 2769
TIVA (total intravenous anesthesia), in children, 2592
Tl 201 (thallium 201) imaging, for hyperparathyroidism, 1784-1785
TLESR (transient lower esophageal sphincter relaxation), 954, 968
TLM. *See* Transoral laser microsurgery (TLM).
TLND (therapeutic lymph node dissection), for melanoma, 1114, 1116
TLRs. *See* Toll-like receptors (TLRs).
TM. *See* Tympanic membrane (TM).
TMC1 (transmembrane channel-like gene 1), in deafness, 2051t-2058t
TMDs. *See* Temporomandibular disorders (TMDs).
TMHS (tetraspan membrane protein of hair cell stereocilia) gene, in deafness, 2051t-2058t
TMIE (transmembrane inner ear expressed gene), in deafness, 2051t-2058t
TMJ. *See* Temporomandibular joint (TMJ).
Tmprss1 (transmembrane protease serine 1) gene, in murine deafness, 2058t-2060t
TMPRSS3 (transmembrane protease serine 3) gene, in deafness, 2051t-2058t
TMS (transcranial magnetic stimulation), for tinnitus, 2135-2136
TNE. *See* Transnasal esophagoscopy (TNE).
TNF (transnasal fiberoptic laryngoscopy), for extraesophageal reflux, 898
TNF (tumor necrosis factor), 609t-610t
TNF-α (tumor necrosis factor α), in gene therapy, 21
TNF-β (tumor necrosis factor β), 609t-610t
TNFerade, in gene therapy, 21
TNM classification. *See* Tumor-node-metastasis (TNM) classification.
TOAE (transitory otoacoustic emission), for otitis media, 2762
Tobacco
  and Graves' ophthalmopathy, 1807
  and skin flap survival, 1075
  and squamous cell carcinoma
    of head and neck, 1016
    of larynx, 1491, 1512-1513
    of oral cavity, 1293-1294, 1365
Tobacco smoke exposure, and otitis media, 2767
Tobramycin, for rhinosinusitis, 734-735, 735t
Tobramycin with dexamethasone (Tobradex), for otitis externa, 1952, 1959t-1960t
Tolerance, immune, 1023
Toll-like receptors (TLRs), 598
  activators of, 598
  and adaptive immune response, 598
  expression and distribution of, 598
  and host, 598
Tolnaftate (Tinactin), for fungal otitis externa, 1954-1955, 1959t-1960t
Tone(s), 1838-1839
Tone-pips, in auditory brainstem response testing, 1896-1897
Tongue
  anatomy of, 1297
  fungiform papillae on, 1208
  leukoplakia of, 1362f
  lymphatic drainage of, 1297, 1298f
  muscles and reflexes of, 1205
  neurologic examination of, 833
  physical examination of, 98
  in swallowing
    in oral preparatory stage, 1215, 1216f
    in oral stage, 1215, 1216f
  tactile sensitivity of, 1201, 1201f
  taste buds on, 1208
Tongue base
  anatomy of, 1359, 1359f
    radiographic, 1399f
  lymphatics of, 1361f
Tongue base cancer
  cervical lymph node metastasis of, 1361t
  clinical presentation of, 1365
  management of, 1369-1370
Tongue base extension, laryngeal cancer with, supraglottic laryngectomy for, 1555
Tongue base procedures, for obstructive sleep apnea, 259
Tongue base reconstruction, 1387-1391
  algorithm for, 1391f
  free flaps for, 1389
    lateral arm, 1389
    radial forearm, 1389
  goals of, 1387
  healing by second intention for, 1387-1388
  local flaps for, 1388
  primary closure for, 1387-1388
  regional flaps for
    latissimus dorsi, 1389
    pectoralis major myocutaneous, 1388-1389
    platysmal myocutaneous, 1389
  skin grafting for, 1388
  after total or subtotal glossectomy, 1389-1390
    innervated free latissimus dorsi musculocutaneous flap for, 1389-1390, 1390f
    microvascular reconstruction as, 1390
    money pouch–like method for, 1390, 1390f
    sensate fasciocutaneous flaps for, 1390-1391
Tongue base retraction, during pharyngeal swallow, 1217
Tongue carcinoma, 1305-1306
  advanced-stage, 1306
  cervical lymph node metastases of, 1306
  clinical presentation of, 1305
  composite resection of, 1305, 1305f-1306f
  differential diagnosis of, 1305
  epidemiology of, 1295, 1305
  etiology of, 1305
  gross pathology of, 1305f
  hemiglossectomy for, 1305-1306, 1305f
  hemimandibulectomy for, 1306f
  local invasion by, 1305, 1305f-1306f
  palatal augmentation prosthesis for, 1342-1343, 1344f

Tongue carcinoma *(Continued)*
reconstruction for, 1305-1306
survival with, 1306
wide local excision for, 1305
Tongue flaps, for oropharyngeal reconstruction, 1376
Tongue prosthesis, 1342-1343, 1344f
Tongue reduction surgery, for obstructive sleep apnea in children, 2609
Tongue resection, palatal augmentation prosthesis for, 1342-1343, 1344f
Tongue surgery, swallowing disorders due to, 1219
Tongue suspension, for obstructive sleep apnea in children, 2610
Tonic activity, in facial nerve monitoring, 2387, 2547, 2547f
Tonotopic map, 2060-2061, 2063f
Tonotopic map reorganization
age-related, 1877, 1879, 1882f
experimental studies of
after cochlear lesions, 1877-1878, 1878f-1879f
in adult subjects, 1878-1879, 1881f

for primary malignant tumors, 1617
anesthetic management in, 1617
carinal resections in, 1619, 1621f-1623f
release maneuvers in, 1618-1619, 1620f
subglottal resections in, 1619, 1620f
tracheal resection and primary reconstruction in, 1617-1618, 1618f-1620f
results of, 1622
for unresectable tumors, 1619-1624
therapeutic bronchoscopy in, 1619-1622
Tracheal prostheses, synthetic, for tracheal stenosis, 2934, 2934f
Tracheal resection, 1617-1618, 1618f-1620f
release maneuvers with, 1618-1619, 1620f
Tracheal stenosis, 943-952
due to anterior wall collapse, 951
cervical, 951, 951b, 951f
in children, 2925-2934
anomalies associated with, 2927
due to arterial compression, 2925-2926
classification of, 2927, 2927t
conservative management of, 2927-2928
diagnosis of, 2926-2927
dilation for, 2928, 2928f
embryology of, 2925-2926
endoscopic evaluation of, 2926-2927
imaging of, 2927
laser therapy for, 2928, 2929f
long-segment, 2926, 2926f
treatment of, 2934
open repair for, 2930-2934
complications of, 2934
costal cartilage tracheoplasty in, 2930-2931, 2931f
granulation at graft site with, 2931
long-segment, 2934
partial tracheal resection, posterior end-to-end anastomosis, and anterior repair with resected trachea in, 2933-2934
pericardial patch in, 2930, 2931f
segmental resection in, 2931-2932, 2932f
short-segment, 2934
slide tracheoplasty in, 2932-2933, 2933f
synthetic tracheal prostheses in, 2934, 2934f
tracheal homograft transplantation in, 2933, 2934f
wedge resection in, 2931, 2931f
short-segment, 2926, 2926f
treatment of, 2934
stents for, 2928-2930, 2930f
due to vascular rings, 2925
cicatricial membranous, 951
classification of, 944, 944t
complete, 951-952, 952f
diagnosis of, 2926-2927
dysphagia due to, 2954
local application of mitomycin C for, 946
long-segment, 2926, 2926f
pathophysiology of, 943-944, 944b
short-segment, 2926, 2926f
surgical management of, 943-952
for chronic disease, 947-952
endoscopic *vs.* open, 945
goals and assessment in, 944, 945f
planning for, 946-947
skin and mucosal grafts in, 946-947
timing of, 945
Tracheal stoma, after total laryngectomy, 1570, 1571f

Tracheal–innominate artery fistula, 1623
Tracheal–pulmonary artery fistula, 1623
Tracheitis, bacterial (exudative), 2809-2810
  clinical features of, 2809
  complications of, 2810
  diagnosis of, 2809, 2809f
  differential diagnosis of, 2806t
  endoscopy of, 2809, 2809f
  epidemiology of, 2809
  imaging of, 2809, 2809f
  management of, 2809-2810, 2809f
  pathogenesis of, 2809
  terminology for, 2809
Tracheobronchial endoscopy, 998-1012
  airway anatomy and nomenclature for, 998-999, 999f
  flexible fiberoptic, 1001-1007
    care of bronchoscopes for, 1001-1002
    diagnostic, 999b, 1003-1007
      for bronchial wash, 1003
      for bronchoalveolar lavage, 1003-1004
      for bronchoscopic brush sampling, 1007
      for endobronchial and transbronchial biopsy, 1004-1005, 1004f-1005f
      general approaches to, 1003
      for transbronchial needle aspiration, 1005-1007, 1005f-1006f
      for visual examination, 1003
    range and special features of bronchoscopes for, 1001, 1002t, 1003f
  imaging prior to, 999-1000
  indications for, 999, 999b
  innovations and future developments in, 1009-1011
    autofluorescence bronchoscopy as, 1009
    endobronchial ultrasonography as, 1011
    endoscopic/bronchoscopic lung volume reduction as, 1011
  interventional, 999b, 1007-1009
    for balloon bronchoplasty, 1009
    for endobronchial stent placement, 1009
    for foreign body removal, 1008
    general principles of, 1007-1008
    patient preparation and instrument selection for, 1008
    for tissue débridement, 1008-1009, 1010t
  patient discussion and informed consent for, 1000
  patient positioning and route of entry for, 1000
  rigid, 1000-1001
  sedation and airway management for, 1000
Tracheobronchial obstruction, in neonate, 2905
Tracheobronchoscopy. *See* Tracheobronchial endoscopy.
Tracheoesophageal diversion, for chronic aspiration, 931-932, 931f-932f
Tracheoesophageal fistula (TEF), 2926
  imaging of, 1409-1410
Tracheoesophageal puncture (TEP)
  in total laryngectomy, 1568-1569, 1569f, 1572
  transnasal esophagoscopy in, 984
  for voice prosthesis, 1459, 1599
    and radiation therapy, 1600, 1602b
    secondary, 1600
Tracheoesophageal (TE) speech
  physiology of, 1597, 1597f
  after total laryngectomy, 1572
Tracheoesophageal voice prosthesis, 1459
Tracheomalacia, 2925
  dysphagia due to, 2954
Tracheoplasty, 2930-2934
  balloon, 2928, 2928f
  complications of, 2934
  costal cartilage, 2930-2931, 2931f
  granulation at graft site with, 2931
  long-segment, 2934
Tracheoplasty *(Continued)*
  partial tracheal resection, posterior end-to-end anastomosis, and anterior repair with resected trachea in, 2933-2934
  pericardial patch in, 2930, 2931f
  segmental resection in, 2931-2932, 2932f
  short-segment, 2934
  slide, 2932-2933, 2933f
  synthetic tracheal prostheses in, 2934, 2934f
  tracheal homograft transplantation in, 2933, 2934f
  wedge resection in, 2931, 2931f
Tracheostoma, after total laryngectomy, 1570, 1571f
Tracheostomy, 125-126
  for deep neck space infections, 205
  and recurrent respiratory papillomatosis, 2887
  for Robin sequence, 2673
Tracheostomy tube, for children, 2906-2907
Tracheostomy tube insertion, in cricothyrotomy, 127, 128f
Tracheotomy
  for chronic aspiration, 927
  for difficult airway, 114t
  for obstructive sleep apnea, 260-261
    in children, 2610
  for stridulous child, 2906
    complications of, 2907
    emergency, 2904
    indications for, 2906, 2906t
    patient positioning for, 2906, 2907f
    preoperative planning for, 2906
    surgical decannulation of, 2907-2908
    surgical procedure for, 2906-2908, 2907f
    techniques to avoid, 2906, 2906f
    ward decannulation of, 2907
Tracking systems, for image-guided sinus surgery, 681
Traction diverticula, 986
Tragus, 476-477, 476f
  anatomy of, 1824f, 2742f
Tragus reconstruction, in microtia reconstruction, 2747, 2748f
"Train" activity, in facial nerve monitoring, 2387, 2547, 2547f
Tranquilizers, dizziness due to, 2310t
trans elements, 5f
Transantral approach, for middle cranial base surgery, 2455t, 2458, 2459f
Transantral orbital decompression, for Graves' ophthalmopathy, 1812-1814
  complications of, 1814
  modifications of, 1814
  outcome of, 1812-1814, 1813f-1814f
  technique for, 1812
    ethmoidectomy in, 1812, 1812f
    incisions into periorbital fascia in, 1812, 1813f
    removal of orbital floor in, 1812, 1813f
    sublabial buccogingival incision in, 1812, 1812f
Transantrosphenoidal approach, for middle cranial base surgery, 2455t, 2458, 2459f
Transbasal approach, for anterior cranial base surgery, 2453-2454, 2454f
Transbronchial biopsy (TBBX), flexible fiberoptic bronchoscopy for, 1004-1005, 1004f-1005f
Transbronchial needle aspiration (TBNA), flexible fiberoptic bronchoscopy for, 1005-1007, 1005f-1006f
Transcanal approach, for tympanoplasty, 2001, 2001f
Transcanal infracochlear approach, for skull base lesions requiring drainage, 2539, 2540f
Transcartilaginous approaches, for nasal tip refinement, 522, 523f-526f
Transcaruncular approach, for pediatric facial fracture, 2701-2702, 2705f
Transcervical approach, for excision of tumors in parapharyngeal space, 1174-1176, 1175f
Transcervical diverticulectomy, 991f
Transcervical incision and drainage, for deep neck space infections, 207
Transclival approach, for transnasal endoscopic-assisted anterior skull base surgery, 2479-2481, 2480f-2481f
Transcochlear approach
  to petrous apex, 2499-2500, 2500f
  for posterior fossa neoplasms, 2532t, 2537
    advantages and disadvantages of, 2532t, 2537
    basic features of, 2537
    indications for, 2532t, 2537
    surgical exposure in, 2537f
    technique of, 2537, 2537f
Transconjunctival blepharoplasty, 448-449, 450f
Transcranial electrical stimulation–induced facial motor evoked potentials, to assess facial nerve function, 2389
Transcranial magnetic stimulation (TMS), for tinnitus, 2135-2136
Transcranial motor evoked potential (tcMEP), for intraoperative monitoring, 2555, 2555f
Transcranial repair, for CSF rhinorrhea, 792
Transcribriform approach, for transnasal endoscopic-assisted anterior skull base surgery, 2482
  with bilateral access, 2482, 2482f
  with unilateral access, 2482
Transcription, of genes, 4, 5f, 11-12, 12f
Transcription factor cellular promotor 2-like 3 *(TFCP2L3)* gene, in deafness, 2051t-2058t
Transcutaneous carbon dioxide pressure ($TcPCO_2$), in skin flaps, 1068
Transcutaneous electric stimulation, for tinnitus, 2136-2137
Transcutaneous oxygen pressure ($TcPO_2$), in skin flaps, 1068
Transdomal suturing
  for nasal tip projection, 536
  for nasal tip refinement, 522, 530f-531f
Transduction channels, in hair cell transduction, 2071-2073
  effects of deficiencies of, 2079-2080
  gating of, 2073-2074
  ion selectivity of, 2073, 2073f
  structure of, 2076f
Transduction efficiency, with traditional hearing aid, 2204-2205
Transesophageal echosonography, 1396
Transethmoidal access, for transnasal endoscopic-assisted anterior skull base surgery, 2478-2479, 2479f-2480f
Transethmoidal encephalocele, 2687t
Transethmoidal sphenoidotomy, for middle cranial base surgery, 2455-2457, 2455t, 2456f
Transfacial approach, for middle cranial base surgery, 2464-2467, 2467f
Transfection, 15-16, 15f
Transfixion incision, for septoplasty, 488, 489f
Transforming growth factor (TGF), 609t-610t
Transforming growth factor α (TGF-α), in wound healing, 1076
Transforming growth factor β (TGF-β), 609t-610t
  in wound healing, 1076
Transglottic cancer
  anatomic basis for, 1486
  imaging of, 161, 164f, 1475f, 1476, 1478f
Transhyoid pharyngotomy approach, for oropharyngeal cancer, 1371, 1372f
Transient evoked otoacoustic emissions (TEOAEs), 1891, 1905
  with acoustic neuroma, 1891-1892, 1893f
  advantages of, 1891
  analysis of, 1905
  clinical applications of, 1905-1907

Transient evoked otoacoustic emissions (TEOAEs) *(Continued)*
defined, 1891, 1905
in infants, 2720-2721
in noise-induced hearing loss, 2146-2147, 2147f-2150f
with normal hearing, 1892f
Transient lower esophageal sphincter relaxation (TLESR), 954, 968
Transient receptor potential (TRP) channel, in gustatory transduction, 1209-1210
Transition register, 851
Transition voice, 851
Transition zones, of laryngeal carcinoma, 1489, 1490f
Transitory otoacoustic emission (TOAE), for otitis media, 2762
Translabyrinthine approach
for facial nerve decompression, 2041-2042
for intratemporal facial nerve surgery, 2411
advantages and uses of, 2411
limitations and complications of, 2411
technique of, 2411, 2411f-2412f
for posterior fossa neoplasms, 2530-2533, 2532t
advantages and disadvantages of, 2532t, 2533
basic features of, 2530
indications for, 2530, 2532t
requiring drainage, 2539
surgical exposure in, 2531f
technique of, 2530-2532, 2533f
tumor removal in, 2532-2533
Translation
of DNA, 4, 11-12, 12f
vs. head tilt, 2307, 2307f
with unilateral loss of function of, 2299-2300
anatomic and physiologic basis for, 2299-2300
clinical importance of, 2300, 2300f
Translational vestibulo-ocular reflexes, 2306-2307, 2309f
Translocase of mitochondrial inner membrane 8A *(TIMM8A)* gene
in deafness, 2051t-2058t
in Mohr-Tranebjaerg syndrome, 2097
Translocation, 4-5
Transmandibular approach, for middle cranial base surgery, 2455t, 2458, 2460f
Transmastoid approach
for facial nerve decompression, 2041-2042, 2411
for intratemporal facial nerve surgery, 2410-2411
advantages and uses of, 2411
limitations and complications of, 2411
technique of, 2410, 2410f
Transmastoid labyrinthine drainage, of cholesterol granuloma, 2540f
Transmaxillary approach, for transnasal endoscopic-assisted anterior skull base surgery, 2482-2483, 2483f
Transmembrane channel-like gene 1 *(TMC1),* in deafness, 2051t-2058t
Transmembrane inner ear expressed gene *(TMIE),* in deafness, 2051t-2058t
Transmembrane protease serine 1 *(Tmprss1)* gene, in murine deafness, 2058t-2060t
Transmembrane protease serine 3 *(TMPRSS3)* gene, in deafness, 2051t-2058t
Transmission, of laser energy, 28-29, 29f
Transnasal access, direct, for transnasal endoscopic-assisted anterior skull base surgery, 2477, 2477f
Transnasal endoscopic sinus approach, 742
Transnasal endoscopic-assisted anterior skull base surgery, 2471-2486
anesthesia for, 2476
combined approaches for, 2484
complications of, 2485
Transnasal endoscopic-assisted anterior skull base surgery *(Continued)*
craniocervical junction–odontoid approach for, 2483-2484, 2484f
instrumentation for, 2476
patient preparation for, 2475-2476
pedicled septal flap in, 2476-2477
postoperative care after, 2484-2485
preoperative assessment for, 2475, 2475f
reconstruction after, 2484
surgical anatomy for, 2471-2475
anterior cranial fossa in, 2471, 2472f
clivus in, 2474, 2474f
nasal cavity in, 2471-2473, 2472f-2473f
nasopharynx in, 2474
paranasal sinuses in, 2473-2474, 2473f
retroclival region in, 2474-2475, 2474f-2475f
surgical team setup for, 2476f
transcribriform approach for, 2482
with bilateral access, 2482, 2482f
with unilateral access, 2482
transmaxillary-transpterygoidal-infratemporal approach for, 2482-2483, 2483f
transsellar and parasellar approaches for, 2479, 2480f
transsphenoidal approach for, 2477-2481
with direct transnasal access, 2477, 2477f
with petrous apex access, 2481
with transclival access, 2479-2481, 2480f-2481f
with transethmoidal access, 2478-2479, 2479f-2480f
with transseptal access, 2477-2478, 2477f-2478f
with transseptal-transnasal access, 2478, 2479f
transtuberculum-transplanum approach for, 2482
Transnasal esophagoscopy (TNE), 981-985
accuracy of, 982
in Barrett's esophagitis, 983, 983f
complications of, 984
in dysphagia, 983-984, 984f
of early glottic carcinoma, 1516, 1516f
equipment for, 981, 982f
for extraesophageal reflux, 899
in head and neck oncology, 983
history of, 981
indications for, 983-984
normal findings in, 982-983, 983f
in stricture dilation, 984, 984f
technique for, 982, 982f
therapeutic applications of, 984
tolerance of unsedated examination in, 981-982
in transesophageal puncture, 984
Transnasal fiberoptic laryngoscopy (TFL), for extraesophageal reflux, 898
Transnasal pressure, in rhinomanometry
measurement of, 645-647, 648f
nasal airflow and, 643
Transoral approach
for middle cranial base surgery, 2455t, 2458, 2461f
for oropharyngeal cancer, 1370-1371, 1370f-1371f
Transoral esophagoscopy, for extraesophageal reflux, 899
Transoral incision and drainage, for deep neck space infections, 206-207
Transoral injection, for vocal fold medialization, 906
Transoral laser microsurgery (TLM)
for hypopharyngeal cancer, 1429-1430, 1442
outcomes of, 1436-1438
for laryngeal cancer, 1525-1538
advanced, 1531-1532, 1532f-1533f
complications of, 1533-1534, 1534f
conclusions on, 1536-1537
contraindications to, 1534
costs of, 1534
Transoral laser microsurgery (TLM) *(Continued)*
early, 1530-1531
glottic, 1496
supraglottic, 1498-1500
glottic
with anterior commissure involvement, 1497
in early stage, 1496
historical background of, 1527
instruments for, 1528-1529
intermediate, 1531
and neck dissection, 1532
vs. open conservation surgery, 1528
pathology issues with, 1530
and radiotherapy, 1532-1533
results of, 1534-1535
Gottingen Group, 1535-1536
supraglottic, in early stage, 1498-1500
techniques for, 1529-1530
theoretical basis of, 1527-1528
very advanced, 1532
very early, 1530
terms and definitions for, 1525-1526
Transoral robotic surgery (TORS), for laryngeal cancer, 1560-1561
Transorbital projection, of temporal bone, 131
Transotic approach, for posterior fossa neoplasms, 2532t, 2537-2538
advantages and disadvantages of, 2532t, 2538
basic features of, 2537
indications for, 2532t, 2537-2538
technique for, 2538, 2538f
Transpalatal advancement pharyngoplasty, for obstructive sleep apnea, 258, 260f
Transpalatal approach, for middle cranial base surgery, 2455t, 2458, 2461f
Transplantation
and cervical lymphadenopathy, 219
and hearing loss, 224-225
and non-Hodgkin's lymphoma, 213t, 215-216
posttransplantation lymphoproliferative disorder after, 213t, 215, 217
and sinonasal infection, 219-221
diagnosis of, 220-221, 220f
presentation and pathogenesis of, 219-220
treatment of, 221
and squamous cell carcinoma, 215
and xerostomia, 218
Transposition flaps, 344, 344f
for cheek defects, 358-359, 361f
bilobed, 357, 359f
rhombus shaped, 355
for lip defects, 353
for nasal defects, 348, 349f, 365-366, 366f
Transpterygoid approach, for transnasal endoscopic-assisted anterior skull base surgery, 2483
Transsellar approach, for transnasal endoscopic-assisted anterior skull base surgery, 2479, 2480f
Transseptal access, for transnasal endoscopic-assisted anterior skull base surgery, 2477-2478, 2477f-2478f
Transseptal coaptation sutures, 546-547, 547f
Transseptal sphenoidotomy, for middle cranial base surgery, 2455-2457, 2455t, 2456f
Transseptal-transnasal access, for transnasal endoscopic-assisted anterior skull base surgery, 2478, 2479f
Transsphenoidal approach, for transnasal endoscopic-assisted anterior skull base surgery, 2477-2481
with direct transnasal access, 2477, 2477f
with petrous apex access, 2481
with transclival access, 2479-2481, 2480f-2481f
with transethmoidal access, 2478-2479, 2479f-2480f
with transseptal access, 2477-2478, 2477f-2478f
with transseptal-transnasal access, 2478, 2479f

Transsphenoidal encephalocele, 2687t
Transsphenoidal-transclival approach, for transnasal endoscopic-assisted anterior skull base surgery, 2479-2481, 2480f-2481f
Transtemporal approach
  for intratemporal facial nerve surgery, 2407-2409
    advantages and uses of, 2408-2409
    for Bell's palsy, 2409-2410, 2409t-2410t
    limitations and potential complications of, 2409
    technique of, 2407-2408, 2408f-2409f
  for middle cranial base surgery, 2461
Transtracheal jet ventilation, for difficult airway, 114t
Transtracheal needle ventilation, 128-129
Transtuberculum-transplanum approach, for transnasal endoscopic-assisted anterior skull base surgery, 2482
Transverse arytenoid cartilage, 1542f
Transverse arytenoid muscle, 1359f
Transverse cervical artery
  anatomy of, 2579
  in root of neck, 2581-2582, 2581f
Transverse cervical lymph nodes
  anatomy of, 1360f
  in neck dissection, 1705f
Transverse cervical vein, 2579
Transverse crest, in surgical anatomy of lateral skull base, 2437f, 2439
Transverse electromagnetic mode (TEM), 27, 28f
Transverse sinus, in surgical anatomy of lateral skull base, 2436f, 2439f
Trapdoor flaps, 346
  for tracheal stenosis, 2928, 2929f
Trapdoor fracture, of orbital floor, pediatric, 2712, 2714f
Trapezius muscle, anatomy of, 2578f-2579f
Trapezius musculocutaneous flap, for oropharyngeal reconstruction, 1378-1379
Trapezoid body, in auditory pathway, 1846
Trauma
  acoustic, 2121-2122, 2121f-2122f, 2141
  chronic aspiration due to, 926b
  CSF rhinorrhea due to, 786b, 794-795
  esophageal, 941-942
    caustic, 942, 977-978
      clinical features of, 977
      etiology of, 977
      grading of, 977, 978t
      prognosis for, 977-978
      squamous cell carcinoma due to, 978
      strictures due to, 977-978, 978f-979f
    external, 941-942
    mechanisms of injury in, 933, 934f
  facial (*See* Facial trauma)
  laryngeal (*See* Laryngeal trauma)
  neck (*See* Neck trauma)
  peripheral vestibular disorders due to, 2343
    baro-, 2343
    nonpenetrating, 2343
      blast, 2343
      labyrinthine concussion as, 2343
    penetrating, 2343
  to salivary glands, 312, 313f
    in children, 2863-2865
    sialocele and salivary fistula due to, 313-314
  sensorineural hearing loss due to, 2121-2122, 2121f-2122f
    sudden, 2128
  soft tissue, 302-317
    approach to, 302-306
      anesthesia in, 304
      cleaning in, 304-305, 305f
      history taking in, 302-303
      infection control in, 305
      physical examination in, 303-304, 303f
      repair in, 305-306, 306f
      tetanus prophylaxis for, 303
Trauma *(Continued)*
    to ears, 308f, 310, 310f
    etiology of, 302
    to eye, 303
    to eyelids, 303, 303f, 307-309, 308f
    to facial nerve, 309
    to lacrimal apparatus, 307-309, 308f
    with large-segment, composite avulsions or amputations, 312, 312f
    to lips, 309-310, 309f
    to nose, 310-312, 311f
    to parotid duct, 312-313, 314f
    to salivary glands, 312, 313f
      sialocele and salivary fistula due to, 313-314
    types of injuries in, 306-307
      abrasion as, 306
      avulsions as, 307, 308f
      laceration as, 307
  temporal bone (*See* Temporal bone fractures)
  vertigo due to, 2039, 2201
Traumatic condition(s), of oral cavity, 1288-1290
  amyloidosis as, 1289-1290, 1290f
  fibroma as, 1288-1289, 1289f
  mucosal ulcerations as, 1289, 1289f
  necrotizing sialometaplasia as, 1289, 1299
  pyogenic granuloma as, 1289, 1289f
Traumatic facial paralysis, 2398-2399, 2398f
Traumatic granuloma, of oral cavity, 1240
  clinical features of, 1240, 1240f
  defined, 1240
  differential diagnosis of, 1240
  etiology of, 1240
  histopathologic features of, 1240, 1240f
  treatment of, 1240
Traumatic pharyngitis, 194, 194f
Traumatic tattoos, 305, 305f
Trautmann's triangle, in surgical anatomy of lateral skull base, 2436f
Traveling wave, in cochlear transduction
  active, 2062-2069, 2064f
  passive, 2060-2062, 2062f-2063f
Treacher Collins syndrome
  branchial arch structures in, 2585
  craniofacial abnormalities in, 2633-2635, 2633b, 2635f, 2646
  deafness in, 2051t-2058t, 2094t, 2096
TREACLE gene, in mandibulofacial dysostosis, 2633
Treacle protein, in deafness, 2051t-2058t
Treatment, assessment of, 53
Treatment bias, 53
Tregs (regulatory T cells), 602-603
Tremor
  defined, 840
  essential, laryngeal hyperfunction due to, 840-841
  voice (vocal), 840-841
Treponema denticola, 1252
Treponema pallidum
  oral manifestations of, 1252
  pharyngitis due to, 194
    in children, 2786
Treponema vincentii, Vincent's angina due to, 2786
Tretinoin (Retin A, Renova, Micro Retin A, Avita)
  for aging skin, 403-404
  with chemical peels, 392-393
  for chemoprevention of oral cancer, 1315
TRH (thyrotropin-releasing hormone), in control of thyroid function, 1739
Triamcinolone (Nasacort), for nonallergic rhinitis, 700t
Triangular fossa, of ear, 2742f
Triangularis muscle, 321f
Tricellulin *(TRIC)* gene, in deafness, 2051t-2058t, 2081
Trichilemmal cysts, 289
Trichion, 378-379
Trichloroacetic acid (TCA)
  for chemical peels, 392-393
    history of, 391, 393
    Jessner's solution before, 393
    postoperative care after, 394
    results of, 394f
    technique of, 393-394, 393f-394f
  for ear hygiene or chronic ear drainage, 1958
Trichoepithelioma, 292
Tricyclic antidepressants (TCAs)
  for migraine, 2350
  for neuropathic pain, 244-245
Trigeminal depression
  anatomy of, 1822, 1822f
  in surgical anatomy of lateral skull base, 2435f, 2436-2437
Trigeminal gasserian ganglion block, for neuropathic pain, 246t
Trigeminal impression
  anatomy of, 1823f
  in surgical anatomy of lateral skull base, 2435f
Trigeminal nerve
  intraoperative monitoring of, 2550, 2550f
  in olfactory stimulation, 628-629
  in surgical anatomy of anterior cranial base, 2473f
  in surgical anatomy of lateral skull base, 2439f
Trigeminal nerve block, 242
Trigeminal nerve toxicity, due to stereotactic irradiation, 2563
Trigeminal nerve transposition, for facial nerve paralysis, 2419
Trigeminal neuralgia, 248
  microvascular decompression for, facial nerve monitoring with, 2548-2549
  vs. myofascial pain dysfunction syndrome, 1284t
Trigeminal neuromas, 2522, 2522f
Trigeminal pain, 1203
Trigeminal schwannoma, 2512f
Trigeminal system, central projections of, 1203
Trigonocephaly, synostotic, 2642-2643, 2643f, 2648f
  front-orbital advancement for, 2645, 2654f
3,5,3′-Triiodothyronine (T_3), 1737. *See also* Thyroid hormone(s).
  serum free, 1740
  in thyrotoxicosis, 1742
TRIOBP, in deafness, 2051t-2058t, 2076
Trismus
  due to deep neck space infection, 185-186
  due to masticator space infection, 184, 186f
  due to paranasal sinus tumor, 1123
Trisomies, 5
Trisomy 21. *See* Down syndrome.
Trisomy E, inner ear anomalies in, 2735
Triticeal cartilage, 1542f
Trivalent inactivated influenza vaccine (TIV), to prevent otitis media, 2769
Trochlear nerve
  intraoperative monitoring of, 2549-2550, 2550f
  in surgical anatomy of lateral skull base, 2439f
Trochlear notch, 322f
Trolamine polypeptide oleate-condensate (Cerumenex), for cerumen removal, 1958t
Tropomycin–receptor kinase A, in thyroid carcinoma, 1753
Trotter's syndrome, *vs.* myofascial pain dysfunction syndrome, 1284t
TRP (transient receptor potential) channel, in gustatory transduction, 1209-1210
Trpm13, in murine deafness, 2058t-2060t
TRT (tinnitus retraining therapy), 2134-2135
  for hyperacusis, 2139
True vocal folds
  anatomy of, 1359f
    radiographic, 1472, 1472f-1473f
  carcinoma of, imaging of, 1474-1475, 1474f
  physical examination of, 100

Trufill (polyvinyl alcohol), for embolization, 1933
Tryptans, for migraines, 247
TSGs. *See* Tumor suppressor genes (TSGs).
TSH. *See* Thyrotropin (TSH).
TT. *See* Tensor tympani (TT).
t-test, 70-71
TTH (tension-type headache), 247
TTS (temporary threshold shift), 2121, 2141
TTS (through-the-scope) balloons, for esophageal strictures, 966
Tubal artery, 1870
Tubal lumen, of eustachian tube, 1867f, 1870
Tuberculosis (TB)
  cervical lymphadenopathy due to
    in children, 2818, 2819f
    in HIV-positive patients, 219
  deep neck space infections due to, 201
  laryngeal and tracheal manifestations of, 885-886, 886f, 892
  of oral cavity, 1250-1251
  otologic manifestations of, 2101-2103, 2102f-2103f
    otorrhea as, 2196
  pharyngitis due to, 195
  of salivary glands, 1158
    in children, 2858
Tuberculous esophagitis, 1405
Tuberculous nodal mass, 166f
Tuberculous otitis media, 2101-2103, 2102f-2103f
Tuberculous salivary gland infection, 1158
Tuberous sclerosis, oral manifestations of, 1257
Tubulotympanic recess, 1866
Tufted angioma (TA), 2824-2825
  Kasabach-Merritt phenomenon with, 2825
Tufted cell, of olfactory bulb, 628f
Tularemia, pharyngitis due to, 195
Tullio phenomenon, 2316
  due to acquired cholesteatoma, 2196
  with labyrinthine fistula, 1989
  in superior canal dehiscence syndrome, 2290, 2329-2330, 2339
Tumarkin attacks, due to intratympanic gentamicin, 2189
Tumor burden, in melanoma, 1111-1112
Tumor (T) classification, for melanoma, 1111, 1111t, 1113f
Tumor necrosis factor (TNF), 609t-610t
Tumor necrosis factor α (TNF-α), in gene therapy, 21
Tumor necrosis factor β (TNF-β), 609t-610t
Tumor suppressor genes (TSGs), 12
  in Fanconi's anemia, 1020
  in head and neck squamous cell carcinoma, 1016, 1020
  modification of, 21-22
Tumor ulceration, with melanoma, 1111-1112
Tumor vaccines, for head and neck squamous cell carcinoma, 1023-1024
Tumor-infiltrating lymphocytes (TIL), genetic modification of, 13, 20-21
Tumor-node-metastasis (TNM) classification
  for melanoma, 1111, 1111t
    metastatic (M) classification (distant metastases) in, 1111t, 1113
    nodal (N) classification (regional disease) in, 1111-1113, 1111t
    tumor (T) classification (localized disease) in, 1111, 1111t, 1113f
  for thyroid cancer, 1754, 1755t-1756t
Tuning, tonotopic
  of afferent auditory neurons, 1845
  of basilar membrane, 1840-1842, 1844f
  of hair cells, 1844, 1844f
Tuning curves, of basilar membrane, 1844, 1844f
Tuning fork testing, 97-98, 98t
Tunnel of Corti, 1832, 1832f
Turbinates
  anatomy and embryology of, 482-483
  hypertrophy of, 486
  and nasal breathing function, 641
  in surgical anatomy of anterior cranial base, 2472, 2472f
Turbinectomy, in vocal professional, 858
Turn-down flaps, 346
Turner's syndrome, 5
  oral manifestations of, 1257
Turn-in flaps, 346
Turricephaly, synostotic, 2645, 2645f
TVP muscle. *See* Tensor veli palatini (TVP) muscle.
TW (tympanometric width), with otitis media, 2762
T1WI (T1-weighted images), 134, 135f-136f
T2WI (T2-weighted images), 134, 135f-136f
Twisted nose
  rhinoplasty for, 551-554
    in noncaucasian patient, 573, 576f
    osteotomies in, 551-554
      intermediate, 553, 554f
      lateral, 552-554, 553f
      medial, 552-553, 552f-553f
    preoperative examination of, 551, 552f
    results of, 511f-512f, 553f-554f
    septal reconstruction in, 551
    spreader grafts in, 554, 555f
  varieties of, 552f
Two-flap palatoplasty, 2669-2670, 2670f
  surgical technique for, 2670-2671, 2670f-2671f
Two-hit effect, 6
Two-mass model, of phonation, 811
Two-thirds tumor, 1277
Two-wall decompression, of superior-lateral orbit, for Graves' ophthalmopathy, 1816
Tympanic anulus, 1825-1826, 1825f
Tympanic bone, 2434-2435, 2435f, 2439f
Tympanic canaliculus, 1822-1823
Tympanic cavity, 2585f
Tympanic cover layer, 2050
Tympanic membrane (TM)
  anatomy of, 1824-1825, 1825f
  in auditory physiology, 1839-1840, 1840f, 2018-2019
  in cochlear transduction, 2050-2060, 2062f
  hearing loss due to total loss of, 2019, 2019t
  in otitis media, 2761-2762
  physical examination of, 97, 98f
  in surgical anatomy of lateral skull base, 2436f
  tympanoplasty with atrophic and atelectatic, 2003-2004
Tympanic membrane perforation, 1969-1971
  diagnosis of, 1969, 1970f
  hearing loss due to, 2000, 2019, 2019t
    management of, 2022-2023
  management of, 1971
  with ossicular disruption, hearing loss due to, 2019, 2019t
  due to otitis externa, 1947
  pathogenesis of, 1970-1971, 1971f, 1971t
  repair of (*See* Tympanoplasty)
  due to small fenestra stapedotomy, 2034
  traumatic, 2038
Tympanic membrane sources, of otorrhea, 2195-2196, 2195b
Tympanic membrane surface electrode, electrocochleography with, 1894, 1894f
Tympanic part, of temporal bone, 320f, 1822f, 1823, 2010f
Tympanic segment
  anatomy of, 1826f
    surgical, 2404, 2404f
  vulnerability to injury of, 1826f, 1829
Tympanic sulcus, 2435
Tympanocentesis, for acute otitis media, 2771
Tympanogram, for nasopharyngeal carcinoma, 1354
Tympanomastoid fissure, 2010f
Tympanomastoid suture, 2434-2435, 2435f
Tympanomastoid suture line, 1822f, 1823
Tympanomeatal flap, in tympanoplasty, 2001, 2001f
  with lateral graft technique, 2002
  with medial graft technique, 2003, 2004f
Tympanomeningeal fissure, 2736
Tympanometric test, nine-step inflation-deflation, 1874
Tympanometric width (TW), with otitis media, 2762
Tympanometry, 1890-1891, 1890f
  for conductive hearing loss, 2020
  for eustachian tube assessment, 1874
  for otitis media, 2762
  for sensorineural hearing loss, 2117
Tympanoplasty, 1999-2005
  with atrophic and atelectatic tympanic membrane, 2003-2004
  cartilage, 2004-2005
  classification of, 1999
  defined, 1999
  formal procedure for, 2001
    anesthesia in, 2001
    approaches and incisions in, 2001-2002, 2001f
    graft placement in, 2002
      lateral graft (overlay) technique for, 2002-2003, 2002f
      medial graft technique for, 2003, 2004f
  functional considerations with, 1999-2000
  graft materials for, 2000
  minimalist techniques for, 2000-2002
  pediatric, 2005
  preoperative evaluation for, 2000
  with tympanosclerosis, 2003
Tympanosclerosis, 1974-1975
  audiometric correlates of, 2005-2006
  diagnosis of, 1974, 1974f
  epidemiology of, 1974
  management of, 1975, 1975f
  ossiculoplasty for, 2007-2008, 2024-2025
  pathogenesis of, 1974-1975, 1975f
  pathophysiology of, 2005
  tympanoplasty with, 2003
  with tympanostomy tubes, 2775
Tympanosquamous suture, 2434, 2435f
Tympanosquamous suture line, 1822f, 1823, 1824f
Tympanostomy tubes, 2773-2776
  blockage of, 2775
  chronic otitis media with, 1970-1971, 1981
  complications and sequelae of, 2774-2776
    cholesteatoma as, 2775
    displacement into middle ear as, 2775
    early extrusion as, 2775
    otorrhea as, 1971, 2774-2775
    persistent perforation as, 2775
    retained tubes as, 2775
    tube blockage as, 2775
    tube displacement into middle ear as, 2775
    tympanosclerosis, atrophy, and retraction pockets as, 2775
  indications for, 2774
  for otitis media
    acute, 2771
    with effusion, 2772
  placement of, 2773-2774
    aspiration of effusions during, 2773-2774, 2774f
    perioperative and postoperative ototopical drops for, 2774
    postsurgical follow-up after, 2774
  rationale for, 2773
  selection of, 2774
  water precautions with, 2775-2776
Tympanum, congenital malformations of. *See* Congenital aural atresia (CAA).

Type I error, 65, 66t
Type II error, 65, 66t
Typewriter tinnitus, 2133
Typical carcinoid (TC), of larynx, 1507

U

UARS (upper airway resistance syndrome), 251-252
  in children, 2602-2603
UDPGT (uridine diphosphate-glucuronosyl transferase), in head and neck squamous cell carcinoma, 1017
UES. *See* Upper esophageal sphincter (UES).
UGI (upper gastrointestinal) series, for dysphagia in children, 2949
ULC (upper lateral cartilage), of nose, 496, 497f, 509f
  revision rhinoplasty for collapse of, 585-586, 586f
Ulcer(s), contact, of vocal folds, 874-875, 874f
  diagnosis of, 875
  epidemiology of, 874
  due to extraesophageal reflux, 902, 902f-903f
  management of, 875
  pathophysiology and pathology of, 874
Ulceration(s)
  aphthous, 1289, 1289f
    in HIV, 227, 227f
    recurrent, 1236-1239
      clinical features of, 1237-1238
      defined, 1236-1237
      differential diagnosis of, 1238, 1238t
      etiology and pathogenesis of, 1237, 1237t
      herpetiform-type, 1238, 1238f
      histopathologic features of, 1239
      major, 1237-1238, 1238f
      minor, 1237, 1238f
      treatment of, 1239
  of melanoma, 1111-1112
Ulcerative colitis, oral manifestations of, 1254
Ulcerative oral mucosal lesions, 1231-1240
  erythema multiforme as, 1239-1240, 1254
    clinical features of, 1239, 1239f-1240f
    defined, 1239
    differential diagnosis of, 1239
    etiology and pathogenesis of, 1239
    histopathologic features of, 1239-1240
    treatment of, 1240
  herpes simplex infection as
    primary, 1235, 1252
      clinical features of, 1235, 1235f, 1252
      defined, 1235
      diagnosis of, 1235
      differential diagnosis of, 1235
      etiology and pathogenesis of, 1235
      treatment of, 1235, 1252
    recurrent, 1235-1236, 1252
      clinical features of, 1236, 1236f
      defined, 1235
      differential diagnosis of, 1236
      etiology and pathogenesis of, 1235-1236
      histopathology of, 1236, 1237f
      vs. recurrent aphthous stomatitis, 1238, 1238t
      treatment of, 1236
  mucous membrane (cicatricial) pemphigoid as, 1233-1235, 1254
    clinical differential diagnosis of, 1234, 1234t
    clinical features of, 1233-1234, 1233f-1234f
    defined, 1233
    etiology and pathogenesis of, 1233
    histopathologic features of, 1234-1235, 1234f
    treatment of, 1235
  pemphigus vulgaris as, 1231-1233, 1254
    clinical differential diagnosis of, 1232
    clinical presentation of, 1232, 1232f
    defined, 1231-1232
    etiology/pathogenesis of, 1232
Ulcerative oral mucosal lesions *(Continued)*
    histopathologic features of, 1232-1233, 1232f-1233f
    treatment of, 1233
  recurrent aphthous stomatitis as, 1236-1239
    clinical features of, 1237-1238
    defined, 1236-1237
    differential diagnosis of, 1238, 1238t
    etiology and pathogenesis of, 1237, 1237t
    herpetiform-type, 1238, 1238f
    histopathologic features of, 1239
    major, 1237-1238, 1238f
    minor, 1237, 1238f
    treatment of, 1239
  traumatic (eosinophilic) granuloma as, 1240
    clinical features of, 1240, 1240f
    defined, 1240
    differential diagnosis of, 1240
    etiology of, 1240
    histopathologic features of, 1240, 1240f
    treatment of, 1240
Ulnar forearm flap, for free tissue transfer, 1082t
Ultimobranchial body, 2584f-2585f
Ultra-frequency sounds, adverse effects of, 2149
Ultrasonic liposuction, 452
Ultrasonography (US), 137
  applications of, 143-144
  basics of, 1643-1644
  B-mode, 1643
  of deep neck space infections, 204-205
  Doppler, 137
    color, 1644
      of salivary glands, 1167-1168
    of oropharyngeal cancer, 1366
  endobronchial, 1011
  for fine-needle aspiration biopsy, 1653-1654, 1655f
    of parathyroid tumor, 1789
  of Graves' ophthalmopathy, 1810
  of head and neck cancer, 1647-1653
  for hyperparathyroidism, 1786, 1789f
  of infrahyoid neck, 143-144
  of metastatic lymphadenopathy, 143
  of neck masses, 1636-1637, 1637t
  of neck neoplasms, 1657
  parathyroid, 1644-1645, 1650f-1652f
  of pharynx and esophagus, 1396
  of salivary glands, 143, 1148-1149, 1149f, 1167, 1645-1647
    with acute infections, 1647
    with calculous lesions, 1647
    color Doppler, 1167-1168
    with cystic disease, 1647
    with parotid mass, 1654f
    in Sjögren's syndrome, 1647
    with submandibular pleomorphic adenoma, 1653f
  for swallowing disorders, 1219
  technique of, 1643-1644, 1645f
  terminology for, 1643
  of thyroid gland, 1644, 1757
    with colloid nodule with comet-tail or ring-down artifact, 1644, 1647f
    with cystic nodule, 1644, 1645f
    with lymph node metastases, 1644, 1648f-1649f
    with malignant tumor, 1644, 1646b, 1646f
    multinodular, 1644
    with recurrent thyroid carcinoma, 1644
    with solid hyperfunctioning nodule, 1644
    with solitary nodule, 1644
  utility and limitations of, 1644
  vocal cord, for stridor, 2901
Ultraviolet light exposure, and oral cancer, 1294, 1294f
Ultravoice, after total laryngectomy, 1572
Umami, 1207, 1209, 1213
Umbo, of tympanic membrane, 97, 98f, 1824, 1825f

Unimate, 38
Unipedicle advancement flaps, 345, 345f
Unithroid (levothyroxine, oral synthetic), for hypothyroidism, 1748-1749
Universal Newborn Hearing Screening (UNHS), 2719
University of Washington Quality of Life scale (UW-QOL), 56
Unknown primary
  melanoma of, 1109
  squamous cell carcinoma metastatic to neck from, 1641-1642, 1641t, 1664, 1665f
Unloading reflex, 1204, 1204f
Unrestricted toxicity, 603-604
Upper aerodigestive tract, in geriatric patients
  presbyphagia of, 237
    diagnostic testing for, 237
    treatment of, 237
  presbyphonia of, 234-237
    acoustic changes in, 236
    dental/mandibular changes in, 236
    factors affecting vocal quality in, 234, 235t
    glandular changes in, 236
    histologic changes in, 234-235, 235f
    laryngoscopic appearance in, 235-236
    mucosal changes in, 236
    respiratory changes in, 236
    and sense of taste, 236
    treatment of, 236-237
Upper airway obstruction
  after adenotonsillectomy, 2800
  in children (*See* Stridulous child)
  due to chronic adenotonsillar hypertrophy, 2789f-2790f, 2790-2793, 2795
  decongestion for, 655
  due to foreign body, 2936-2937
  in neonate
    expected, 2904-2905
    unexpected, 2905
      laryngeal, 2905
      supralaryngeal, 2905, 2905f
      tracheobronchial, 2905
  posterior to valve area, 655-656
  in Robin sequence, 2673
  sleep-related, 2607
  valve area stenting for, 655
Upper airway resistance syndrome (UARS), 251-252
  in children, 2602-2603
Upper airway stenosis, 943-952
  classification of, 944, 944t
  local application of mitomycin C for, 946
  pathophysiology of, 943-944, 944b
  surgical management of, 943-952
    for chronic disease, 947-952
      anterior glottic, 948
      due to anterior wall collapse, 951
      cervical tracheal, 951, 951b, 951f
      cicatricial membranous, 951
      complete glottic, 949-950
      complete tracheal, 951-952, 952f
      laryngeal release procedures in, 952
      posterior glottic, 948-949, 949f
      subglottic, 945f, 950-951
      supraglottic, 947-948
    endoscopic *vs.* open, 945
    goals and assessment in, 944, 945f

Upper airway stenosis *(Continued)*
microsurgical débridement in, 946, 946b, 946f
planning for, 946-947
skin and mucosal grafts in, 946-947
stent placement in, 947, 947f
timing of, 945
Upper deep cervical node, 1297f
Upper esophageal sphincter (UES)
anatomy of, 953, 954f
in GERD, 894-895
incompetence of, 1399
manometry of, 958, 959f
during pharyngeal swallow, 1216-1217, 1216f
physiology of, 954, 955f
Upper eyelid
aesthetic analysis of, 445, 446f
paralysis of, 2421
Upper eyelid blepharoplasty, 447-448, 447f-449f
Upper eyelid blepharoplasty incision, 328-329, 329f
Upper eyelid crease, 442, 443f
Upper eyelid ptosis
evaluation of, 446-447, 447f
repair of, 447-448, 447f-449f
Upper eyelid retractors, 444
Upper gastrointestinal (UGI) series, for dysphagia in children, 2949
Upper jugular lymph nodes, in neck dissection, 1704, 1704f-1705f, 1706t
Upper lateral cartilage (ULC), of nose, 496, 497f, 509f
revision rhinoplasty for collapse of, 585-586, 586f
Upper lip, of vocal folds, in mucosal wave propagation, 848-849
Upper lip defects
algorithm for, 351, 355f
large, 352
Upper motor neuron diseases, preoperative evaluation of, 106
Upper respiratory infection (URI)
olfactory loss after, 633-637
and otitis media, 2767
pediatric anesthesia with, 2594-2595
UPPP (uvulopalatopharyngoplasty), for obstructive sleep apnea, 251, 258, 258f, 259t
in children, 2609
Uremic stomatitis, 1255
Uridine diphosphate-glucuronosyl transferase (UDPGT), in head and neck squamous cell carcinoma, 1017
Urinary tract symptoms, of hyperparathyroidism, 1781
Urokinase, for flap salvage, 1075
US. *See* Ultrasonography (US).
USH1C, in deafness, 2051t-2058t
USH2A, in deafness, 2051t-2058t

acoustic assessment of, 830
aerodynamic assessment of, 828t, 829
anatomic basis for, 2676, 2677t
Velopharyngeal inadequacy, defined, 2678
Velopharyngeal insufficiency
after adenotonsillectomy, 2800
defined, 2678
impact of, 2679
after palatoplasty, 2673
Velopharyngeal mislearning, 2678-2679
Velopharyngeal port, 2676
Velopharyngeal sphincter, in cleft palate, 2666-2667
Velopharynx
functional anatomy of, 2676, 2677t
muscles of, 2676, 2677t
VEMPs (vestibular evoked myogenic potentials), 2300, 2324, 2325f
in Meniere's disease, 2337
in superior canal dehiscence syndrome, 2341
Venlafaxine, for neuropathic pain, 244-245, 245t
Venous lakes, 288f, 291
Venous malformations, 2832
clinical presentation of, 2832, 2833f
imaging of, 2824f
of neck, 2817
of salivary glands, 1172
treatment of, 2832, 2833f
embolization for, 1942, 1942f
Venous outflow, of skin flaps, 1068
Venous stroke, due to lateral skull base surgery, 2513
Vent, for hearing aids, 2270
Ventilating bronchoscope, 2903, 2903f
Ventilation
control of, in children, 2569-2570
difficult (*See* Difficult airway)
larynx in, 808-809, 808f-809f
Ventilation tubes, for otitis media, with cleft palate, 2675
Ventilation-perfusion relationships, in children, 2570, 2571t
Ventral acoustic stria, 1835, 1835f
Ventral cochlear nucleus, 1835, 1845
Ventral nucleus of trapezoid body (VNTB), in auditory pathway, 1834f
Ventral stria, in auditory pathway, 1846
Ventricular ligament, surgical anatomy of, 1544f

Veramyst (fluticasone furoate), for nonallergic rhinitis, 700t
Verapamil, and skin flap viability, 1073
Verbal Descriptor Scale (VDS), 240
Vergence eye movements, 2305-2306, 2306f, 2307t
  evaluation of, 2314
Verification, of hearing aids, 2273
Vermilion border, 1295f, 1296-1297
Verocay bodies, in schwannomas, 1663
Verruca vulgaris, 282-283
  filiform, 282, 282f
  flat, 282, 283f
  due to molluscum contagiosum, 282-283, 283f
Verruciform xanthoma, oral, 1229
  clinical features of, 1229
  defined, 1229
  etiology and pathogenesis of, 1229
  histopathologic/diagnostic features of, 1229
  treatment of, 1229
Verrucous carcinoma (VC)
  of larynx, 1505-1506, 1505f
  of oral cavity, 1299
Verrucous hyperplasia, of oral cavity, 1299
Verrucous leukoplakia, proliferative, 1225, 1225f
Vertebral artery, 2351f
  in root of neck, 2581-2582, 2581f
  in surgical anatomy of anterior skull base, 2481f
  in surgical anatomy of lateral skull base, 2439f
Vertebral osteophytes, compression of pharynx and esophagus due to, 1408, 1409f
Vertebrobasilar arterial occlusion, sensorineural hearing loss due to, 2123
Vertebrobasilar insufficiency, 2355f
Vertex resistance, in rhinomanometry, 650
Vertical buttresses, 331, 331f
Vertical closure level, laryngeal videostroboscopy of, 821
Vertical crest, in surgical anatomy of lateral skull base, 2437-2439
Vertical hemilaryngectomy, 1547-1549
  complications of, 1549
  extended, 1548
  frontolateral, 1548
  functional outcome of, 1548
  with imbrication laryngoplasty, 1548, 1548f
  key surgical points for, 1549
  oncologic results of, 1547-1548, 1547t-1548t
  posterolateral, 1548
  surgical technique for, 1548
Vertical hemilaryngectomy (VHL)
  for glottic cancer, 1496, 1518f, 1519t, 1547-1549
    with anterior commissure involvement, 1497
  historical background of, 1540
  radiographic appearance after, 1476, 1479f
Vertical laryngoplasty, for chronic aspiration, 928-929, 930f
Vertical partial laryngectomy, 1540, 1547
Vertical phase, of vocal fold vibration, 848-849
Vertical ramus, biomechanics of, 333
Vertical slot defect, after scalp reductions, 385, 386f
  Frechet triple flap repair for, 385, 386f
Vertical transmission, 2088
Vertico-ocular reflex, in vestibular compensation, 2375
Vertigo, 2201-2202. *See also* Dizziness.
  ablative surgery for
    labyrinthectomy as, 2366-2368, 2367f
    patient selection for, 2364-2366
      clinical history in, 2364-2365
      consideration of other potential treatments in, 2366
      identification of intracranial pathology in, 2366
      identification of offending labyrinth in, 2365-2366
      poor compensation *vs.* unstable labyrinthine disease in, 2364, 2365t

Zellballen, in paragangliomas, 1657, 1658f
Zenker, Friedrich Albert von, 987
Zenker's diverticulum(a), 974, 986-997
  classification of, 987, 991t
  defined, 986
  diagnosis of, 986-987, 989f-990f
  differential diagnosis of, 986-987, 990t
  epidemiology of, 986
  history of, 986-987, 987f
  imaging of, 1401, 1402f
  management of, 987-997
    algorithm for, 997, 997f
    endoscopic techniques for, 992-997
      complications of, 995
      electrocautery technique in, 993f
      equipment for, 994f
      history of, 992, 993f
      laser technique in, 993f
      positioning for, 993f
      procedure for, 992-995, 995f-996f
      results of, 994-995
Zenker's diverticulum(a) *(Continued)*
    external techniques for, 988-992
      complications of, 992
      diverticulopexy technique as, 992f
      history of, 988-990
      inversion technique as, 992f
      procedure for, 990-992
      transcervical diverticulectomy as, 991f
    recurrence after, 995-997
  pathophysiology of, 986-987
  presentation of, 986-987
Zeus telerobotic system, 39, 40f
Zileuton
  for allergic rhinitis, 620-621
  for rhinosinusitis, 735t, 736
Zinc, for olfactory dysfunction, 639
Zinc deficiency, oral manifestations of, 1254
Zinc gluconate, for rhinosinusitis, 731, 735t
Z-line, in transnasal esophagoscopy, 982
Zones of perfusion, 1064-1065, 1065f
Zonisamide, for neuropathic pain, 244t
Zostavax (varicella vaccine), 2159
Zovirax (acyclovir)
  with chemical peels, 397
  for herpes zoster, 2396
  for recurrent respiratory papillomatosis, 2890t, 2892
Z-palatoplasty, for obstructive sleep apnea, 258, 260f
Z-plasty, for scar revision, 298, 298f-299f
Zygoma
  anatomy and physiology of, 319, 320f-321f
  biomechanics of, 332
  in surgical anatomy of lateral skull base, 2435f-2436f
Zygomatic arch(es)
  anatomy and physiology of, 319, 320f
  biomechanics of, 332
  depressed, *vs.* myofascial pain dysfunction syndrome, 1285t
Zygomatic bone, 320f
Zygomatic branch, of facial nerve, 1194f
Zygomatic fractures
  imaging of, 325
  repair of, 336
  surgical access to, 328-329
Zygomatic injury, physical examination of, 324
Zygomatic process
  anatomy of, 1821, 1822f-1823f, 2010f
  articular tubercle of, 1822f
Zygomatic root, 1822f, 1824f
Zygomatic "tripod," biomechanics of, 332
Zygomaticofacial nerve, 321f
Zygomaticomalar complex fractures, pediatric, 2707-2708, 2710f
Zygomaticus major muscle, 321f, 442f, 444
Zygomaticus minor muscle, 442f, 444
Zyrtec (cetirizine)
  for nonallergic rhinitis, 701t
  for rhinosinusitis, 734t
